Subject: DHC-6 Twin Otter - Component Maintenance Manual (CMM) PSM1-6-6A

From: Viking Technical Services

To our valued customers,

All CMMs in PSM1-6-6A are to be used for reference only and information contained therein is to be validated directly with the appropriate Original Equipment Manufacturers. All Temporary Revisions that were issued against the CMM will not be incorporated into a new full revision of PSM1-6-6A.

If it is determined that a revision of an individual CMM that is proprietary to Viking Air Limited is warranted, i.e., CMM for P/N C6U1103 Main Landing Gear Leg in Chapter 32, then at that time any outstanding Temporary Revisions against that specific CMM will be incorporated.

Sincerely,

Mr. Kevin Rude
Manager, Technical Services

Date: December 18, 2001

Subject: Twin Otter Component Maintenance Manual PSM 1-6-6A, Revision No. 12 dated December 18, 2001

This Revision is to PSM 1-6-6A dated May 15, 1987 and introduces new material received since the last Revision.

A vertical line in the left hand margin of the revised Contents pages indicates the new material added by the Revision.

Incorporate this Revision as follows:

1. Insert Technical Publications Manual Change Request (MCR) form following Volume one, frontispiece page.
2. Remove and destroy the existing Temporary Revision Index page and replace with the revised Temporary Revision Index page.
3. Remove and destroy the existing List of Chapters page and replace with the revised List of Chapters page.
4. Remove and destroy the existing Introduction pages and replace with the revised Introduction pages.
5. Remove and destroy the existing Table of Content pages for Chapters 21, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 52, 61, 61-References, 71, 71-References, 72, 73, 77, 79 and 80 and replace with the revised Table of Content pages for Chapters 21, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 52, 61, 61-References, 71, 71-References, 72, 73, 77, 79 and 80.
6. Insert the new and revised documents as follows. Refer to the Revision Highlights section of this transmittal letter to identify the chapter into which each document is to be inserted, and then use the revised Table of Contents page(s) for that chapter as a guide to the placement of each document within the chapter.
7. Record the incorporation of the Revision in the Record of Revision pages at the front of Volume 1.

Revision Highlights:

You will note that all Table of Contents pages either have a full page revision bar in the left-hand margin or a footer length revision bar in the left-hand margin. This revision bar is to indicate; a new header and footer, This page left intentional blank statement, title change, table structure change, fount change, introduction of ATA Number column, Revision Status Column, Service Bulletins/Temporary Revision column and general TOC format changes. Details as to specific changes to Vendor's manuals will be stipulated below.

Chapter 21: Listing of Barber-Colman CMM for Micropositioners, P/N F-5114-4 dated May 1, 1961.

Amendment to Table of Contents to reflect that FL Aerospace is now owners of the Vendor Janitrol Aero Division CMM, Mixing Valve Assembly CMM, P/N A58D72.

Chapter 21 Cont'd

Amendment to Table of Contents to reflect addition of reference, address, phone, facsimile number, E-mail address and contact name to indicate that Keith Products will supply their CMM for Vapor Cycle Air-conditioning Systems, P/N TR-128.

Amendment to Table of Contents to reflect that Whittaker Controls is now owners of the following CMM's from Sundstrand Aviation, Bleed Air Shutoff Valve, P/N 26440051, ATA 30-40-1 and Solenoid Actuated (Pilot) Poppet Shutoff Valve Assembly, P/N 320195, ATA 75-10-02.

Incorporation of revision1 to the CMM for Whittaker Controls, Solenoid Actuated (Pilot) Poppet Shutoff Valve Assembly, P/N 320295, ATA 75-10-02 dated February 1, 1998. This manual is issued in its entirety. Remove and destroy your copy of Whittaker Controls, Solenoid Actuated (Pilot) Poppet Shutoff Valve Assembly, P/N 320295, ATA 75-10-02 and replace with supplied CMM for Whittaker Controls, Solenoid Actuated (Pilot) Poppet Shutoff Valve Assembly, P/N 320295, ATA 75-10-02 dated February 1, 1998.

Chapter 23:

Amendment to Table of Contents to reflect that the manufacturer AirMed title has changed to AirMed A Clement Clark Communication Company.

Chapter 24:

Incorporation of CMM for Eldec, a Crane Company, Proximity Sensor, P/N 1-899, ATA 24-09-08, Revision 8 dated August 1, 2001. This manual is issued in its entirety by the vendor. Insert this manual at the beginning of Chapter 24.

NOTE: Revision 6 & 7 "Revision Transmittal" pages to Eldec, a Crane Company, Proximity Sensor, P/N 1-899, ATA 24-09-08 are supplied as reference material only.

Incorporation of CMM for Electro Development Corporation which is supported by Eldec, a Crane Company, Proximity Switch, P/N 2-899 and Sensor Assembly, P/N 1-899, ATA 24-09-01 revised date of April 1, 1969. This manual is issued in its entirety by the vendor. Insert this manual following the Eldec, a Crane Company, Proximity Sensor, P/N 1-899, ATA 24-09-08.

Amendment to Table of Contents to reflect that the manufacturer Flite-Tronics title has changed to Flite-Tronics Products a Marathon Power Technologies Company.

It has been brought to our attention that some holder of the CMM for Marathon Power Technologies, Aircraft Static Inverter, Models PC14 through PC-14D many be missing the new frontus page, Page i and Page ii. If you are in possession on these page then discard these pages in a secure facility. If you are not in possession of these pages then insert at the beginning of the Marathon Power Technologies CMM.

Incorporation of CMM for Flite-Tronics, Static Inverter, P/N PC15 and PC15B and PC-15BC, 10th printing dated June 1975. Remove and destroy your copy of the Flite-Tronics, Static Inverter, P/N PC15 and PC15B and PC-15BC CMM and replace with supplied Flite-Tronics, Static Inverter, P/N PC15 and PC15B and PC-15BC, 10th printing dated June 1975 CMM. This manual is issued in its entirety.

Chapter 24: Cont'd

Amendment to Table of Contents to reflect that the manufacture Garrett has changed to Honeywell Canada.

Incorporation of CMM for Marathon Flite-Tronics, 250 VA Static Inverter, P/N PC-250, ATA 24-20-03, revision 3 dated June 1, 1982. This manual is issued in its entirety. Insert this manual following the Flite-Tronics, Static Inverter, P/N PC15BC manual, ATA 24-20-XX.

Incorporation of CMM for Phoenix Aerospace Inc., Solid State Static Inverter (Transverter), P/N 095165 (DH-1030-24-600-CS, Type IIB), ATA 24-20-X dated January 3, 1992. This manual is issued in its entirety. Insert this manual following the Phoenix Aerospace Inc. CMM for Solid State Static Inverter (Transverter), P/N 095032 (DH-1030-24-600-CS), ATA 24-20-X.

Incorporation of CMM for SAFT, Electrical Storage Battery, P/N 4076, ATA 24-30-22 dated January 30, 1986. This manual is issued in its entirety. Remove and destroy pervious copy of SAFT, Electrical Storage Battery, P/N 4076 and replace with supplied Electrical Storage Battery, P/N 4076, ATA 24-30-22 dated January 30, 1986.

Incorporation of TRW Aeronautical Systems, Lucas Aerospace, Service Information Letter Number 23704 dated August 24, 2001. Insert this SIL at the beginning of CMM for TRW Aeronautical Systems, Lucas Aerospace, DC Starter Generator, P/N 23048, ATA 24-30-74.

Incorporation of CMM for TRW Aeronautical/Lucas Aerospace was Lear Siegler, A Division of Lucas, DC Starter Generator, P/N 23048-001 through -028, ATA 24-30-74 dated December 15, 2000. This manual is issued in its entirety. Insert this manual following the Spar Aerospace CMM for Static Power Inverter, P/N 5590F1-1 (Model SPS48).

Amendment to Table of Contents manufacture column to reflect that the manufacture Weston Component Maintenance Manuals are now supported by Ametek Aerospace.

Chapter 25:

Amendment to Table of Contents to reflect addition of reference, address, phone, facsimile number and contact name to indicate that B/E Aerospace will supply their CMM for Liquid Container, Model No. 306, ATA 25-32-03.

Incorporation of CMM for TUL Safety Equipment Ltd., Life Preserver, Adult, Type 35 MK IV (-2) and (-3), P/N TUL-6174, ATA 25-60-05 at revision 5 dated December 2, 1991. This manual is issued in its entirety. Remove and destroy your copy of the TUL Safety Equipment Ltd., Life Preserver, Adult, Type 35 MK IV ( ) and (-1), P/N TUL-6174, ATA 25-60-05 and insert this TUL Safety Equipment Ltd., Life Preserver, Aircrew, Type 35 MK IV ( ) and (-1), P/N TUL-6174, ATA 25-60-05 at revision 5 dated December 2, 1991 in its place.

Chapter 26:

Incorporation of CMM for Flag Fire Equipment Ltd., Portable Fire Extinguisher & Bracket, Model No. HAL-035-AVH, ATA 26-25-02 , revision 2 dated January 4, 1994. This manual is issued in its entirety by the vendor. Insert this manual following the America Standard, Extinguisher, Bulletin Number 601-004-001.

Chapter 26: Cont'd

Incorporation of CMM for Pacific Scientific Walter Kidde HTL/Kin-Tech Division, Fire Extinguisher, P/N 17300/17400, ATA 26-20-200, revision 3 dated March 15, 1999. This manual is issued in its entirety by the vendor. Remove and destroy your copy of the Kidde/HTL Advanced Technology, Fire Extinguisher, P/N 17300/17400, ATA 26-20-200 and insert this Pacific Scientific Walter Kidde HTL/Kin-Tech Division, Fire Extinguisher, P/N 17300/17400, ATA 26-20-200, revision 3 dated March 15, 1999 in its place.

NOTE: This issue of Pacific Scientific Walter Kidde HTL/Kin-Tech Division, Fire Extinguisher, P/N 17300/17400, ATA 26-20-200, revision 3 dated March 15, 1999 is accompanied with Service Bulletin Part No. 17310, Revision A dated of May 22, 1980; SB P/N 17400; SB P/N 30100010 Rev. A dated February 2, 1997; SB 31000010-26-2 Rev dated December 9, 1983 & SB P/N 30700002.

Incorporation of CMM for Pacific Scientific Walter Kidde HTL/Kin-Tech Division, Fire Extinguisher, 37 Cubic Inch through to 988 Cubic Inch, ATA 26-20-202, Initial issue dated July 15, 1999. This manual is issued in its entirety by the vendor. Insert this manual following the CMM for Pacific Scientific Walter Kidde HTL/Kin-Tech Division, Fire Extinguisher, P/N 17300/17400, ATA 26-20-200.

NOTE: This issue of Pacific Scientific Walter Kidde HTL/Kin-Tech Division, Fire Extinguisher, 37 Cubic Inch through to 988 Cubic Inch, ATA 26-20-202, Initial issue dated July 15, 1999 is accompanied with Supplement Number 30100043 dated July 15, 1999.

Incorporation of CMM for Walter Kidde Aerospace Division of KIDDE Technologies Inc., Discharge Indicators, P/N 800495, 843787, 843969 & 922315, ATA 26-20-50 was 26-20-00, revision 8 dated November 30, 1995. This manual is issued in its entirety by the vendor. Remove and destroy your copy of the Kidde, Discharge Indicators and Connectors, P/N 800495, 843787, 843969 & 922315, ATA 26-20-00 and insert this Walter Kidde, Discharge Indicators, P/N 800495, 843787, 843969 & 922315, ATA 26-20-50 was 26-20-00, revision 8 dated November 30, 1995 in it place.

Incorporation of CMM for Walter Kidde Aerospace; Division of KIDDE Technologies Inc., Control Unit Fire Detecting System Continuous Type DC with Short Discriminator Circuit, P/N 893229-0350 through to -0500-1, ATA 26-10-30, revision No. 3 dated September 15, 1998. This manual is issued in its entirety by the vendor. Insert this manual following the CMM for Walter Kidde Aerospace, Discharge Indicators, P/N 800495, 843787, 843969 & 922315, ATA 26-20-50 was 26-20-00.

Incorporation of CMM for Walter Kidde Aerospace; Division of KIDDE Technologies Inc., Power Device Cartridges, ATA 26-21-34 dated May 15, 1996. This manual is issued in its entirety by the vendor. Insert this manual following the CMM for Walter Kidde Aerospace, Division of KIDDE Technologies Inc., Control Unit Fire Detecting System Continuous Type DC with Short Discriminator Circuit, P/N 893229-0350 through to -0500-1, ATA 26-10-30.

NOTE: Walter Kidde Aerospace manuals in the Table of Contents have been reorganized to maintain the Alpha/numeric manual consistency.

Chapter 27: Incorporation of revision 2 to the CMM for the Bombardier Aerospace/de Havilland, Geared Tab Gearing Mechanism Assembly, P/N C6CF1174, ATA 27–26–11 dated December 17, 2001. Incorporate revision as instructed by the Letter of Transmittal for the BA/dHI, Geared Tab Gearing Mechanism Assy., P/N C6CF1174, ATA 27–26–11.

Incorporation of CMM for Eldec Corporation, Solid State Proximity Switch PC Assembly, P/N 8–060–02, –07 & –10, ATA 27–09–01, revision 9 dated June 30, 1991. This manual is issued in its entirety by the vendor. Insert this manual at the beginning of the Chapter 27 CMM's.

NOTE: This issue of Eldec Corporation, Solid State Proximity Switch PC Assembly, P/N 8–060–02, –07 & –10, ATA 27–09–01, revision 9 dated June 30, 1991 is accompanied with Service Information Letter Number 27–02 dated February 28, 1975.

Chapter 28: Incorporation of CMM for De Laval Turbine, a Adel Division, Fuel Booster Pump, P/N 71383–3 & –3A, ATA 28–20–6 dated March 1, 1969. This manual is issued in its entirety by the vendor. Insert this manual at the beginning of the Chapter 28 CMM's.

Deletion of the manufacturer Auto Valve from manufactures column. Remove and destroy Overhaul manual for Drain Valves, P/N 996B and 996C.
Quote – "AVI Technical Information and Repair Policy
Technical information, drawings, part numbers and spare parts are supplied only to direct AVI customers and cannot be supplied to end–users or repair facilities. All questions related to these issues should be directed to the appropriate aircraft manufacturer or original equipment manufacturer (OEM).
The quality and reliability of field repaired units can not be ensured, therefor, there are NO authorized facilities permitted to repair or rebuild any AVI assemblies. As of 1 December 1995, all AVI repair kits and maintenance manuals are considered invalid and will no longer be issued or updated. The repair or rebuild of these assemblies may be performed by AVI when requested through the appropriate OEM.
Requests for repair or technical information from the OEM to AVI should be made in writing by letter or FAX. To ensure the validity of these requests, a signed and dated "Affidavit of Material Usage" (supplied by AVI) will be required for new customers and/or customers that do not have a current affidavit on file. – rev B 5/27/98"
End of Quote.

Incorporation of CMM for Crane (Hydro–Aire), Fuel Booster Canister Pump, P/N 72266–3 & 72390–2, ATA 28–20–24, revision 1 dated February 21, 1986. This manual is issued in its entirety by the vendor. Remove and destroy your copy of Crane (Hydro–Aire), Fuel Booster Canister Pump, P/N 72266–3 & 72390–2, ATA 28–20–24, Initial issue revision dated July 1, 1977 and insert this Crane (Hydro–Aire), Fuel Booster Canister Pump, P/N 72266–3 & 72390–2, ATA 28–20–24 at revision 1 dated February 21, 1986 in its place.

Incorporation of CMM for Simmonds Precision Products, Inc., Liquid Quantity Transmitter, P/N 391088–002 through –006, ATA 28–41–04, revision A dated July 29, 1988. This manual is issued in its entirety by the vendor. Remove and destroy your copy of the Simmonds Precision Products, Inc., Liquid Quantity Transmitter, P/N 391088–002 through –006, ATA 28–41–04 and insert this Simmonds Precision Products, Inc., Liquid Quantity Transmitter, P/N 391088–002 through –006, ATA 28–41–04, revision A dated July 29, 1988 in its place.

Chapter 29: Incorporation of revision number 3 to the CMM for PTI Technologies Inc., Filter, P/N 50220 dated June 30, 1993. This manual is issued in its entirety by the vendor. Remove and destroy the vendor Purolator Products Incorporated CMM, P/N 50220 and substitute with PTI Technologies Inc., Filter, P/N 50220, revision 3 dated June 30, 1993.

Incorporation of revision to the CMM for Teledyne Republic, Hydraulic Hand Pumps, P/N 3–1158–18 (914 – AN6201–1). This manual is issued in its entirety by the vendor. Remove and destroy the vendor Republic Manufacturing Co., Hydraulic Hand Pumps dated March 1, 1968 and substitute with Teledyne Republic, Hydraulic Hand Pumps, P/N 3–1158–18 (914 – AN6201–1).

Chapter 30: Incorporation of CMM for B.F. Goodrich Aerospace / Rosemount Aerospace Inc., Windshield Wiper Motor Assembly, P/N 2311M95, 96 & 97, ATA 30–42–10 dated October 1, 1993. This manual is issued in its entirety by the vendor. Refer to Rosemount Aerospace Inc. Highlights page for reason for reason for issuing. Insert this manual following the CMM for B. F. Goodrich Aerospace was Bendix, Water Separator, P/N 44E06–2A.

Incorporation of the CMM for Lucas Western, Deicer Distributing valve, P/N 1532–2A,–3A,–3B,–3C,–6A, & –6C, Publication No. 1532U–23–865B, revision 1 dated October 1993. This manual is issued in its entirety by the vendor. Insert this manual following the CMM for B.F. Goodrich Aerospace / Rosemount Aerospace Inc., Windshield Wiper Motor Assembly, P/N 2311M95, 96 & 97, ATA 30–42–10.

Incorporation of CMM for Lucas Western, Deicer Distributing valve, P/N 1532–8A,–8C,–10A & –10C, Publication No. 1532U–23–865G revised dated of October 1990. This manual is issued in its entirety. Insert manual following Lucas Western, Deicer Distributing valve, P/N 1532–2A,–3A,–3B,–3C,–6A, & –6C, Publication No. 1532U–23–865B, revision 1 dated October 1993.

Incorporation of CMM for Lucas Western, Regulating & Relief Valve, P/N 38E96–2C through –6A, Publication No. 38U–23–8511B revised dated of January 1995. This manual is issued in its entirety. Insert manual following Lucas Western, Deicer Distributing valve, P/N 1532–8A,–8C,–10A & –10C, Publication No. 1532U–23–865G revised dated of October 1990.

Incorporation of CMM for Lucas Western, Water Separator & Filter, P/N 44E15–1A through –2B, Publication No. 44U–23–8511A revised dated of March 1992. This manual is issued in its entirety. Insert manual following Lucas Western, Regulating & Relief Valve, P/N 38E96–2C through –6A, Publication No. 38U–23–8511B.

Chapter 31: No CMM changes, only page structure changes to TOC.

Chapter 32: Incorporation of Service Letters (SL) for Aircraft Braking Systems Corporation (ABSC) numbers; GS–SL–46 dated October 10, 1997, GS–SL–47 dated February 28, 1998, GS–SL–48 dated June 15, 1998 and GS–SL–49 dated October 15, 1998. Insert these SL's at the beginning of the Chapter 32 CMM's or as instructed by the specific SL.

Incorporation of CMM for Aircraft Braking Systems Corporation (ABSC) was Goodyear, Wheel Assembly, P/N 5000444, –1 & –3, ATA 32–40–12 dated September 28, 1990. This manual is issued in its entirety by the vendor. Remove and destroy the CMM for Goodyear, Main Wheel Assembly, P/N 5000444, –1, –2 & 5006586, ATA 32–40–12 Insert this manual following ABSC Service Letter Number GS–SL–49 dated October 15, 1998.

Chapter 32: Cont'd

NOTE: This issue of the CMM for Aircraft Braking Systems Corporation (ABSC) was Goodyear, Wheel Assembly, P/N 5000444, −1 & −3, ATA 32−40−12 dated September 28, 1990 is accompanied with Temporary Revision number 32−2 dated October 20, 1992.

Incorporation of CMM for Aircraft Braking Systems Corporation (ABSC), Brake Assembly P/N 5001571. −1 through −6, ATA 32−43−12 dated January 15, 1990. This manual is issued in its entirety by the vendor. Insert this manual at the following Aircraft Braking Systems Corporation (ABSC), Wheel Assembly, P/N 5000444, −1 & −3, ATA 32−40−12.

NOTE: This issue of the CMM for Aircraft Braking Systems Corporation (ABSC), P/N 5001571. −1 through −6, ATA 32−43−12 dated January 15, 1990 is accompanied with Service Bulletin No. ARAVA−102−32−2, ARAVA−201−32−2 & ARAVA−202−32−2 dated June 7, 1990 and Temporary Revision number 32−2 dated December 3, 1992.

Incorporation of CMM for Aircraft Braking Systems Corporation (ABSC), Main Wheel Assembly, P/N 95443832, −1 & −2, ATA 32−40−24 dated October 30, 1988. This manual is issued in its entirety by the vendor. Insert this manual following Aircraft Braking Systems Corporation (ABSC), P/N 5001571. −1 through −6, ATA 32−43−12.

NOTE: This issue of the CMM for Aircraft Braking Systems Corporation (ABSC), P/N 5001571. −1 through −6, ATA 32−43−12 dated January 15, 1990 is accompanied with Temporary Revision number 32−4 dated December 11, 1992.

Incorporation of CMM for Aircraft Braking Systems Corporation (ABSC), Brake Assembly, P/N 9550377, −1, −2 & −4, ATA 32−43−23 dated July 1, 1990. This manual is issued in its entirety by the vendor. Insert this manual following Aircraft Braking Systems Corporation (ABSC), P/N 95443832, −1 & −2, ATA 32−40−24.

NOTE: This issue of the CMM for Aircraft Braking Systems Corporation (ABSC), Brake Assembly, P/N 9550377, −1, −2 & −4, ATA 32−43−23 dated July 1, 1990 is accompanied with Temporary Revision number 32−5 dated July 1, 1993 and Temporary Revision number 32−6 dated March 12, 1999.

Incorporation of CMM for Parker Fluid Connectors/Stratoflex/Waterman Products, Hydraulic Fuse, P/N G831−8−10A (de Havilland P/N 7SC0110), ATA No. 32−42−00 issue dated January 22, 1998. This manual is issued in its entirety. Insert this manual following Aircraft Braking Systems Corporation (ABSC), Brake Assembly, P/N 9550377, −1, −2 & −4, ATA 32−43−23.

NOTE: This issue of the CMM for Parker Fluid Connectors/Stratoflex/Waterman Products, Hydraulic Fuse, P/N G831−8−10A (de Havilland P/N 7SC0110), ATA No. 32−42−00 issue dated January 22, 1998 is accompanied with Service Bulletin number G831−32−1 dated October 17, 1991 and Temporary Revision number 32−1 dated June 5, 1992.

Chapter 33: Incorporation of Parts Breakdown Sheet for Grimes, Tandem Oscillating Light, Model Number 41905. Insert this Sheet following Aircraft Navigational Rotating Warning Light, P/N G8400A36−24, ATA 33−40−21.

Chapter 34: Incorporation of CMM for Litton Aeronetics, Radio Magnetic Indicator, P/N 2105–210L through 2109–2109L dated November 21, 1969. This manual is issued in its entirety by the vendor. Insert this manual following Kollsman, Altimeter, P/N 671CPX–6–051.

Incorporation of CMM for SIRS Navigation Ltd., Standby Compass, P/N KCA0104W, ATA 34–25–21 dated January 20, 2001. This manual is issued in its entirety by the vendor. Remove and destroy the CMM for Smith Industries Limited, Standby Compass, P/N KCA 0104W, ATA 34–20–38/53, Dated November 1978 and replace with supplied CMM for SIRS Navigation Ltd., Standby Compass, P/N KCA0104W, ATA 34–25–21 dated January 20, 2001.

NOTE: This issue of the CMM for SIRS Navigation Ltd., Standby Compass, P/N KCA0104W, ATA 34–25–21 dated January 20, 2001 is accompanied with Service Information Letter number 34–47 dated June 2000.

Chapter 35: Incorporation of CMM to Adams Rite Sabre International, Portable Oxygen Cylinder assembly, P/N 900–700–039–04,–06,–12 & –29, Model 4113, ATA No. 35–31–08, revision 1 dated November 20, 1986. This manual is issued in its entirety. Insert this manual at the beginning of Chapter 35.

NOTE: This issue of Adams Rite Sabre International, Portable Oxygen Cylinder assembly, P/N 900–700–039–04, –06, –12 & –29, Model 4113, ATA No. 35–31–08, revision 1 dated November 20, 1986 is accompanied with Service Procedure No. SP 0002 dated May 18, 1995. Insert this SP 0002 as directed by item three, Instructions.

Introduction of CMM for Scott Aviation, Portable Oxygen Breathing Equipment, P/N 5500 Series and 5600 Series, ATA 35–30–78, revision 10 dated May 31, 1989. This manual is issued in its entirety. Insert this manual following the CMM for Alar Products, Continuous Flow Oxygen Regulator, P/N A–2000W.

Introduction of CMM for Scott Aviation, Cylinder and Valve Assembly, P/N 6350 Series, ATA 35–21–19, revision 6 dated June 1/1981. This manual is issued in its entirety. Insert this manual following the CMM for Scott Aviation, Portable Oxygen Breathing Equipment, P/N 5500 Series and 5600 Series, ATA 35–30–78.

Introduction of CMM for Scott Aviation, Cylinder and Valve Assembly, P/N 6350 Series, ATA 35–21–20 was 35–30–120, revision 8 dated October 15/1986. This manual is issued in its entirety. Remove and destroy the CMM for Scott Aviation, Cylinder and Valve Assembly, 6350 Series revision dated Dec 15/1966 and insert this CMM for Scott Aviation, Cylinder and Valve Assembly, P/N 6350 Series, ATA 35–21–20, revision 8 dated October 15/1986 following the CMM for Scott Aviation, Cylinder and Valve Assembly, P/N 6350 Series, ATA 35–21–19.

Chapter 36: No CMM changes, only page structure changes to TOC.

Chapter 52: Incorporation of CMM for Eldec Corporation, Proximity Switch assembly, P/N 8–240–04, ATA No. 52–70–02 initial issue dated May 1, 1979. This manual is issued in its entirety. Insert this manual following the Adams Rite, Locks Door and Related Handles and Latches, P/N AR24B9 or AR24B12.

Chapter 61: No CMM changes, only page structure changes to TOC.

Chapter 61–: References No CMM changes, only page structure changes to TOC.

Chapter 71: No CMM changes, only page structure changes to TOC.

Chapter 72–: References No CMM changes, only page structure changes to TOC.

Chapter 73: Incorporation of revision to the CMM for Sundstrand Corporation, Power Driven Rotary Pump, P/N 025323–402 through –402D, ATA No. 73–10–04, revision 8 dated March 1, 1995. Insert this manual by using the instruction from Sundstrand Corporation Highlights page.

Chapter 77: Incorporation of revision to the CMM for Aircraft Appliances and Equipment Limited (AMI), Tachometer Generator, P/N 32005–007 through –037, Manual No. M–7084, dated August 1997. This manual is issued in its entirety and supercedes File No. 3206. Remove and destroy AMI CMM for Tachometer Generator Model 32005–7 & Difference Data Sheets –008, –023 and replace with supplied CMM for AMI, Tachometer Generator, P/N 32005–007 through –037, Manual No. M–7084, dated August 1997.

Incorporation of CMM for Allied – Bendix Aerospace, Indicators, New P/N 3571810–0003 (Old P/N 25510B25B8A3 through 25516C96A14A3), ATA No. 77–10–40, revision 2 dated October 2, 1987. This manual is issued in its entirety by the vendor. Insert this manual following the CMM for Bendix Flight & Engine Instruments Division, Tachometer Indicator, New P/N 3571260–7001 (Old P/N 34107C1AG13–1A3), ATA 70–6–4.

Incorporation of revision 24 to the CMM for Smith Industries, Millivoltmeter Temperature Indicators, ATA 77–20–205 / 5, revision dated January 15, 1991. Insert this manual by page comparison to Smith Industries Millivoltmeter Temperature Indicator List of Effective Pages.

NOTE: This issue of CMM for Smith Industries, Millivoltmeter Temperature Indicators, ATA 77–20–205 / 5 is accompanied with Service Bulletin 77–119 dated July 1970 & SB 77–102, Revision No 1 dated November 1970. Insert these SB's in–front of the CMM for Smith Industries, Millivoltmeter Temperature Indicators, ATA 77–20–205 / 5

Chapter 79: No CMM changes, only page structure changes.

Chapter 80: No CMM changes, only page structure changes.

NOTE: We recommend that this letter of transmittal be retained for record purposes and inserted in the front of the manual.

THIS PAGE INTENTIONALLY LEFT BLANK.

INTRODUCTION

1. GENERAL

This manual contains component maintenance manuals for components manufactured by Bombardier / de Havilland and selected vendors. Additional manuals and revisions will be forwarded periodically as they are originated by Bombardier / de Havilland or received from vendors. This manual is organized according to ATA chapterization. Each ATA chapter contains a table of contents which lists the vendor component maintenance manuals in alphabetical order of vendor.

2. AVIONICS COMPONENTS

Manuals are not included for most avionics components as the avionics configuration varies considerably from customer to customer. Operators will receive avionics manuals directly from the vendors. Most vendors of avionics components prefer to deal directly with de Havilland's customers. It is recommended that you contact the appropriate vendors for the avionics components installed in your aircraft to ensure you are on their mailing list for follow–up revisions, bulletins or newsletters. Following para. 6 is a list of all vendors who supply Bombardier / de Havilland with avionics components at this time. This list will be amended as new vendors are added.

3. PROPELLER AND AIR CONDITIONING SYSTEM (HARTZELL)

Component Maintenance Manuals for these systems are not included in this manual but are available from the vendor. The manuals that are available are listed on the appropriate contents page along with the address of the vendor. Operators will receive propeller component maintenance manuals directly from the vendor.

4. ENGINE

Engine and accessory overhaul manuals for PT6A–20 P/N No. 3011403 (Series 100/200) or PT6A–27 Engine Overhaul Manual No. 3013242 (Series 300) are not included in this publication but are available on request at the following address. Operators will receive engine manuals directly from the vendor:

Pratt & Whitney Canada Corp.,

* Refer to following Customer Support Information Bulletin No. 23 for revision service.

5. REVISIONS

(a) Normal Revisions

Revisions to this manual will be made as required and holders will receive copies without request.

(b) Temporary Revisions

Temporary revisions will be issued at the earliest opportunity to notify the operator of important changes effecting the maintenance of these components. These temporary revisions will be printed on yellow paper for instant identification when inserted in the manual, and will be followed up by normal revision procedures.

6. MICROFICHE

This Component Maintenance manual is also available in microfiche.

WIRING DIAGRAM

AYLF 3001-1

TEMPERATURE SENSING ELEMENT

BARBER-COLMAN COMPANY
Rockford, Illinois

OVERHAUL MANUAL

BYLB 9304-10 AND -11 ELECTRO-MECHANICAL ROTARY ACTUATED VALVE

1. DESCRIPTION AND OPERATION

A. The function of the mixing valve is to control the cabin temperature at a pre-selected level.

B. LEADING PARTICULARS

(1) Valve Data

(a)	Diameter	- 0.937 inches
(b)	Maximum Pressure	- 80 PSIG at 470°F or 68 PSIG at 580°F
(c)	Proof Pressure	- 102 PSIG at 580°F
(d)	Burst Pressure	- 136 PSIG at 580°F
(e)	Leakage (Max.)	
	(1) Int Leakage	- 0.20 LB/MIN @ 80 PSIG and 470°F
	(2) Ext Leakage	- 0.02 LB/MIN @ 80 PSIG and 470°F

(2) Actuator Data

(a)	Motor Number	- DYLM 43400-13
(b)	Motor Type	- Split Series
(c)	Operating Voltage	- 28 Volts DC
(d)	Rated Current	- 0.4 Amps
(e)	Rated Load	- 5 lb in.
(f)	Time Stroke	- 22 - 38 sec/90° at 5 lb in.
(g)	Duty Cycle	- Continuous
(h)	Gear Reduction	- 50131/1
(i)	Enclosure	- Explosion Proof
(j)	Rheostat	- 90 Ohms/90°
(k)	Weight (approx)	- 1 lb
(l)	Temperature Range	- -65°F to +160°F

NOTE: Improved rheostat assembly makes BYLB 9304-10 into BYLB 9304-11.

2. DISASSEMBLY (See Figure 4)

A. Index numbers in Figure 4 are in disassembly order except for the attaching parts which follow immediately after the part that they attach; disassemble in this manner except where noted below:

CAUTION: EXERCISE CARE WHEN BREAKING THE SEAL BETWEEN GEAR PLATE ASSEMBLY (39) AND GEAR TRAIN HOUSING (61) TO AVOID SCARRING THE MATING EDGES.

2. DISASSEMBLY (Continued)

(1) Do not attempt to remove bearings from gear plate assembly (39).

CAUTION: TAG ALL GEAR ASSEMBLIES TO INSURE SETS BEING KEPT TOGETHER AND NOT INTERMIXED WITH THOSE OF OTHER UNITS.

(2) Do not remove ring (11) from butterfly assembly unless replacement is necessary.

NOTE: Refer to Barber-Colman Company publication for overhaul of drive motor (61).

3. CLEANING

A. Clean non-electrical parts with an approved cleaning solvent, Trichlorethylene, Specification MIL-T-7003, or equivalent, and dry with compressed air.

CAUTION: DO NOT CLEAN OILITE BEARINGS OR ASSEMBLIES CONTAINING OILITE BEARINGS IN CLEANING SOLVENT. USE A CLEAN, DRY, LINT-FREE CLOTH.

B. Clean electrical parts with a clean, dry, lint-free cloth.

4. INSPECTION

A. Inspect all parts visually for cracks, excessive wear, deformities, or damaged threads to determine their suitability for reuse.

B. Thoroughly inspect all parts listed in Table 1.

(1) Replace all parts not meeting requirements listed.

(2) If steel bearings contained in gear plate assembly (39) and gear housing assembly (61) are damaged or do not meet the requirements listed, replace the assembly containing the defective bearing.

C. Inspect ball bearings (59 and 60) for excessive wear or looseness. Replace if necessary.

D. Switches (34) can be inspected for continuity or breakdown; however, it is recommended that they be replaced at overhaul.

E. Inspect all gears for excessive play between teeth and inspect pinion shafts for wear.

4. INSPECTION (Continued)

F. Inspect rheostat assembly (25) for dirt or other foreign material. Check that the windings are smooth, tight, and intact.

G. Inspect wiper arm assembly (22) for roughness that may damage the rheostat assembly.

5. REPAIR OR REPLACEMENT. The design of the valve and actuator limits repair to the removal of slight dents and deformities in covers, supports, plates, etc. All other parts found to be defective during visual inspection and testing shall be replaced.

6. ASSEMBLY

A. Assembly is essentially the reverse order of disassembly paying particular attention to the following:

Material Used During Assembly

Grease	A mixture consisting of ten percent by weight of Molybdenum disulfide, Specification MIL-M-7866, to grease, Specification MIL-G-7118.
Grease	Aeroshell No. 7A per MIL-G-23827.
Glyptal	General Electric Company No. 1201.
Gasoila	Federal Process Company
Tape	Minnesota Mining and Manufacturing Company No. 56.

(1) See Figure 1 for proper gear train installation.

(a) Lubricate bearings, studs, and gear assemblies forming the gear train with a mixture consisting of ten percent by weight of Molybdenum disulfide, Specification MIL-M-7866, to grease, Specification MIL-G-7118. The total amount of lubricant shall not exceed one level teaspoon.

CAUTION: DO NOT PACK GEAR PLATE HOUSING WITH GREASE AS OVER LUBRICATING WILL AFFECT OPERATION IN EXTREME TEMPERATURE.

6. ASSEMBLY (Continued)

(2) When assembling motor and housing assembly (61) to gear train plate assembly (39), dip threads of screws (40) in Glyptal, General Electric Company, No. 1201, or equivalent, prior to assembly.

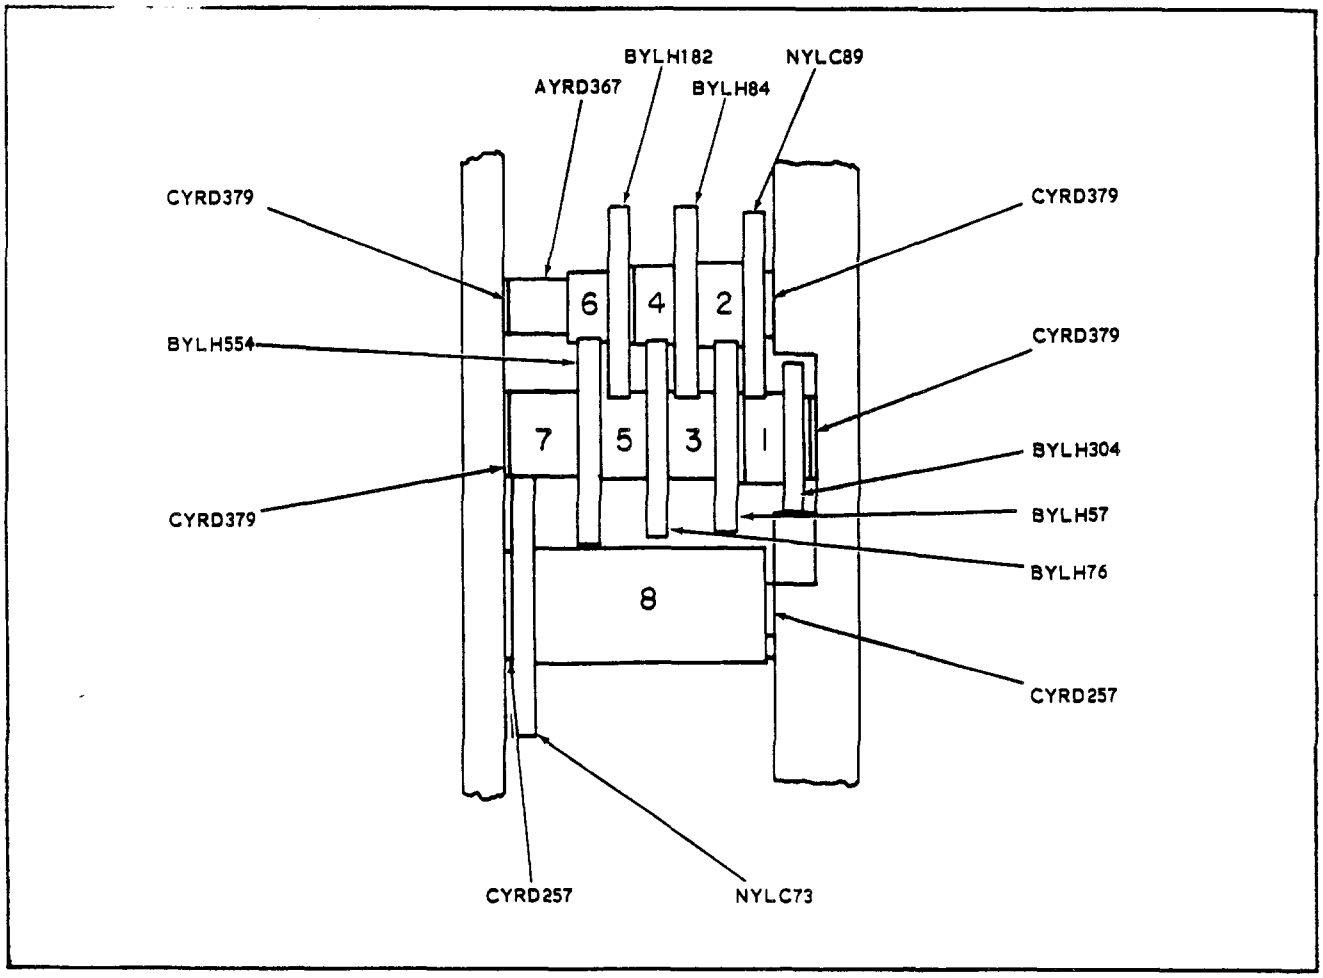

Figure 1. Gear Train Installation

(3) Fill ball bearing (60) 1/3 full of grease per MIL-G-23827.

(4) Install washers (57) as required to obtain minimum end play of output shaft (56). End play must be 0.001 to 0.005 inch.

6. ASSEMBLY (Continued)

(5) Seal mating edges of gear train plate assembly (39) and gear train housing assembly with Gasoila, manufactured by the Federal Process Company, Cleveland, Ohio, or equivalent.

(6) Adjust cam assemblies (29) so that travel is $90^{\circ} \pm 3^{\circ}$ before mounting the rheostat assembly (25). (See Actuator Adjustment.)

(7) Run the actuator to the counterclockwise end of travel and set wiper arm assembly (22) at corresponding end of travel on rheostat assembly (25).

(8) Locate key of connector (16) toward top end of actuator.

(9) Dip nameplate screws (3) in Glyptal.

(10) Safety wire switch housing screws (19 and 20), gear train plate assembly screws (40), and connector screws (17).

(11) Tape or securely fasten all leads so they cannot come in contact with moving or sharp parts.

(12) Rewire, if necessary, in accordance with Figure 2.

(13) Gap ring (11) to 0.006 - 0.003 inch, if necessary.

B. Actuator Adjustment

(1) Mount actuator in a suitable test fixture, and connect to test circuit, as shown in wiring diagram, Figure 2.

(2) Install a pulley wheel at least eight inches in diameter on the main shaft and weight to load the actuator to 5 lb in. Be sure the weight is always hanging on the side of the pulley so the weight is lifted when the actuator is operating.

(3) Mount a protractor on the main shaft. Apply power to pin "C" and rotate the shaft to its clockwise limit. Set the pointer on the protractor to the 0° mark.

(4) Apply power to pin "B" to rotate the shaft to its counterclockwise limit. The protractor shall show a rotation of $90^{\circ} \pm 3^{\circ}$.

(5) Adjust travel, if required, by removing the switch housing cover (18), the rheostat housing (21), the rheostat assembly (25), and the wiper arm

6. ASSEMBLY (Continued)

assembly (22). Loosen the hex nut (26) and rotate the cam assemblies (29) until a travel of $90^{\circ} \pm 3^{\circ}$ has been obtained. Tighten the nut (26) securely after adjustment of the cam assemblies. Run the actuator to the counter-clockwise position and remove from the test fixture.

C. Assemble the valve making sure that the butterfly coupling (62) shows correct butterfly position. Place the butterfly valve in the closed position and mount the actuator to the valve with screws (4).

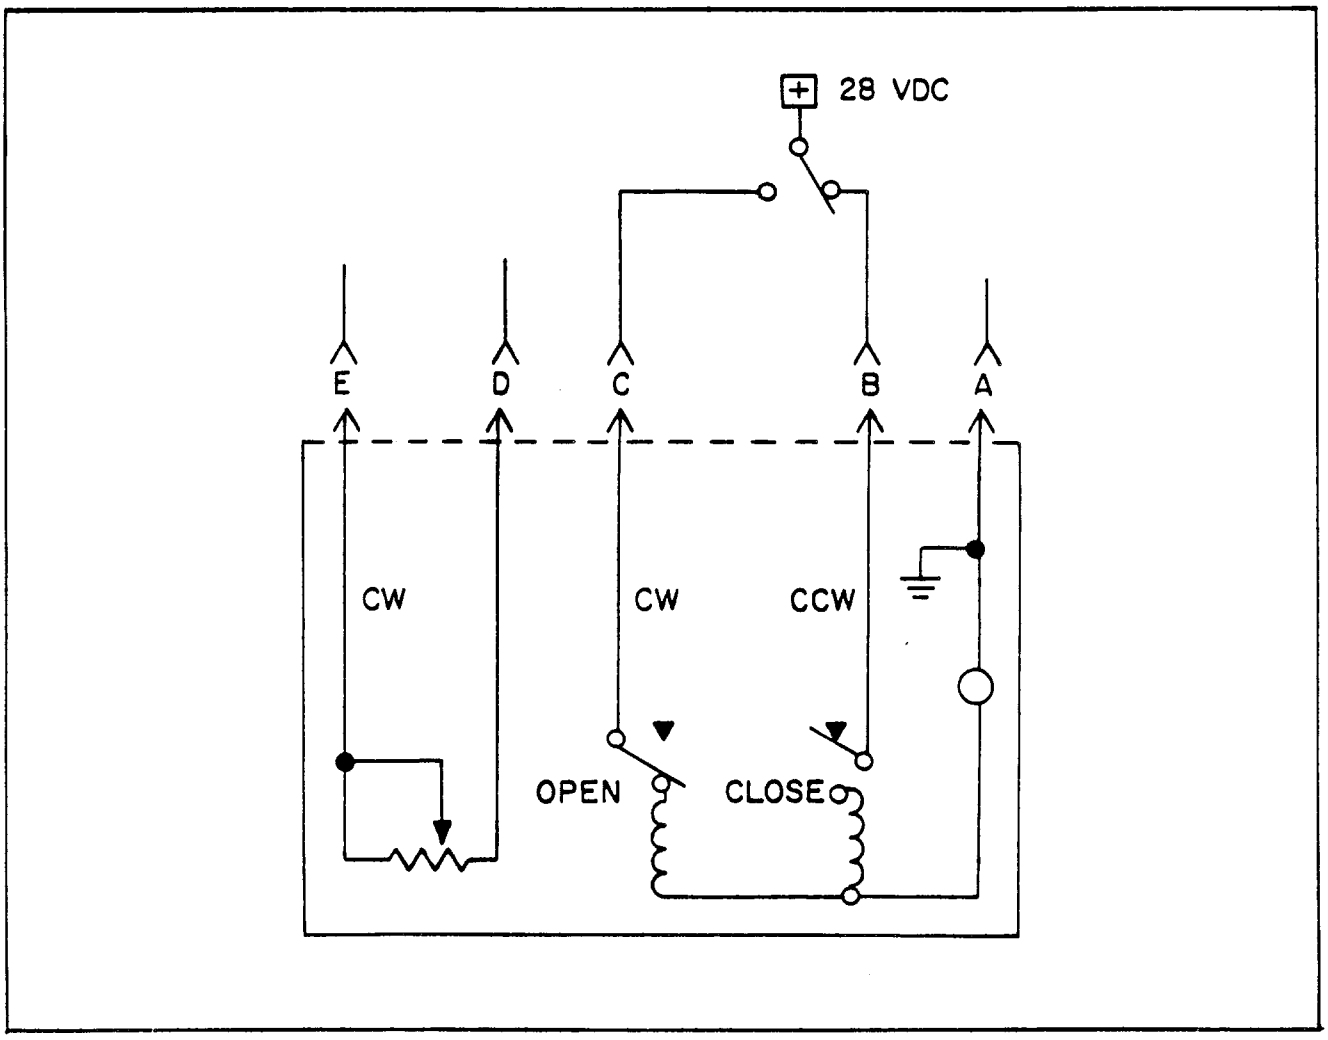

Figure 2. Internal Wiring and Test Circuit Diagram

BARBER-COLMAN COMPANY

OVERHAUL MANUAL

BYLB 9304-10 AND -11 ELECTRO-MECHANICAL ROTARY VALVE

TEMPORARY REVISION NO. 1
Insert Adjacent to Page 7

7. FITS AND CLEARANCES

Table 1. Wear Limits

Index No.	Nomenclature	Maximum Clearance (Inches)
53	Worm Gear Assembly (OD of Shaft)	0.003
39	Gear Train Plate Assembly (ID of Bearing)	
39	Gear Train Plate Assembly Shafts OD	0.003
42, 43, 44, 45, 46, 47, 50	Spur Gear Assembly ID	

8. TESTING

A. Mount the assembled valve and actuator in a suitable test fixture similar to Figure 3.

B. Apply power to pin "B". The valve must move to the full closed position.

C. The resistance between pins "D" and "E" shall be 1 ± 1 ohm.

D. Internal leakage must be checked with butterfly valve closed and shut-off valve open. Internal leakage shall not exceed 0.20 LB/MIN at 80 PSIG and room temperature.

E. Apply power to pin "C". The valve shall move to the full open position ($90^{\circ} \pm 3^{\circ}$).

F. The resistance between pins "D" and "E" shall be 90 ± 5 ohms.

G. External leakage must be checked with butterfly valve open and shut-off valve closed. External leakage shall not exceed 0.02 LB/MIN at 80 PSIG and room temperature.

H. Check timing. The valve shall travel $90^{\circ} \pm 3^{\circ}$ to the full open or full closed position within 22 to 38 seconds at 80 PSIG and room temperature.

7. FITS AND CLEARANCES

Table 1. Wear Limits

Index No.	Nomenclature	Maximum Clearance (Inches)
53	Worm Gear Assembly (OD of Shaft)	0.003
39	Gear Train Plate Assembly (ID of Bearing)	
39	Gear Train Plate Assembly Shafts OD	0.003
42, 43, 44 45, 46, 47 50	Spur Gear Assembly ID	

8. TESTING

A. Mount the assembled valve and actuator in a suitable test fixture

Note: See Temporary Revision For This Page

osi-

hut-
80

D. Apply power to pin "C". The valve shall move to the full open position ($90^{\circ} \pm 3^{\circ}$).

E. External leakage must be checked with butterfly valve open and shut-off valve closed. External leakage shall not exceed 0.02 LB/MIN at 80 PSIG and room temperature.

F. Check timing. The valve shall travel $90^{\circ} \pm 3^{\circ}$ to the full open or full closed position within 22 to 38 seconds at 80 PSIG and room temperature.

NOTE: Please see the TEMPORARY REVISION that revises this page.

8. TESTING (Continued)

OVERHAUL MANUAL

SPLIT SERIES DRIVE MOTOR

DYLM 43400-13

1. DESCRIPTION AND OPERATION.

A. The subject motor is used in a Barber-Colman Company actuator. For overhaul of actuator see actuator overhaul instructions.

B. Refer to table 1 for characteristics of motor.

2. DISASSEMBLY. (See figure 1.)

A. Index numbers in figure 1 are in disassembly order except for the attaching parts which follow immediately after the parts which they attach; disassemble in this manner except as noted below:

(1) Using a bearing puller, remove and discard gear (1) and bearings (16) from armature assembly shaft.

(2) Unsolder brush cables from terminals in rear end cap assembly (11) and discard brushes (8).

CAUTION: DISASSEMBLY OF COMPONENT PARTS OF REAR END CAP ASSEMBLY (11), COIL ASSEMBLY (14), OR ARMATURE ASSEMBLY (17) IS NOT RECOMMENDED.

3. CLEANING.

A. Clean all non-electrical parts with an approved cleaning solvent and dry with compressed air.

B. Clean electrical parts with a clean, dry, lint-free cloth.

4. INSPECTION.

A. Visually inspect all parts for cracks, dents, excessive wear, stripped threads or other damage to determine their suitability for reuse.

B. Check bearing bores in end caps (11 and 15). Replace end caps if the bearings do not fit with a snug slip fit in bearing bores.

5. REPAIR.

A. The design of the motor limits repair to the removal of the slight dents and deformities in metal parts.

(1) If the armature assembly commutator is pitted, grooved, or burned replace the armature assembly (17).

B. No other repair of component items shall be attempted. All other parts found defective during inspection and testing shall be replaced with new or servicable parts.

C. Replace gear (1), brushes (8), bearings (16) and all other items of a similar nature which are not recommended for reuse, at overhaul.

6. ASSEMBLY. (See figure 1)

A. Press bearings (16) on armature assembly shaft using a bearing installer.

CAUTION: WHEN INSTALLING BEARINGS, APPLY PRESSURE ON INNER RACE ONLY.

B. Press a new gear (1) on armature assembly shaft. Support the armature assembly by the shaft in a suitable fixture to press gear in position. Gear (1) must not slip with ten lb. in. torque applied.

CAUTION: BE CERTAIN ARMATURE ASSEMBLY IS SUPPORTED BY SHAFT TO PREVENT DAMAGE TO BEARINGS.

C. Pull leads through front end cap (15). Assembly front end cap (15), coil assembly (14) and rear end cap assembly (11) over armature assembly (17) and secure with screws (12) and washers (13). Seal between coil assembly (14) and front end cap assembly (15), between coil assembly (14) and rear end cap assembly (11) with 3M Co. EC 801 potting compound or equivalent. Dip threads of screws (12) in General Electric Co. Glyptal No. 1201 or equivalent before assembly.

D. Install washers (10) and retainer ring (9). Check end play of armature assembly shaft, installing washers (10) as required to obtain proper shaft end play of 0.002 to 0.012 inch with ten pound axial load causing movement.

E. Solder brush cables to terminals on rear end cap assembly with 580° F solder. Insert brushes in brush guides and place end of spring in slot in end of brush thus holding the brush in position.

(1) Brush cables shall have a minimum of 5/8 inch free length between the brush and the terminal solder point and must be bent toward the brush spring.

(2) Cables must not be stiff from excess solder nor shall they contain any frayed leads.

F. Insulate inside of rear cover (2) with Minnesota Mining and Manufacturing Co. No. 27 tape or equivalent.

G. Position cover on rear of assembly. Seal between cover (2) and rear end cap assembly (11) with 3M Co. EC 801 potting compound or equivalent.

H. Secure cover (2) using washer (4) and screws (3) and (5). Dip threads of screws in General Electric Co. Glyptal No. 1201 or equivalent.

I. Cycle motor at 27 vdc for a period of four hours using a duty cycle of one minute on, 30 seconds off, reversing direction after every off interval.

7. TESTING.

A. Connect drive motor to a 27 volt d-c supply containing a SPDT center off switch and check for proper rotation and operation as follows:

(1) Viewing motor from shaft end, the shaft shall rotate CW with the "plus" side of DC power supply connected to red lead and "minus" connected to the white lead.

(2) Motor shall reach no load speed as specified in table 1 within 20 seconds after start in either direction of rotation.

(3) Running current at no load must not exceed that specified in table 1 in either direction of rotation.

BARBER-COLMAN COMPANY
Rockfor, Illinois

OVERHAUL MANUAL

BYLF 7469 THERMISTOR AND BLOWER ASSEMBLY

1. DESCRIPTION AND OPERATION

A. The blower assembly is to provide sufficient airflow to obtain a representative air sampling across the sensing element.

2. DISASSEMBLY (See figure 3)

A. Index numbers in figure 3 are in disassembly order except for the attaching parts which follow immediately after the parts which they attach.

NOTE: Refer to overhaul instructions F-10447 for overhaul of drive motor (6).

3. CLEANING

A. Clean non-electrical parts with an approved cleaning solvent and dry with compressed air.

B. Clean electrical parts with a clean, dry, lint-free cloth.

4. INSPECTION

A. Inspect all parts for cracks, excessive wear, deformities, or damaged threads to determine their suitability for reuse.

5. REPAIR

A. Remove scratches, dents, or other minor damages to metal parts.

B. Replace all parts found to be defective during inspection or testing with new or serviceable parts.

6. ASSEMBLY

A. Reassemble all parts which were removed during disassembly paying particular attention to the following:

(1) Dip threads of screws (7) in Glyptal, General Electric No. 1201, or equivalent before installing.

6. ASSEMBLY (Continued)

(2) Assemble connector (10) with key located toward top of unit.

(3) Rewire as shown in figure 1.

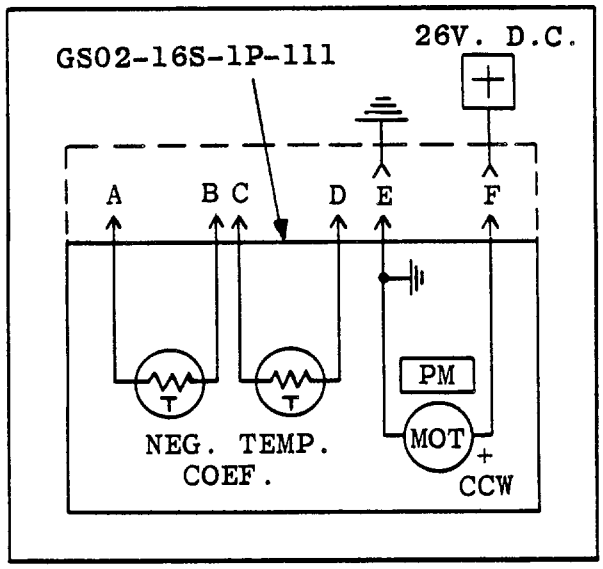

FIGURE 1. WIRING DIAGRAM

(4) Make certain there is free running clearance between blower wheel and cover and also between the blower wheel and the mounting plate.

7. TESTING (figure 1)

A. Connect the unit to an external 26-volt d-c source through a suitable switch to pin E (-) and F (+).

(1) The motor shall operate the blower to draw air into the louvers on the front face of the unit.

B. The unit shall be placed in air chamber having a controlled temperature of 75° ± 5°F. The velocity of the air in the chamber shall be sufficient to prevent stratification.

7. TESTING (figure 1) (Continued)

(1) Use a resistance measuring device * of a very low current type to keep self-heating to a minimum.

(2) The resistance between pins C and D shall be 220 ohms ± 6 ohms. RESISTANCE A-B = C-D.

NOTE: The resistance of the element may slowly decrease. This is due to the potential applied with the resistance measuring device. *

C. Check resistance between each pin and the connector shell at 500 volts d-c. Minimum resistance shall be 5 megohms.

* Wheatstone bridge, or equivalent.

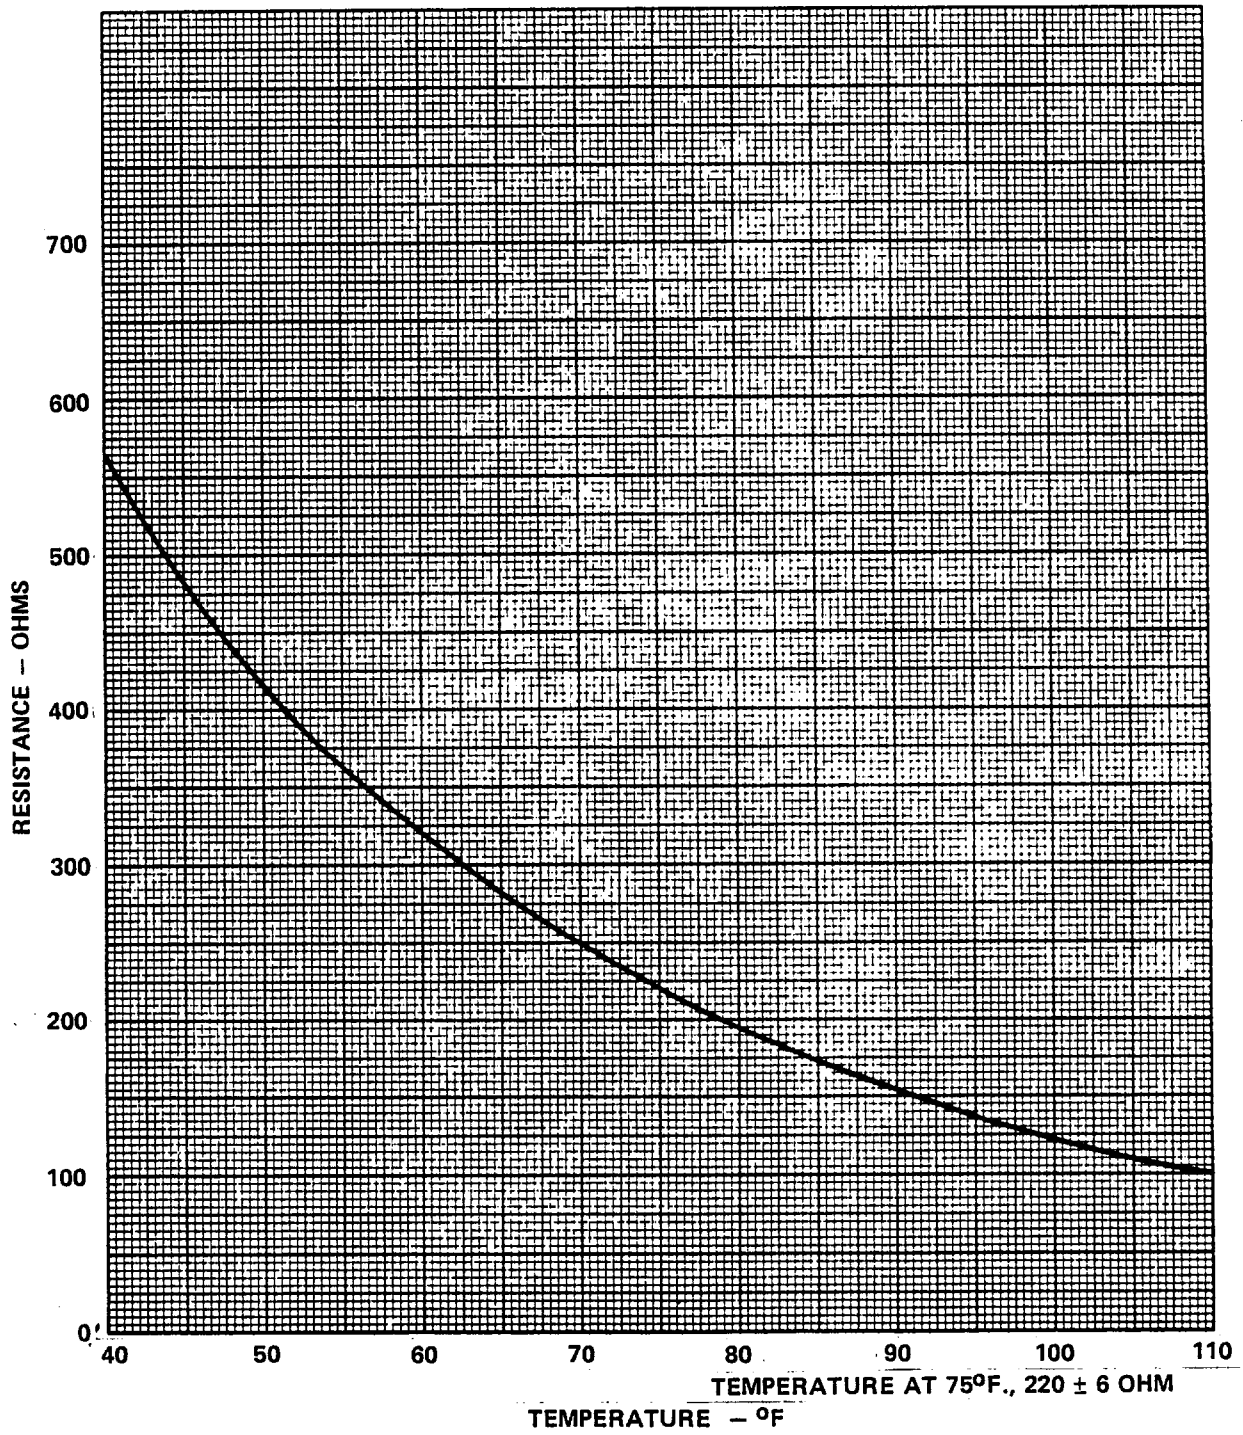

FIGURE 2. RESISTANCE - TEMPERATURE GRAPH

OVERHAUL MANUAL

FYLM 23800-2 PERMANENT MAGNET DRIVE MOTOR

1. DESCRIPTION AND OPERATION

A. The FYLM 23800-2 drive motor is used in Barber-Colman Company Sensing Elements. For overhaul of individual sensing elements see applicable overhaul instructions.

B. This is a permanent magnet motor with an operating voltage of 27 V DC.

2. DISASSEMBLY (SEE FIGURE 3)

A. Index numbers in figure 3 are in disassembly order except for the attaching parts which follow immediately after the parts that they attach; disassemble in this manner except as noted below:

(1) Using a bearing puller, remove bearings (12) from armature assembly shaft.

(2) Unsolder brush cables from terminal in rear end cap assembly (2) and discard brushes (5).

CAUTION: DISASSEMBLY OF COMPONENT PARTS OF REAR END CAP ASSEMBLY (2), MOTOR HOUSING (16), OR ARMATURE ASSEMBLY (11) IS NOT RECOMMENDED.

3. CLEANING

A. Clean all non-electrical parts with an approved cleaning solvent and dry with compressed air.

B. Clean electrical parts with a clean, dry, lint-free cloth.

4. INSPECTION

A. Visually inspect all parts for cracks, dents, excessive wear, stripped threads, or other damage to determine their suitability for reuse.

B. Check bearing bores in end cap (2). Bearing should fit with a snug fit in bearing bores.

5. REPAIR

A. The design of the motor limits repair to removal of slight dents and deformities in metal parts and refinishing of the armature assembly commutator.

(1) If the armature assembly commutator is slightly pitted, grooved, or burned, polish with silica sand polishing sandpaper, or equivalent.

(a) If the pitting has progressed deeper, turn the commutator on a lathe to approximately 100 micro-inch finish, 250 threads per inch when measured visually with a set of standard comparator gauge blocks.

CAUTION: DO NOT DRESS THE COMMUTATOR DIAMETER SMALLER THAN 0.437 INCHES.

B. No other repair of component items shall be attempted. All other parts found defective during inspection and testing shall be replaced.

C. Replace brushes (5), bearings (12), and all other items of a similar nature which are not recommended for reuse, at overhaul.

D. Replace end cap (2) if fit between bearings and bearing bores of either end cap is loose (See Step 4.B).

6. ASSEMBLY (SEE FIGURE 3)

A. Press bearing (12) on armature assembly shaft using a bearing installer.

CAUTION: WHEN INSTALLING BEARINGS, APPLY PRESSURE ON INNER RACE ONLY.

B. Install washer (14) and retainer ring (13). Check end play of armature assembly shaft installing washers (14) as required to obtain proper shaft end play of 0.004 to 0.012 inch with approximately 2 pounds axial load causing movement.

CAUTION: BE CERTAIN ARMATURE ASSEMBLY IS SUPPORTED BY SHAFT TO PREVENT DAMAGE TO BEARINGS.

C. Solder brush cables to terminals on rear end cap assembly with a high temperature (over 550°F) solder. Insert brushes in brush guides and place end of spring in slot in end of brush thus holding the brush in position.

(1) Brush cables shall have a minimum of 5/8 inch free length between the brush and the terminals solder point and must be bent toward the brush spring.

(2) Cables must not be stiff from excess solder nor shall they contain any frayed leads.

(3) Do not allow flux or solder to run down onto the brush spring.

NOTE: After complete assembly run in brushes by operating motor continuously at no-load and rated voltage until 75% of each brush face is in contact with the commutator.

D. Remagnetize the magnets as follows:

(1) Place the motor in a magnetizer which has pole faces curved to fit the curvature of the motor. Magnetize so that, as viewed from the shaft end, plus voltage at red lead will produce CCW rotation.

NOTE: Magnetizing force shall be 30,000 ampere turns minimum.

E. Insulate inside of rear end cap (2) with pressure sensitive teflon tape.

7. FITS AND CLEARANCES

A. Bearings (12) should fit with a snug fit in bearing bores of end cap (2).

8. TESTING

A. Connect the motor to test circuit as shown in Figure 1. Viewing motor from shaft end, plus voltage at red lead will produce CCW rotation.

B. Within 20 seconds the running current and speed at no load must be within the limits specified in Table I in either direction of rotation.

INSPECTION AND OVERHAUL INSTRUCTIONS

FOR BARBER-COLMAN

CONTROL UNIT

TYPE CYLZ 3230 (24V)

INSPECTION AND OVERHAUL INSTRUCTIONS FOR CYLZ 3230 (24V)

TEST EQUIPMENT REQUIRED

Ohmmeter and Wheatstone Bridge

500 volt d-c megger

Equipment necessary to make up test circuit as shown in F6852. Equipment necessary to make Micropositioner calibration fixture and other overhaul tools as described in Micropositioner Overhaul sections, F5114-2.

FUNCTIONAL INSPECTION

Remove the control box cover. With no external connections to the box, check resistance values as follows:

PINS	ITEM	RESISTANCE
N-I	R1	164 ± 6 ohms
L-I	R2 CW	0 + 2 - 0 ohms
	R2 CCW	75 ± 8 ohms

NOTE

Operational tests on the control box must be performed in an area which is reasonably free from electric fields. The presence of a strong electric field will affect the calibration of the control box.

Connect test circuit as shown in F6852.

Rotate R2 rheostat in CW direction. Mark where red indicator lamp lights. Turn R2 rheostat in CCW direction. Mark where green indicator lamp lights. Set R2 rheostat midway between points where lamps light.

Seal shaft of R2 rheostat. Disconnect test circuit and check resistance to ground of all pins. It should be 5 megohms or more.

Check all electrical wiring and soldered joints. All wiring to connector pins and rheostat lugs should be covered with sleeving.

All wires should be securely cabled with cabling twine. Solid wire resistor leads should be as short as possible.

OVERHAUL INSTRUCTIONS

(Refer to Assembly drawing of CYLZ 3230. F6883.)

All parts found to be defective or damaged should br replaced. Disassemble the receptacle insert from the shell by removing the snap ring.

Micropositioner may be unplugged after removal of screw No. 24. Refer to Micropositioner Overhaul Instructions F5114-2 for inspection, overhaul and calibration.

Inspect relay coil shunting resistors No. 21 to see that they are intact and of proper resistance. (1000 ohms).

Inspect dividohm No. 13 to see that it is intact. Check for a mounting washer No. 12 between the mounting plate No. 25 and the dividohm, and between the dividohm and the stop nut No. 14. Resistance of dividohm No. 13 should be set at 164 ohms.

Check the arc suppressor No. 27. It is a hermetically sealed unit containing two .25 MFD., 100 W.V. d-c condensors and one 560 ohm, 1/2 watt resistance connected in a "Y" circuit.

The rheostat No. 17 (R2) has a resisttance of 75 ohms. It is a wire-wound screwdriver adjusted unit, and must be sealed after final calibration is made.

Check all electrical wiring and soldered joints. All wires to receptacle pins must be protected with glyptal and sleeving. Wiring should be securely laced.

Clean up burned or pitted contacts with a burnishing tool and/or hard finish paper.

Repeat functional test procedure.

Subject: Micropositioner, Method of Overhaul,

Barber-Colman Company has recommended in the past that Micropositioners be returned to the factory for overhaul. However, because of the expense and time required with customs regulations and foreign exchange for foreign operators, we are issuing these instructions for your optional use. We continue to recommend that Micropositioners be returned to us for overhaul whenever possible, since our production fixtures, techniques, and test equipment are essential for best results.

Special equipment required:

To adequately overhaul the Micropositioner, it is recommended that the following tools and fixtures be obtained.

Magnetizer - the magnetizer should consist of coils of approximately 30,000 total ampere-turns. The poles of the magnetizer must be large enough to contact the entire surface of the upper and lower pole pieces of the Micropositioner. It is essential that the polarity of the unit be clearly shown to insure that the Micropositioner be polarized in the correct direction.

Armature Shims - brass shims to protect the armature from the sudden impulse of the magnetic field during magnetizing should be made as shown in Figure 1.

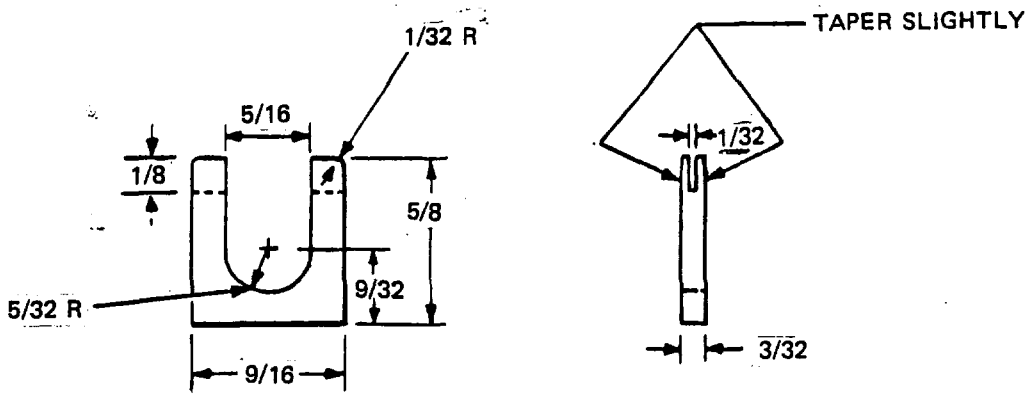

Figure 1

Demagnetizer - the demagnetizer should be an air core type coil operating on alternating current regulated by a 'variac' transformer. This is necessary to allow control of the degree of demagnetizing. An approximate recommended value for the coil is 1000 ampere-turns. If a variable power source is not available, the degree of demagentizing may be controlled by the proximity to the coil.

Calibration Fixture - Refer to Figure 2. This fixture is used for adjusting the sensitivity of the Micropositioner and checking the contact gap. It should incorporate an accurate direct current millivoltmeter with a one milliampere movement, zero center. Suitable multipliers should be provided to give a range of 500 millivolts. The load specified in Table 1, page 10, should be used. Refer to your system wiring diagrams for correct polarity.

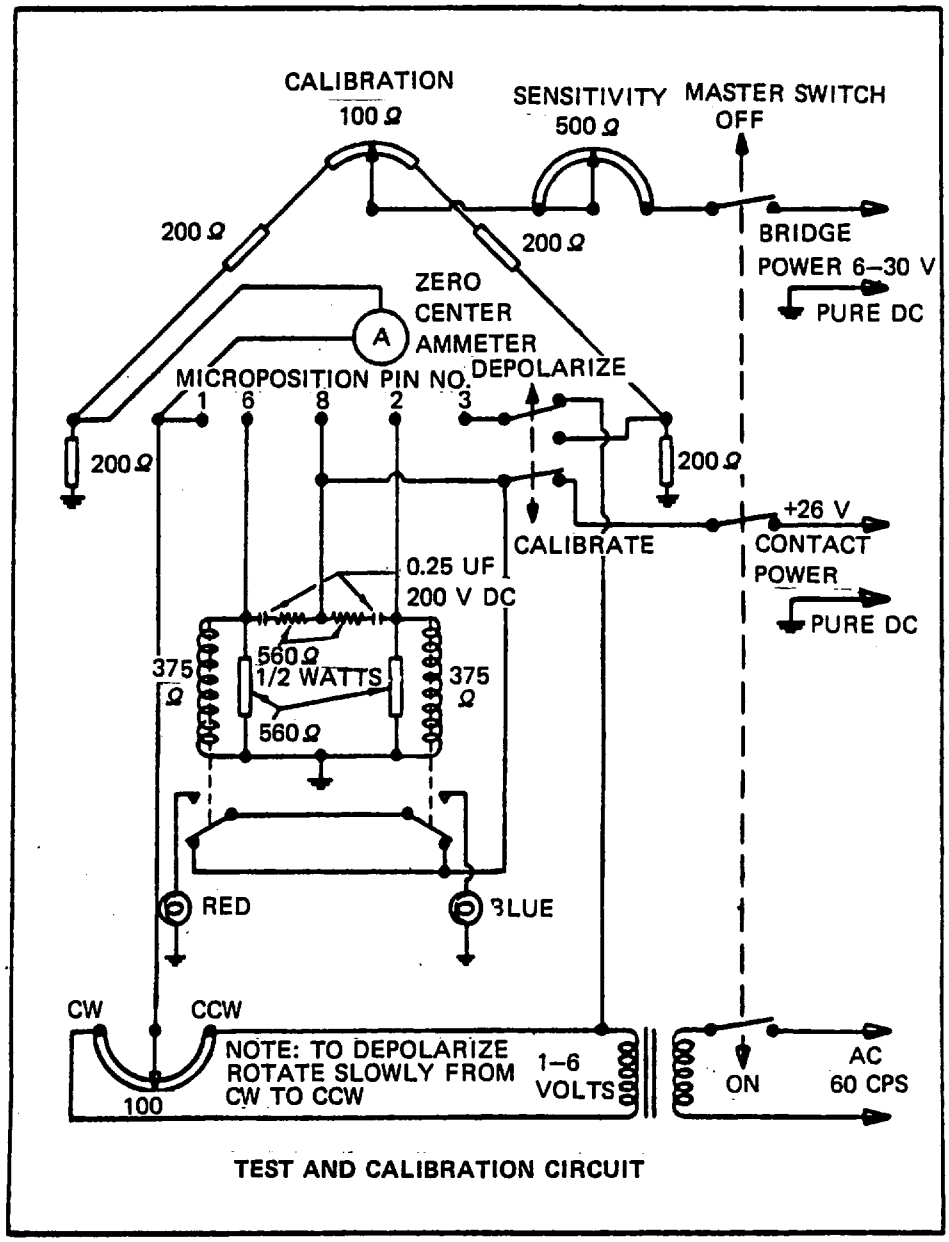

Figure 2

Solder Pot - the pot should have a center tube which will protect the bakelite locating pin on the octal plug.

Shunt Bar Adjustment Wrench - this wrench may be made from a piece of non-magnetic 1/4" round stock as shown in Figure 3.

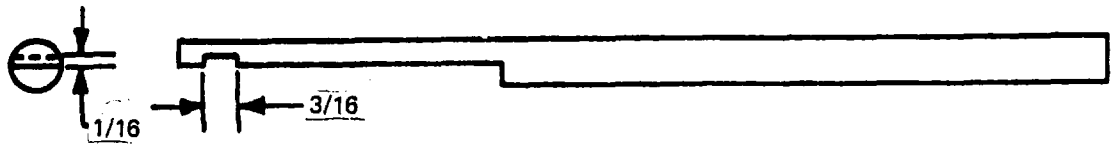

Figure 3

Contact Screw Adjustment Wrench - this wrench should be a small 3/16" open end type of nonmagnetic material to make contact gap adjustments.

Contact Screw Installation Wrench - this wrench may be a standard 3/16" hex head screwdriver type socket wrench modified as shown in Figure 4 to protect the contacts. It is used for the installation and removal of the contact screws.

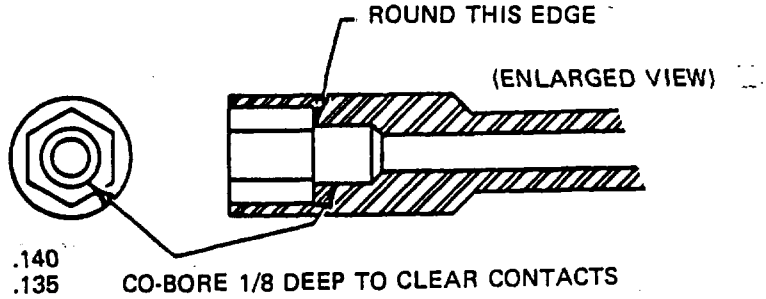

Figure 4

Double Toothed Screwdriver - this tool may be made by milling or grinding a slot in a standard blade screwdriver (maximum torque of 10 lb. in.). It is used in the assembling of the base mounting nut, AYLZ 112. Refer to Figure 5.

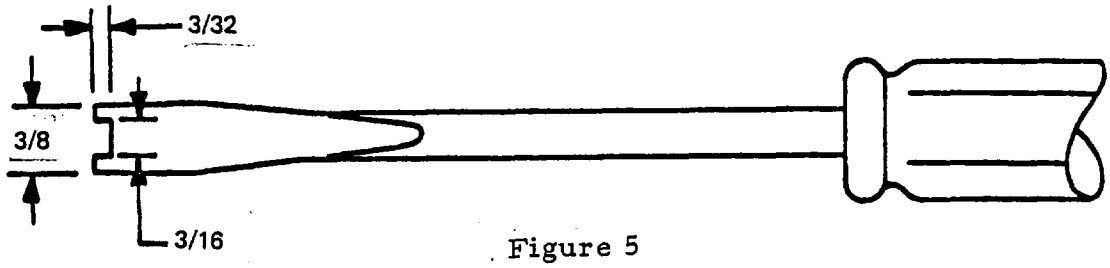

Figure 5

Feeler Gauge - clean, smooth feeler gauges of the following sizes are required: .006", .008", .011", and 013". They are used for adjusting contact gaps.

Magnifier - an eye glass type magnifier (jeweler's loupe) is recommended so that the contact gap may be set accurately.

Overhaul Instructions:

1. Demagnetize the complete Micropositioner by inserting inside the demagnetizing coil as shown in Figure 6. If a variable power source is used, be sure that the voltage is gradually reduced to zero before removing the Micropositioner from the coil. If a fixed power source is used, the Micropositioner should be slowly withdrawn from the coil field until outside of its effective magnetic field.

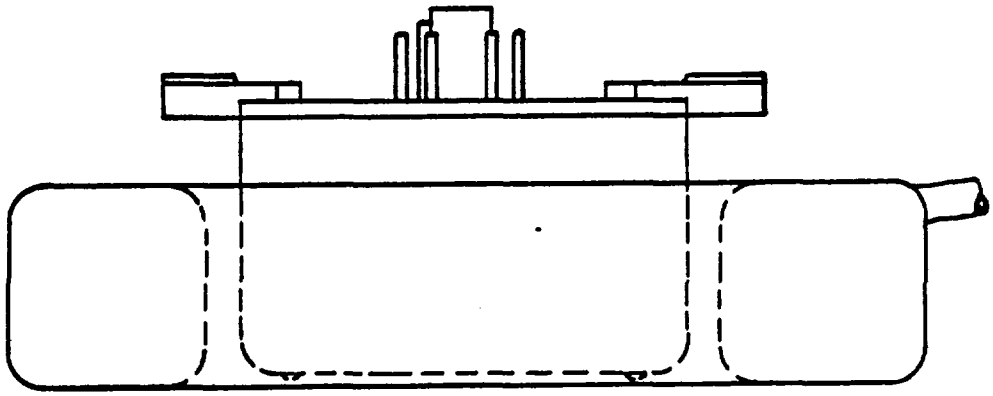

Figure 6

2. Remove cover from Micropositioner. (AYLZ 211-1)

NOTE

AYLZ 237-1 base permits armature to be replaced without complete disassembly. Loosen screws AYLZ 110 and AYLZ 30. Remove armature. Replace stationary contacts if necessary. Install new armature. Set contact gaps and calibrate per Table I.

3. Remove two screws AYLZ 32, nut AYLZ 112, and spring washer AYLZ 111, attaching bakelite base to Micropositioner subassembly. Refer to Figure 7, page 5.

4. For octal plug type - remove the wires from the pins on base plug by dipping the plug in a solder pot equipped with a center metal tube to protect the bakelite locating post.

   For other types - the wires are removed individually by means of a soldering iron.

   IT IS EXTREMELY IMPORTANT that all coil wires be securely tagged or otherwise identified since the proper recalibration of the Micropositioner will depend upon correct coil polarities.

5. Remove the four shunt bars AYLZ 77-2 from the pole piece AYLZ 90. Refer to Figure 8, page 6.

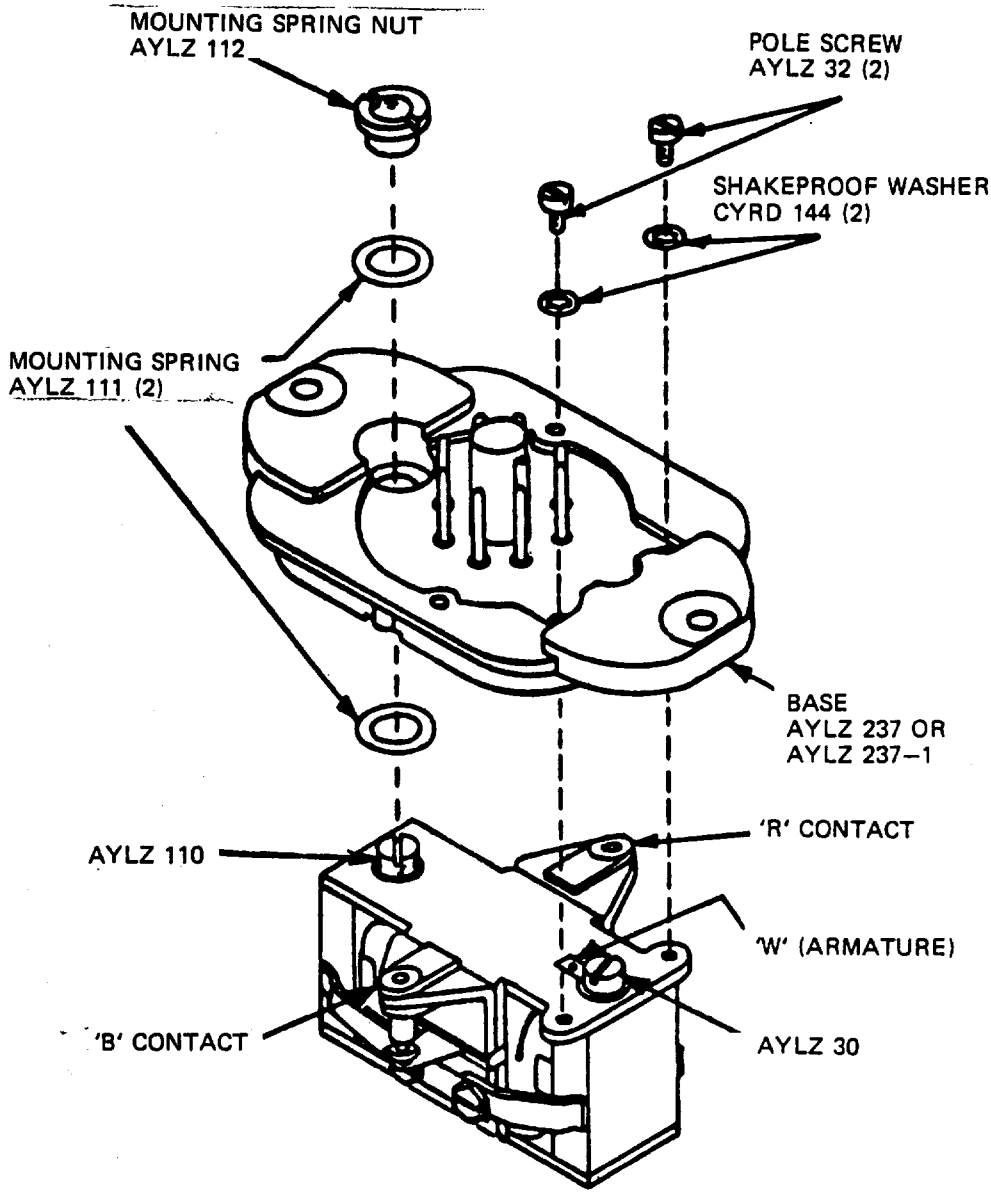

Figure 7 - Octal Base Micropositioner

6. Remove the magnet screws AYLZ 110 and AYLZ 30.

NOTE

Use a sharp knife or other suitable instrument to remove cement bonding upper and lower pole pieces to coil.

7. Remove and discard coil (if necessary), armature, and contact screws. Replacement parts are furnished as noted in Table 1.

8. Inspect lower pole piece assembly for loose contact supports and cracked insulating washers. Replace if damaged.

Figure 8

9. Install coil, armature, and contact screws. Brass shim stock, .005 inch thick, is used to center the armature in the coil slot. Refer to Figure 9. Before assembling the magnets and pole pieces it is recommended that the mating surfaces be thoroughly inspected for corrosion or foreign particles so that a good magnetic circuit is obtained.

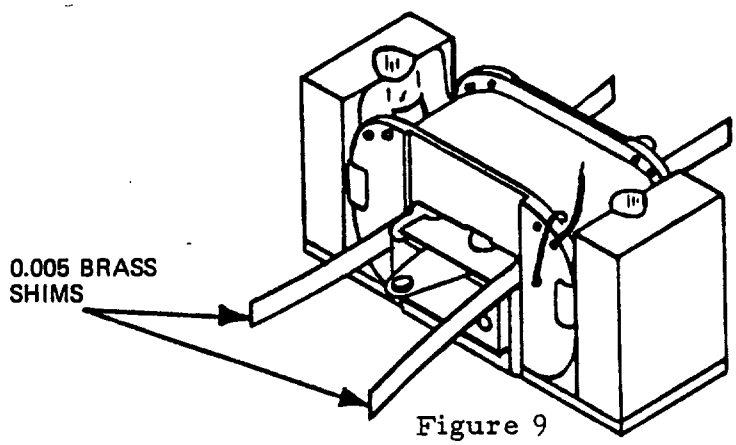

Figure 9

10. Alternately tighten magnet screws until snug. When clamping magnets between upper and lower pole pieces, place enough finger pressure on the magnets toward the coil to allow magnets to be clamped flush with the ends and sides of the pole pieces. Inspect for centering and alignment of armature. Especially note that 'side rails' are at right angles to face of pole pieces. Then securely tighten magnet screws. Caution: Do not exceed 10 lb. in. torque on screwdriver.

11. Reinstall shunt bars AYLZ 77-2, link AYLZ 113, and screws AYLZ 530 on the assembly, moving the shunt bars to the top of the magnet (toward the AYLZ 90 pole piece). Refer to Figure 8.

12. Adjust the contact gaps, first by rotating the stationary contacts with a 3/16" open end wrench until a gap approximately equal to half that specified in Table I is obtained on both contacts. After the approximate gap is obtained, the total gap should be measured and adjusted as shown in Figure 10. The total gap values in inches are given in Table I; tolerances of plus or minus .001 inch are allowable. Recheck the gap on each contact.

    It should be explained that the factory method of overhaul differs at this stage from the above procedure in that the contact gap is not measured in terms of distance, but rather as a particular torque value which is obtained by applying a specific weight to a shop fixture. The weight closes the contact when the correct value of torque is reached. This method is generally too elaborate for field use.

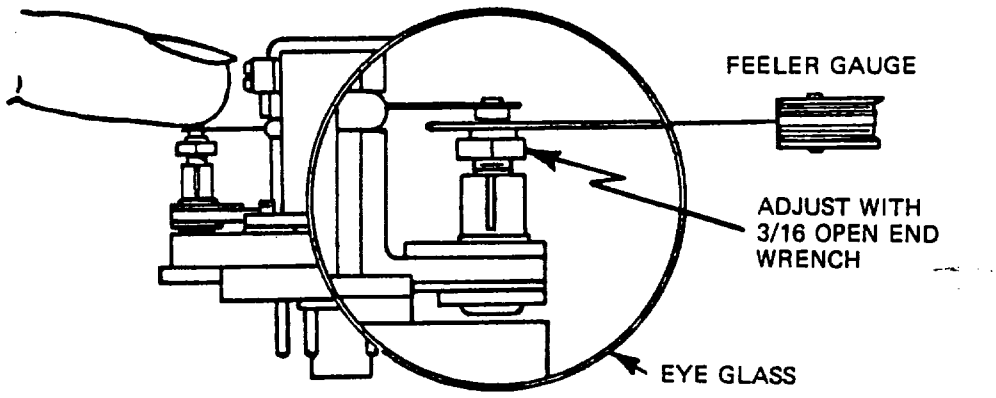

Figure 10

13. Place the assembly in the magnetizer. Insert the nonmagnetic shims in the armature to protect it from the sudden impulse of the magnetic field during magnetizing. Upper pole piece AYLZ 90 forms the south pole; lower pole piece forms the north pole. Therefore, the Micropositioner should be placed in the magnetizer with AYLZ 90 adjacent to the magnetizer's north pole. Magnetize the assembly.

14. Solder leads from the detent coils to the correct contacts. Caution: Correct polarity is essential for proper operation.

15. Prepare remaining leads for soldering to plug.

16. Install the Micropositioner subassembly on the bakelite base with two AYLZ 32 screws and AYLZ 112 nut. Two spring washers AYLZ 111 are placed one on each side of the base as shown in Figure 7. They should be placed so that the convex surface is adjacent to the base. It is very important that the washers be properly centered so as to provide a resilient mounting.

17. Wire all connections to their respective pins or lugs. In the case of the octal plug-in type, the pin should be dipped into a solder pot with the bakelite centering post inserted into the protecting metal tube. Refer to Table II, page 11, for wiring diagram.

    Note that the recommended solder is standard 50/50 type with no resin core. A noncorrosive flux is very important. A recommended flux is Kester #415T. The whole soldered area must be cleaned with a solution of alcohol after completion. All fumes from flux and soldering iron must be kept away from contacts. Gyptal solvent fumes also foul contacts. It is recommended that the cover be on the Micropositioner whenever possible during soldering operations.

18. Insert the Micropositioner into the calibration test fixture and apply a variable AC voltage to the coil to insure depolarization. Reduce AC voltage slowly to zero. Using the calibration bridge, calibrate the unit to the values shown in Table I with an allowable tolerance of plus or minus 20%.

When checking the sensitivity, check the sensitivity of one contact, adjust shunt bars, if necessary, and then reverse the coil voltage toward making the opposite contact before rechecking the first contact.

The shunt bars are to be adjusted up or down with the nonmagnetic shunt bar adjustment wrench. Raising shunt bars causes contact to close at lower voltage; lowering shunt bars causes contact to close at high voltage. Adjustment of shunt bars on one side of the Micropositioner will be found to have the greatest effect on the contact on the opposite side. When adjusting shunt bars, move each shunt bar an equal amount to obtain proper sensitivity. Keep shunt bars symmetrically adjusted.

The shunt bars should be approximately centered on the sides of the magnets when calibrated. If the shunt bars are near the bottom of the magnets, the units should be demagnetized slightly with the demagnetizing coil. Maximum stability is obtained when the magnets are demagnetized slightly after the initial magnetization.

19. Remove Micropositioner from the test fixture and replace cover. Recheck calibration with cover installed.

Charges: Barber-Colman Company will supply the required parts as listed in Table I.

Optional: Barber-Colman Company continues to recommend that whenever possible, the Micropositioner should be returned to the factory for overhaul. Factory overhaul is accomplished at a nominal charge of approx. $5.00 each net plus price of any parts which need replacement.

Further information:

1. The Micropositioner should be treated as a delicate instrument and it is strongly recommended that the above method of overhaul be carried out in the instrument shop.

2. Caution: To insure accurate and reproducible calibration of the Micropositioner, the units should not be calibrated or checked in the immediate vicinity of any other magnetic fields, either direct or alternating current. Other troubles sometimes encountered in checking and calibrating fixtures are: Ferrous panels, tables, or table supports; unshielded permanent magnet instruments; heavy current bus bars; and d-c or a-c generators.

3. If a Micropositioner is exposed to sudden shock, such as that resulting from rough handling or dropping, the unit should be completely recalibrated.

4. It is recommended that periodic service checks be made of the contacts and calibration. The contacts can be cleaned with a fine burnishing tool or #4/0 polishing paper if thoroughly cleaned afterwards with C.P. carbon tetrachloride or any equivalent solvent which will not leave a residue.

* REFER TO TABLE II

Footnotes,
Table I:

1 The sensitivity is the voltage or current necessary to close either contact.

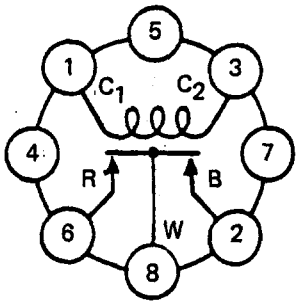
When current flow from C1 to C2 (C1 is plus with respect to C2), W closes to contact R. Opposite flow of current causes W to close to contact B.

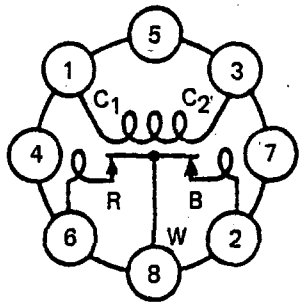
2 Maximum differential between make and break of the Micropositioner contacts indicates the amount under the make voltage or current that the contacts should reopen. This is dependent upon the load if detent coils are used.

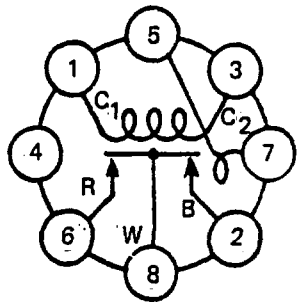
3 Note power source for contacts; be sure polarity agrees with actual application. Refer to your system wiring diagrams for the correct wiring circuit of the simulated load.

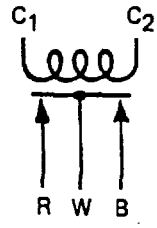
4 Detenting is that action caused by auxiliary coils wound around the main coil to aid in eliminating armature bounce. The load current forms a magnetic field which aids in holding the contact closed. Detents are also used to provide a maximum frequency limit on heater cycling controls.

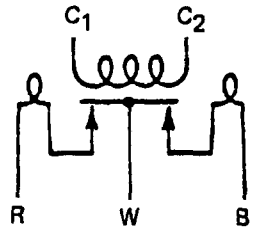
5 Current 5 to 7 detents contact R. Current 7 to 5 detents contact B.

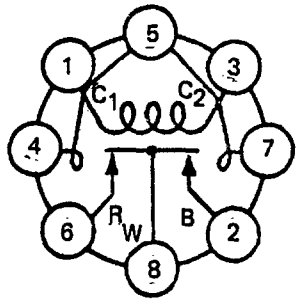


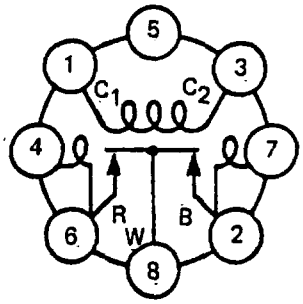


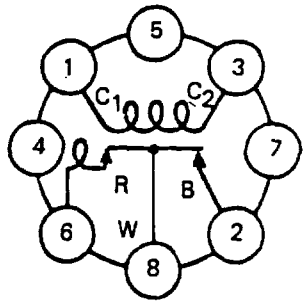












6 CYZP 175 relays are available at a unit net price of $10.60 It is a 26 V. d-c, 375 ohm coil relay.

7 Plus symbol indicates detent current flow from "W" to "R" or "B". Negative symbol indicates current flow in reverse direction.

8 Inherent make to break differential on the micropositioners is approximately 5% of sensitivity.

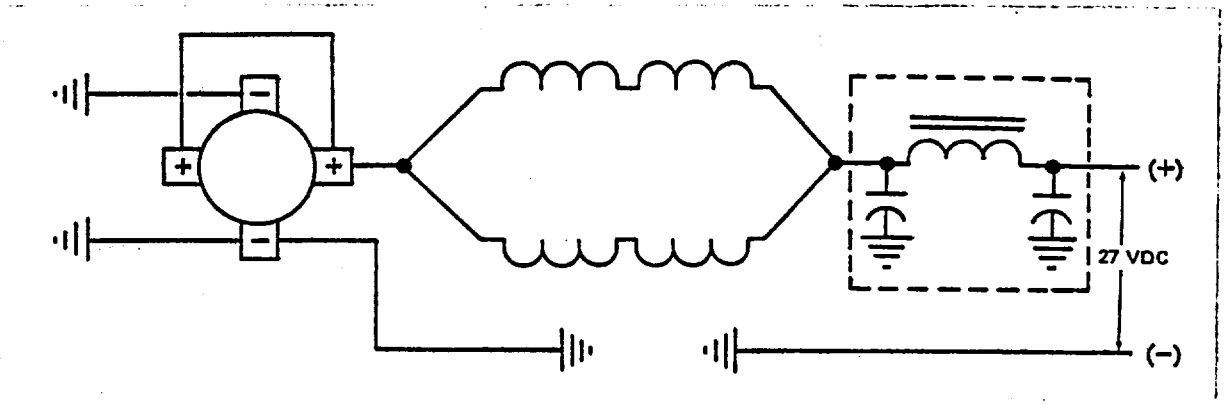
DYNAMIC AIR M5861AD-6B

INTRODUCTION

This manual contains instructions for the overhaul of the Dynamic Air Engineering Vaneaxial Blower M5861AD-6B complete with motor M3424CB.



1. Description and Operation

A. Physical Characteristics

The vaneaxial blower consists of a propeller driven by a series type, dc electric motor and enclosed in a housing having beaded ends for connection to inlet and outlet ducts by means of clamps. The motor is energized through a low-pass, pi-section filter (see Figure 1) to prevent transmission through the aircraft wiring of any electromagnetic interference which may be generated by the motor.

B. Operation

The blower is used to circulate air through an airconditioning duct and is driven by 27 volts dc (nominal).

Internal Wiring Diagram

Figure 1

C. Leading Particulars

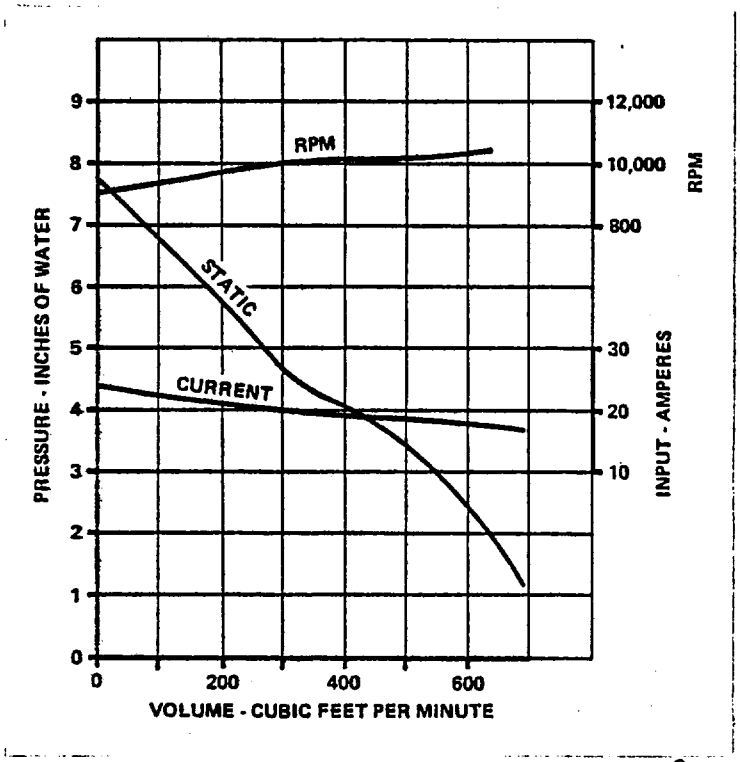
The leading particulars of the blower are shown in Table 1.

Table 1

Leading Particulars

Energizing Voltage	27 volts dc (nominal)
Operating Current	21 amperes (maximum)
Operating Speed	10,450 rpm (minimum)
Service Duty	Continuous, sea level to 8000 ft
Performance (nominal)	See Figure 2
Operating Temperature	-54°C (-65°F) to +121°C (+250°F)
Electromagnetic Interference	Filtered
Motor Brushes	Body Length, New, 9/16 inch Useful Length 7/16 inch
Rotation	Counterclockwise viewed from propeller end
Minimum Useful Diameter of Commutator	1.0625 inches
Bearing Insert Seats, Inside Diameter	1.1810/1.1814 inches
Weight	7 1/4 pounds

2. Disassembly



NOTE: If unit is operative, perform test procedure as outlined in paragraph 8 before disassembly.

A. Disassemble Vaneaxial Blower (Figure 3)

(1) Remove pin (2) and detach propeller (3) from motor shaft.

(2) Disconnect electrical leads at housing by removing nuts (4, 6), washers (5, 7, 8, 9, 11, 12), insulator (10) and bolts (13).

(3) Cut and remove lockwire from bolts (14). Remove bolts (14), washers (15) and spacers (16). Slide housing and nameplate assembly (17) off motor and filter assembly. Do not remove nameplate (18) from housing (19).

Performance at Standard Air Density 0.0765 at 15°C(59°F)

Figure 2

(4) Disconnect electrical leads at filter (22) by removing nuts (23) and washers (24, 25). Remove lead (27).

(5) Detach filter (22) from motor assembly (31) by removing nuts (20) and washers (21). Remove spacers (26).

(6) Detach lead (30) from cap assembly (34) by removing nut (28) and washer (29). Detach negative motor lead from cap assembly.

NOTE: Identify negative and positive motor leads for guidance on reassembly.

(7) Detach cap assemblies (34) by removing nuts (32) and washers (33).

(8) Remove brush and spring assemblies (35) from motor, and inspect as detailed in paragraph 4.

NOTE: Mark each brush and spring assembly and corresponding holder so that brush and spring assemblies can be reassembled in the original positions if replacement is not required.

(9) Remove screws (36) and washers (37). Remove end head (38) from motor.

(10) Remove armature assembly (43) complete with ring (39), washer (40), bearings (41) and shields (42). Separate ring, washer, bearings and shields from armature assembly.

(11) Remove bridges (45) and grommet (46) from stator and end head assembly.

(12) Remove screws (47, 48, 49), holder and lead assemblies (50, 52), and holders (51, 55) from end head (53). Note wiring connections for guidance on reassembly.

(13) Separate end head (53) from stator assembly (54).

(14) Remove holder (55) from stator assembly (54).

3. Cleaning

A. General

(1) Clean electrical leads and motor parts using clean, dry compressed air and a clean, lint-free cloth.

CAUTION: DO NOT SPIN BEARINGS WITH COMPRESSED AIR.

(2) Other parts may be washed in kerosene or solvent (refer to Table 2). After cleaning, dry parts thoroughly using clean, dry, compressed air and a clean, lint-free cloth.

WARNING: USE SOLVENT AND KEROSENE IN A WELL-VENTILATED AREA. AVOID BREATHING FUMES. AVOID SKIN CONTACT. KEEP AWAY FROM FLAME.

Table 2

Cleaning Materials and Compounds

MATERIAL	SPECIFICATION OR MANUFACTURER
Kerosene Solvent	VV-K-211 P-D-680

4. Inspection/Check (Figure 3)

A. General

(1) Inspect all parts for obvious wear, damage or corrosion.

(2) Inspect electrical leads for damage such as broken wires, broken or deteriorated insulation.

(3) Inspect threaded parts for damaged, stripped or crossed threads.

(4) Check brush and spring assemblies (35) for amount of wear. Wear must not exceed 20 percent of useful length (refer to Table 1).

(5) Inspect bearing seat inserts in end heads (38, 53) for physical damage, fret-corrosion, or evidence of rotating bearings. Check inside diameter of each bearing seat insert. If inside diameter exceeds 1.1814 inches, reject end head.

(6) Check that bearings (41) rotate freely with no binding or roughness.

(7) Inspect armature assembly (43) for commutator wear and eccentricity. Minimum diameter of commutator should be greater than 1.0625 inches.

(8) Check stator assembly (54) for physical damage.

B. Perform Dielectric, Insulation and Continuity Tests

CAUTION: MAKE SURE THAT ALL CARBON DUST HAS BEEN REMOVED WITH COMPRESSED AIR BEFORE

MAKING DIELECTRIC, INSULATION AND CONTINUITY TESTS.

(1) Make dielectric and insulation tests of armature assembly between commutator and shaft. Armature assembly shall withstand ac hi-potential test of 500 volts rms at 60 Hz for one minute without signs of insulation breakdown. Dc insulation resistance shall be 200 megohms or greater. Check armature windings for continuity.

(2) Make dielectric and insulation tests of stator assembly between leads and frame. Stator assembly shall withstand ac hi-potential test of 500 volts rms at 60 Hz for one minute without signs of insulation breakdown. Dc insulation resistance shall be 200 megohms or greater. Check stator windings for continuity.

5. Repair (Figure 3)

A. General

(1) Replace all parts that do not pass inspection and are damaged beyond simple repair.

(2) Remove minor scratches, burns and corrosion from steel parts using crocus abrasive cloth (refer to Table 3).

(3) To refinish defective cadmium-plated surfaces, smooth out using abrasive paper, clean thoroughly and restore plating in accordance with Specification QQ-P-416.

(4) To refinish defective painted areas, smooth out using abrasive paper, clean thoroughly and apply one coat of primer. Allow to air-dry for 18 hours. Then apply two coats of black lacquer in accordance with manufacturer's directions.

(5) Replace bearings (41) if unit has been in service for 500 hours or longer since last overhaul or if brush and spring assemblies are being replaced.

(6) To true up commutator, mount armature assembly (43) on lathe and turn commutator concentric with armature shaft,

Table 3

Repair Materials and Compounds

MATERIAL	SPECIFICATION OR MANUFACTURER
Crocus Abrasive Cloth	P-C-458
Abrasive Paper (Grit No. 600)	P-P-101
Primer	MIL-P-8585
Black Lacquer	Commercial (to match existing finish)
Kraft Paper	UU-P-268

removing minimum metal necessary and checking that commutator diameter remains greater than 1.0625 inches. After turning, undercut mica between commutator bars to approximately 0.031 inch deep being careful to remove all mica particles. Polish commutator with abrasive paper. Thoroughly clean using dry, compressed air. Repeat dielectric and insulation tests. Wrap armature assembly in lint-free cloth or kraft paper until reassembly.

6. Assembly (Figure 3)

A. Assemble Motor Assembly

(1) Install holder and lead assemblies (50, 52) and holders (51, 55) into end head (53), making sure that they will clear commutator by 1/32-inch and that the rectangular portion of each will be exactly parallel to the centerline of the commutator. Retain by installing set screws (47, 48, 49). See Figure 1 for electrical connections.

(2) Install grommet (46) into end head (53), pass electrical leads through grommet and position stator assembly (54) in correct alignment to end head.

(3) Install bridges (45) in stator assembly.

(4) Install one shield (42), one bearing (41) and washer (40) on commutator end of shaft of armature assembly (43).

CAUTION: SPRING FINGERS OF WASHER (40) MUST BEAR AGAINST OUTER RACE OF BEARING (41). UP-

SET CENTER OF SHIELD (42) MUST BEAR AGAINST INNER RACE OF BEARING.

(5) Apply a very thin film of LUB 300 to the outer race of bearing (refer to Table 4).

NOTE: Bearings (41) are prepacked with grease. Specification MIL-G-3278.

(6) Install armature, shield, bearing and washer subassembly into stator and end head assembly, making sure that bearing seats properly in end head.

(7) Install shield (42), bearing (41) and ring (39) on propeller end of armature shaft.

CAUTION: UPSET CENTER OF SHIELD MUST BEAR AGAINST INNER RACE OF BEARING.

(8) Apply a very thin film of LUB 300 to the outer race of bearing and install end head (38), making sure that bearing seats properly in end head.

(9) Check clearances and alignment of holder and lead assemblies (50, 52) and holders (51, 55) to commutator and adjust if necessary.

(10) Secure end head (38) to stator and end head assembly (44) using screws (36) and washers (37). Take care not to trap electrical leads.

(11) Install brush and spring assemblies (35) and cap assemblies (34). Secure with nuts (32) and washers (33).

NOTE: Two nuts (32) are used at set screw (48).

(12) Attach propeller (3) to motor shaft and secure with cotter pin (2).

(13) Connect negative motor lead to set screw (48) and secure temporarily with nut (28).

B. Seating of Motor Brushes

WARNING: SECURE MOTOR TO TEST BENCH AND ENCLOSE PROPELLER WITH A SUITABLE CAGE TO PROTECT PERSONNEL BEFORE APPLYING POWER TO MOTOR.

(1) When new brushes have been installed, or commutator has been trued, operate motor on 8 to 14 volts dc until brushes are 75 to 90 percent seated. Check that air flow direction is from propeller towards armature end of motor. If air flow direction is incorrect, check internal wiring connections.

(2) After brushes are seated satisfactorily, operate motor on 27 volts dc for 20 minutes. Then check that operating current is not greater than 20.8 amperes and operating speed is not less than 9650 rpm. Disconnect motor from dc power supply.

C. Assemble Vaneaxial Blower

(1) Install spacers (26) on set screws (49), and then install filter (22) and secure with nuts (20) and washers (21).

(2) Connect positive motor lead to filter using one nut (23), one washer (24) and one washer (25).

(3) Remove nut (28) from set screw (48) leaving negative motor lead connected to set screw. Connect lead (30) to set screw (48) and secure with nut (28) and washer (29).

(4) Connect lead (27) to filter (22) using one nut (23), one washer (24) and one washer (25).

(5) Install motor assembly into housing and nameplate assembly (17) and secure loosely with bolts (14), washers (15) and spacers (16). Torque bolts (14) to 10 pound-inches initially, then to 20 pound-inches and finally to 30 pound-inches. Lock adjacent pairs of bolts together using lockwire MS20995C32.

(6) Connect lead (30) to housing and nameplate assembly (17) at NEG position, using one bolt (13), two washers (12), one washer (8), one washer (7) and one nut (6).

(7) Connect lead (27) to housing and nameplate assembly (17) at POS position, using one bolt (13), one washer (12), washer (11), insulator (10), washer (9), one washer (8), one washer (7) and one nut (6).

(8) Install washers (5) and nuts (4) on NEG and POS terminals.

Table 4

Assembly Materials and Compounds

MATERIAL	SPECIFICATION OR MANUFACTURER
LUB300 Wire, Corrosion-resistant	Dynamic Air MS20995C32

7. Fits and Clearances

Not applicable.

8. Testing

A. Test Equipment

Refer to paragraph 11.

B. Test Procedure

(1) Apply 27 volts dc to blower NEG and POS terminals and operate for 20 minutes.

(2) Then check that operating current is not greater than 21 amperes and operating speed is not less than 10,450 rpm.

(3) Check blower for bucking and excessive vibration. Vibration must not exceed 2 mils.

C. Test Results

(1) Blowers which meet the requirements of the test procedure, may be put into service.

(2) If any blower fails to meet the requirements of the test procedure, refer to the trouble shooting procedure.

9. Trouble Shooting

A. If the blower fails to meet the requirements of the test procedure, refer to Table 5 to determine the possible cause and correction for the malfunction.

Table 5

Trouble Shooting Information

TROUBLE	POSSIBLE CAUSE	CORRECTION
1. Blower fails to operate.	Open wiring.	Replace defective wiring.
	Defective filter.	Replace filter.
	Brushes not in contact with commutator.	Replace brush and spring assemblies.
	Open field windings.	Replace stator assembly.
2. Excessive current and low speed.	Bearings misaligned or preloaded.	Move armature back and forth to relieve any preload.
	Bearings defective.	Replace bearings.
3. Low speed.	Brushes not properly seated.	Reseat brushes.
4. Excessive current and high speed.	Shorted field windings.	Replace stator assembly
5. Excessive current and bucking.	Shorted armature windings.	Replace armature assembly.
6. Bucking.	Open armature windings.	Replace armature assembly.
7. Excessive vibration.	Armature out of balance.	Rebalance or replace armature assembly.
	Propeller out of balance.	Rebalance or replace propeller.
	Propeller damaged.	Replace propeller.

10. Storage Instructions

A. Preparation

(1) Wrap vaneaxial blower in water vapor resistant barrier material, including a desiccant (refer to Table 6).

(2) Affix label giving following information:

(a) Identification

(b) Date of overhaul

(c) Inspection

Table 6

Storage Materials and Compounds

MATERIAL	SPECIFICATION OR MANUFACTURER
Barrier Material	MIL-B-121
Desiccant	MIL-D-3464

11. Special Tools

No special tools are required. Overhaul of the blower can be accomplished with the use of tools, fixtures and other equipment normally available at overhaul facilities. The equipment described in Table 7 is required for use in overhaul of this unit.

Table 7

Overhaul Equipment

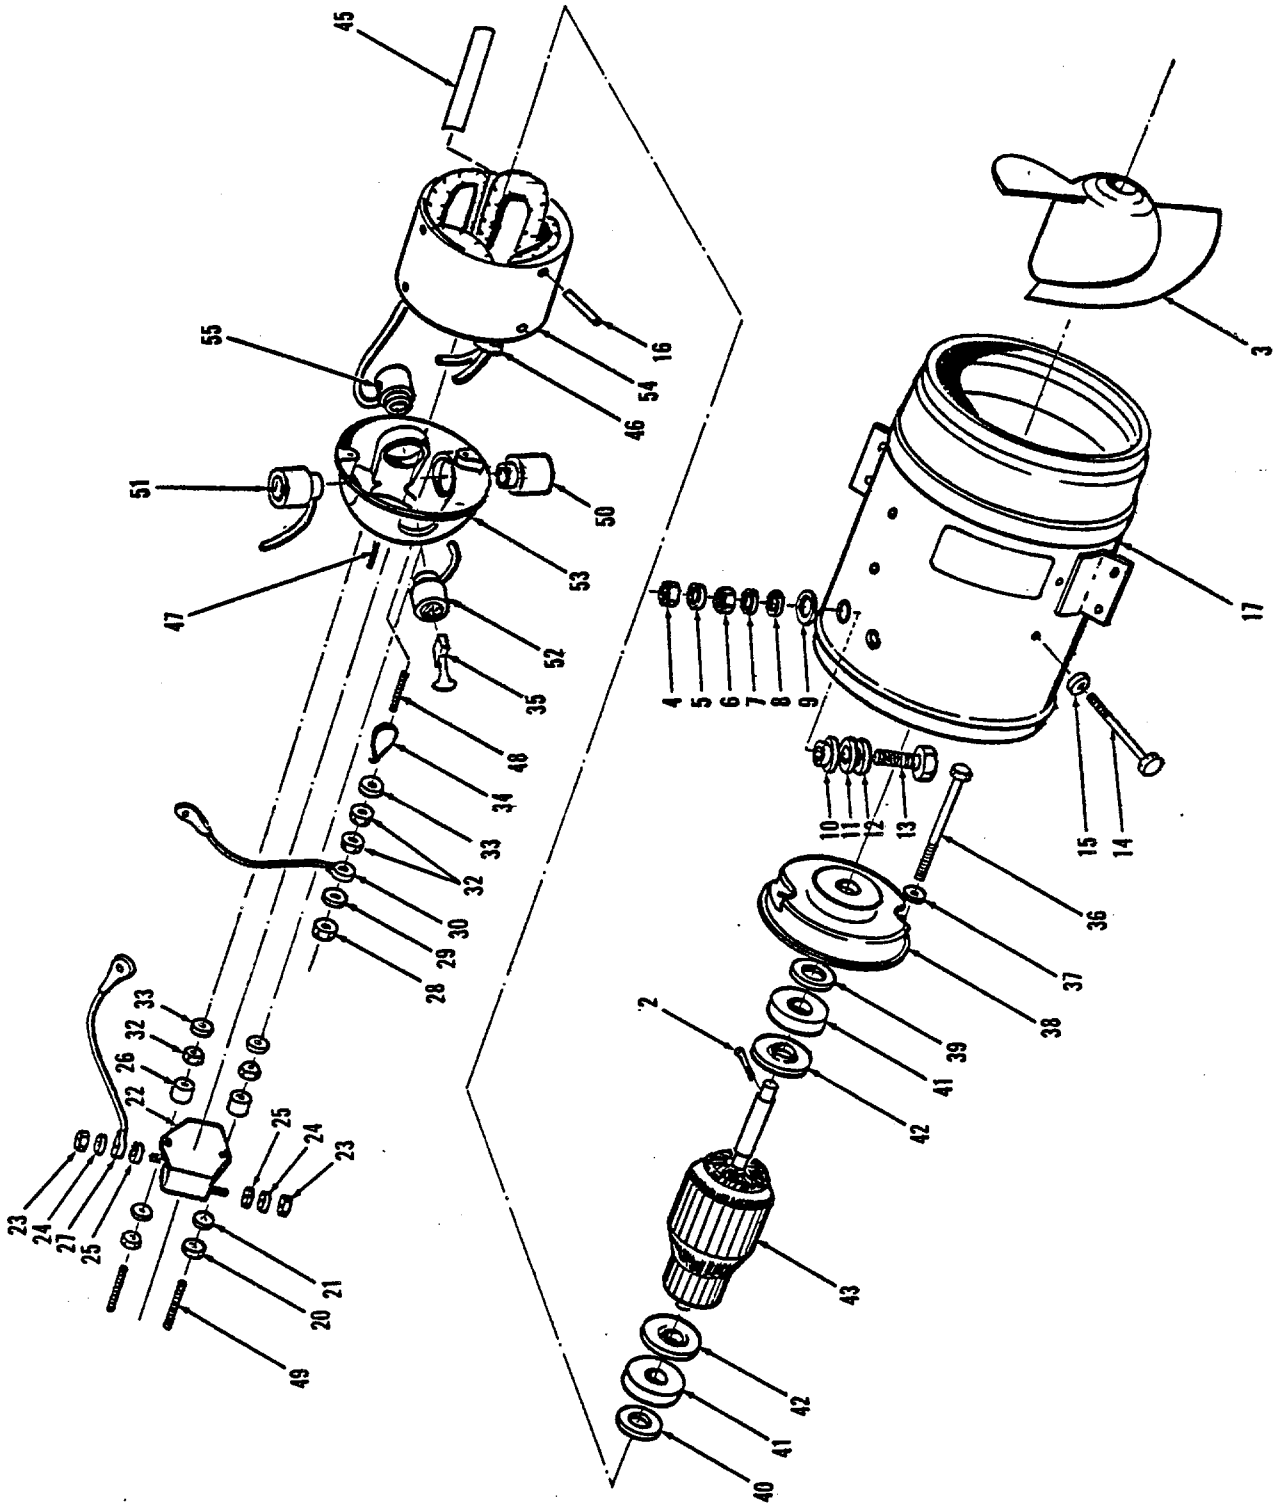
EQUIPMENT	CAPABILITIES	APPLICATION
Dielectric Tester	500 volts ac rms, 60 Hz	Dielectric tests
Megger	0 - 200 megohms minimum	Insulation tests
Ohmmeter	Low resistance range	Continuity tests

Table 7 (Cont'd)

Overhaul Equipment

EQUIPMENT	CAPABILITIES	APPLICATION
Torque Wrench	30 pound-inches torque	Assembly of blower
Dc Power Supply	27 volts, 21 amperes (minimum)	Assembly and testing
Dc Ammeter	0 - 21 amperes (minimum)	Assembly and testing
Stroboscopic Tachometer	0 - 12, 000 rpm (minimum)	Assembly and testing
Vibration Meter	0 - 2 mils (minimum)	Testing

12. Illustrated Parts List



A. For explanation of vendor codes used in the illustrated parts list, refer to Table 8.

B. Item numbers preceded with a dash (-) are not illustrated.

JANITROL AERO DIVISION
OVERHAUL MANUAL WITH
ILLUSTRATED PARTS LIST
A58D72

DESCRIPTION AND OPERATION

1. Description

The A58D72 Mixing Valve Assembly (see figure 1) is designed for use in an aircraft bleed air cabin heating system. Its function is to mix a hot air stream with a cold air stream in such proportions that the outlet temperature of the valve will be maintained within the range of 270° F to 350° F. The valve will shut off downstream flow entirely at outlet temperatures exceeding 350° F, a primary safety feature.

Mixing Valve Assembly
Figure 1

2. Operation

The A58D72 Valve consists of a cast cylindrical body, which provides a hot air inlet port, a cold air inlet port, and a common outlet for the mixed bleed air stream. A thermal element with a moving piston controls the position of a closely fitted spool inside the valve body. This spool opens and closes the hot and/or cold air ports to regulate downstream temperatures within the desired range.

3. Leading Particulars

Refer to figure 2 for leading particulars.

Envelope size (inches)	3.0 dia x 7.0 long
Weight	2.0 lbs approx
Inlet air pressure range	0-100 psia
Inlet air temperature range	+150° F to +562° F
Outlet air temperature range	+150° F to 350° F

Leading Particulars
Figure 2

DISASSEMBLY

NOTE: The valve should be disassembled for inspection or repair as outlined below.

1. Remove cap (2, IPL figure 5).

2. Remove gasket (4) and spring (3) from body (12).

3. Remove slide and stator assembly (5), with stem (6) attached. Slide and stator are matched parts and must be replaced as an assembly.

4. Remove cotter pin (7) and stem (6). Remove packings (8) from slide and stator assembly.

5. Remove element (9) and ring (11) as an assembly by inserting a hooked tool through the body (12) from the large end and pulling the ring through the body. Under no circumstances is pressure to be used against the end of element (9) to push the parts out.

6. Cut lockwire (10). Unscrew and remove element (9) from ring (11). No more than 5 in/lb of torque should be applied to element (9) during removal.

CLEANING

Clean all metal parts in cleaning solvent, Federal Specification P-D-680. If foreign material is difficult to remove, use a soft bristle brush to aid in the cleaning process. Dry the parts thoroughly with dry, filtered, compressed air.

WARNING: USE SOLVENT IN A WELL-VENTILATED AREA. AVOID PROLONGED INHALATION OF VAPOR AND PROLONGED OR REPEATED CONTACT WITH SKIN. KEEP AWAY FROM HEAT OR OPEN FLAME. DO NOT APPLY SOLVENT TO NEW GASKETS AND PACKINGS.

INSPECTION/CHECK

1. Inspect cap (2, IPL figure 5) for cracks or damaged threads.

2. Check spring (3) for distortion or loss of tension. Normal spring tension is 10 lbs when compressed to 1.40 inches; 15 lbs when compressed to 0.90 inch length.

3. Check mating surfaces of slide and stator (5) for scoring or wear patterns, and nicks or burrs which might cause binding of the slide.

4. Check stem (6) for damaged threads.

5. Check housing for cracks or damaged port flanges.

REPAIR

The only repair to the A58D72 Valve Assembly consists of replacement of those parts found to be defective during the inspection procedure.

ASSEMBLY

1. Secure element (9, IPL figure 5) to ring (11) and install lockwire (10).

2. Install packings (8) onto stator (5).

3. Place body (12) in a holding fixture. Install element ring (11) with element assembled. Install stator (5). Place slide inside stator (5) and align the hot air ports of both parts. Check alignment by viewing the ports through the hot air inlet on the side of the body.

4. When the hot air ports are properly aligned, install a wood or rubber plug through the hot air port in the slide and stator, to hold the parts in alignment.

5. Install stem (6) in slide, screwing in until the stem just touches the piston of element (9). Carefully remove slide and stem from stator, and secure stem (6) in place by installing pin (7).

   NOTE: If slots in slide and hole in stem (6) do not align, turn stem counter-clockwise until the thru hole lines up with the nearest slot, and install pin (7).

6. Reassemble stem and slide into stator. Install spring (3), gasket (4) and cap (2). Tighten cap to 40-50 in/lbs torque.

7. Lockwire cap (2) to body after completion of testing.

TESTING

1. Test Equipment Required

   A. Pressure Regulator, 0-150 psig

   B. Pressure Gage, 0-150 psig (P_1)

   C. Temperature Gage, 0-500° F (2 required - T_1 and T_2)

   D. Heating device to produce 120 cfm of heated air at variable temperatures between 250° F and 400° F, and 30 $\pm$ 5 psig pressure

   E. Flowmeter, 0-30 cfm

   F. Water Manometer, 0-50 in H_2O

   G. Ductwork and fittings as shown in figure 3.

Test Set-up
Figure 3

2. Test Procedures

A. Install valve in the test set-up as shown in figure 3.

B. Open shutoff valve No. 1, and close shutoff valve No. 2.

C. Apply inlet air pressure at 30 ±5 psig and adjust temperature T_1 to 250° F.

D. Slowly increase inlet air temperature (T_1). Continue to increase T_1 temperature while observing T_2 temperature. When T_2 reaches 335° F, increase P_1 to 100 ±5 psig.

E. Continue to increase T_1 until T_2 reaches 350° F or valve shutoff occurs. Valve shutoff occurs when the flowmeter reading is less than 29.7 cfm. If manometer shows a pressure drop at the venturi of greater than .15 in. H_2O, shutoff has not occured. Check flowmeter reading by closing valve No. 1 and opening valve No. 2, only when venturi pressure drop is less than .15 in. H_2O.

NOTE: When the valve shutoff occurs, the thermal element begins to cool. After approximately one minute, the valve will reopen. As soon as shutoff occurs, check flowmeter reading; then close shutoff valve No. 2 and open shutoff valve No. 1, to prevent flowmeter damage when valve reopens.

F. If valve shutoff does not occur, shut off the air heater. Allow T_2 to decrease to below 250° F. Reduce inlet pressure to zero, then remove the valve cap and the adjusting screw cotter pin. Rotate the adjusting screw one full turn in the clockwise direction. Replace the cotter pin and cap. Repeat steps A through E.

G. If valve shutoff occurs at a temperature less than 340° F shut off the air heater and allow T_2 to decrease to less than 250° F. Reduce inlet pressure to zero, then remove the valve cap and cotter pin. Rotate the adjusting screw one full turn in the counterclockwise direction. Replace cotter pin and cap. Repeat steps A through E.

H. If valve shutoff occurs between 340° F and 350° F at T_2, the valve operation is acceptable. Shut off the air heater, and reduce P_1 pressure to 30 psig, allowing T_2 to cool to less than 250° F, before removing valve from fixture.

I. If valve fails to perform as specified, and adjustments cannot be made to bring performance to within specifications, return the valve to Janitrol Aero Division, Midland-Ross Corporation, for replacement and calibration of a new thermal element.

TROUBLE SHOOTING

Refer to figure 4 for trouble shooting procedures.

TROUBLE	CAUSE	ISOLATION PROCEDURES	REMEDY
Downstream air temperature too high or too low	Slide stuck in stator	Disassemble valve and check slide for freedom of movement inside stator.	Replace slide and stator as a matched set.
	Thermal element not properly adjusted	Test valve as outlined under Testing section.	Adjust stem adjusting screw as outlined in Testing section.
	Thermal element defective	Test valve as outlined under Testing section.	Return unit to Janitrol Aero for installation and calibration of new element.
	Leakage in one or both inlet air lines	Check inlet air lines for leaks.	Repair or replace as necessary.
		Check for loose or defective band clamps.	Tighten or replace clamps as necessary

Trouble Shooting
Figure 4

STORAGE INSTRUCTIONS

1. Wrap the Mixing Valve Assembly with cushioning material, Military Specification MIL-C-81013.

2. Enclose the assembly, with desiccant, Military Specification MIL-D-3464, in heat sealable film, Military Specification MIL-F-22191, and seal the film using a sealing iron, Military Specification MIL-S-43336.

3. Store the assembly in an area with a temperature range of 65° F to 120° F.

ILLUSTRATED PARTS LIST

1. This illustrated parts list describes and illustrates the detail parts of the Mixing Valve Assembly, Part No. A58D72.

2. All parts of the equipment are listed except parts which lose their identity by being welded or otherwise permanently fastened to other parts of assemblies and not subject to disassembly.

3. Explanation of Columns Used in the Parts List.

   A. Figure and item number column: The figure and item numbers key the parts breakdown list to the applicable illustration. The number preceding the dash is the figure number of the illustration. The item numbers are arranged in sequence and generally reflect the order of disassembly.

   B. Part number column: This column contains the manufacturer's part number.

   C. Nomenclature column: This column identifies the parts being listed by noun name followed by modifiers when applicable.

   D. Effect Code column: This column is used to designate part number variations within assemblies by use of a letter code. When blank, parts are applicable to all models. An explanation of Effect Codes is presented at the end of the parts list.

   E. Units per assembly column: This column indicates the quantity of parts required for the assembly or subassembly in which that part appears. The quantities listed indicate the number of parts used in one assembly.

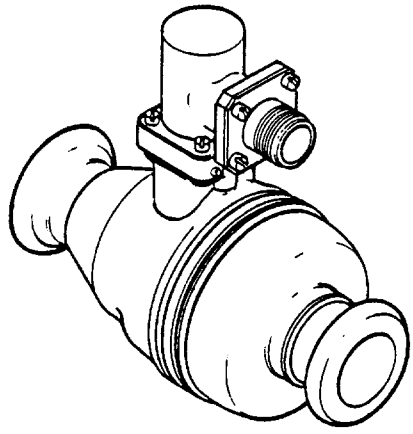
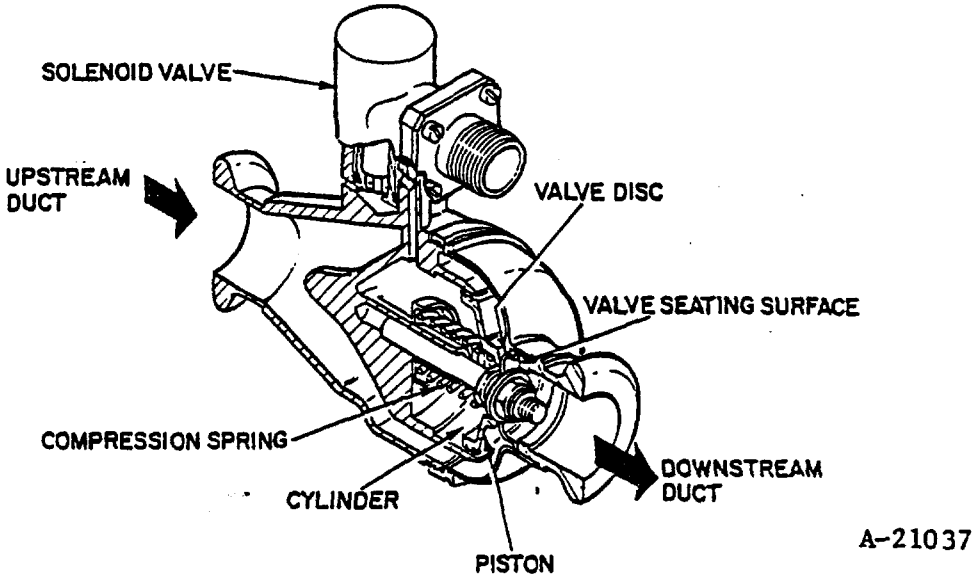
DESCRIPTION AND OPERATION



1. Description

The inline shutoff valve, part number 26440051 (Figure 1), controls the flow of hot bleed air from the engine by means of a pneumatically operated piston. The valve is a poppet type shutoff valve with 1.00 inch (25.4 millimetres) inlet and outlet ports. The valve contains a coaxially mounted piston that travels to the open position pneumatically, and returns to the closed position mechanically by means of a compression spring. The valve is manufactured by Sundstrand Aviation Mechanical, Unit of Sundstrand Corporation, Rockford, Illinois 61101.

2. Operation

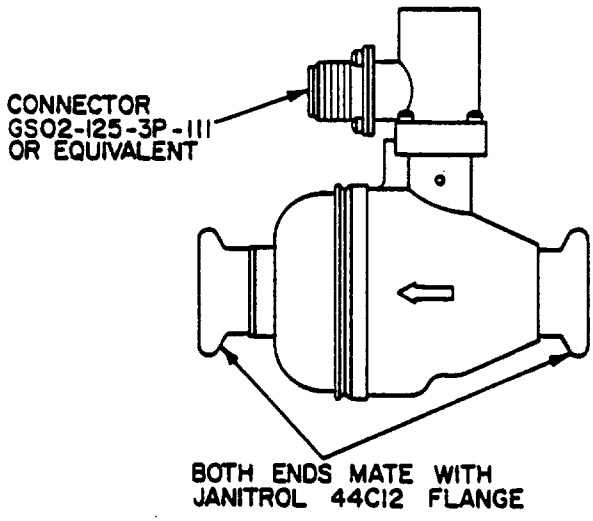


The shutoff valve is pilot solenoid operated. It is spring loaded closed and will open when the pilot solenoid is in the open position (energized) and the upstream bleed air ducting is pressurized. When the pilot solenoid is energized, an air passage between the actuation chamber and the pilot solenoid is opened to atmosphere reducing the actuation chamber pressure to atmospheric pressure (refer to Figure 2). The resultant pressure force acts upon the piston to move it in the open direction. This force is equal to the difference between the inlet duct and actuation chamber pressures times the difference between the actuation chamber area and the valve disc area.

As the piston moves toward the open position, the entire disc area is exposed to the pressure and the resultant force is great enough to overcome the spring force and all frictional forces.

A-21036

Shutoff Valve
Figure 1



Cutaway View
Figure 2

In response to closing the solenoid pilot valve (solenoid de-energized) the control line from the actuation chamber is closed and the actuation chamber pressure increases to the inlet duct pressure level. When the pressures on both sides of the piston have equalized, the spring force moves the piston toward the closed position. As the piston and disc move toward the closed position a pressure drop occurs across the disc face. This pressure differential provides an additional closing force.

Shutoff valve leading particulars are listed in Figure 3. Mating flange and connector information is shown in Figure 4.

Flow Media	Air
Ambient Altitude Range	
Minimum	0 ft (0 M)
Maximum	50,000 ft (15,240 M)
Ambient Air Temperature Range	
Minimum	-65°F (-54°C)
Maximum	+300°F (+149°C)
Inlet Air Temperature (Maximum)	+610°F (+321°C)
Inlet Air Pressure (Maximum)	250 in. Hg A (844 kPaA)
Pressure Required to Open (Maximum)	3 psig (20.7 kPag)
Duty	Continuous
Useful Life	25,000 cycles
Overall Dimensions:	
Height	4.76 in. (120.90 mm)
Width	2.63 in. (66.80 mm)
Length	4.80 in. (121.92 mm)
Weight	1.8 lbs (0.816 kg)
Solenoid Voltage	18 to 30 Vdc
Solenoid Current (at 24 Vdc and 70°F/21°C)	1 Adc maximum

TESTING AND TROUBLESHOOTING

1. Testing

A. General

(1) For shutoff valves removed from service proceed as follows:

(a) Visually check shutoff valve for external damage or defects that could affect serviceability.

(b) Check shutoff valve for contamination, corrosion, or other obstructions that could affect its performance. Manually depress piston and observe that it returns to the normally closed position.

CAUTION: APPROPRIATE FLANGE ADAPTERS SHOULD BE USED FOR TESTING AS THE USE OF ANY TYPE OF COMPRESSION (CLAMPING) FIXTURE COULD RESULT IN VALVE DAMAGE.

(c) If shutoff valve has no obvious defects, it should be tested according to the following conditions and tests.

(d) If shutoff valve passes all the tests it may be returned to service.

(e) If shutoff valve fails any test condition, proceed with troubleshooting and maintenance.

(2) On completion of any maintenance, it will be necessary to verify proper operation of shutoff valve. Verification is obtained by testing shutoff valve according to the following tests, conditions, and setups.

B. Test Conditions

(1) The test setups used to test shutoff valve are shown in Figure 101, 102, 103, and 104 and includes the following test equipment:

(a) Pressure gage, Ashcroft Model 1220 (or equivalent) . . . . . 0 to 15 pounds per square inch gage (0 to 103.5 kilopascals gage)

(b) Pressure gage, Marsh Model 103 (or equivalent) . . . . . 0 to 150 pounds per square inch gage (0 to 1035 kilopascals gage)

(c) Pressure gage, Marsh Model 103 (or equivalent) . . . . . 0 to 300 pounds per square inch gage (0 to 2070 kilopascals gage)

(d) Flowmeter, Brooks Model 1412, Size 8 (or equivalent) . . . . . 0 to 3.05 standard cubic feet per minute (0 to 0.086376 standard cubic metres per minute)

(e) Ammeter, Simpson Model 1349 (or equivalent) . . . . . 0 to 2 amperes direct current

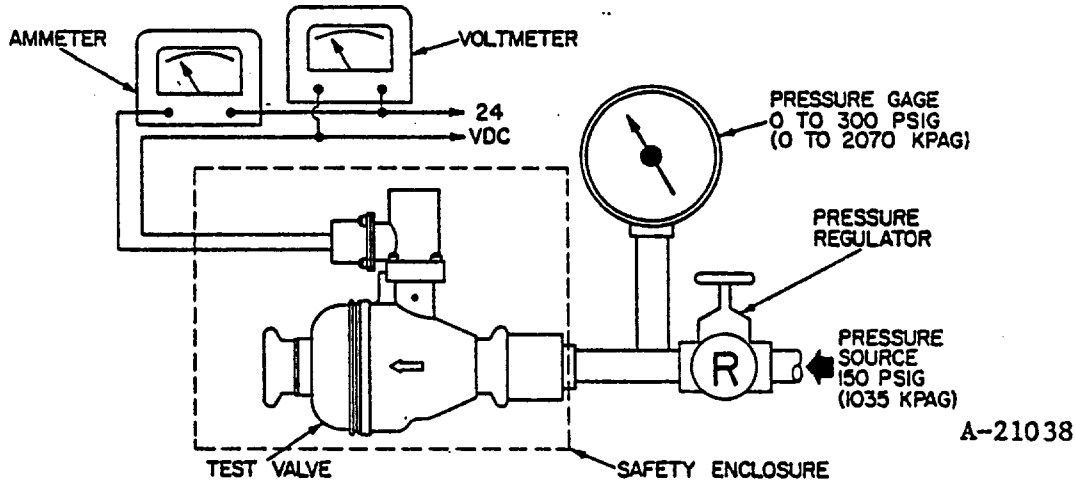
(f) Voltmeter, Assembly Products Model 561 (or equivalent) . . . . . 0 to 35 volts direct current

(2) The test setups used to test the shutoff valve require the following compressed air conditions:

(a) Pressure . . . . . 0 to 150 pounds per square inch gage (0 to 1035 kilopascals gage)

(b) Temperature . . . . . 65° to 75° Fahrenheit (18.33° to 23.88° Celsius)

(c) Conditioning . . . . . Dry, filtered



(3) The test setups used to test the shutoff valve require 24 volts direct current.

C. Proof Pressure Test

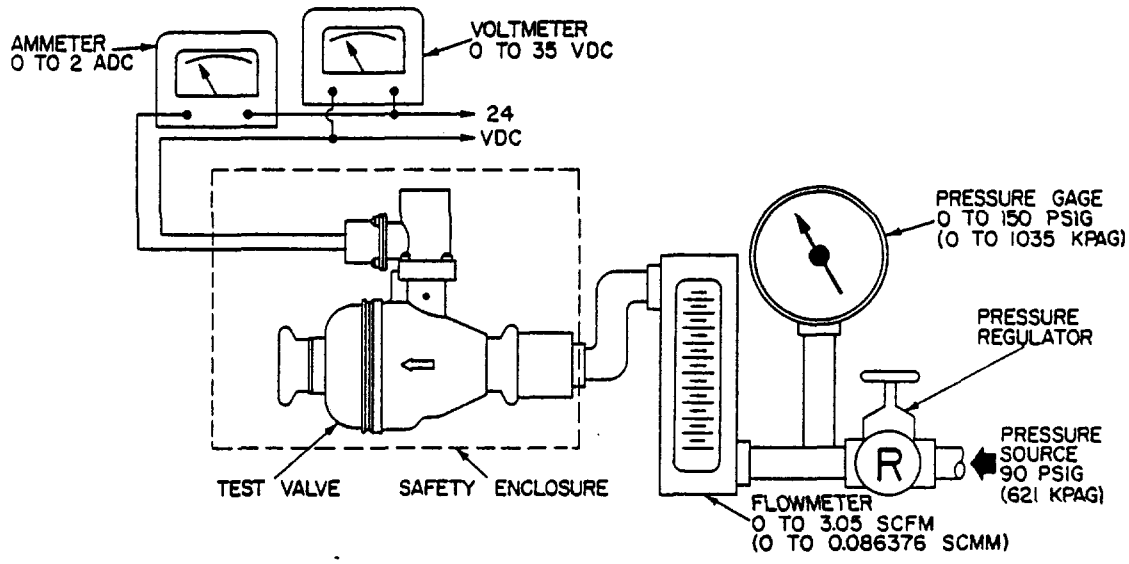
(1) Install shutoff valve in setup shown in Figure 101.

CAUTION: CONDUCT ALL TESTS WITH THE UNIT IN A SAFETY ENCLOSURE CAPABLE OF CONTAINING PARTS SHOULD THE UNIT FAIL UNDER PRESSURE.

(2) De-energize the shutoff valve, and gradually apply a pressure of 150 pounds per square inch gage (1035 kilopascals gage) to the valve inlet port.

Proof Pressure Test Setup
Figure 101

(3) Maintain the 150 pounds per square inch gage (1035 kilopascals gage) pressure for 1 minute, then reduce to atmospheric pressure.



(4) Remove shutoff valve from test setup. Visually inspect shutoff valve for damage. There must be no damage or deformation of components.

D. Total Leakage Test

(1) Install shutoff valve in setup shown in Figure 102.

(2) De-energize the shutoff valve, and apply a pressure of 75 pounds per square inch gage (517.5 kilopascals gage) to valve inlet port.

(3) Maintain pressure of 75 pounds per square inch gage (517.5 kilopascals gage) and observe total leakage as indicated by flowmeter. Total leakage must not exceed 0.20 pound per minute (0.075 standard cubic metre per minute).

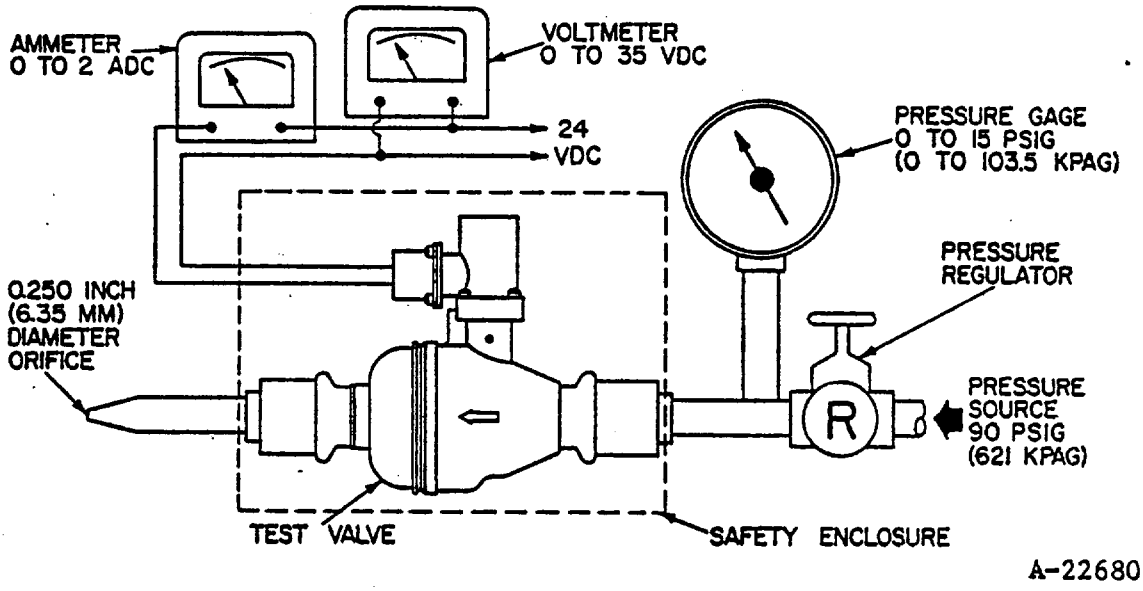
A-21039

Total Leakage Test Setup
Figure 102

E. Operational Test

(1) Install shutoff valve in setup shown in Figure 103.

(2) With solenoid energized, gradually increase air pressure to shutoff valve inlet port and observe inlet air pressure required to open shutoff valve. Shutoff valve must open before inlet air pressure exceeds 3.0 pounds per square inch gage (20.7 kilopascals gage).



F. Performance Test

(1) Install shutoff valve in setup shown in Figure 103.

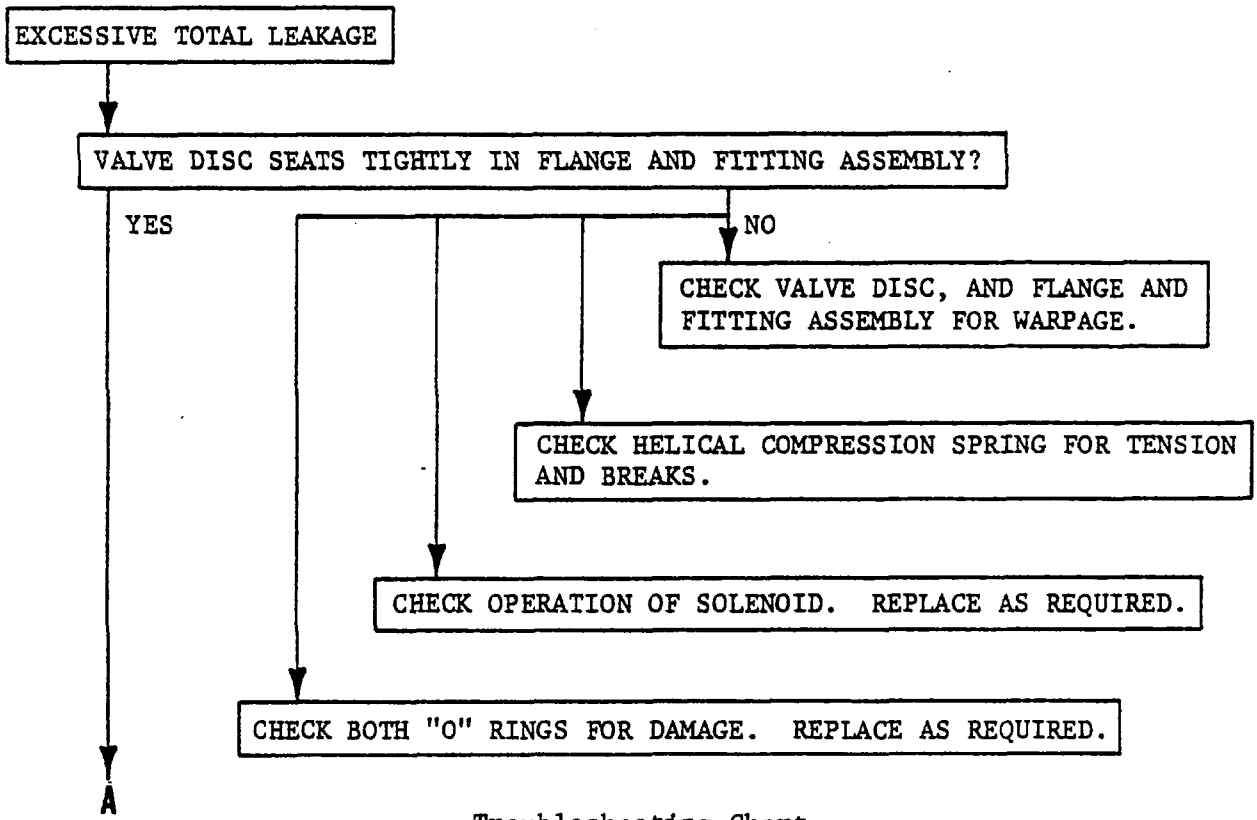
(2) Energize solenoid air valve with 24 volts direct current.

(3) Check that current through solenoid coil does not exceed 1.0 ampere.

(4) Apply a pressure of 75 pounds per square inch gage (517.5 kilopascals gage) to shutoff valve inlet port and alternately de-energize and energize solenoid three times. Check that shutoff valve alternately opens and closes.

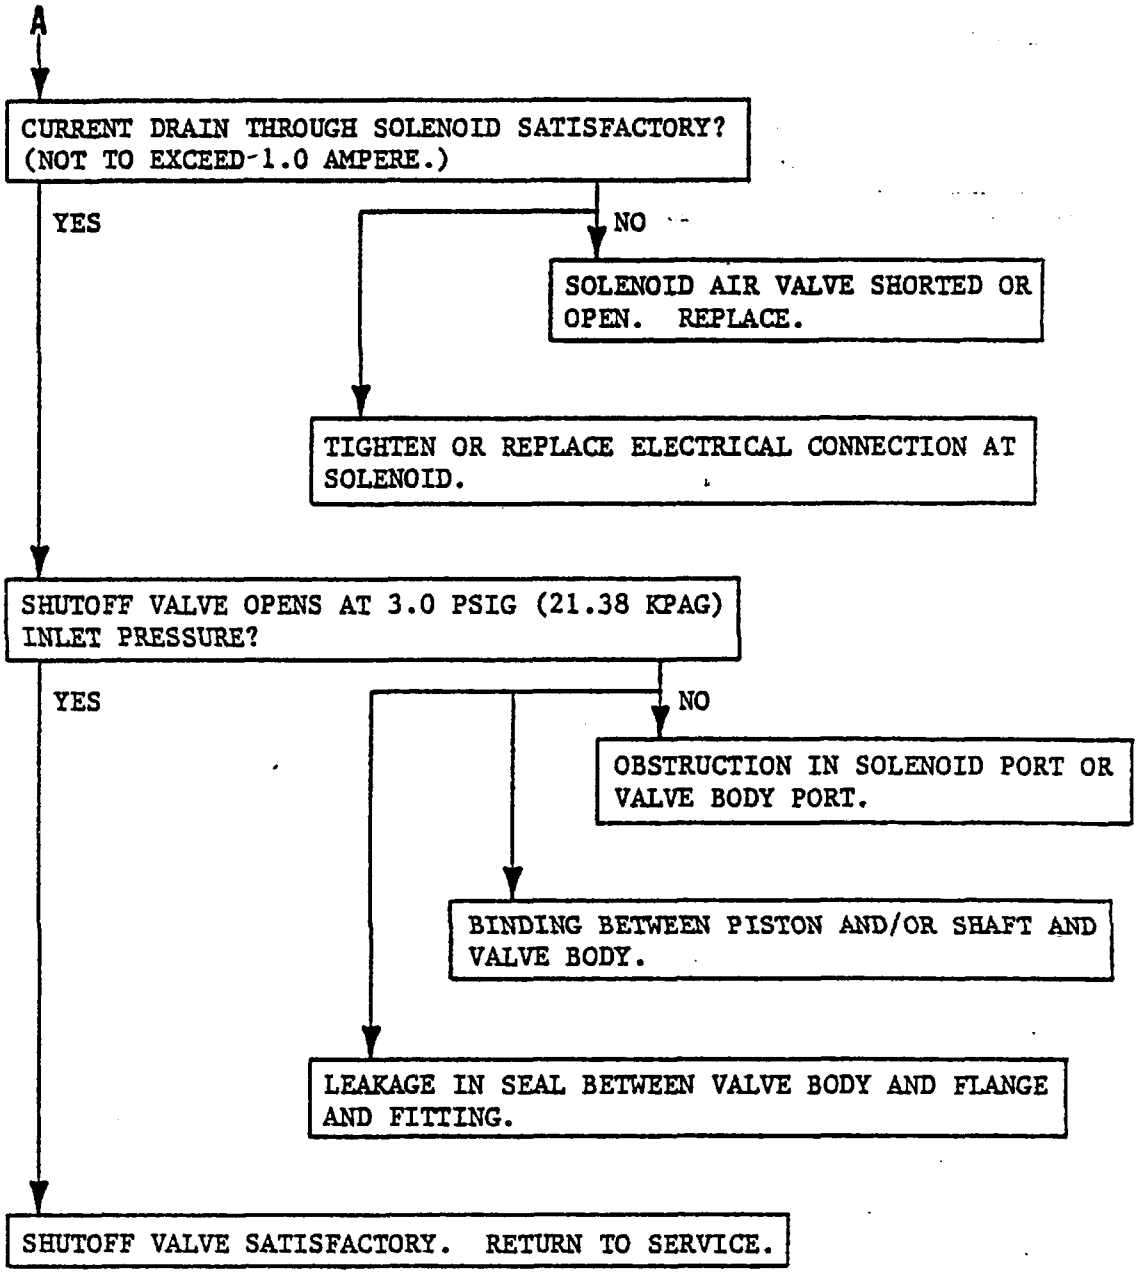
Operational and Performance Test Setup
Figure 103

2. Troubleshooting



A. General

The troubles covered in this section are those that can be located using maintenance test equipment. They do not include those troubles that might develop in related equipment and may appear to be the fault of the shutoff valve. They include troubles apt to be found in after-maintenance test and in equipment prematurely removed from service.



B. Troubleshooting Chart

Troubles most likely to occur in the shutoff valve are listed in Figure 104 along with their possible cause, isolation procedure, and correction.

Whenever a problem is encountered during test, shut off all pressure sources. Relieve pressure in shutoff valve by de-energizing solenoid. Remove shutoff valve. Disassemble and inspect parts, with particular emphasis on components listed in the troubleshooting chart. Repair or replace defective parts and assemble the shutoff valve according to ASSEMBLY. Repeat all tests to determine if corrective action has solved the problem.

Troubleshooting Chart
Figure 104 (Sheet 1 of 2)

Troubleshooting Chart
Figure 104 (Sheet 2 of 2)

DISASSEMBLY

1. General

A. If shutoff valve removed from service shows no visual indication of damage, corrosion, or contamination (reference CHECK) the shutoff valve shall be tested in accordance with TEST AND TROUBLESHOOTING to determine if maintenance is required.

B. Shutoff valves that require maintenance shall be disassembled to the extent required to correct fault (reference TEST AND TROUBLESHOOTING) according to the instructions in this section.

C. Parts recommended for discard are listed in Figure 301.

D. Refer to FITS AND CLEARANCES for summarized disassembly procedures.

IPL Figure 1001, Item Number and Description
15 and 20 ("O" RINGS)
35 (SELF-LOCKING NUT)
50 (PISTON RINGS)

Parts Recommended for Discard
Figure 301

2. Disassembly

A. Perform disassembly as follows:

WARNING: WEAR EYE PROTECTION WHEN REMOVING LOCKWIRE.

(1) Remove all accessible lockwire.

(2) Remove screws (10, Figure 1001) and lift off solenoid (5).

(3) Remove "O" ring (15) from recess in valve body (85) and "O" ring (20) from groove in solenoid air valve (5).

WARNING: REMOVE FLANGE AND FITTING ASSEMBLY (25) SLOWLY AND CAREFULLY. HELICAL COMPRESSION SPRING (60) IS UNDER COMPRESSION.

CAUTION: BEFORE PLACING SHUTOFF VALVE IN BOTTOM CLAMP AND THE TOP CLAMP AND FIXTURE ONTO THE SHUTOFF VALVE, MAKE CERTAIN THAT ALL MATING SURFACES ARE CLEAN AND FREE OF FOREIGN MATERIAL.

(4) Using top clamp and fixture assembly CES-20611 and bottom clamp CES-20612 (refer to Figures 901 and 902) unscrew flange and fitting assembly (25) from valve body (85).

(5) Remove nut (35), spacer (40), valve disc (30), piston (45), piston rings (50), and shaft (55) from valve body (85) as an assembly.

(6) Remove nut (35), spacer (40), and valve disc (30) from shaft (55).

(7) Slide piston (45) off shaft (55); then, remove piston rings (50) from grooves in piston (45).

(8) Remove helical compression spring (60) and spring seat (65) from valve body (85).

(9) Do not remove identification plate (70) or screws (75) unless identification plate has been damaged or is illegible.

(10) Do not remove bearing ball (80).

CLEANING

1. General

Solvents and materials required for cleaning are listed in Figure 401. Clean according to procedures in paragraph 2.

Brush, Soft Bristle	Commercially Available
Wipers, Cotton	Commercially Available
Solvent, 1,1,1 Trichloroethane Technical Inhibited (Federal Specification O-T-620C)	Commercially Available
NOTE: Equivalent substitutes may be used for above items.	

Cleaning Materials
Figure 401

2. Cleaning

WARNING: USE SOLVENT IN WELL VENTILATED AREA AND AVOID BREATHING FUMES. KEEP SOLVENT AWAY FROM OPEN FLAME.

A. Clean all metallic parts except solenoid (5, Figure 1001) by immersion in grease dissolving solvent using a small brush with the solvent to loosen accumulation of foreign matter.

WARNING: DO NOT DIRECT COMPRESSED AIR AGAINST SKIN.

CAUTION: AFTER CLEANING AND AIRBLOWING PARTS DRY, ALLOW PARTS TO COME UP TO ROOM TEMPERATURE. THIS IS NECESSARY TO REMOVE THE FILM OF MOISTURE THAT MAY CONDENSE ON SURFACES DUE TO THE COOLING EFFECT OF AIRBLOWING DRY.

B. Dry parts with compressed air at 30 pounds per square inch gage (207 kilopascals gage) maximum.

CHECK

1. General

Visually check all parts for obvious wear, corrosion, or damage. Repair or replace defective parts. Perform detailed checks of parts according to paragraph 2, Check Notes. Refer to FITS AND CLEARANCES for summarized check procedures.

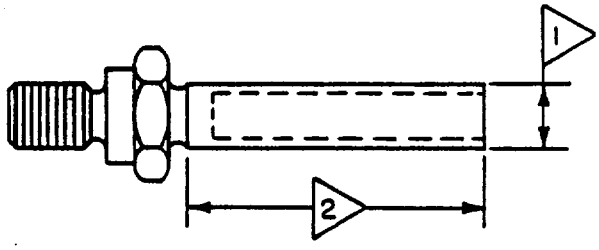
2. Check Notes

Note 1: Check threaded parts for stripped threads, cross-threading, and wear.

Note 2: Check all parts for damage or deformation.

Note 3: Check seating surface of valve disc (30, Figure 1001) to assure that surface is not damaged in any way that would prevent tight sealing.

Note 4: Check that assembled shaft (55), piston (45), and piston rings (50) slide freely in valve body (85).



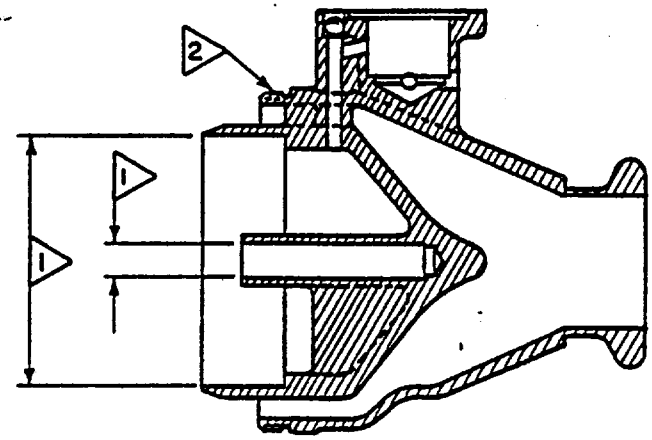
Note 5: Check piston rings (50) according to FITS AND CLEARANCES.

Note 6: Check diameter and hard chrome plating of shaft (55) according to Figure 501. Replace shaft if it is worn below minimum diameter.

Note 7: Check for deformed spring (60). Spring may be dimensionally checked according to FITS AND CLEARANCES. Replace spring if defective.

Note 8: Check identification plate (70) for illegibility and damage. If it is illegible or damaged refer to REPAIR.

Note 9: Check valve body (85) according to Figure 502.



A-20144

NOTES AND DIMENSIONS

1 Noted diameter shall be 0.245 inch (6.223 millimetres) minimum.

2 Check hard chrome plating over this area for wear.

Check of Shaft 25816570
Figure 501

A-21043-1

NOTES

1 Inspect noted bores. If metallic surface of bores is scored, replace the valve body. If dry-film lubricant is worn evenly through to the metal, reapply dry-film lubricant according to instructions in REPAIR or replace the valve body.

2 Inspect noted threads. If dry-film lubricant is worn through to the metal, reapply dry-film lubricant according to instructions in REPAIR or replace the valve body.

Check of Valve Body 26446031
Figure 502

REPAIR

1. General

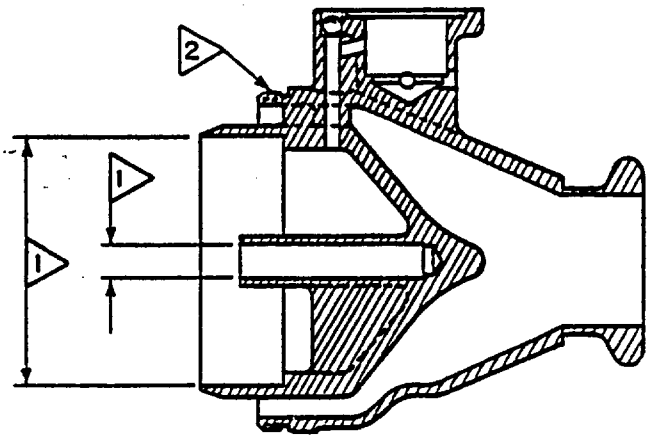
Repair procedures are provided in this section in the form of text. Materials required for repair are listed in Figure 601. Refer to FITS AND CLEARANCES for summarized repair procedures.

Adhesive Tape No. 202 (or equivalent)	3M Company 3M Center St. Paul, MN 55101
Aluminum Oxide Grit, 120 mesh MMS411	Commercially Available
Cloth, Crocus Abrasive	Commercially Available
Dry-film Lubricant 4396	Electrofilm Corp. 7116 Laurel Canyon Blvd. North Hollywood, CA 91605
Masking Tape No. 250 (or equivalent)	3M Company 3M Center St. Paul, MN 55101

Repair Materials
Figure 601

2. Repair Notes

Note 51: Remove minor nicks, surface scratches, or surface corrosion in ferrous parts, on other than microfinished surfaces, by polishing with crocus abrasive cloth. (Refer to Figure 601.)



Note 52: If check reveals illegible or otherwise damaged identification plate (70, Figure 1001), prepare a new plate by vibro-etching the serial number and manufactured date (as it appears on old plate) on new plate.

Note 53: If check reveals worn dry-film lubricant, strip completely and reapply dry-film lubricant as follows:

CAUTION: TAKE SPECIAL PRECAUTIONS TO ASSURE THAT ALL HOLES AND DRILLED PASSAGES ARE PLUGGED OR OTHERWISE COVERED TO PREVENT CONTAMINATION WITH GRIT.

1. Refer to Figure 602. Using masking tape (refer to Figure 601) mask surfaces not to be gritblasted.

2. Gritblast surfaces to be coated using 120 mesh aluminum oxide, with low pressure compressed air, 10 to 15 pounds per square inch gage (69.0 to 103.5 kilopascals gage).

A-21043-1

NOTES

1. If dry-film lubricant is worn evenly through to the metal, reapply dry-film lubricant according to instructions in steps 1 through 8, or replace the valve body.

2. If dry-film lubricant is worn through to the metal, reapply dry-film lubricant according to instructions in steps 1 through 8, or replace the valve body.

Valve Body 26446031
Figure 602

CAUTION: WEAR CLEAN COTTON GLOVES TO HANDLE CLEANED PARTS. DO NOT HANDLE CLEANED PARTS WITH BARE HANDS AS SKIN OILS CAN CAUSE POOR ADHESION OF THE DRY-FILM LUBRICANT.

3. Remove masking tape.

4. Thoroughly clean parts. Refer to CLEANING.

5. Use masking tape to mask surfaces not to be coated with dry-film lubricant.

WARNING: PROLONGED BREATHING OF DRY-FILM LUBRICANT SOLVENT VAPORS OR CONTACT WITH SKIN IS HARMFUL. USE IN WELL VENTILATED AREA. PROTECT HANDS WITH RUBBER GLOVES.

CAUTION: IMPROPER APPLICATION OF DRY-FILM LUBRICANT ON PARTS MAY LEAD TO PREMATURE FAILURE OF THE VALVE.

6. Apply dry-film lubricant to parts with air brush as noted in Figure 602. Thin concentrate as prescribed by manufacturer for proper viscosity. Thickness of dry-film lubricant to be 0.00015 to 0.00040 inch (0.00381 to 0.01016 millimetres) with no runs or drips and a uniform appearance (color) when dry.

7. Remove masking material and cure dry-film lubricant in an air circulating oven at 375° Fahrenheit (191° Celsius) for 1-1/2 hours.

8. Visually inspect for smooth appearance, free of blisters, runs, or irregularities. There shall be no trace of grit, rough particles, or separation of ingredients. Scratches that have penetrated through to the pretreated surface of the base material shall be cause for rejection.

9. With parts at room temperature inspect for adhesion using the following method: firmly press a piece of adhesive tape onto the coated area covering a minimum of 1/2 square inch (12.7 square millimetres). Remove tape in an abrupt stripping motion and visually examine tape. The presence of traces of fine powdery material is acceptable: however, the presence of particles or flakes shall be cause for rejection.

10. Parts failing inspection shall be completely stripped and reworked according to steps 1 through 8. Touchup is not permissible.

11. Protect coated dry-film lubricated surfaces against rubbing or scratching.

ASSEMBLY

1. General

Assembly procedures are provided in this section in the form of text. When it is necessary, assembly illustrations are also provided. The item numbers in the assembly illustrations are identical to those in the ILLUSTRATED PARTS LIST. Materials required during assembly are listed in Figure 701. Refer to FITS AND CLEARANCES for summarized assembly procedures and torque values.

Lockwire, MS20995-C20 (0.020 inch, corrosion resistant steel)	Commercially Available
Silastic Compound P/N S-2007	Dow Corning Corp. S. Saginaw Rd. Midland, MI 68640

Assembly Materials
Figure 701

2. Assembly

A. Assemble shutoff valve as follows:

(1) Polish piston bore of valve body (85, Figure 1001) with a soft lint-free cloth.

(2) Apply silastic compound (refer to Figure 701) to threaded surface of valve body (85).

(3) Place spring seat (65) and helical compression spring (60) in valve body (85, Figure 1001).

(4) Assemble piston (45), valve disc (30), and spacer (40) on shaft (55) and secure with self-locking nut (35). Tighten self-locking nut (35) for 12 to 15 inch pounds torque.

(5) Install piston rings (50) on piston (45) and set piston ring gaps 180 degrees apart from each other.

(6) Insert piston (45), valve disc (30), spacer (40), shaft (55), piston rings (50), and self-locking nut (35) in valve body (85) as an assembly.

CAUTION: DO NOT ALLOW PISTON RINGS TO DISENGAGE FROM BORE DURING INSTALLATION OF FLANGE AND FITTING ASSEMBLY OR PARTS WILL BE DAMAGED.

(7) Assemble flange and fitting assembly (25) on valve body (85) and tighten for 70 to 80 foot pounds torque. Refer to Figures 901 and 902.

(8) Manually operate piston (45, Figure 1001) and check for smooth travel and unrestricted return to normal position.

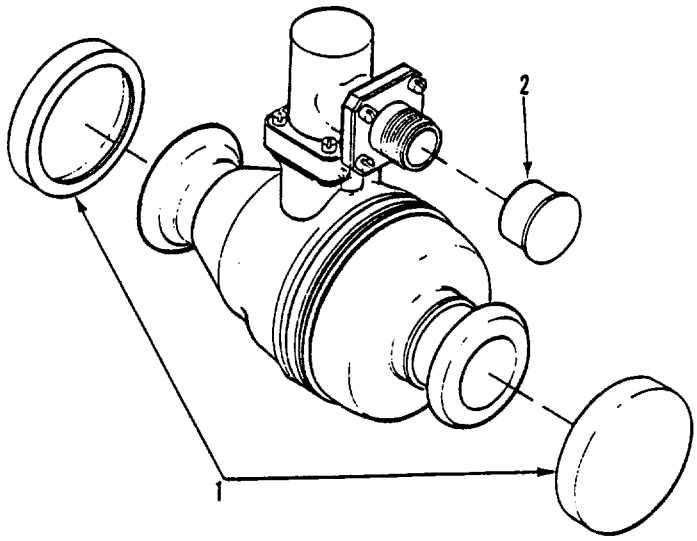
WARNING: USE CARE HANDLING HEATED PARTS TO AVOID BURNS.

(9) Cure silastic compound by placing shutoff valve in an air circulating oven at 250° Fahrenheit (121° Celsius) for 3 hours.

(10) After shutoff valve has returned to room temperature, place large "O" ring (15) into recess in valve body (85) and small "O" ring (20) in groove around solenoid (5).

(11) Insert end of solenoid (5) into valve body (85) orienting solenoid connector toward outlet end of valve, and secure with screws (10). Tighten screws (10) evenly for 10 to 12 inch pounds torque.

(12) If removed, install identification plate (70) and secure with screws (75).



(13) Test the assembled solenoid according to TESTING AND TROUBLESHOOTING.

(14) Lockwire all external screws and other parts drilled for lockwire in accordance with MS33540 (refer to Figure 701). Location of lockwire is optional.

3. Storage After Assembly

A. Apply protective plastic covers on valve ports and electrical connector. (Refer to Figure 702.)

B. Seal valve in a dust and moisture proof bag and place in a paper or wooden box. Store in a dry location.

A-21045

FIGURE ITEM	PART NUMBER	NOMENCLATURE	UNITS PER ASSY

2	MS25178-12	CAP - DUST	1

Storage Parts
Figure 702

FITS AND CLEARANCES

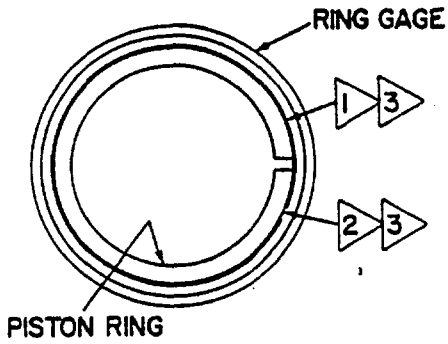
1. General

This section contains fits and clearances data required for assembly and inspection. Where applicable, permissible wear tolerances are also included.

2. Fits and Clearances

A. Torque values are shown on summarized assembly view, Figure 804.

B. Spring specifications are listed in Figure 801.



C. Determine light-tightness of piston rings (50, Figure 1001) when placed squarely in a 1.8765 inch (47.663 millimetres) diameter ring gage according to Figure 802.

D. A summary of disassembly and check information is shown in Figure 803. Notes 1 through 50 are keyed to check notes in CHECK. Notes 51 through 100 are keyed to repair notes in REPAIR.

E. A summary of assembly information including special assembly and reference to figures with FITS AND CLEARANCES is shown in Figure 804.

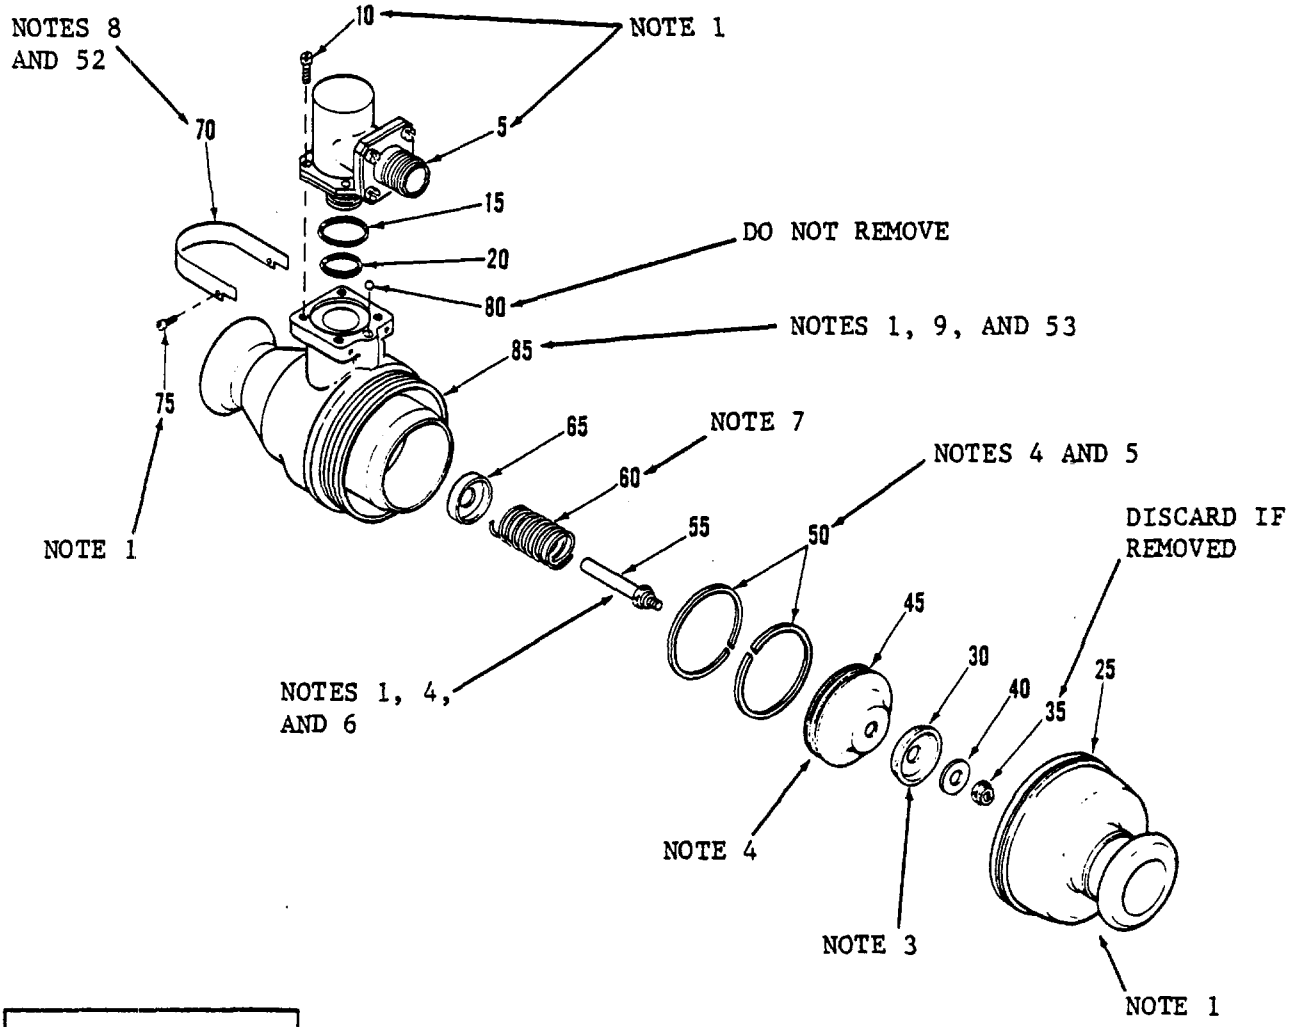
Item Number (IPL Fig. 1001)	Identifying Dimensions		Inspection Dimension
	Spring Diameter	Wire Diameter	Load/Height
60	0.750 ± 0.005 inch (19.05 ± 0.127 millimetres)	0.062 ± 0.005 inch (1.575 ± 0.127 millimetres)	5.960 ± 0.596 pounds (2.703 ± 0.270 kilograms) at 0.656 inch (16.662 millimetres) 2.490 ± 0.249 pounds (1.129 ± 0.113 kilograms) at 1.031 inches (26.187 millimetres) Solid compressed height shall be 0.562 inch (14.275 millimetres) maximum. Free length shall be 1.30 ± 0.13 inches (33.02 ± 3.302 millimetres)

Spring Specifications
Figure 801

A-21046

NOTES AND DIMENSIONS

1 Ring gage inside diameter.



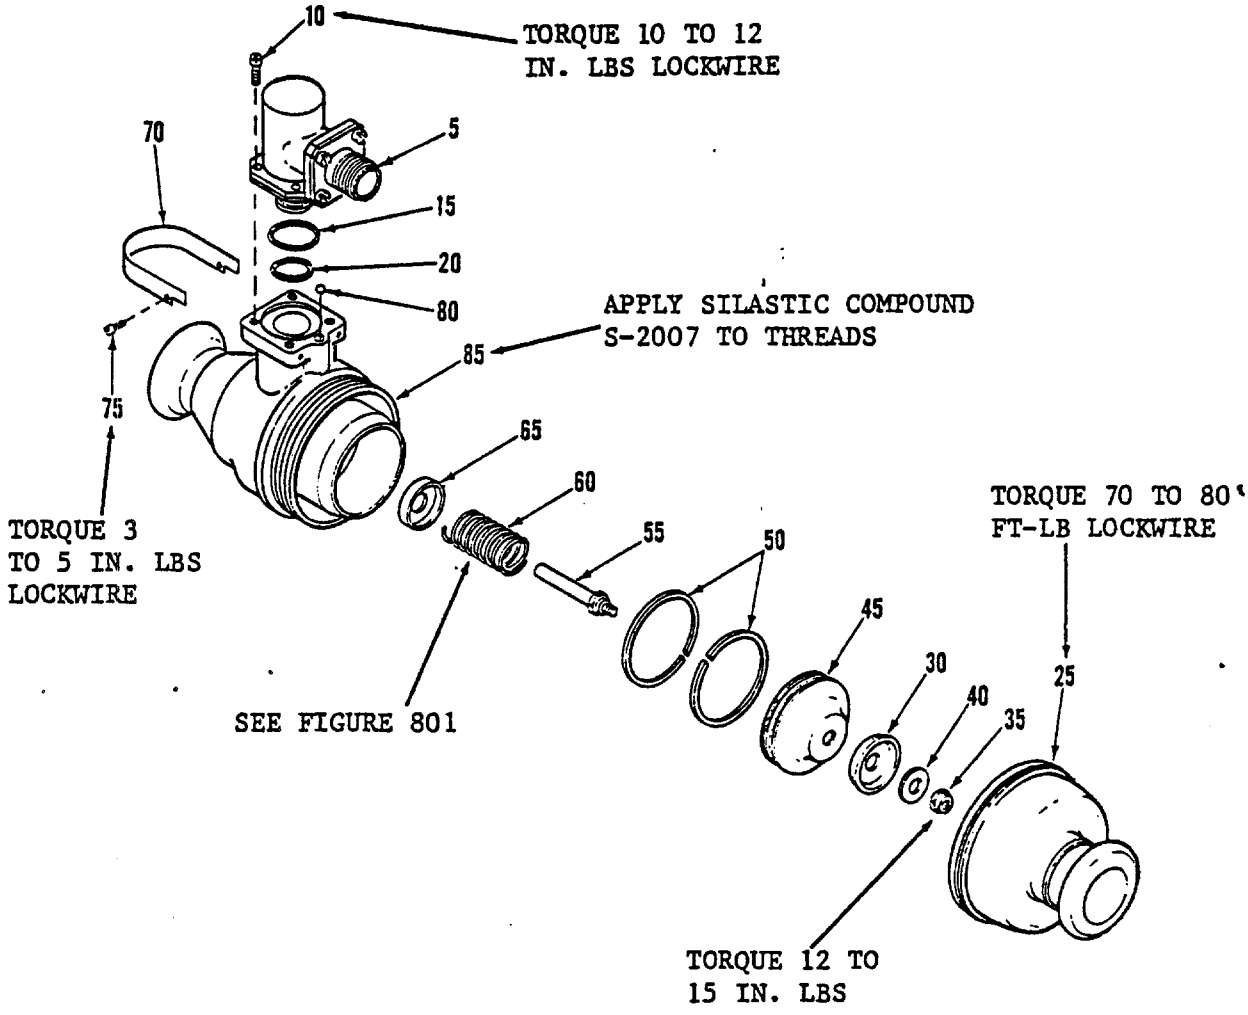
2 Piston ring outside diameter.

3 The fits between the dimensions noted by 1 and 2 shall be 75% light-tight. (75% of the ring circumference shall exclude the passage of light.)

Determination of Light-tightness
Figure 802

NOTE: REFER TO IPL FIGURE 1001 FOR ASSOCIATED PART NUMBERS.

CAUTION: WEAR EYE PROTECTION WHEN REMOVING LOCKWIRE.



REPLACE "O" RINGS IF DISTURBED

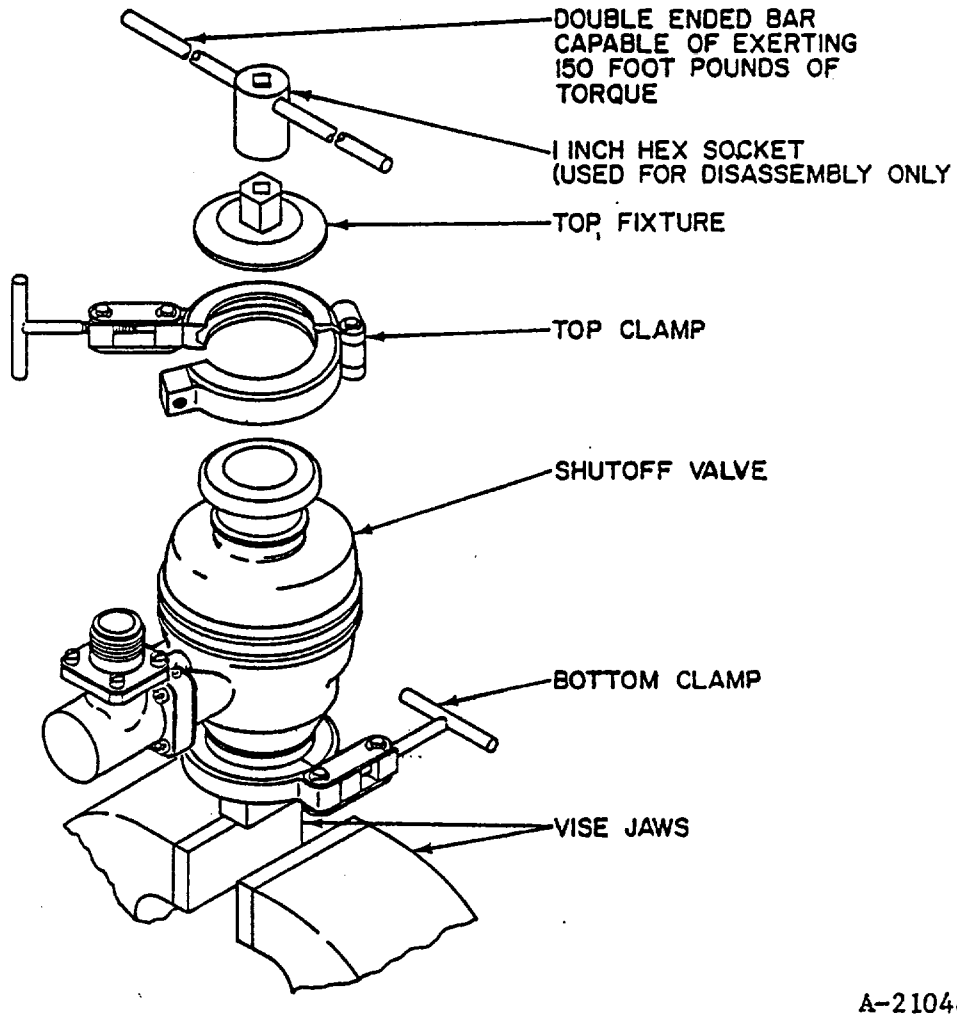
SPECIAL TOOLS, FIXTURES, AND EQUIPMENT

1. General



Special tools, fixtures and equipment required are listed in Figure 901.

2. Test Equipment

All general equipment required for testing is listed in TESTING AND TROUBLE-SHOOTING. The list includes information about equipment requirements, accuracy, and sources.

TOOL NUMBER	TOOL NAME	TOOL USE
CES-20611	Top Clamp and Fixture Assembly	Used to separate during disassembly, and torque during assembly the flange and fitting assembly and valve body.
CES-20612	Bottom Clamp	

Special Tools, Fixtures, and Equipment
Figure 901

Disassembly and Assembly Tools in Use
Figure 902

ILLUSTRATED PARTS LIST

1. Introduction

This Illustrated Parts List contains a Detailed Parts List and a breakdown of the equipment that illustrates, lists, and describes all assemblies and subassemblies that can be disassembled, reassembled, or replaced.

A. Detailed Parts List

(1) Order of Listing. The Detailed Parts List consists of illustrations and associated columnar listings of parts arranged in the sequence of disassembly. Attaching parts are listed following the items attached and are preceded by the words (Attaching Parts). A separation symbol (***) is used to indicate the end of each attaching part group.

(2) Figure and Item Number Column. Figure and item numbers are separated by a blank space. The figure (or illustration) number is shown only at the beginning of each page. Since index numbers are assigned to all parts, some parts that are not illustrated will be listed with a dash before the index number to indicate they are not illustrated.

(3) In general, identical parts occurring in the same general location in the equipment are illustrated and indexed only once. Then identical parts in the same assembly, removed at the same time, are illustrated for clarity only. One index number will be assigned. Where necessary to indicate disassembly sequence, identical parts will be assigned different index numbers.

(4) Part Number Column. Part numbers are used to identify all items listed. Government standard part numbers are listed when applicable. All other part numbers are those of the design manufacturer, either the prime contractor or a vendor, as applicable. If the item is a vendor part, code is inserted in parentheses following the description of the part (refer to paragraph 6).

(5) Nomenclature Column. The Description Column contains the design manufacturer's drawing nomenclature, plus modifiers and additional description as required to identify the item.

(6) All manufacturer's code numbers are cross referenced to manufacturer's (vendor's) in Figure 1101. The absence of a code following a part, other than a government standard part in the nomenclature column, indicates that the part is manufactured by Sundstrand Aviation Mechanical, Unit of Sundstrand Corporation, 4747 Harrison Avenue, Rockford, Illinois 61101 USA.

(7) The description is indented to show relationship of parts, the indent code being shown at the top of the column. The first position (no indentation) is reserved for the first item in a list; this may be the end article assembly or subassembly. Second position (indent 1) items will either be detail parts of the first position item or lower order assemblies (or subassemblies). Each group of items with greater indentation will always be a part of a preceding item with one less indent. This system follows drawing relationship and provides rapid determination of the parts comprising an assembly, or the next higher assembly for any particular part. In scanning for item relationship, remember that attaching parts follow the part attached and threrfore an attaching part group may precede the breakdown of an assembly.

(8) When a separate illustration and list are used for the breakdown of an assembly, the initial listing of the item will refer to the applicable illustration and list by figure number. Regardless of the indent number of the initial listing, the item will be listed in the first position in the separate breakdown as a convenience in preparing the list.

(9) The Effect Code Column. This column shows differences between two or more similar units or assemblies listed together in the same parts list. Parts not used in all of the units of assemblies bear the code letter or letters for the particular unit or assembly in which the parts are located. When the column is blank, the part is used in all of the units of assemblies listed together.

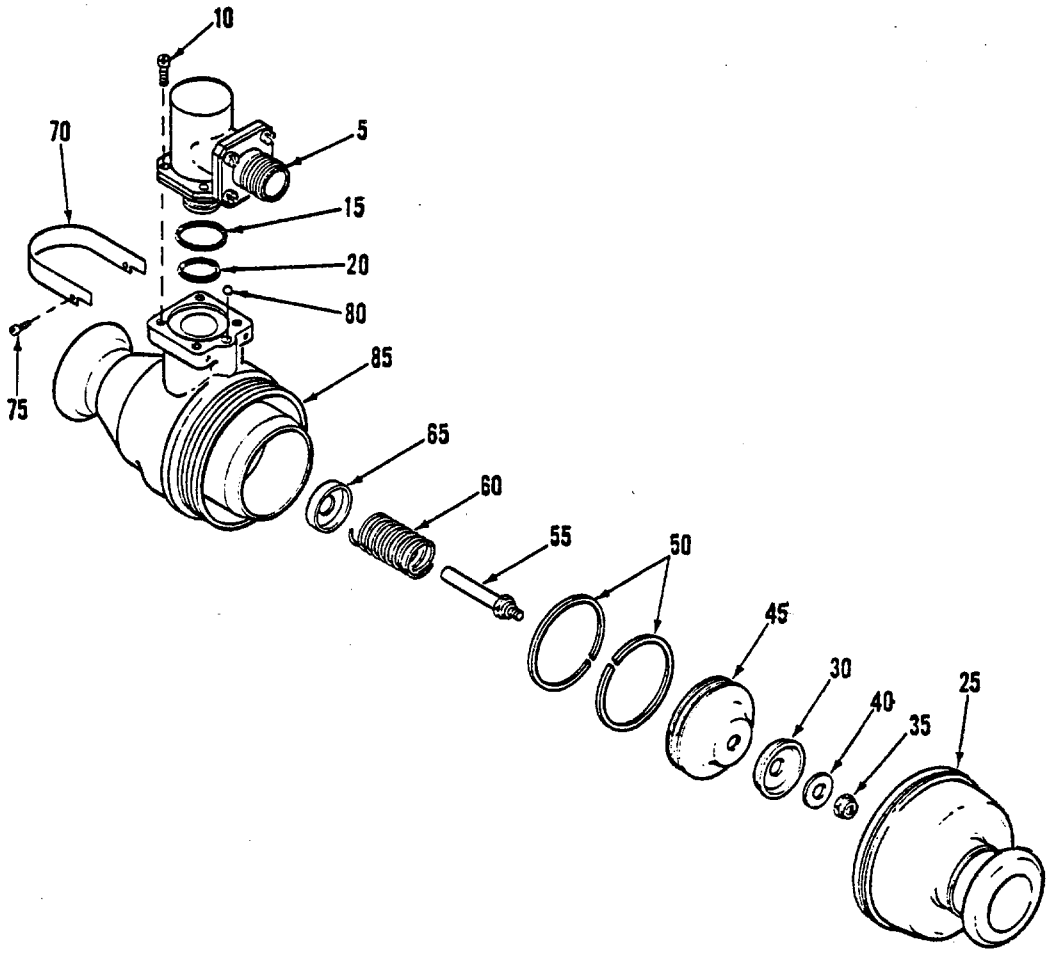
(10) Units Per Assembly Column. With the exception of attaching parts, this column contains the number of units required per assembly, or per subassembly, as applicable. If more than one assembly is required, the total used is shown. When the same item in the same location is listed a second time, one listing will show the quantity in the Units Per Assembly column, and the other listing will show the abbreviation "RF" in the Units Per Assembly column, indicating that reference must be made to the other listing for units per assembly. The quantities shown for attaching parts are per part attached.

B. Numerical Index

The Numerical Index has been omitted because of the small number of parts in the Detailed Parts List.

2. How to Use the Illustrated Parts Breakdown

A. If the part number is not known, but its location, index number or shape are known, proceed as follows:



(1) Turn to figure and locate the desired part on the illustration.

(2) From the illustration, obtain the index number assigned to the part desired. Refer to the accompanying description in the Detailed Parts List for specific information regarding the part.

B. If the part number is known, but its location, index number or shape are not known, proceed as follows:

(1) Turn to the Detailed Parts List and locate the desired part number.

(2) From the FIG. ITEM column, note the Illustrated Parts List figure and index number. The location of the part may be determined by locating the index number in the illustration.

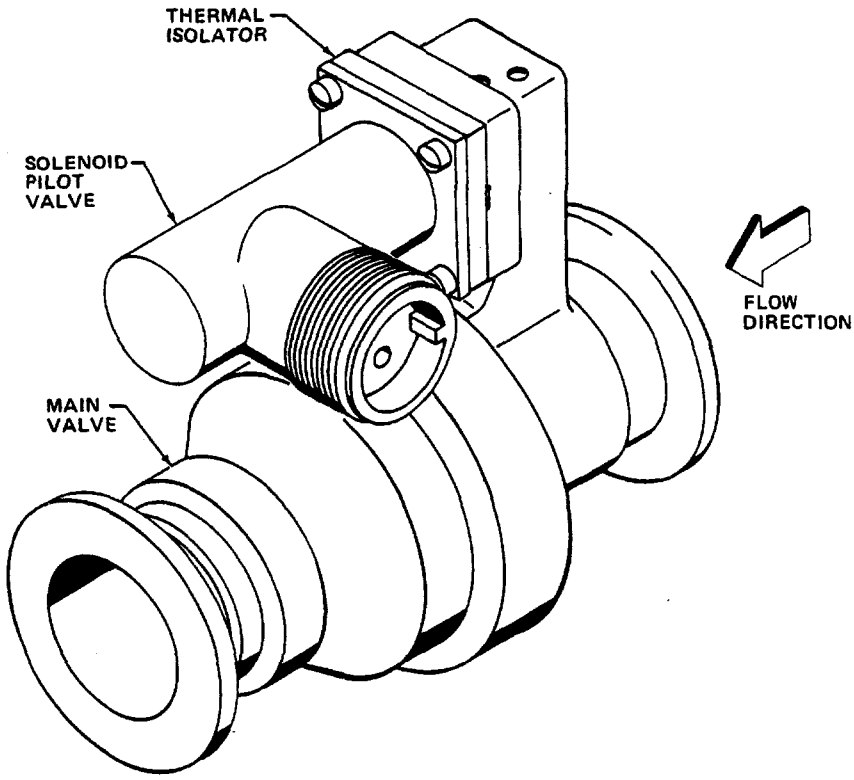
INTRODUCTION

This manual provides procedures that will enable the technician to restore the equipment to a usable condition. The procedures in this manual are presented for use by the technician performing shop work, and not for the aircraft mechanic.

Corrective maintenance in this manual is based primarily in connection with correcting malfunctions that occur during test and assembly checkout operations.

1. Description and Operation



A. Description (Ref Fig. 1)

(1) The Solenoid Actuated (Pilot) Poppet Shutoff Valve (hereinafter called the "valve") is a two position valve, used in a turbine engine bleed air system. The valve is essentially a poppet-type, two position main valve controlled by a solenoid operated two position, three-way pilot valve.

(2) The valve inlet and outlet ports are designed for "V"-band couplings, with flanges in accordance with Marman Division, Aeroquip Corporation, Specification MFM 68660-100.

(3) The electrical connector on the solenoid valve is designed to mate with an MS3106-12S-3S electrical plug.

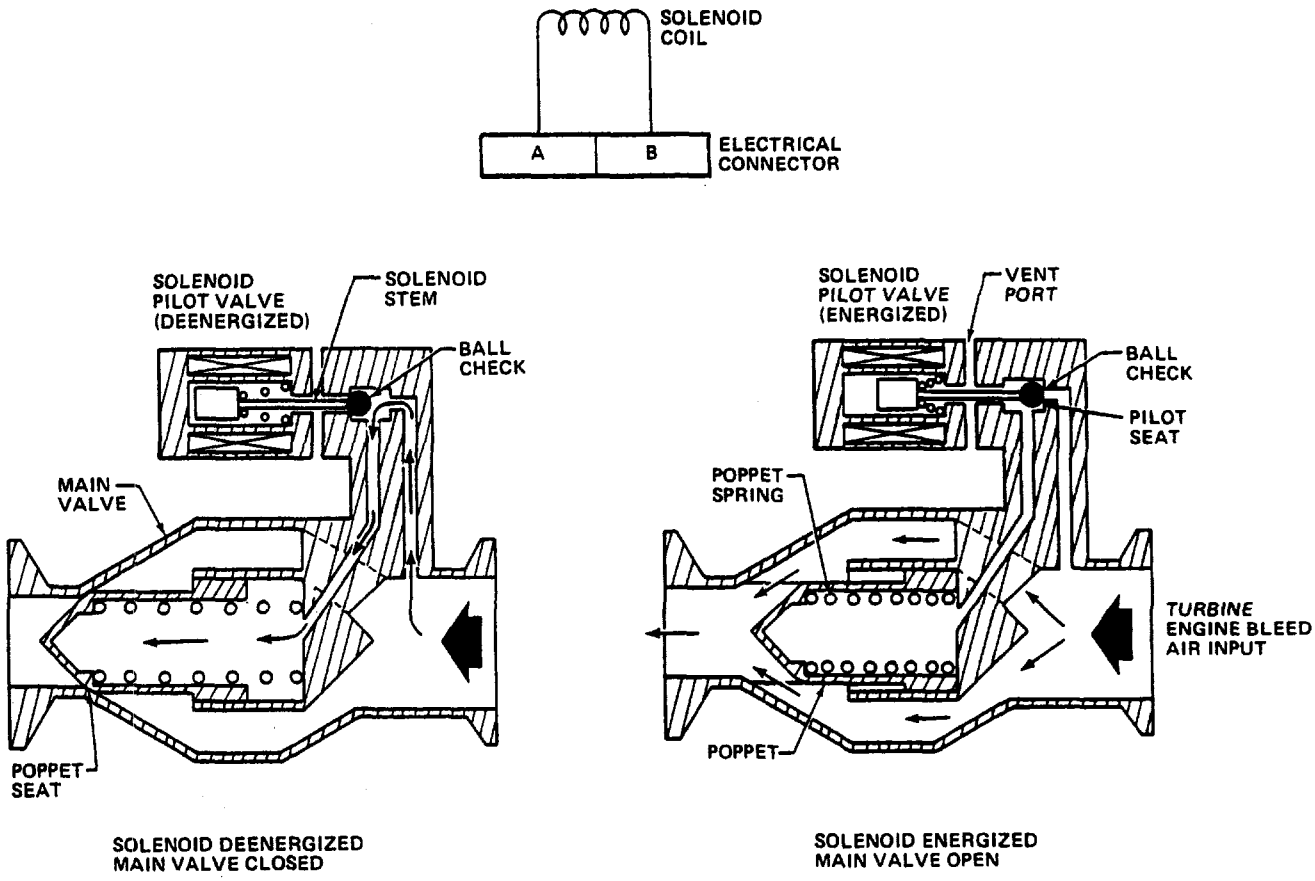
(4) The main valve housing, poppet, and flange are manufactured from 17-4 PH CRES, passivated per Whittaker requirements. The solenoid stem is made from CRES, Rc35 minimum harness, with no plating. The piston OD of the poppet is chrome plated.

Valve - General Arrangement
Figure 1

(5) A thermal isolator (Mykroy-1100 or Supramica-1100) between the solenoid and main valve housing gives the solenoid thermal protection from the heat (engine bleed air) to which the main valve is exposed.

(6) The seat in the pilot valve (ball seat) is made from CRES 316, 321, or 347; per QQ-S-763, and is ball-lapped for minimum leakage.

(7) The main valve poppet spring is made from Inconel X-750 per AMS 5699, and passivated per Whittaker requirements.



(8) The two piston rings for the main valve poppet are carbon ACF-10QE, and maintained in contact against the main valve housing by means of a CRES 301 or 302 expander, hardened per QQ-S-766, and passivated per Whittaker requirements.

B. Operation (Ref Fig. 2)

(1) The valve has two positions: open and closed. Valve position is controlled by the solenoid pilot valve and applied turbine engine bleed air pressure. When the solenoid is deenergized, the main valve is closed; when the solenoid is energized, the main valve will start to open when turbine engine bleed air pressure reaches 3 psig, and will reach full open when turbine engine bleed air pressure reaches 5 psig. At pressures above 5 psig, the main valve will be maintained in the open position. If turbine engine bleed air pressure subsequently drops below 5 psig, the main valve will begin to close, reaching full closed when turbine engine bleed air pressure drops below 3 psig.

(2) In the solenoid deenergized condition, the main valve poppet is held closed by the internal spring, plus any inlet pressure that reaches the interior of the poppet from the pilot valve. If there is no inlet pressure to the main valve, the ball check in the pilot valve will effectively be free, and the poppet interior will be vented to atmosphere. If there is inlet pressure present, that pressure will push the ball check onto the pilot valve vent seat, and the inlet pressure will be applied to the interior of the poppet, increasing the effective seating force of the poppet on the poppet seat of the main valve.

(3) When the solenoid is energized (18 to 30 volts dc applied to the electrical connector of the solenoid), the solenoid coil assembly causes the stem of the solenoid to push the ball check off the vent port of the pilot valve, and to seat the ball check on the pilot seat. This action shuts off the input pressure (turbine engine bleed air pressure) to the interior of the main valve poppet, and vents the interior of the poppet to atmosphere, leaving only the poppet spring to hold the poppet closed on the main valve poppet seat. As turbine engine bleed air pressure

Flow and Electrical Schematics - Simplified
Figure 2

increases, that air pressure is applied to the effective flat plate area of the seating end of the main valve poppet; when the inlet pressure reaches 3 psig, the effective force on the seat end of the poppet is sufficient to begin overcoming the spring force applied to the closing side of the poppet, and the poppet begins to move away from the main valve poppet seat. When turbine engine bleed air pressure reaches 5 psig, the pressure applied to the poppet is sufficient to completely overcome the spring-load force, and the poppet will be moved to the main valve full open position. The poppet will stay in the valve open position as long as turbine engine bleed air pressure remains above 5 psig.

(4) With the pilot valve solenoid held energized, and on reducing turbine engine bleed air pressure to below 5 psig, the main valve poppet will begin to close, and the poppet spring force will be sufficient to completely close the main valve if the turbine engine bleed air pressure drops below 3 psig.

(5) With turbine engine bleed air pressure above 5 psig and the pilot valve solenoid energized, the main valve will remain open until the turbine engine bleed air pressure drops as just described. If the pilot valve solenoid is deenergized while the main valve is open, then the ball check will be pushed off the pilot seat and seated on the pilot vent seat, and the turbine engine bleed air pressure will be applied to the interior of the main valve poppet, adding to the poppet spring force and closing the main valve poppet.

C. Leading Particulars

Service . . . . . Turbine Engine Bleed Air
Performance Data:
Flow . . . . . In direction shown on Fig. 1
Operating Pressure . . . . . 3 to 175 psig
Leakage:
Internal. . . . . 0.2 pound per minute maximum
External. . . . . 0.05 pound per minute maximum
Operating Time:
Open . . . . . 1 second maximum
Close . . . . . 1 second maximum
Temperature:
Ambient. . . . . -65°F to +300°F (-53.9°C to +148.9°C)
Bleed Air. . . . . +650°F (+343.3°C) maximum
Electrical Data:
Voltage. . . . . 18 to 30 volts dc, continuous duty solenoid
Current. . . . . 1.5 amperes maximum operating current
Installation Data:
Valve Ports. . . . . "V"-Band coupling. Flanges per Marman Division, Aeroquip Corporation, Specification MFM 68660-100
Electrical Connector . . . . . Mates with MS3106-12S-3S plug
Operation:
Open . . . . . Energize solenoid; valve starts to open at 3 psig; full open at 5 psig
Close . . . . . Deenergize solenoid
Weight (calculated) . . . . . 1.40 pounds

2. Testing and Troubleshooting

NOTE: If the valve passes the tests in the following paragraphs prior to disassembly, return to service.

A. Test Equipment and Materials

NOTE: Equivalent substitutes may be used for the items listed below.

Equipment/Materials	Description
Pressure Source	Capable of supplying air pressure at 0 to 300 psig, at a temperature of +70 ±20°F (+21.1 ±11.1°C) and filtered to 10 microns.
Inlet Pressure Gage (proof test)	0 to 1000 psig; accuracy ±2% of full scale.
Inlet Pressure Gage (other tests)	0 to 300 psig; accuracy ±0.5% of full scale.
Downstream Pressure Gage	0 to 300 psig; accuracy ±0.5% of full scale.
Flowmeter (leakage tests)	0 to 0.25 pound per minute; accuracy ±0.5% of full scale.
Voltmeter (electrical tests)	0 to 50 volts dc; accuracy ±0.2% of full scale.
Ammeter (current tests)	0 to 5 amperes dc; accuracy 0.5% of full scale.
Electrical Power Supply	12 to 30 volts dc, adjustable; current capability is 1.5 amperes.

B. Test Conditions

(1) The following tests may be accomplished under normal shop ambient conditions.

C. Operational Tests and Troubleshooting

(1) Proof Test

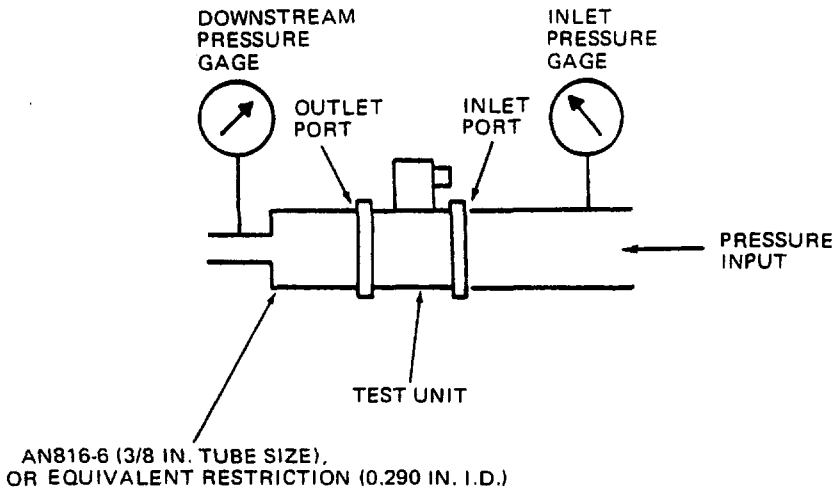
(a) Connect air pressure source to both inlet and outlet ports of main valve.

(b) With solenoid deenergized, simultaneously apply 290 to 300 psig to the main valve inlet and outlet ports, and maintain pressure for one minute; then, reduce pressure to zero.

(c) There shall be no evidence of failure, distortion, or permanent set. If any malfunctions are observed, replace defective component(s).

(2) Actuation Test

(a) Connect valve into test setup (Ref Fig. 101).



(b) Connect 12 to 30 volt dc electrical power supply to solenoid connector. Set power supply at 12 to 13 volts dc.

(c) With solenoid energized, slowly increase inlet port pressure, starting from zero psig, until the valve opens (as evidenced by flow from outlet port); opening pressure shall be a maximum of 5 psig. Reduce pressure to zero psig and deenergize solenoid.

(d) Repeat step (c) three times.

(e) If valve fails to open on increasing pressure with solenoid energized, check the following:

Possible Cause	Remedy
Solenoid not energized	Check external power supply.
Solenoid defective	Replace solenoid assembly.
Ball check stuck	Replace ball in pilot valve.
Poppet stuck in main valve (poppet must move freely in main valve flange without sticking or binding)	Check poppet; replace if defective. Make sure piston rings are not damaged. Make sure bore of valve flange not damaged, preventing poppet motion; replace if defective. Check poppet is lubed sparingly (Ref Assembly, paragraph 7, for lubrication details).
Defective piston rings on poppet (excessive leakage into poppet)	Replace piston rings and expander.

Test Setup - Typical
Figure 101

(f) If opening pressure is too low or too high, but valve does open, check that poppet spring is not broken (too low opening pressure) or cocked, stuck, or otherwise applying too much force (opening pressure too high). Replace if defective.

(g) Raise inlet pressure to 5 psig, and energize solenoid with 12 to 13 volts dc; valve shall open within one second. Deenergize solenoid; valve shall close within one second. Reduce inlet pressure to zero psig.

(h) Repeat step (g) at 25 psig, 90 psig, 130 psig, and 175 psig; same requirements must be met.

(2) Current Drain Test

(a) Energize solenoid by applying 29 to 30 volts dc to solenoid connector pins.

(b) Check that solenoid current drain does not exceed 1.5 amperes.

(c) If current drain is excessive, check for shorts in wiring leading from electrical power supply to solenoid electrical connector; correct test wiring as necessary. If wiring is satisfactory, excessive current drain may be caused by a faulty solenoid assembly; replace defective solenoid assembly.

(4) Internal Leakage Test

(a) Connect valve in test setup (Fig. 101), with a flowmeter connected downstream of the outlet port of the valve under test.

(b) With solenoid deenergized, slowly increase inlet pressure from zero psig to 175 psig, and measure internal leakage indicated on flowmeter.

(c) Internal leakage through valve shall not exceed 0.2 pounds per minute at inlet pressure from 5 to 175 psig.

(d) If internal leakage is excessive, check the following:

Possible Cause	Remedy
Poppet not seating on poppet seat of main valve flange	Poppet stuck; free up as may be necessary.
	Flange not smooth for poppet travel; repair or replace as necessary. Make sure poppet is properly lubed.
	Check seat end of poppet; repair or replace if nicked, scored, or damaged.
	Check poppet seat on flange; repair or replace as necessary.
	Check poppet spring not cocked, broken, or weakened; replace if defective.
Solenoid in energized position	If solenoid stuck open; free or replace. Make sure solenoid stem is not stuck, holding ball check partially off vent seat or against pilot seat in main valve housing (signaling poppet to open).

(5) External Leakage Test

(a) Block outlet port of valve under test.

(b) Connect inlet port of valve under test to air pressure source, with flowmeter installed upstream from valve.

(c) With solenoid deenergized, raise pressure at inlet port to 5 psig, and measure external leakage (total leakage indicated on upstream flowmeter. Reduce inlet pressure to zero.

(d) Repeat step (c), except raise pressure to 175 psig.

(e) Repeat steps (c) and (d), except with solenoid energized with 12 to 13 volts dc.

(f) The external leakage measured during each of the preceding tests shall not exceed 0.05 pound per minute.

(g) If external leakage is observed in both the solenoid energized and deenergized conditions:

Possible Cause	Remedy
Poor seal between flange and main valve housing	Check with soap solution under pressure. If leakage is observed, disassemble and repair or replace the defective component. Particularly check condition of mating surfaces. Make sure threads are properly lubricated before reassembling.
Ball in pilot valve not seated (leakage out pilot vent port)	Check pilot vent port for leakage (use soap solution or listen for audible noise).

(h) If external leakage is observed only with solenoid deenergized (leakage within limits when solenoid is energized):

Possible Cause	Remedy
Solenoid stem may be stuck partially extended, holding ball check off seat.	Check solenoid; replace if defective.
Defective pilot vent port seat.	Check for damage to ball-lapped seat; repair or replace if defective. Make sure seat is not leaking past threads.

(i) If external leakage is observed only with solenoid energized (leakage within limits when solenoid is deenergized):

Possible Cause	Remedy
Solenoid stem may not be seating ball check on pilot seat.	Check solenoid stroke; make sure ball is not stuck, and that seat on housing is not damaged; repair or replace defective components.
Leakage past piston rings may be excessive.	Check for air leakage out of pilot vent port with solenoid energized; this can be piston ring leakage and/or ball check leakage (see above); replace defective components.

3. Disassembly

NOTE: See Testing and Troubleshooting, paragraph 2, to establish the condition of the unit or the most probable cause of malfunction. This is to determine the extent of disassembly required without completely tearing down the unit.

A. Disassemble the valve as follows (Ref IPL Fig. 1):

(1) If installed, remove closures (75) from ports of valve.

(2) If installed, remove closure (70) from electrical connector of solenoid assembly (5).

(3) Remove four screws (10), and separate solenoid assembly (5) from housing assembly (65).

(4) Remove any installed washers (15, 16, 17) from solenoid assembly (5) or housing assembly (65). Tie washers together to retain previously established shim thickness to facilitate later reassembly.

(5) Remove thermal isolator (20) from housing assembly (65).

(6) Unscrew seat (25) from housing assembly (65).

NOTE: The seat (25) is bonded to the housing assembly with sealing compound during assembly; some slight resistance may be encountered when breaking this seal in order to unscrew the seat from housing assembly (65).

(7) Remove any installed washers (30, 31, 32) from seat (25) or housing assembly (65). Tie washers together to retain previously established shim thickness to facilitate later reassembly.

(8) Hold housing assembly (65) with port for solenoid assembly (5) down, and allow ball (35) to fall out of housing assembly.

(9) Unscrew flange (40) from housing assembly.

CAUTION: THE POPPET (45) IS SPRING-LOADED INSIDE THE HOUSING ASSEMBLY (65) TO CAUSE IT TO SEAT ON THE FLANGE (40). USE CARE WHEN THE FLANGE FINALLY SEPARATES FROM THE HOUSING ASSEMBLY TO PREVENT THE POPPET FROM BEING FORCIBLY EJECTED FROM THE VALVE, AND POSSIBLY FALLING AND BEING DAMAGED. IF CARE IS TAKEN TO RESTRAIN ANY SUDDEN SEPARATION OF THE FLANGE AND HOUSING ASSEMBLY, THE POPPET WILL BE HELD INSIDE THE FLANGE AT SEPARATION, AND THE SPRING WILL BE RETAINED INSIDE THE FLANGE OR HOUSING ASSEMBLY.

(10) Remove poppet (45) from flange (40), and remove spring (50) from poppet or housing assembly (65).

(11) Remove two rings (55) and expander (60) from ring groove of poppet (45).

4. Cleaning

A. Cleaning Materials

NOTE: Equivalent substitutes may be used for the items listed below.

Solvent, Cleaning (P-D-680)	Commercially Available
Cloth, Lint-free	Commercially Available
Brush, Stiff Bristle	Commercially Available

B. Cleaning Procedure

WARNING: SOLVENT MAY BE TOXIC. USE ONLY IN A WELL-VENTILATED AREA. AVOID PROLONGED INHALATION OF FUMES AND DIRECT CONTACT WITH SKIN. USE NECESSARY FIRE PRECAUTIONS. DO NOT DIRECT COMPRESSED AIR AGAINST SKIN.

(1) Immerse and wash all metallic parts in solvent.

(2) Dry all parts thoroughly with a clean, lint-free cloth, or use low-pressure air blast (20 psig maximum nozzle pressure).

(3) Use a stiff bristle brush to dislodge stubborn dirt and other material accumulations in threads and cavities.

(4) Place cleaned parts in a dust-proof container until ready for check and reassembly.

5. Check

A. Equipment Required

NOTE: Equivalent substitutes may be used for the equipment listed below.

Insulation Resistance Tester (500 volts dc; to 100 megohms)	Commercially Available
Dielectric Tester. (600 volts rms, 60 Hz; leakage current to 1.5 milliamperes)	Commercially Available

B. General

(1) A preliminary check of parts before initial cleaning may facilitate the location of obvious defects.

(2) Visually check all hardware and piece parts using a strong light and preferably some means of magnification, and note any nicks, cracks, cuts, corrosion, excessive wear (see NOTE), and any other obvious defects that can impair the efficient and proper operation of the valve.

NOTE: Excessive wear shall be defined as any obvious deformation or deterioration of a part which may render the part inoperative. If doubt exists concerning the serviceability of a part, replace the part.

C. Detail Checks (Ref IPL Fig. 1)

(1) Solenoid Assembly (5)

(a) Threads clean and undamaged.

(b) Electrical connector terminals clean and undamaged; no evidence of arc-over or burning.

(c) Apply 600 volts rms at 60 Hz between solenoid housing and connector terminals (bussed together); there shall be no evidence of breakdown or arc-over, and leakage current shall not exceed 1.5 milliamperes.

(d) Apply 500 volts dc between solenoid housing and connector terminals (bussed together); insulation resistance shall be at least 100 megohms.

(e) Check that at 0.025 inch stroke (minimum) of solenoid stem, the solenoid exerts a 16-pound push force (minimum) against the force of the solenoid return spring, with 12 to 13 volts dc applied (at room temperature).

(f) In the solenoid energized condition, the stem shall protrude from the solenoid (measured between the surface that contacts thermal isolator (20) or any installed shim washers and the exterior end of the stem) 0.520 to 0.522 inch.

(2) Thermal Isolator (20).

(a) Not cracked or broken.

(b) No visible burrs.

(3) Seat (25).

(a) Threads clean and undamaged.

(b) Seat for ball (35) lapped to 0.001 to 0.003 inch wide; smooth, and free of nicks, scratches, and corrosion.

(4) Flange (40).

(a) Threads clean and undamaged.

(b) Inside diameter for poppet (45) not worn over 0.9540 inch; smooth to 16 microinch rms finish.

(c) Seating surface for poppet (45) smooth and free of nicks, scratches, and corrosion; smooth to 32 microinch rms finish.

(5) Poppet (45).

(a) Chrome plating on outside diameters that ride inside flange (40) and housing assembly (65) not worn through to bare metal.

(b) Outside diameter that rides inside flange (40) free of nicks, scratches, and corrosion; not worn below 0.9483 inch; smooth to 32 microinch rms finish.

(c) Outside diameter that rides inside housing assembly (65) free of nicks, scratches, and corrosioh; not worn below 1.1545 inch; smooth to 32 microinch rms finish.

(d) Seat on poppet that contacts seating surface in flange (40) free of nicks, scratches, and corrosion; smooth to 32 microinch rms finish.

(6) Spring (50).

(a) Free length approximately 1.29 inches.

(b) Shall compress to 1.13 inches long under a load of 0.79 ±0.10 pound.

(c) Shall compress to 0.80 inch long under a load of 2.44 ±0.20 pounds.

(7) Housing Assembly (65).

(a) Threads clean and undamaged.

(b) Passages from inlet port to pilot valve section and from pilot valve section to poppet valve section clean and unobstructed.

(c) Inside diameter for rings (55) of poppet (45) free of nicks, scratches, and corrosion; not worn over 1.1575 inches; smooth to 16 microinch rms finish.

6. Repair

A. Repair Materials

NOTE: Equivalent substitutes may be used for the items listed below.

Crocus Abrasive Cloth (P-C-458). . . . . (for ferrous materials)	Commercially Available
Aluminum Oxide Abrasive Cloth (P-C-451). . . . . (for aluminum materials)	Commercially Available
Lapping Compound	Commercially Available
Tiodize No. 1175	Tiodize Company Inc. 15701 Industry Lane Huntington Beach, CA
Chrome Acid (Chromium Trioxide). . . . . Technical Grade (Fed Spec O-C-303)	Commercially Available
Sulphuric Acid, Technical Grade. . . . . (Fed Spec O-S-809A)	Commercially Available
Hydrochloric Acid (Muriatic) . . . . . Technical Grade (Fed Spec O-A-86)	Commercially Available
Manganesed-Phosopholine No. 7	Western Reserve Laboratories Cleveland, OH
Trichloroethylene or Perchloroethylene	Commercially Available

B. General Repairs

(1) Minor nicks, scratches, scoring, and corrosion may be removed from parts with the proper abrasive cloths.

(2) Thoroughly clean any repaired parts.

C. Detail Repairs (Ref IPL Fig. 1)

(1) Seat (25).

(a) The seating surface of the pilot seat (25) may be lapped if damaged to remove minor scoring and scratching, using a 0.1562 ±0.0002 inch diameter ball and lapping compound.

(b) If seat surface exceeds 0.004 inch in width, replace with new seat.

NOTE: Original factory-manufacture requirements for the seat are to ball lap to obtain a GITS test value of 22 inches of mercury minimum (gauge reading) for 20 seconds minimum.

(2) Poppet (Ref 45, IPL Fig. 1)

(a) If chrome plated diameters that ride in flange (40) and/or housing assembly (65) are damaged by wear, nicks, scoring, or corrosion, they may be machined down to bare metal and replaced. Chrome plating shall be accomplished as described in paragraph 6D below. Chrome plating shall be 0.0002 to 0.0003 inch thick.

(b) Outside diameter that rides in flange (40) shall be 0.9488 to 0.9493 inch after chrome plating.

(c) Outside diameter that rides in housing assembly (65) shall be 1.1550 to 1.1554 inch after chrome plating.

(d) Apply Tiodize No. 1175 to external surfaces of poppet; internal surfaces are optional.

D. Chrome Plating of Poppet (Ref 45, IPL Fig. 1)

(1) Vapor degrease using trichloroethylene or perchloroethylene.

(2) Descale, when necessary, by dipping in Manganesed-Phosopholine No. 7 (Western Reserve Laboratories, Cleveland, Ohio) or by vapor blast using glass beads.

(3) Alkaline clean, using 8 ounces of Oakite 90 to 1 gallon water at, or above, 190°F.

(4) Rinse thoroughly in water at room temperature.

(5) Dip poppet in an aqueous solution of 5 to 10% muriatic acid for 5 to 10 seconds at room temperature. Solution density will be 4° to 7° Be.

(6) Chromium plate. Plating shall conform to Procedure I or II (step (9) or (10) below). Thickness of plating shall be 0.0002 to 0.0003 inch.

(7) Rinse thoroughly in room temperature water.

(8) Rinse in 160° to 180°F water and allow to dry.

(9) Procedure I

NOTE: Chromium plating in accordance with Procedure I will resist corrosion under both moderate and high temperature (700°F) environmental conditions.

Approved processes:

Microplate No. 2 - Microplate Company, 1013 West Hilcrest, Inglewood, California.

Multichrome No. 2 - Multichrome Company, 11165 Tennesses Avenue, Los Angeles, California.

(a) Plating solution shall be 150°F and shall consist of 35.0 to 46.5 ounces per gallon chromic acid, and 0.12 to 0.125 ounces per gallon sulfate ion (derived from 99% sulfuric acid), and water. Solution density will be 22° to 28° Be.

(b) Current shall be applied gradually at 3.0 to 5.0 amps per square inch.

(c) Plating rate shall be approximately 0.00002 inch per minute and the material shall be evenly distributed over the entire surface on which it is deposited.

(d) Parts to which chromium plate has been applied by this procedure should resist corrosion when subjected to 750°F for one (1) hour followed by a fifty-hour salt spray.

(e) Reference information: Plating should be free of microscopic cracks, and have an approximate superficial rockwell hardness of Rc60 to 62.

(10) Procedure II

NOTE: Chromium plating in accordance with Procedure II will resist corrosion when environmental conditions are moderate. Wear resistance and anti-galling qualities are good.

Approved processes:

Electrolizing - Electrolizing Company, 1947 Hooper Avenue, Los Angeles, California.

Microplate No. 1 - Microplate Company, 1013 West Hilcrest, Inglewood, California.

Multichrome No. 1 - Multichrome Company, 11176 Tennessee Avenue, Los Angeles, California.

NOTE: Processing shall be as outlined in Procedure I with the following exceptions:

(a) Applied current shall be 3 amps per square inch.

(b) Plating rate shall be approximately 0.00003 to 0.00005 inch per minute.

(c) Reference information: Plating should be free of microscopic cracks and have an approximate superficial Rockwell hardness of Rc 70 to 72.

7. Assembly

A. Assembly Materials

NOTE: Equivalent substitutes may be used for the items listed below.

Lockwire MS20995C20 (install per MS33540)	Commercially Available
Tiodize, No. 1175	Tiodize Company, Inc. 15701 Industry Lane Huntington Beach, CA
Lube SS-30	Jet-Lube Inc. Houston, TX
Sealant RTV 106	General Electric Company Silicone Products Business Department Waterford, NY 12188
Thread Lubricant	Parker Hannifin Corp. Cleveland, OH

B. Lubrication (Ref IPL Fig. 1)

(1) Apply Tiodize No. 1175 to external surfaces of poppet (45).

(2) Apply Lube SS-30 sparingly at joint of mating edges of flange (40) and housing assembly (65).

(3) Coat threads of screws (10) with thread lubricant.

C. Assembly Procedure (Ref IPL Fig. 1)

(1) Using two new rings (55), break rings one place only each ring, and install new expander (60) and rings on poppet (45). Orient gaps (broken points) of the two rings 180 degress apart.

(2) Install sopring (50) in housing assembly.

(3) Compress rings (55), and carefully install poppet (45) in housing (65), being careful that rings do not catch or break on housing before poppet is fully installed. Hold poppet in housing assembly against spring pressure.

(4) Carefully install flange (40) over poppet (45), using care to prevent the poppet being forced sufficiently out of housing assembly (65) to expose carbon rings (55), and engage flange threads with threads of housing assembly. Tighten flange into housing assembly to 75 to 100 pound-inches torque.

(5) Using a wooden dowel or other non-metallic device, push on visible end of poppet (45) (end visible through outlet port of flange) and make sure that poppet moves freely in flange and housing assembly, with the only restriction being that of the force of the spring (50). The poppet must move freely without sticking or binding.

(6) Place a new ball (35) on seat (25), and using a depth micrometer inserted through the seat and resting on the top of the ball, measure the distance from the top of the ball to a convenient reference point on the seat.

(7) Remove ball (35) from seat (25), and install the seat in housing assembly (65); torque to 6 to 8 inch-pounds.

(8) Place thermal isolator (20) on housing assembly (65), and using the same reference point on the top of seat (25) as in step (6), measure distance from top of seat to exterior flat surface of thermal isolator.

(9) Energize solenoid (5) with 18 volts dc, and measure distance from flat surface of solenoid housing to extended end of solenoid stem.

(10) Add the two dimensions obtained in steps (6) and (8), and subtract from the dimension obtained in step (9). The difference is the amount of travel of the solenoid stem when it pushes ball (35) off seat (25). Stroke distance should be 0.025 to 0.030 inch. When assembling seat (25) and solenoid assembly (5) on housing assembly (65), use shim washers (15, 16, 17) to decrease the stroke, and shim washers (30, 31, 32) to increase the stroke.

(11) Remove seat (25) and place new ball (35) in pilot valve section of housing assembly (65).

(12) Install selected number of shims (30, 31, 32) on seat (25), coat threads of seat with RTV 106, and install seat in housing assembly (65). Torque seat to 6 to 8 pound-inches.

(13) Install thermal isolator (20) on housing assembly (65).

(14) Install selected number of shim washers (15, 16, 17) on solenoid assembly (5), orient solenoid connector as shown in IPL Fig. 1 (also shown in Fig. 1 of this manual), and secure to housing assembly with four screws (10). Torque screws to 7 to 8 pound-inches, and install lockwire between the screws, in pairs.

CAUTION: DO NOT OVERTORQUE SCREWS (10); EXCESSIVE TIGHTENING MAY CRUSH OR BREAK THERMAL ISOLATOR (20).

(15) Check that identification data has been electro-etched on housing assembly (65) as follows (0.10 to 0.14 inch high letters):

WHITTAKER CONTROLS, A UNIT OF WHITTAKER CORPORATION
VALVE, SHUT-OFF
PART NO. 320295 (latest change letter)
SER NO. (as applicable)
DATE OF MFG: SPEC NO. US:

D. Storage Instructions

(1) Storage Materials

NOTE: Equivalent substitutes may be used for the items listed below.

Shipping Closures	(Ref 70, 75, IPL Fig. 1)
Polyethylene Bag	Commercially Available
Desiccant	Commercially Available

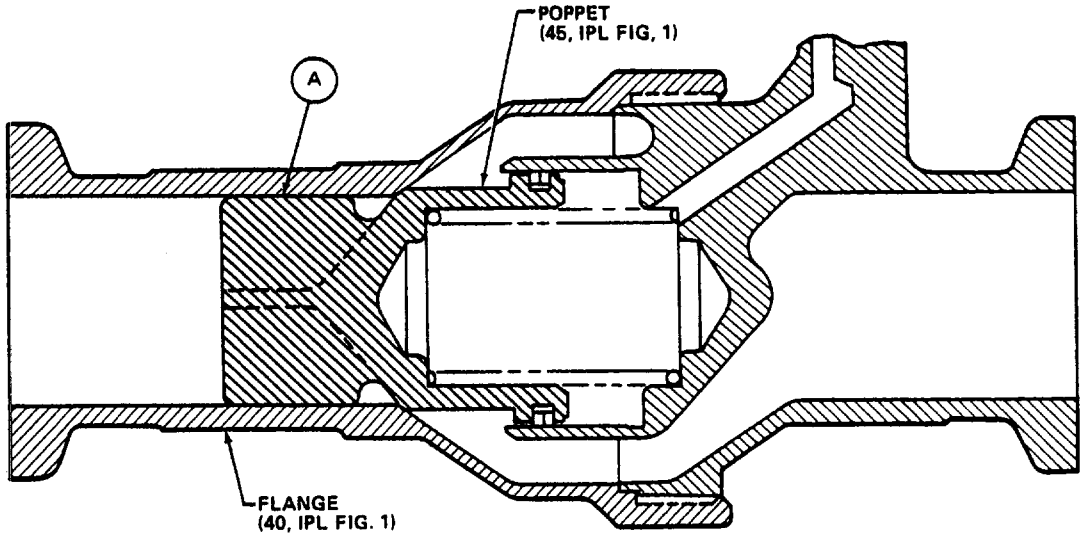
(2) Storage Procedure

(a) Install shipping closures on inlet and outlet ports of valve, and on solenoid electrical connector.

(b) Place valve in polyethylene bag, with desiccant, and seal bag.

(c) Shelf Life: 60 months at room ambient temperature.

8. Fits and Clearances



A. Wear Tolerances

FIG. 801 REF LTR	DIA	MATING ITEM (REF IPL FIG. 1)	MANUFACTURING DIMENSIONS (INCHES)				WEAR LIMITS (INCHES)		
			DIMENSION		ASSEMBLY CLEARANCE		DIM. LIMITS		MAX CLEARANCE ALLOWABLE
			MIN	MAX	MIN	MAX	MIN	MAX

C. Torque Data

ITEM (REF IPL FIG. 1)	NOMENCLATURE	TORQUE REQUREMENTS
10	Screws	7 to 8 pound-inches
25	Seat	6 to 8 pound-inches
40	Flange	75 to 100 pound-inches

9. Special Tools, Fixtures, and Equipment

NOTE: Equivalent substitutes may be used for the items listed below.

A. Special Tools

(None required)

B. Fixtures

(None required)

C. Equipment

(1) Test Equipment: Reference paragraphs 2A and 5A.

10. Illustrated Parts List

A. Introduction

(1) This Illustrated Parts List illustrates and lists parts of the subject equipment.

(2) The identification data stamped on the unit identifies the part number, serial number, and specification data for the unit.

B. Using the Parts List

(1) The Parts List is a breakdown of assemblies, subassemblies, and detail parts of the unit. Item numbers on the accompanying illustrations indicate the order of disassembly of the unit for component maintenance purposes. Component parts are indented to show their relationship to the complete assembly. Attaching parts immediately follow the parts that they attach, and precede any detail components when the attached part is an assembly.

(2) Part numbers and descriptions in the Parts List identify each part. The Item numbers in the Parts List refer to the accompanying illustration, and are used for locating a part in the Parts List after the part has been found on the accompanying illustration.

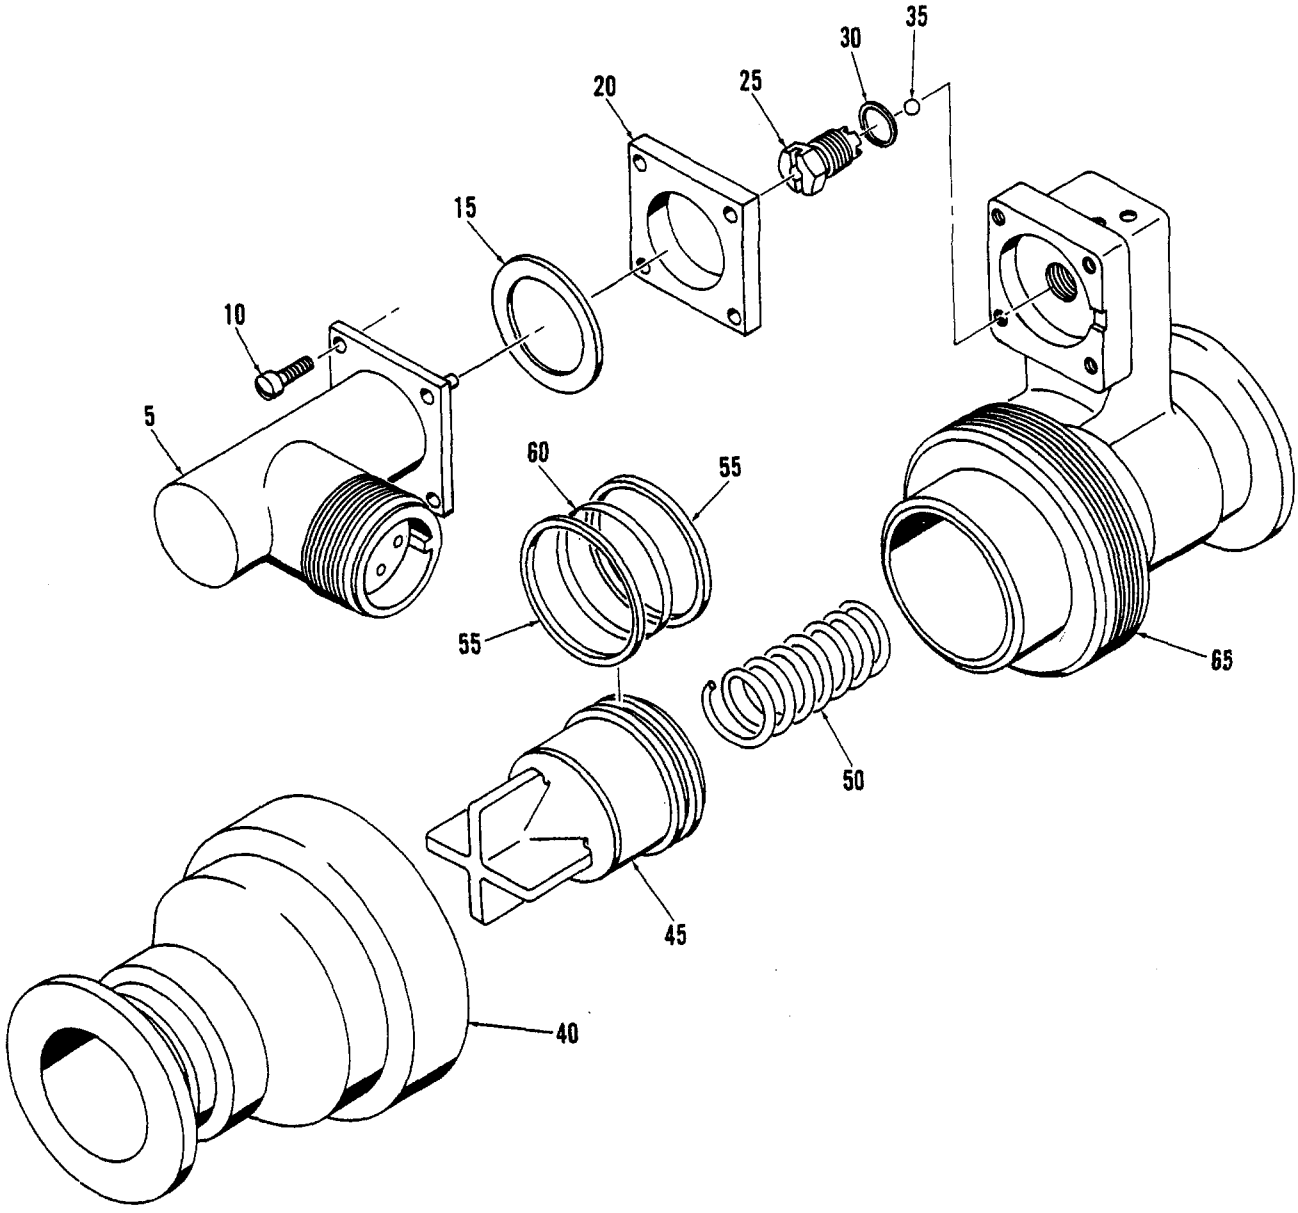
(3) The Effect Code column of the Parts List shows differences between two or more similar units or assemblies listed together in the same Parts List. Parts not used in all of the units or assemblies bear a code letter for the particular unit or assembly in which the parts are used. When the Effect Code column is blank, the part is used in all of the units or assemblies listed in the Parts List.

(4) The Units Per Assy column of the Parts List indicates the quantity of each part required for the next higher assembly.

C. Identifying Parts

(1) If the part number or the reference designation are not known, refer to the illustration of the unit or assembly in which the part is used. Locate the part in the illustration, and obtain the item number of the part. Refer to the Item number in the Parts List accompanying the illustration. The columns following the Item number give the Part Number, Nomenclature, and Units Per Assy of the particular part.

D. Abbreviations and Symbols



AR	As Required
ASSY	Assembly
CRES	Corrosion-Resistant Steel
NO.	Number
RF or REF	Reference
***	End of Attaching Parts
±	Plus or Minus

E. Vendor Codes

Vendor code numbers, preceded by the letter "V", appear in the Nomenclature column of the parts list. The absence of a vendor code following a part nomenclature (other than a Government standard part), indicates the part number is that of a Whittaker Controls part. The following vendor codes and corresponding manufacturers names and addresses are used in this manual:

V79318	Whittaker Controls A Unit of Whittaker Corporation 12838 Saticoy Street North Hollywood, CA 91605

AIRLITE 70 HEADSETS

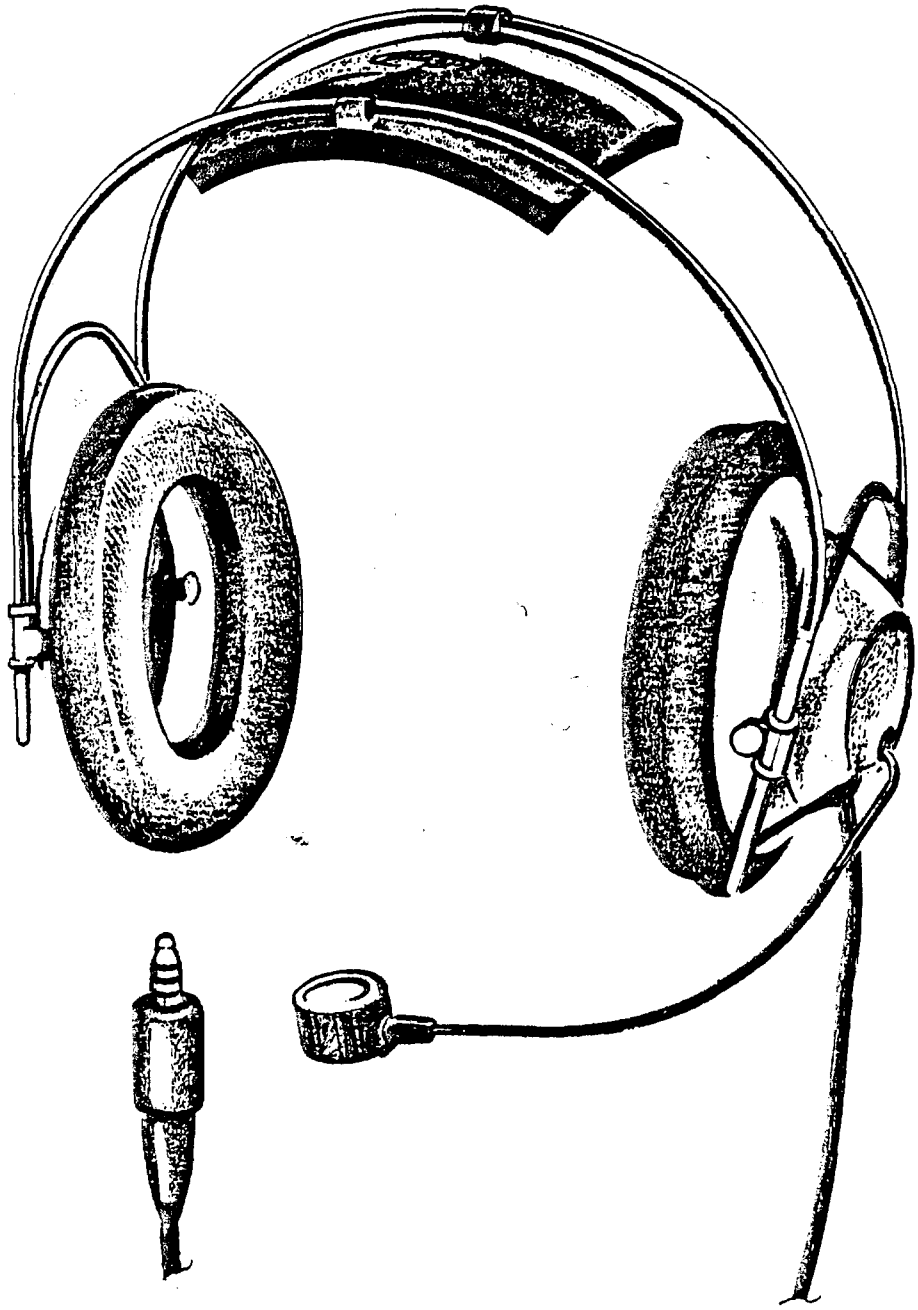
REVISION RECORD

The introduction of any amendment or revision not verified in accordance with British Civil Airworthiness Requirements Section A, Chapter A6-2, will invalidate the statement of certification on Page i. Amendments or revisions embodied in this manual, which have been certified under an approved authorisation other than that applicable to the initial certification must be recorded on separate record sheets.

REV. NO.	INSERTION DATE	BY	REV. NO.	INSERTION DATE	BY	REV. NO.	INSERTION DATE	BY

DESCRIPTION, OPERATION AND DATA



1. Description

The Airlite 70 headset, ref 5850 is the basic model of this headset but several other standards are used. A range of interchangeable microphones, earphone insets and jackplugs identified by a letter coding system enable a large number of variants to be produced. This manual covers the basic headset and makes reference to alternative components where applicable.

The headset incorporates a pair of earphone insets (11) and a moving coil noise cancelling microphone (21). Alternative microphones are electro-magnetic of various impedances, or carbon, and a miniature amplifier may be fitted enabling an electro-magnetic microphone to be used in a carbon microphone circuit. The earphone insets are fitted in plastic earshells (6) and (18) which are provided with detachable earpads (13) and earpad covers (14). The headband (1) which acts as a conductor for the earphones, can be adjusted for length by sliding the earshell assemblies, longitudinally. The headpad (2) which clips onto the headband has a foam cushion for comfort. The microphone is attached to the boom, which is connected to one of the earshells by a ball joint, enabling the microphone to be positioned as required. The main downlead (27) is fitted to the same earshell assembly. The basic headset has a Nato jackplug (34) on the free end of the lead, but alternative jackplugs can be fitted and a switch may be incorporated. All wiring is completely enclosed, connections being made to terminals inside the earshells. Earphones are wired individually and connected to the jackplug in parallel or individually according to the type of plug used. The variations in jackplug impedance reading are obtained by using earphone insets of different impedances.

2. Operation

The headset is brought into use simply by plugging the jackplug into the aircraft jackbox. The downlead may incorporate a switch.

AIRLITE HEADSET REF. AIR 5850
Figure 1

3. Data

A. Basic data

Weight of Air 5850 complete	$7\frac{1}{2}$ ozs.
Earphone impedance	300 ohm each $\pm$ 20% at 1000 c/s
Earphone resistance d.c.	83 ohm $\pm$ 15%
Microphone impedance	300 ohm $\pm$ 20% at 1000 c/s
Microphone resistance d.c.	275 ohm $\pm$ 15%

B. Build standards

Airlite 70 Ref. No.	Microphone	Ear. impedance at Jackplug	Jackplug
Air 5840	300 ohm moving coil with min. pre-amp.	600 ohm	Nato 10H/18575
Air 5850	300 ohm moving coil	150 ohm	Nato 10H/18575
Air 5890	300 ohm moving coil with min. pre-amp.	600 ohm	PL 55 & PL 68
Air 5900	Carbon	600 ohm	Nato 10H/18575
Air 5910	Carbon	600 ohm	PL 55 & PL 68
Air 5920	None	600 ohm	PL 55

C. Variants

Other combinations of alternative components are selected from the following table, using the code letters in the order shown.

Code Letter	Microphone	Earphone	Connecting Plugs	Lead Length	Switches
O	None	None	None	None	None
A		600 ohm			Press-to-talk
B		300 ohm			On-Off
C		60 ohm			PTT key transmit
D	300 ohm moving iron	1200 ohm			On-Off PTT comb
E	50 ohm moving iron	2400 ohm	PL 55 & PL 68 split lead		
F			PL 68	5 ft.	
G	100 ohm carbon		Nato 10H/18575		
H	300 ohm moving coil		RAF 10H/10991		
I	50 ohm moving coil		Deutsch DM 9702-7P		
J	H fitted with pre-amp		Plessey Mk 4 CZ 49017		
K			PL 55		
L			Elcom 8 way PO 8		
M			McMurdo 9 way		
N			Cannon EP/CG/6/15		
P			Cannon EP/CG/8/15		

Headsets are identified by an Airlite 70 reference number as shown on page 3 if applicable, or by the five letter code as shown above. The reference number or five letter code is shown on the nameplate on the outside of the non-boom side earshell. Alternative components which do not appear in the table and have been supplied to special order are coded S, and instructions regarding them are not included in this manual.

DISASSEMBLY

1. General

The earphone insets and microphone are sealed units and no attempt should be made to open them. It is not practicable to dismantle sub-assemblies any further than is described as some components are cemented together and complete replacements are supplied as spares. The jackplug and cord switch, if any, should be opened for inspection but not separated from the main downlead cable unless replacement is necessary.

2. Procedure

A. With microphones D, E, H, I, J.

(1) Remove earpad covers (14) and earpads (13).

(2) Strip off foam discs (12) from inside earshells.

(3) Remove the three Phillips head screws (16) holding earshell cover (20) to earshell (18) and remove cover.

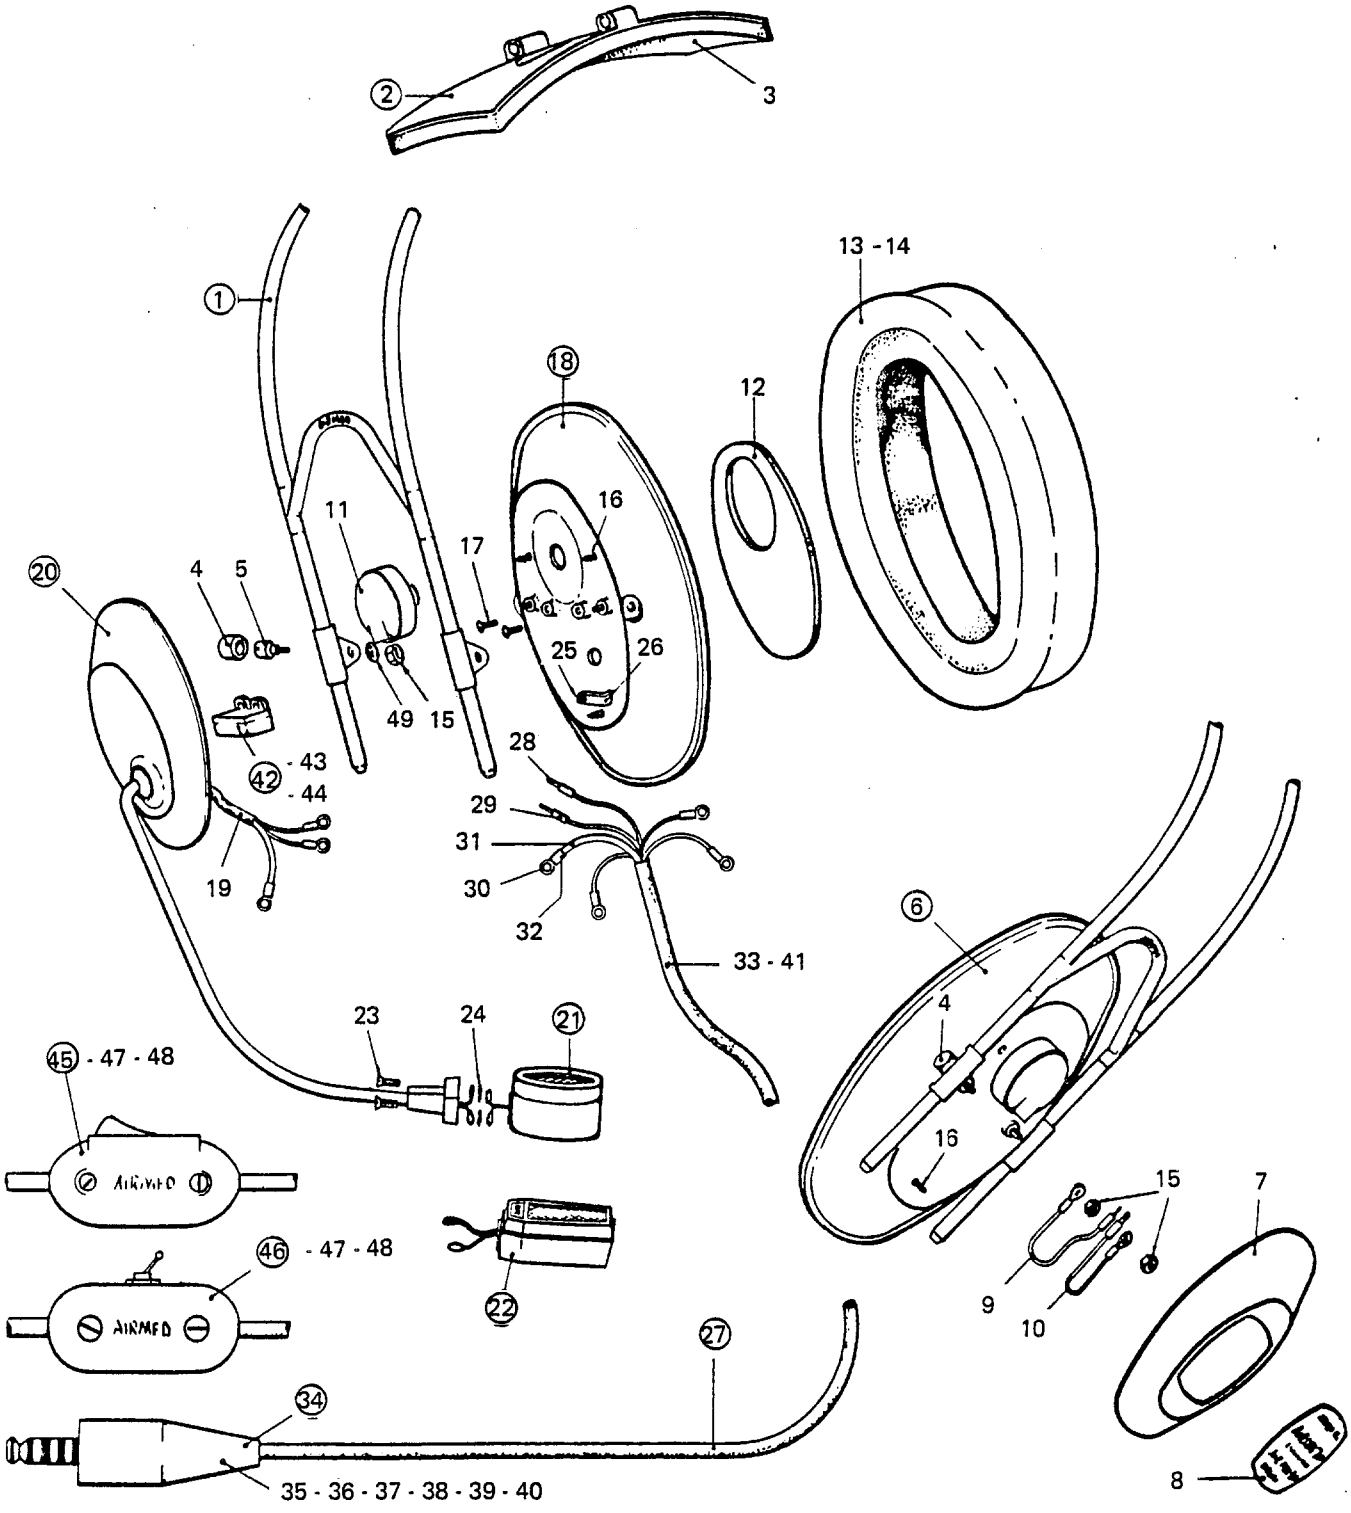
(4) Disconnect and extract earphone inset (11).

(5) Disconnect microphone and downlead cables from amplifier, if fitted, and remove amplifier (42).

(6) Disconnect microphone and downlead cables from terminals.

(7) Unscrew clamping screw (25) and open clamp (26) to release downlead (27).

(8) Unscrew screws (23) and remove microphone (21) or (22) taking care to retain washers (24).



(9) Remove the three Phillips head screws (16) holding earshell cover (7) to earshell (6) and remove cover.

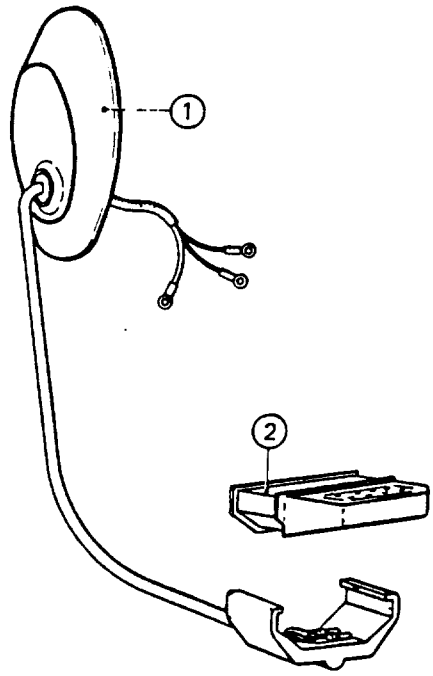
(10) Disconnect connector wires (9) and (10) from terminals and earphone inset (11) and extract earphone inset.

(11) Prise off insulating caps (4).

(12) Unscrew swivel screws (5) and locknuts (15) and remove washers (49) and headband (1).

(13) Remove headpad (2) and strip off headpad cushion (3) if necessary.

EXPLODED VIEW OF HEADSET
Figure 101



B. With Microphone G (Carbon) Index numbers refer to Fig. 101 unless otherwise stated.

(1) Proceed as for A1-7.

(2) Remove the three Phillips head screws (16) holding earshell cover (Fig. 102 (1)) to earshell (18) and remove cover.

(3) Proceed as for A10, 11, 12, and 13.

(4) Slide microphone (Fig. 102 (2)) from clip.

BOOM, CLUTCH & COVER SUB-ASSEMBLY
CARBON MICROPHONE
Figure 102

CLEANING

1. Plastic and metal parts

The headpad moulding and earshells may be washed in warm soapy water, providing that all wiring has been disconnected and earphone insets removed. It is essential that all parts should be dried carefully, by hot air if possible, paying particular attention to earphone cavities and all metal contacts.

All other plastic and metal parts may be wiped with a cloth slightly damped in a dilute disinfectant solution, ensuring that none of the solution enters the earphone insets, microphone capsule, boom, headband or downlead cable.

NOTE: It is very important that all parts are completely dry before commencing re-assembly.

2. Earpad covers and foam pads

Do not attempt to clean dirty earpad covers. Discard them and the foam headpad and earshell discs and fit new ones when the headset is assembled.

INSPECTION/CHECK

1. Headband sub-assembly (1)

   A. Examine for damage.

   B. Check :-

      (1) That the sliders can be moved along the headband but that there is sufficient friction to maintain headband adjustment.

      (2) That the headband has retained its spring and that reasonable pressure is required to part the ends.

2. Headpad (2), headpad cushion (3) and earpads (13)

   Examine for damage.

3. Earshells (6) and (18)

   A. Examine for damage

   B. Check security of terminals and contacts.

4. Connector wires (9) and (10)

   Check security of pins and tags.

5. Earshell cover, non-boom side (7)

   Examine for damage.

6. Boom, clutch and cover sub-assembly (20) or Fig. 102 (1)

   A. Examine for damage.

   B. Check :-

      (1) Free movement of ball joint rotationally and laterally,

      (2) Security on boom of plastic mounting or clip for microphone.

      (3) Security of tags at headset end of microphone cable.

7. Main downlead sub-assembly (27)

   A. Examine for :-

      (1) Damage.

      (2) Perishing of the rubber sleeve on the jackplug.

(3) Security of the soldered connections to the jackplug, or crimping tags if used. To do so will necessitate drawing the plug sleeve, if any, up the cable and unscrewing the plug cover.

(4) Security of tags and pins at headset end of lead.

8. Main lead switch (45) or (46)

A. Examine for damage.

B. Check:-

(1) Security of electrical connections.

(2) Freedom of action.

9. Small parts

Examine :-

(1) All small parts including microphone capsule, earphone insets, amplifier if any, and small plastic parts for damage.

(2) All threaded parts for damage to threads.

REPAIR

The only practical repair process is to change the defective component for a new spare one. Dismantle and re-assemble the headset as far as is necessary in accordance with the instructions given under Disassembly (page 101) and Assembly (page 501).

ASSEMBLY

1. General

The microphone and earphone insets are sealed units which should not have been dismantled so the original units or new replacements must be available for assembly. All other sub-assemblies if faulty or damaged, are to be replaced by complete units to obviate the need for cementing. A new plug and/or switch can be fitted to the main cable if necessary, the cable alone can be replaced or a new complete downlead assembly may be used. Switch connections are shown on Fig. 502, page 503.

2. Procedure

A. With microphones D, E, H and I

(1) Test the microphone lead as described in para. 3A (1), page 701.

(2) Fit microphone (21) or (22) to boom (20) using screws (23) and washers (24), and connect microphone lead to terminals in earshell (18) in accordance with wiring diagram Fig. 501.

(3) Check as described in para. 3A (2) page 701.

(4) Check downlead as described in para. 3A (3) page 701.

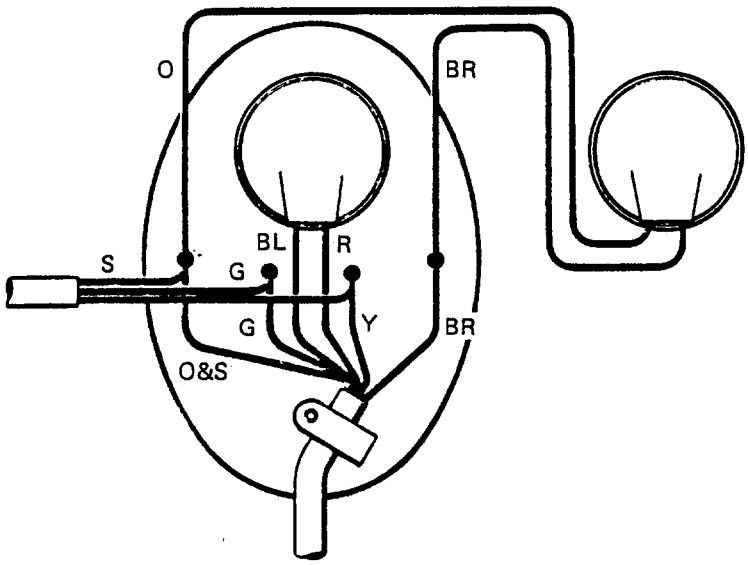
(5) Connect downlead (27) to terminals in earshell (18) in accordance with wiring diagram Fig. 501.

(6) Check as in 3A (4) page 702.

(7) Clamp downlead into position with (25) and (26).

(8) Fit connector wires (9) and (10) to earshell (6) in accordance with wiring diagram Fig. 501.

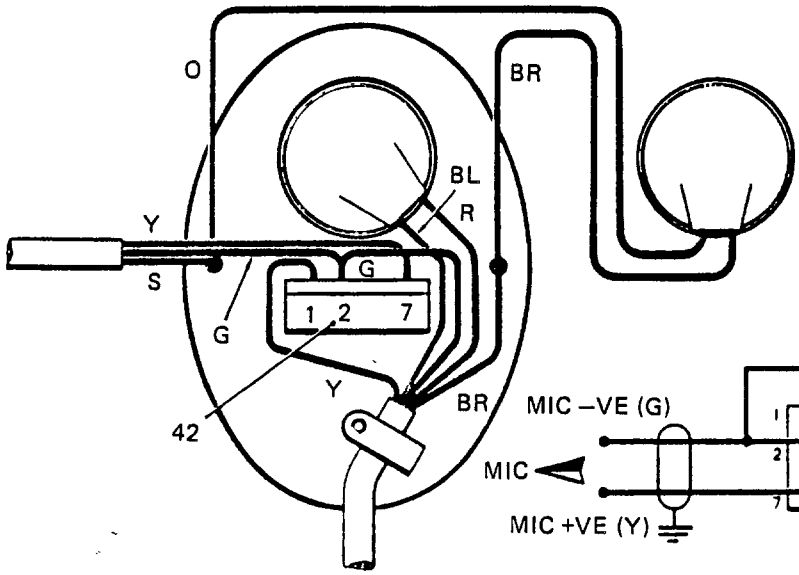
(9) Check as in 3A (5) page 702.



(10) Fit headband (1) to earshell (6) using 2 off screws (5), locknuts (15), and washers (49).

(11) Check as in 3A (6) page 702.

(12) Fit headband to earshell (18) using remaining screws (5), locknuts (15), and washers (49).



(13) Check as in 3A (7) page 702.

(14) Fit insulating caps (4).

(15) Insert earphone insets (11) and connect to leads. Pins are of different sizes so will fit only when correctly connected.

(16) Screw earshell covers (7) and (20) to earshells using screws (16).

(17) Test boom clutch as described in paras. 2A and B page 701 and adjust if necessary.

(18) Fit earshell foam discs (12) earpads (13) and earpad covers (14).

B. With microphone and pre-amplifier J

Follow the above procedure where applicable. Test 3A (2) page 701 is to be carried out with the ends of the microphone lead free. Amplifier (42) is to be fitted in accordance with wiring diagram Fig. 501 after testing microphone lead and downlead and before clamping downlead.

NOTE: It is essential that polarity should be observed.

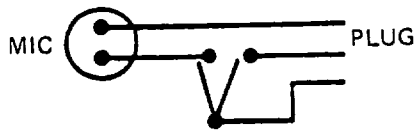
C. With microphone G (carbon) (Index No's. refer to Fig. 101 unless otherwise stated).

(1) Test microphone lead as in 3A (1) page 701.

(2) Connect microphone (Fig. 102 (2)) to boom (Fig. 102 (1)) and microphone lead to terminals in earshell (18) in accordance with wiring diagram Fig. 501.

(3) Proceed as for A3-15.

(4) Screw earshell covers (7) and (Fig. 102 (1)) to earshells (6) and (18) using screws (16).



(5) Continue as for A 17 and 18.

ON-OFF & PRESS TO TALK SWITCHES

FITS AND CLEARANCES

Not applicable.

TESTING

1. General

Two mechanical tests and eight electrical tests are necessary. The mechanical tests and seven electrical tests are made during assembly, and one electrical test is made after assembly. An audio test after assembly is desirable if suitable equipment is available.

2. Mechanical tests

Before fitting the earshell foam discs and earpads, check the boom clutch friction as follows: -

A. Lateral movement

The clutch should just support a weight of approximately 1 oz. attached to the end of the boom.

B. Rotational movement

The clutch should just support a weight of approximately 2 oz. attached to the end of the boom.

The clutch can be adjusted by means of the screw which can be seen through a hole inside the earshell, and is easily accessible through this hole.

3. Electrical tests

A. During assembly

(1) Before fitting microphone or connecting microphone lead to terminals in earshell, check the insulation resistance between each of the microphone boom wires, the screen of the lead, and the boom, by means of a 500V. d.c. tester such as a 'Megger'. The resistance should be at least 100 megohm.

(2) With microphone fitted and microphone lead connected to earshell terminals, check the continuity of the microphone lead in the boom by means of a high impedance (20, 000 ohm/V) d.c. test instrument such as an 'Avometer', moving the boom through its full range to check for intermittency. The d.c. resistance through the microphone should be as stated in para. 3B 1 (b).

(3) Check downlead for continuity by means of a high impedance d.c. test meter, and check insulation resistance between leads using a 'Megger', or suitable instrument. The resistance should be at least 100 megohm.

(4) After connecting downlead to earshell, check for continuity through terminals and contacts.

(5) After assembling connector wires to earshell, check for continuity through terminals.

(6) After fitting headband to non-boom side earshell, check for continuity through headband and earphone connections. Slide earshell on headband and swivel earshell through headband while so doing. The d.c. resistance through the headband should not exceed 0.5 ohm.

(7) After fitting headband to boom side earshell, check for continuity right through from connectors in non-boom side earshell to plug, moving earshell as in (6) while so doing.

B. After assembly

(1) Check d.c. resistance of the earphone insets and of the microphone at the jackplug using a 20,000 ohm/volt ohmeter and moving the earshell and microphone boom through their full range meanwhile.

(a) Earphone insets

The d.c. resistance of the earphone inset is liable to variation according to the type used, impedance, whether polarised etc. The d.c. resistance of a 300 ohm impedance earphone inset should be within ± 15% of one of the following figures:- 48 ohms, 83 ohms, 90 ohms.
This would be with earphone insets connected to the jackplug individually. When the earphone insets are connected in parallel to one pair of pins on the jackplug, the figure should be halved.

(b) Microphones

The d.c. resistance of the microphone should be as follows:-

Moving coil 300 ohm impedance	275 ohm
Moving iron 300 ohm impedance	35 ohm

NOTE: No useful purpose is served by measuring the d.c. resistance of carbon microphones.

(2) An audio test is desirable, and if suitable equipment is available test the headset by speaking into the microphone and listening to the earphones. The boom should be moved through its full range to check for intermittency.

4. Testing of Miniature Amplifier

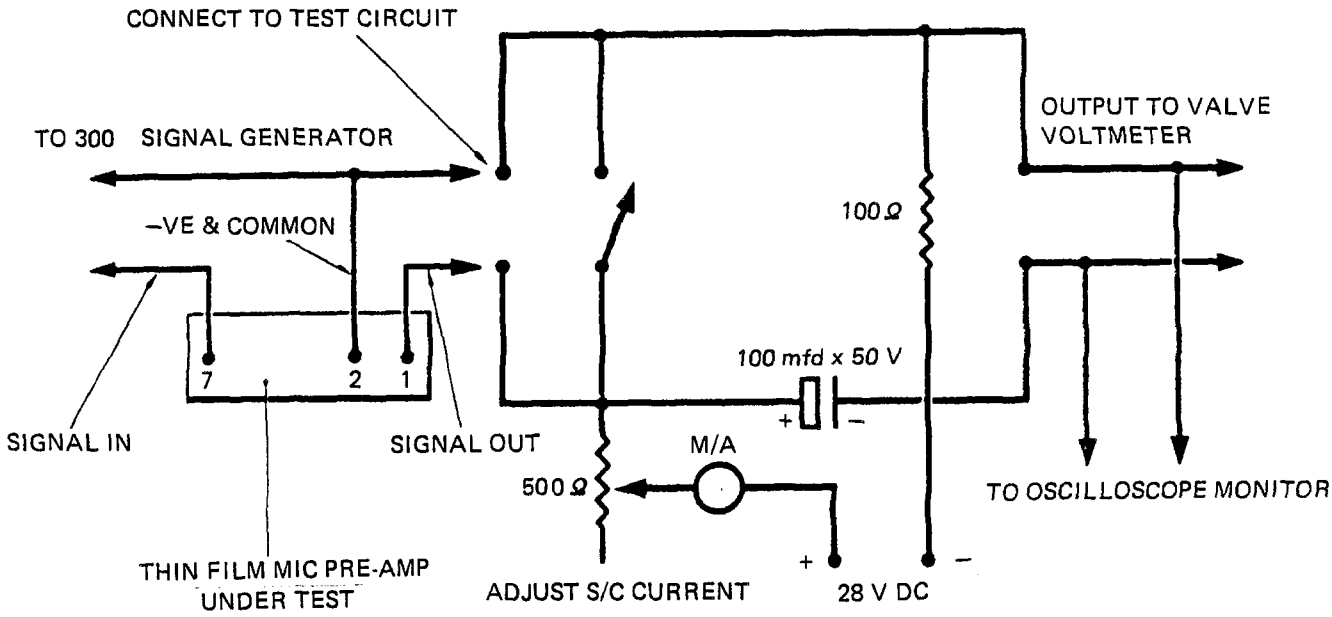
A. General

During the following tests, the output of the amplifier under test should be monitored by an oscilloscope to observe that the output is a smooth sinusoidal wave, with no signs of "clipping" or bad distortion.

The Signal Input reference level of 2 m/v should be finally adjusted when the circuit is operational.

B. (1) To check sensitivity, connect up the amplifier under test as shown in Fig. 701. It is most important to watch polarity, or the Amplifier will be destroyed.

Bearing in mind that:



Pin 1. is positive
Pin 2. is common and negative
Pin 7. is signal 'IN'.

Adjust Signal Generator to 2 m/v output as checked with a valve Voltmeter @ frequency of 1K. c/s.
At a d.c. Supply Voltage of 28 V. d.c. with the Amplifier drawing a current of 5 m/a. through the Carbon Microphone Test Circuit (See Fig. 701). The output from the amplifier under test should be between 300-400 m/v (340 m/v. is a good level).

(2) To check response:-

(a) With a d.c. supply of 28V. and an Input Signal to the Amplifier of 2 m/v. the frequency from the Signal Generator should be adjusted to 200 c/s and the output from the Amplifier should not be lower than 2dB below the level obtained @ 1Kc. under the same test conditions.

(b) With the same test conditions, adjust the frequency of the Signal Generator to 5K. c/s and note the output level from the Amplifier under test, which should not be more than 1.5dB lower than the output level @ 1Kc. under the same conditions of test.

STANDARD CARBON MIC TEST CIRCUIT

TEST NOTES
1 ENSURE CORRECT POLARITY
2 ADJUST S/C CURRENT TO 60 M/A
3 ADJUST 2 M/V INPUT REF SIGNAL UNDER LOADED CIRCUIT CONDITIONS POWER ON

TEST LAYOUT FOR THIN FILM MICROPHONE PRE-AMPLIFIER
Figure 701

TROUBLE SHOOTING

Any defects are likely to be simple and obvious. The only way in which a defect may be in the least obscure, is in the location of an electrical fault. In the event of microphone or earphone system failure, the appropriate cores of the main lead should be checked electrically to find out if the defect is in the microphone or earphone unit itself, or in the lead, plug or connections.

STORAGE INSTRUCTIONS

1. Conditions

A. Temperature climates

(1) Wrap the jackplug and pack the earphone housings with tissue paper.

(2) Wrap the complete headset in tissue paper, insert in polythene bag, and pack it in a strong carton (if possible, of the type in which the headset is supplied).

(3) Prepare and affix a label giving the following information :-

(a) Headset type number and letter coding if applicable.

(b) Date of last overhaul if any.

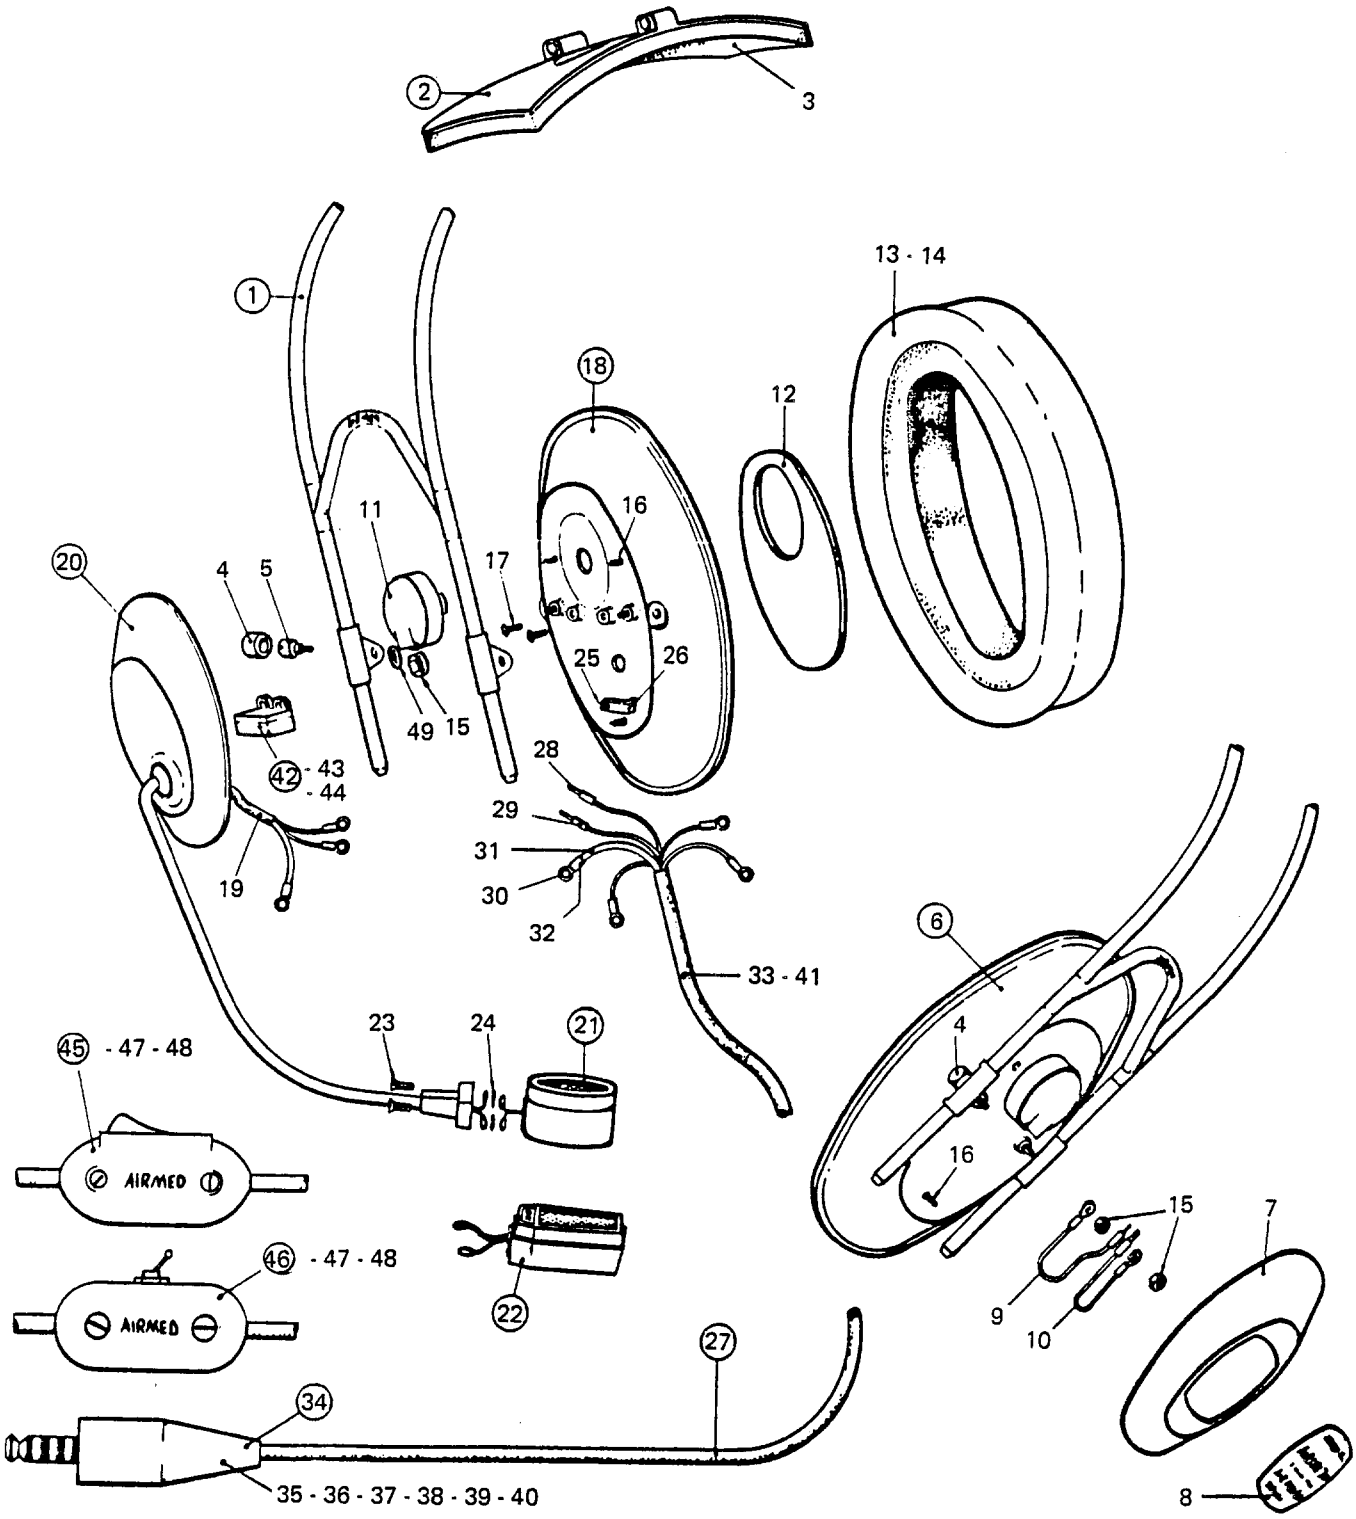
B. Tropical climates

(1) Pack the headset as instructed in A (1) and (2).

(2) Insert the closed carton into a polythene bag or length of polythene tubing, according to the material available: heat-seal the bag or tubing.

(3) Wrap the sealed polythene package in Draft paper, seal it with gummed tape, and attach a label as instructed in A (3).

2. Limiting period



If this headset is stored for long periods it should be overhauled at intervals of three years.

SPECIAL TOOLS, FIXTURES AND EQUIPMENT

The tools, fixtures and equipment normally found in an electrical overhaul workshop will be sufficient to effect the overhaul of this headset.

INTRODUCTION

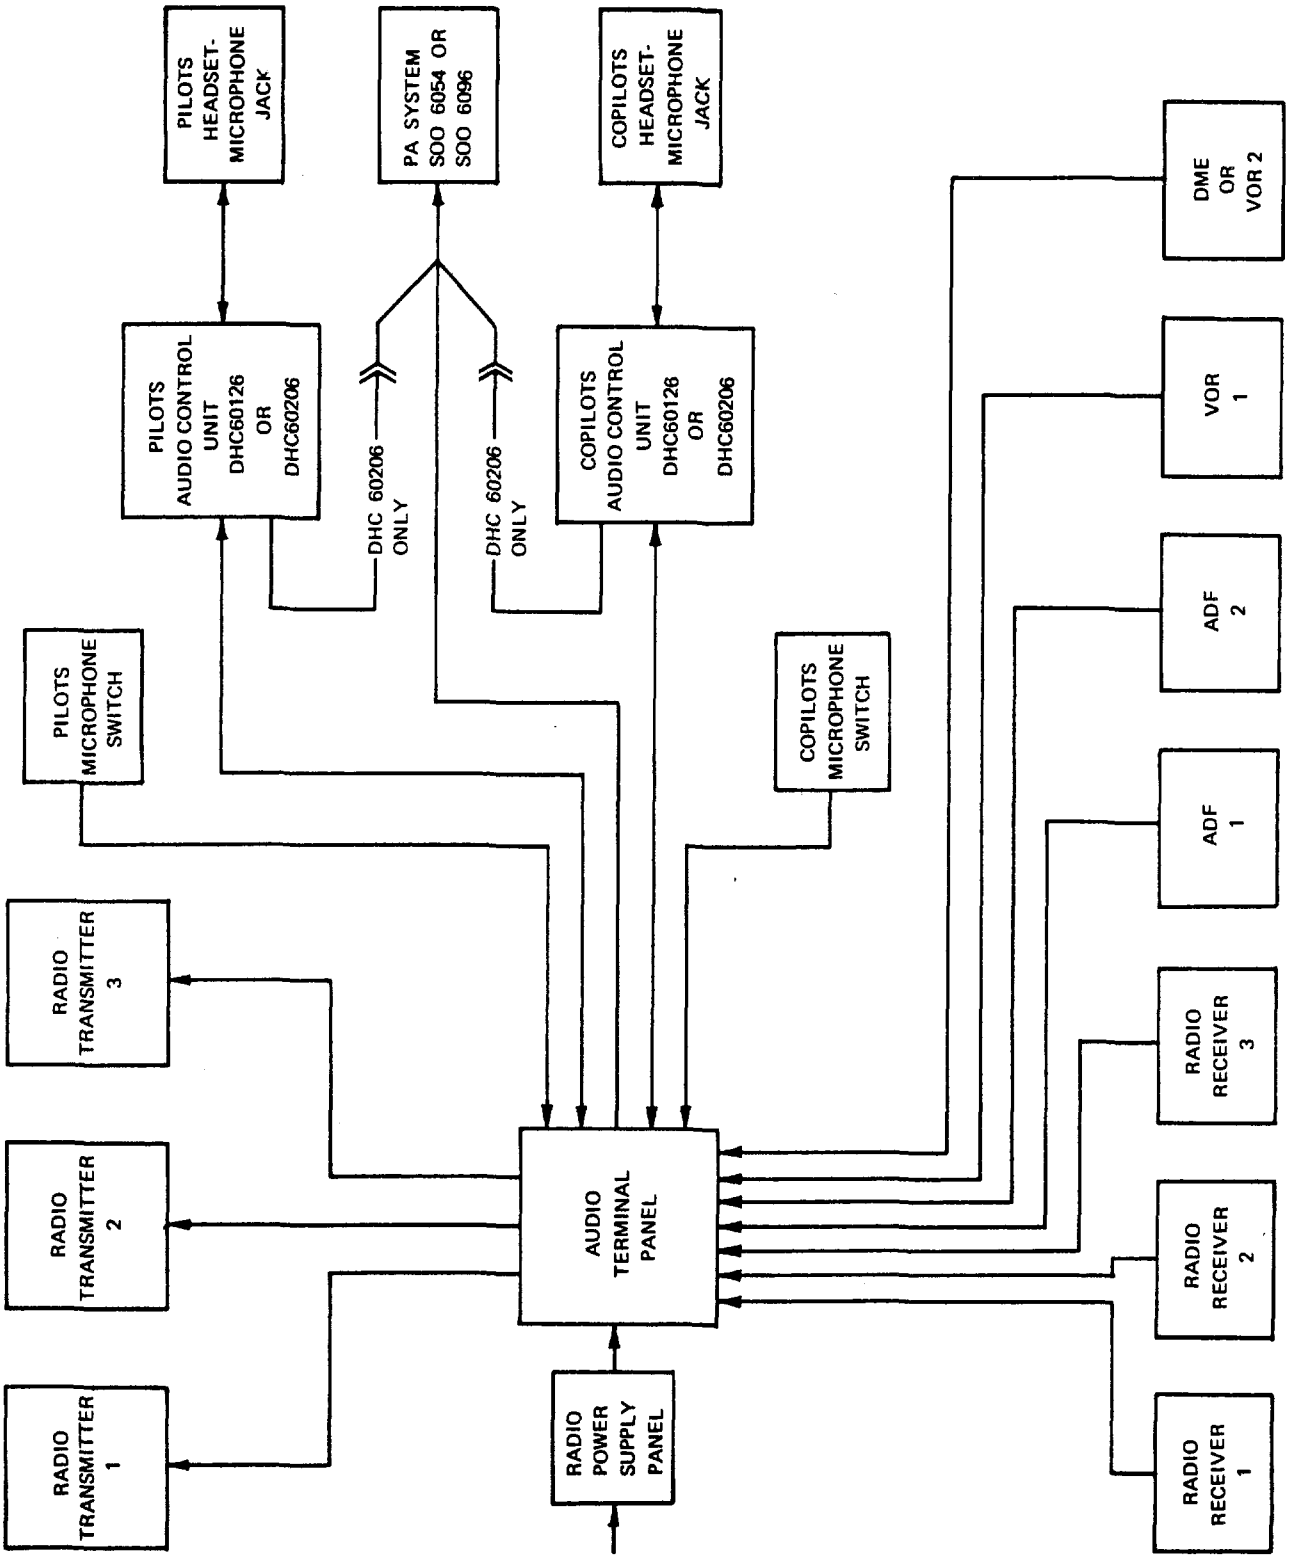
This manual contains instructions for the overhaul of the DeHavilland Audio Control Units, Types: DHC60206 and DHC60126. These units are used in DHC-4 and DHC-6 aircraft.

AUDIO CONTROL UNITS (DHC60126 AND DHC60206) - DESCRIPTION AND OPERATION

1. GENERAL

The Audio Control Units (DHC60126 and DHC60206) are the basis of the aircraft audio integrating system, providing intercommunication between pilot and the crew members and the facility to monitor all communication and navigation receivers and microphone transmission over a selected transmitter. The DHC60206 also has provision for a passenger address (PA) system. (See Fig. 1 for typical installation.) A list of the major components of the control units, with locations and part designations is given in the Illustrated Parts List (Ref para L).

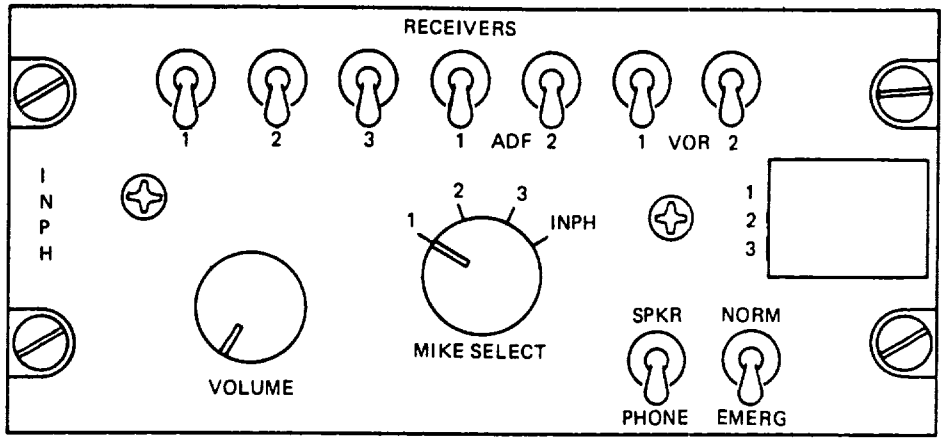
A. Description and Operation



(1) The audio control unit (DHC60126), contains a mike audio (or interphone) amplifier and a receiver audio amplifier, a mike audio and control relay 'K1', interphone audio and 'K1' interlock relay 'K2', a resistor-capacitor network, diodes, switches for receiver audio and microphone selection, volume control for receiver and interphone audio, a loudspeaker - phones select switch and a normal-emergency switch.

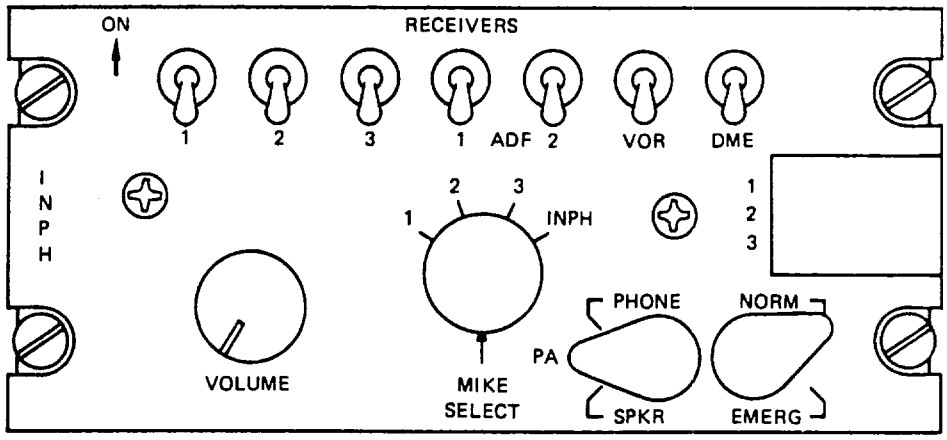
(2) The audio control unit (DHC60206), is basically the same unit as the DHC60126 with the following exceptions which provide the added PA facility: The two amplifiers are isolation amplifiers feeding the PA system and a PA audio relay 'K3' is added; also the loudspeaker - phones switch is changed to a three position, loudspeaker-PA-phones switch.

(3) The front panel of the audio control unit (DHC60126, Fig. 2) has controls as follows: seven receiver monitoring toggle switches marked RECEIVERS 1, 2, 3; ADF 1 and 2; and VOR 1 and 2; a rotary transmitter selector switch marked MIKE SELECT 1, 2, 3 and INPH; a VOLUME control and two toggle switches marked SPKR/PHONE and NORM/EMERG.



(4) The front panel of the audio control unit (DHC60206, Fig. 2) has controls as follows: seven receiver monitoring toggle switches marked RECEIVERS 1, 2, 3; ADF 1 and 2; and VOR 1 and 2 (-3 configuration) or VOR and DME (-7 configuration); a rotary transmitter selector switch marked MIKE SELECT 1, 2, 3 and INPH; a VOLUME control; a three position rotary switch marked SPKR/PA/PHONE, and a two position rotary switch marked NORM/EMERG.

(5) The DHC60126 circuit functions as follows (see Fig. 701). When the RECEIVERS toggle switches are selected to the ON position, three communications receivers, two automatic direction finding (radio compass) receivers, and one VHF omni-directional range receiver (VOR 1) and a second VOR or a DME receiver connected to VOR 2 switch may be monitored singly or in any combination, provided the NORM/EMERG switch is in the NORM position. The audio level of the received signals can be adjusted by the respective volume controls on the individual receiver control panels, and the combined audio of the receivers can be regulated by the VOLUME control on the audio control unit. Signals received from the marker beacon receiver (if installed) are fed directly through the audio control unit to the headset, the volume again being controlled in a similar manner. Positions 1, 2 and 3 of the MIKE SELECT switch are assigned to three communications receiver-transmitters. When the MIKE SELECT switch is selected to one of these positions, and provided the corresponding facility control panel is set for operation, the receiver sidetone and audio is connected to the headset



Typical Audio Integrating System - Block Diagram

Figure 1

DHC60126-1

DHC60206-7

Audio Control Units - Panel Layout

Figure 2

automatically, regardless of whether the RECEIVERS toggle switch is set to ON. When the microphone switch is actuated the operator is transmitting directly on the facility selected. If all communications facilities are not installed and connected to positions 1, 2 and 3, the appropriate switches are inactive. The INPH position of the MIKE SELECT switch is for interphone only; when both audio control units are set to INPH the microphone switches are used for direct intercommunication between the pilot and copilot.

The NORM /EMERG switch should always be in the NORM position except in the case of failure of an audio amplifier in the audio control unit. When selected to the EMERG position, the audio amplifier is bypassed, and only individual receiver audio may be selected, by means of the RECEIVERS toggle switches. The marker beacon audio however, is not connected in the EMERG position, and the automatic pick-up of communications receivers audio from the MIKE SELECT switch is rendered inoperative, as is the VOLUME control and the INPH position of the MIKE SELECT switch. The RECEIVERS toggle switches are wired so that the switch furthest to the left which is selected ON is the only one heard, overriding any others which are switched ON. Failure of one audio control unit will not affect the operation of the other.

The SPKR /PHONE switch must be in the PHONE position for normal operation with the headset. If a speaker system is installed in the aircraft, selecting the SPKR /PHONE switch to SPKR, supplies 28 volts dc to the speaker system and also routes all the receivers and interphone audio to the speakers.

(6) The DHC60206 circuit functions as follows (see Fig. 702). When the rotary MIKE SELECT switch is set to positions 1, 2 or 3, the associated microphone switch is connected to operate the selected transmitter, and the audio and sidetone for the corresponding receiver are also switched on automatically, regardless of the toggle switch setting. In all positions including INPH, the interphone positions on the microphone switches provide interphone operation. The NORM /EMERG switch should be maintained in the NORM position. In the event of failure of the isolation amplifier, the EMERG position permits operation of one receiver at a time, using the toggle switches, and one transmitter. The toggle switches are wired so that the one furthest to the left which is turned on is the only one heard, overriding any others which are switched on. The automatic pick-up of a communications receiver from the MIKE SELECT switch is inoperative, as is the VOLUME control, in emergency operations. The PA switch must be maintained at the PHONES position for normal operation with the headsets. When set to the SPKR position, the headphones are disconnected and audio and a 28-volt dc supply are routed to the speaker system. When PA position is selected audio and a 28-volt dc supply are connected via relay 'K3' to the passenger address system. When MIKE SELECT switch is set to INPH, a ground return is completed to energize 'K2' (single button operations only), thus cutting out receiver audio and allowing only interphone through the speaker.

(7) Both control units can be modified as follows: If two button operation is required a jumper between terminals 9 and 10 in the audio control unit must be removed. Provision for dynamic microphone is provided by removing jumpers from terminals 2 and 4; 1 and 3, and installing a microphone preamplifier (DHC60131, DHC60198 or DHC60203, Fig. 1101). For use with a low impedance headset, remove jumpers from terminals 5 and 6; 7 and 8, and install an impedance matching transformer (DHC60132, or DHC60197, Fig. 1102), 'Hot Mike' operation is provided for by adding a jumper between terminals 11 and 36.

(8) The control units require a 28-volt dc power supply, the supply to the amplifier being filtered by an active-type filter network. The supply to the relays is unfiltered.

(9) The receiver audio and interphone audio amplifiers (DHC60126) and the two isolation amplifiers (DHC60206) are Tramm amplifiers (type 1A160). These are transistorized, miniaturized, hermetically sealed units and are serviced by replacement.

(10) The audio control units (DHC60126 and DHC60206) have various configurations which are annotated by dash numbers and Mod status letters at rear of unit. These are shown in Table 1.

Table 1

Audio Control Unit Configurations

DHC60126-1	Aviation red lighting
-3	Aviation white lighting
DHC60206-1	Aviation red lighting
-3	Aviation white lighting
-5	Aviation red lighting) With DME in lieu of VOR 2
-7	Aviation white lighting) With DME in lieu of VOR 2

B. Disassembly

(1) The disassembly procedure for both units (DHC60126 and DHC60206) is basically the same, and is to be carried out as follows:

(a) Release the two snap fasteners at the rear of unit and slide off the outer cover.

(b) Remove control knobs from front panel and undo the two Philips-type retaining screws. Remove facing panel from backing panel.

(c) Undo the four retaining screws on the backing panel and drop the panel to gain access to the rear, taking care not to tension the interconnecting wiring harness.

(2) Steps (1) (a), (b) and (c) give sufficient access for normal maintenance i.e. replacement of resistors, capacitors or diodes. To replace the component board assembly, amplifiers, switches and relays proceed as follows:

(a) Component board assembly - Unsolder the wiring harness from the component board assembly, taking care to identify the wires as necessary. Undo the three Philips-type retaining screws and remove the component board assembly.

(b) Amplifier - Unsolder the wiring to the amplifier units, taking care to identify the wires as necessary. Undo two Philips-type screws holding the amplifier retaining bracket in position. Remove amplifier.

(c) Switches - Unsolder and identify wires as necessary. Undo the associated retaining nut and remove switch.

(d) Relays - Unsolder and identify wires as necessary. Undo MS21042-04 retaining nuts and remove relay.

C. Cleaning

(1) Clean all electrical components, resistors, capacitors and diodes by wiping with lint-free cloth dampened with dry-cleaning solvent. Dry immediately using compressed air.

(2) Remove dust, dirt or other foreign matter from terminals of electrical connector using a soft-bristle brush in conjunction with compressed air. Wipe body of connector with lint-free cloth dampened with dry-cleaning solvent. Wipe dry with clean, dry lint-free cloth.

(3) Clean terminals of relays and terminal plate using a soft-bristle brush moistened with dry-cleaning solvent.

(4) Clean all wiring using a soft-bristle brush in conjunction with compressed air.

D. Inspection /Check

(1) Visual

(a) Check for damage to outer case and front panel.

(b) Check connector assembly for pin damage.

(c) Check chassis for dents and cracks.

(d) Check component board assembly for cracks.

(e) Check for signs of component overheating.

(2) Electrical (Ref para H.).

E. Repair

(1) Replace all defective or damaged components.

(2) When replacing diode components use the proceedure as follows:

(a) Grasp the diode leads with a pair of long-nosed pliers to form a heat sink. Use a pencil-type or other light-duty soldering iron to attach diode leads to points of termination.

CAUTION: NEVER APPLY HEAT TO THE LEADS CLOSE TO THE DIODE BODY. THE SMALL CRYSTALS USED AS P-N JUNCTIONS IN THE CONSTRUCTION OF SEMICONDUCTOR DIODES MAY BE PERMANENTLY DAMAGED BY THE EXCESSIVE AMBIENT TEMPERATURE CONDITION. BE CAREFUL NOT TO PULL THE DIODE LEAD WITH THE PLIERS.

(b) Hold pliers in place after heat is removed and until diode lead is cool enough to touch with hand.

F. Assembly

(1) The assembly procedure of both units (DHC60126 and DHC60206) is basically the same and is to be carried out as follows:

(a) Relays - Locate in position with MS21042-04 retaining nuts; solder wires to relay terminals.

(b) Amplifier - Locate amplifier in position and secure with mounting bracket and two Philips-type screws. Solder wires in position.

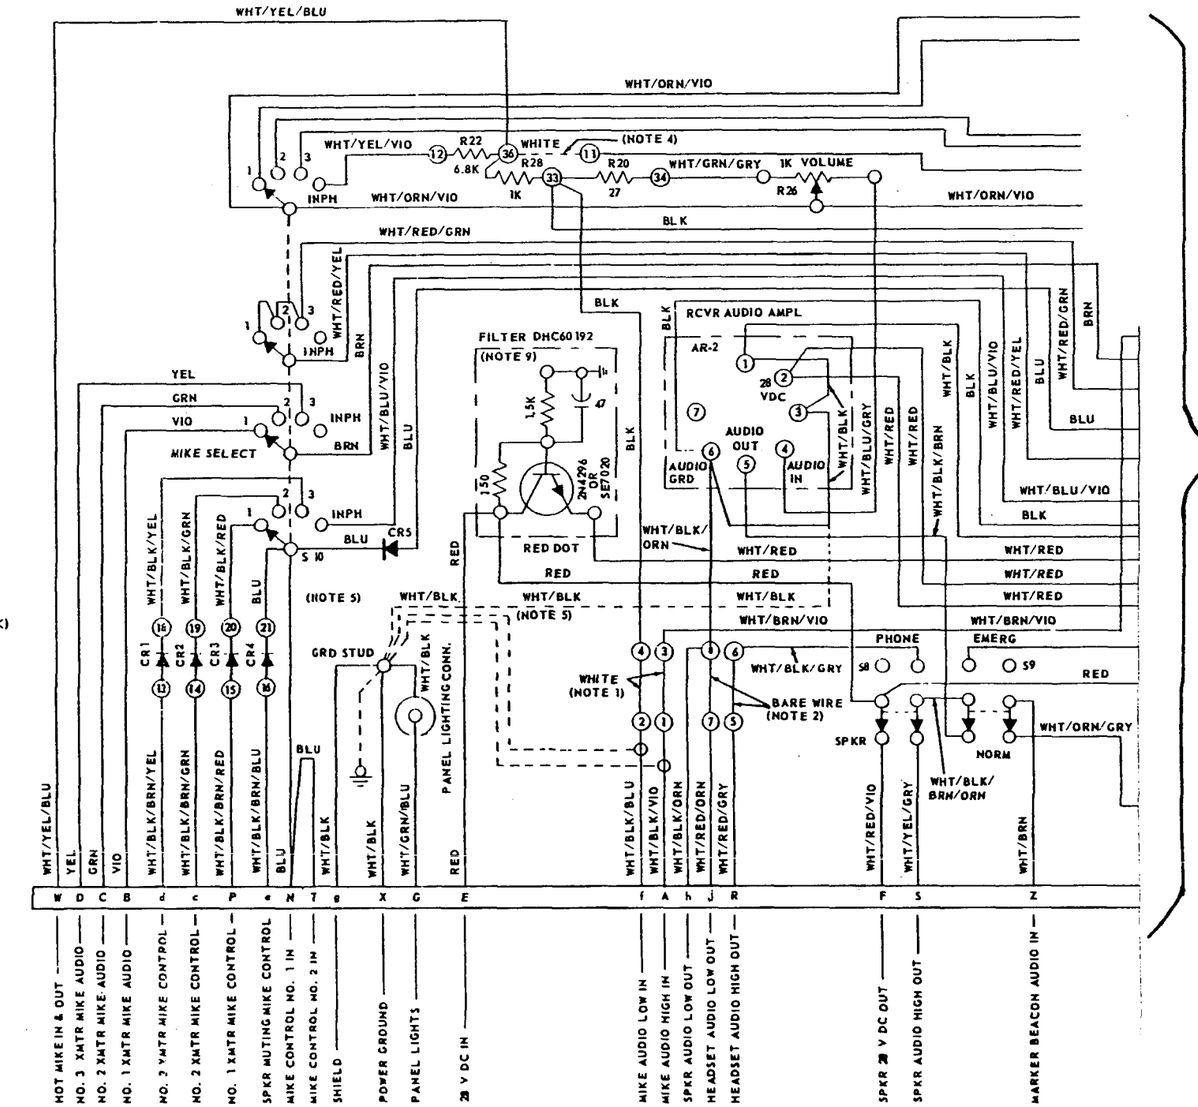
(c) Component board assembly - Locate in position and secure with three Philips-type screws. Solder wires in position.

(d) Fit backing panel assembly onto unit and secure with the four retaining screws.

(e) Switches - Locate switch on panel assembly and secure with retaining nut. Place facing panel on backing panel and secure with two Philips-type screws. Solder wires in position.

(f) Slide on outer cover and secure with the two snap fasteners at rear.

G. Fits and Clearances

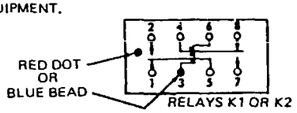


None applicable.

H. Testing

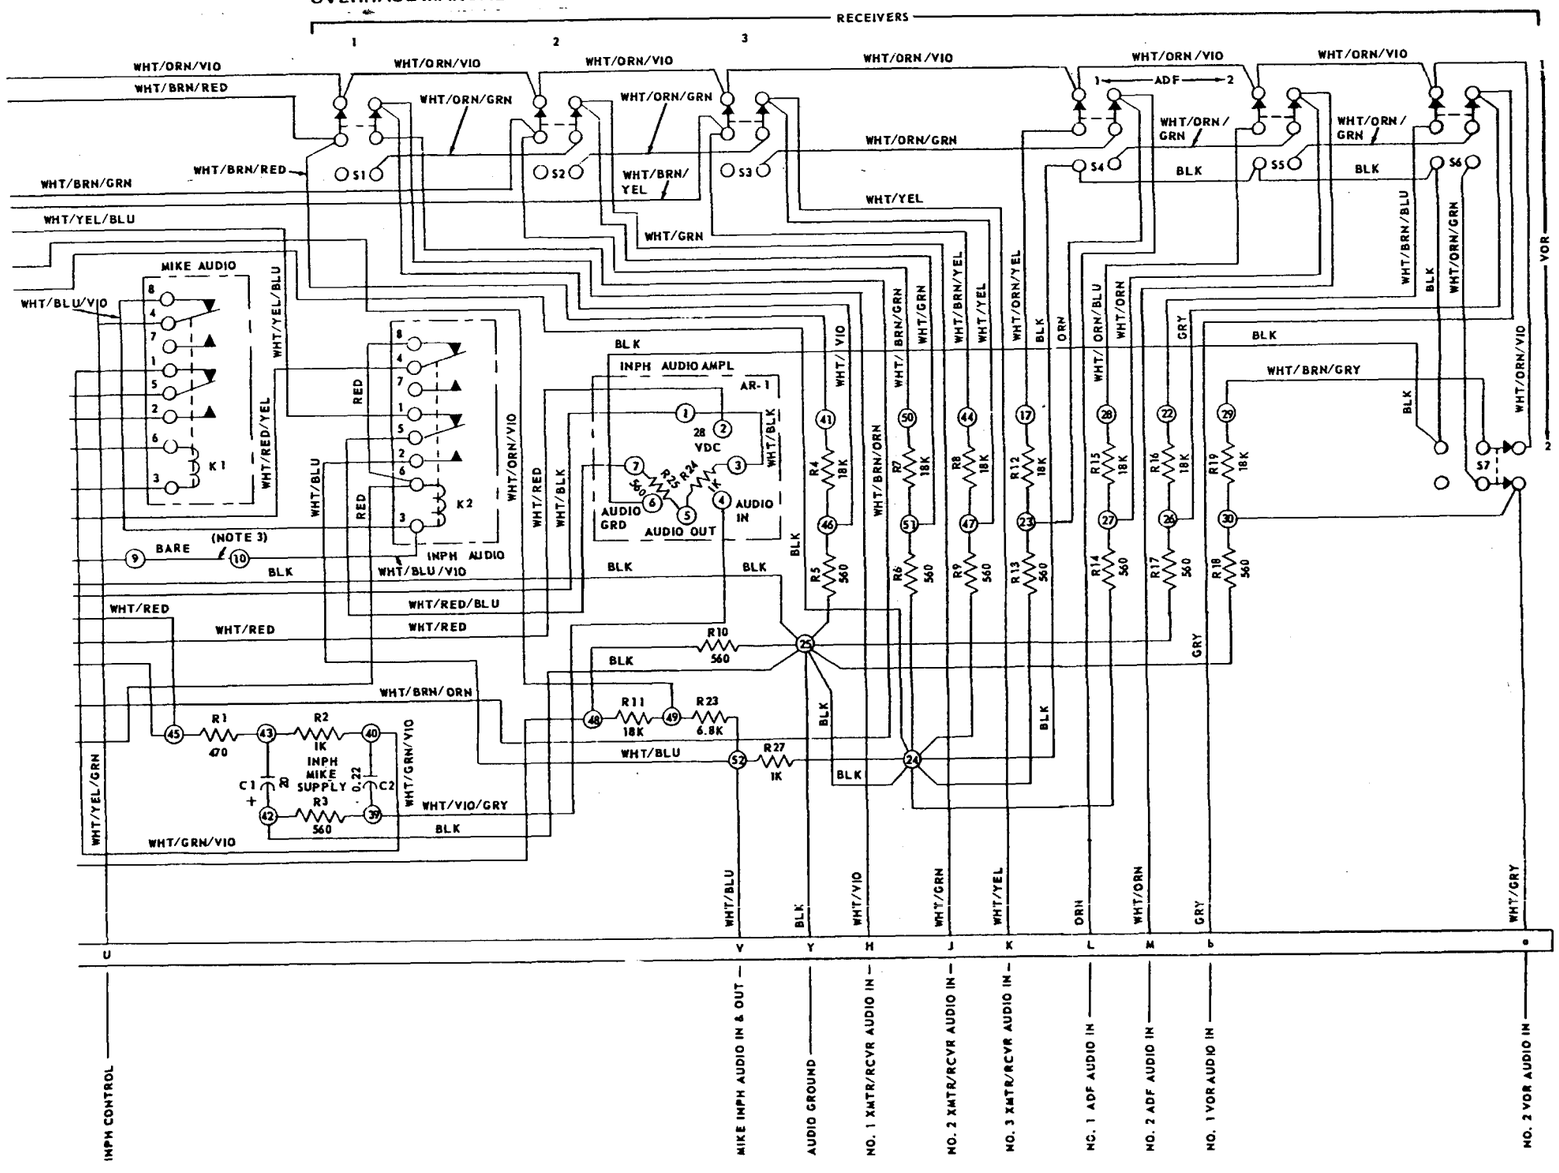
(1) General - Test procedures for the Audio Control Units DHC60126 and DHC60206 consist of a series of continuity tests and resistance measurements using internal wiring and component layout diagrams. (Ref Fig. 703, 704 and 705.)

(2) Continuity checks - Refer to the internal wiring diagrams and check the circuits for continuity for all switch selections. A multimeter, ohmmeter, or low voltage lamp-type continuity checker may be used.



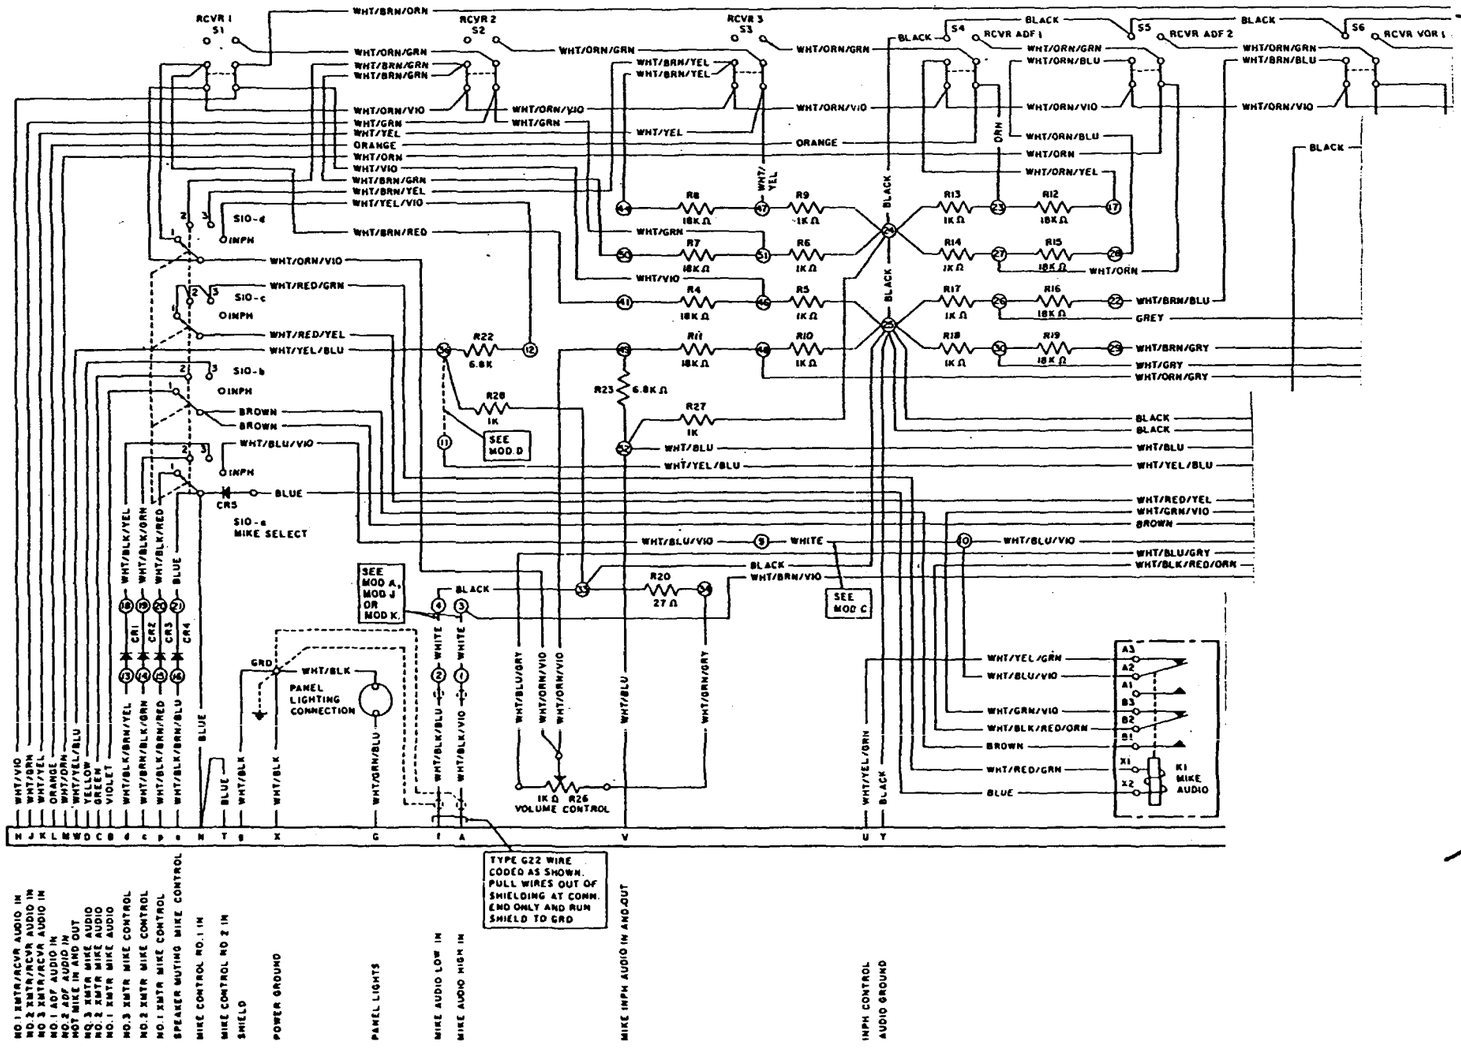
(3) Resistance checks - The resistance checks should be carried out using a multimeter or an ohmmeter with a minimum accuracy of $\pm$ 5%. Resistor values are given on the internal wiring diagrams. (Ref Fig. 701 and 702.)

SEE SHEET 2 OF 2



NOTES:

1. JUMPERS BETWEEN TERMINALS 1 AND 3, AND TERMINALS 2 AND 4 TO BE REMOVED, WHEN MICROPHONE REAMPLIFIER (DHC60131; 60198 AND 60203) IS INSTALLED (MODS A, J, K)
2. JUMPERS BETWEEN TERMINALS 5 AND 6, AND TERMINALS 7 AND 8 TO BE REMOVED WHEN HEADSET IMPEDANCE MATCHING TRANSFORMER (DHC60132 AND 60198) IS INSTALLED (MOD B AND H).
3. JUMPER BETWEEN TERMINALS 9 AND 10 TO BE REMOVED IF SEPARATE INTERPHONE SWITCH (TWO BUTTON OPERATION) IS INSTALLED. (MOD C)
4. JUMPER BETWEEN TERMINALS 11 AND 36 TO BE ADDED IF "HOT MIKE" OPERATION IS DESIRED. (MOD D)
5. WHT/BLK WIRE AT AR2, FROM PIN 3 TO PIN 6, WAS TO GROUND STUD. DIODE ADDED IN BLU WIRE FROM K1 (MOD F).
6. RELAY TERMINAL NUMBERS, AS SHOWN BELOW, DO NOT NECESSARILY APPEAR ON EQUIPMENT.



7. ALL RESISTANCE VALUES EXPRESSED IN OHMS.
8. ALL CAPACITANCE VALUES EXPRESSED IN MICROFARADS.
9. FILTER DHC60192 REPLACES DHC60128 (MOD G).

I. Trouble Shooting

The testing instructions given in para H. can be used as a basis for trouble shooting the audio control units. After a malfunction is corrected, repeat the tests which apply to the corrected part of the circuit.

J. Storage Instructions

Cap electrical connector to keep out foreign matter during storage.

K. Special Tools, Fixtures and Equipment

None applicable.

BOMBARDIER – Temporary Revision

PSM NO. 1–6–6A AIRCRAFT DHC–6 Twin Otter SERIES ALL

PUBLICATION COMPONENT MAINTENANCE MANUAL TEMPORARY REVISION NO. 23–2

Insert in 23–09–01, facing page 1101

AUDIO CONTROL UNITS (DHC–60126 AND DHC60206)

REASON FOR ISSUE:

This Temporary Revision rectifies part number of item 705–K1, K2 of paragraph L., table (1) DHC60126 (Fig. 703 and 705).

ACTION:

On page 1101, paragraph L., table (1) DHC60126 (Fig. 703 and 705), ignore existing Item 705–K1, K2 and substitute revised Item 705–K1, K2 as shown on this Temporary Revision.

L. Illustrated Parts List

TYPE 1U396-002
AUDIO SELECTOR/AMPLIFIER
OVERHAUL MANUAL
WITH PARTS BREAKDOWN

This manual is intended to facilitate proper overhaul of the Type 1U396-002 Audio Selector/Amplifier; therefore, before proceeding, read this manual carefully and study the drawings and photographs thoroughly. Inspect the components individually to insure a complete understanding of their purpose and proper location. This manual should be supplemented with current Customer Acceptance Specifications and applicable addenda published by EDO-AIRE.

PREFACE

This manual was prepared specifically for use of a trained electrical technician, working in an authorized instrument repair shop. Accordingly, the information included here is based on the following assumptions:

- The user of the manual will be generally familiar with aircraft navigation and communication equipment and standard handling and repair procedures.
- The shop will have available ordinary hand tools and test equipment and will maintain suitable conditions of cleanliness, temperature, humidity, and light for instrument repair work.

Accordingly, the manual contains only specific information about the Type 1U396-002 Audio Selector/Amplifier that would be useful to a trained technician, rather than complete step-by-step procedures. The procedures included either are peculiar to this instrument or have been found significantly better in protecting parts from damage or saving time.

The intent of this approach is to increase the usefulness of the manual by excluding the obvious or familiar and concentrating on new and peculiar items. Thus, information should be more readily assimilated on first reading and more quickly located for reference.

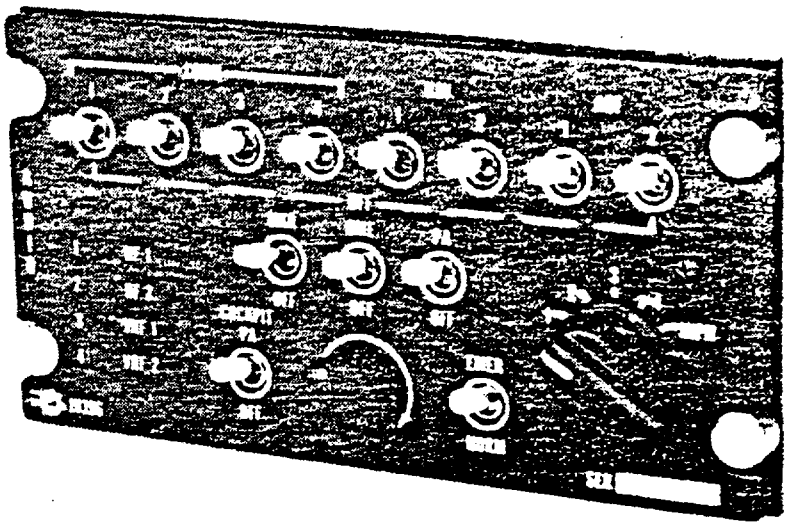

Figure 1-1. Audio Selector/Amplifier

SECTION I

GENERAL INFORMATION

1-1. GENERAL

1-2. This manual provides description and operation information, cleaning procedures, assembly procedures, testing procedures, troubleshooting procedures, and an illustrated parts breakdown for the EDO-AIRE Type 1U396-002 Audio Selector/Amplifier. Refer to figure 1-1.

1-3. PURPOSE OF EQUIPMENT

1-4. The 1U396-002 Audio Selector/Amplifier is a control panel designed to be used in conjunction with up to 10 radio receivers and four radio transmitters. Each audio panel contains a headphone amplifier for monitoring interphone communications on any of the 10 receivers. Provision for an external speaker amplifier for the headphone output is included in the audio panel.

1-5. The 1U396-002 Audio Selector/Amplifier is designed to be used in a system containing from two to six units. An interphone amplifier, with a biased input for a carbon microphone, gives the capability of interphone communication. A microphone select switch offers the option of transmitting on the interphone system or one of four radio transmitters. A public address amplifier produces 10 watts into an eight ohm speaker with less than five percent distortion.

1-6. DESCRIPTION OF FRONT PANEL CONTROLS

1-7. RECEIVER SWITCHES

1-8. The ten radio switches are labeled COM 1, COM 2, COM 3, COM 4, NAV 1, NAV 2, ADF 1, ADF 2, MKR, and DME. Each switch selects one of 10 receivers. With any one switch in the on (up) position, the corresponding receiver signal is heard through the headphones or cockpit speaker (optional). Any of the 10 receivers can be monitored separately or in any combination.

1-9. PA SWITCH

1-10. The PA on-off switch controls the 10 watt amplifier. In the off position, any interphone communication will be heard through the headphones only. When an interphone message originates from a unit with the PA switch on, the message will be heard on the PA speaker and the headphones of all units.

1-11. COCKPIT SPEAKER/HEADPHONE

1-12. This switch allows the choice of monitoring a radio or interphone signal through either the headphones or a cockpit speaker. The 1U396-002 does not contain a cockpit speaker amplifier, therefore, the cockpit speaker mode is not functional without an external amplifier.

1-13. EMERGENCY/NORMAL

1-14. With this switch, it is possible to directly monitor any one of the 10 radio receivers at one time, bypassing all electronics within the 1U396-002. In the emergency position, any one receiver can be monitored by placing the corresponding switch on, all other radio switches off, and the cockpit speaker/headphone switch to headphones. A priority method is used for the 10 receivers when the unit is in the emergency mode. COM 1 has the highest priority, and DME has the lowest. When two or more receiver switches are up in the emergency mode, only the receiver corresponding to the highest priority switch in the up position will be heard.

1-15. MICROPHONE SELECT

1-16. The five position microphone function select switch gives complete control of transmission mode. This switch allows each unit to transmit on any of four communication radios (COM 1, COM 2, COM 3, and COM 4). The interphone position on this switch gives each unit the capability of transmitting on the PA speaker or to the headphones of the other units on the same system.

1-17. VOLUME CONTROL

1-18. The volume control adjusts the loudness of all 10 radio receiver signals. It has no effect on interphone signals or the output level of the PA speaker.

1-19. THEORY OF OPERATION

1-20. The 1U396-002 Audio Selector/Amplifier has two basic modes for communication. Exterior communication radios can be used, or intersystem communication is available. Transmission on four exterior communication radios is accomplished without the use of any electronics within the audio panel itself. The microphone is coupled to one

of the four transmitters through the microphone select switch. To accomplish transmission, the desired transmitter is selected, and the transmit key (MIC PTT button) is pressed. The PTT button will then activate the selected transmitter, and the message can be relayed.

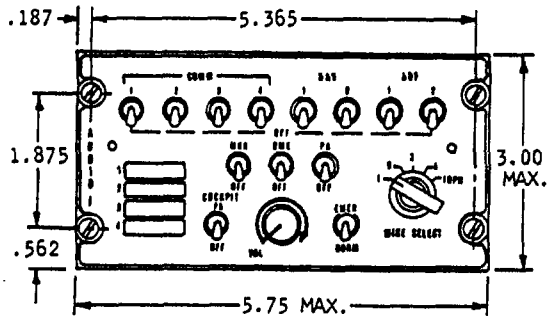
1-21. Each of the 10 receiver inputs has a 1K load to ground. A resistor isolation network provides adequate isolation between each receiver input and mixes all 10 inputs to a single volume control. The output is then fed through another isolation resistor to the headphone amplifier. A toggle switch couples the headphone output to either a set of headphones or an optional speaker amplifier.

1-22. To communicate from one unit to the other units on the same system, the interphone circuit is used. By positioning the microphone select switch to interphone and pressing the PTT button, a relay is activated. Independent of the microphone select switch position, the relay is also activated by grounding the interphone control line. When the relay is activated, the microphone input is fed to the interphone amplifier. An eight volt regulator provides adequate biasing for a carbon microphone. The interphone amplifier produces an output of about 100 mw into 600 ohms (adjustable with level pot).

1-23. The output of the interphone amp is coupled directly to a PA amplifier through a PA select switch. With the PA switch on, the interphone amplifier output will be heard through the PA speaker. The PA amplifier has a level adjust pot for pre-setting the output level.

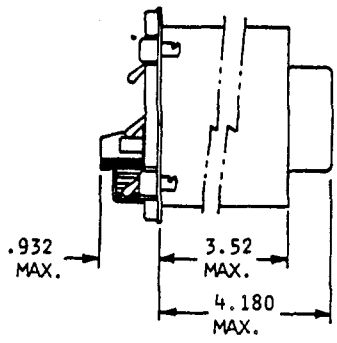
NOTE

Each 1U396-002 unit contains a 10 watt PA amplifier. If more than one PA amplifier is to be connected to the same speaker, there must be suitable isolation circuitry provided to allow the equivalent of an eight ohm load or greater to each amplifier. Two amplifier outputs cannot be "hard wired" together. It is recommended that all unused PA amplifier outputs be terminated with a 1K, ±5%, 1 watt resistor.



1-24. The interphone amplifier output is also connected to the interphone line. It is this line that interconnects all the units on the system. This common point is then tied to a side tone amplifier that provides isolation between the receiver inputs and the interphone line. Compensation for different numbers of units on the system is also accomplished by the side tone amplifier. A resistor, placed between the interphone amplifier output and the interphone line, assures that an interphone message from one unit will not enter any of the other unit's PA amplifiers.

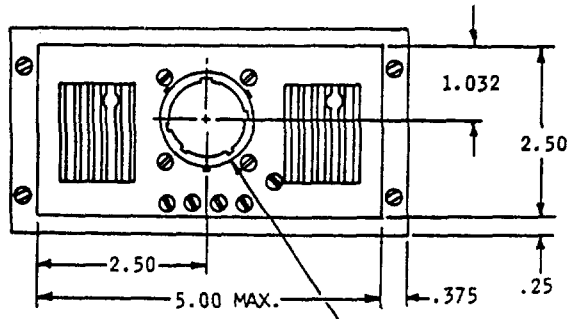
1-25. An interphone message from any unit in the system is passed through the side tone amplifier to the headphone amplifier. In using the interphone mode on the audio panel, the message will be heard in every unit's headphones. Concurrently, the message can be broadcast on the PA speaker.



1-26. STORAGE INSTRUCTIONS

1-27. The 1U396-002 Audio Selector/Amplifier can be temporarily stored on the shelf, but should not be exposed to extremes of temperature, humidity, or other environmental conditions without additional protection. The use of a connector cover is recommended.

1-28. For long term storage, it is recommended that the 1U396-002 Audio Selector/Amplifier be placed in the original shipping carton or equivalent, and that a suitable dessicant such as silicagel be placed within the container. Mark packing date plainly on the container. An alternate method is to store the unit in a location having a carefully controlled, low humidity environment. Storage temperature should be maintained between -65°C and +85°C (-85°F and +185°F).



FRONT VIEW

SIDE VIEW

NOTES:

1. PROVIDES CONTROL OF FOUR TRANSMITTERS, TEN RECEIVERS, AND A FLIGHT INTERPHONE WITH INDIVIDUAL OR COLLECTIVE MONITORING ON HEADPHONE.
2. PROVIDES 150 MILLIWATTS TO HEADPHONE WITH LESS THAN 5% DISTORTION.
3. 40 dB MINIMUM ISOLATION PROVIDED BETWEEN INPUT LINES.
4. "EMER-NORM" SWITCH, WHEN IN EMER. POSITION, BY-PASSES ALL ELECTRONICS TO PROVIDE STRAIGHT HEADPHONE OPERATION IN EMERGENCY SITUATIONS.
5. FRONT PLASTIC PANEL TO BE NON-REFLECTING BLACK WITH WHITE MARKINGS, EDGELIGHTED, LACON PROCESS OR EQUAL TO MIL-P-7788.
6. PANEL LIGHTING - 28V BLUE-WHITE.
7. KNOB COLOR - BLACK.
8. OPTIONAL TRANSMITTER DESIGNATORS INCLUDE HF 1, HF 2, VHF 1, VHF 2, UHF 1, UHF 2, FM, & SPARE.

Figure 1-2. Audio Selector/Amplifier Outline/Dimension Drawing

1-29. SPECIFICATIONS

CHARACTERISTICS	LIMITS
Overall Dimensions	Refer to the outline-dimension drawing (figure 1-2) furnished in this manual
Weight	1.8 pounds typical
Mounting	Panel mounted by four Dzus fasteners
Connector	Cannon type KPT02A20-41P (mating connector, Cannon type KPT06E20-41S)
Input Power Requirements	
Electronics	27.5 vdc, 1.4 amps maximum
Lights	27.5 vdc
Environmental Operating Limits	Meets or exceeds TSO C50b, Cat. BBAAAX
Panel Lights	1. Color - blue-white 2. Voltage - 28 vdc
Panel Color	Flat black with white lettering
Panel Marking	White
Knob Color	Flat black with white indice
Input Power Supply Range	Functional - 18 vdc to 30 vdc Meets all specifications - 22 vdc to 30 vdc
Headphone Output Load	600 ohms (Floating)
Cockpit Speaker Output Load	600-1000 ohms, input impedance to optional exterior amplifier (Floating)
Interphone Output Load	Up to 6 Audio/Selector Amplifiers
PA Amplifier Output Load	8 ohms (Floating)
Microphone Input	7 vdc bias for 150 ohm carbon microphone
External Volume Control Range	20 db from minimum (ccw) to maximum (cw) position
Receiver Input Sensitivity	10 mw (into 1K ohms) for rated output (headphone amplifier gain set at maximum)
Microphone Input Sensitivity	60 mv for nominal interphone output of 9.0 vrms
Headphone Amplifier Gain	Up to 10 db, variable (internal)

Table 1-1. Specifications (Page 1 of 2)

1-29. SPECIFICATIONS (Cont.)

CHARACTERISTICS	LIMITS
Headphone Output With Receiver Input	
Power	150 mw
Frequency Response	± 3 db, 300 Hz to 3000 Hz Down 20 db at 20 KHz
Distortion	Less than 5%
Headphone Output With Microphone Input	
Power	120 mv
Frequency Response	± 3 db, 300 Hz to 2850 Hz Down 20 db at 20 KHz
Distortion	Less than 5%
PA Amplifier Output	
Power	10 watts
Frequency Response	± 3 db, 300 Hz to 3000 Hz Down 15 db at 20 KHz
Distortion	Less than 5%
Input Isolation	
Receiver to Receiver	Greater than 40 db
Microphone to Receiver	Greater than 40 db
Ripple Rejection (Interphone Control Not Activated)	Ripple output greater than 50 db below rated headphone and PA outputs (For supply voltage between 23 vdc to 30 vdc)

Table 1-1. Specifications (Page 2 of 2)

SECTION II

REPAIR PROCEDURES

2-1. If an instrument is to be overhauled, a functional test and careful visual inspection should be made before disassembly. The instrument should have a detailed mechanical inspection. All defective parts must be replaced, wherever possible, with current equivalent replacement parts and, in general, the instrument restored to a like-new condition.

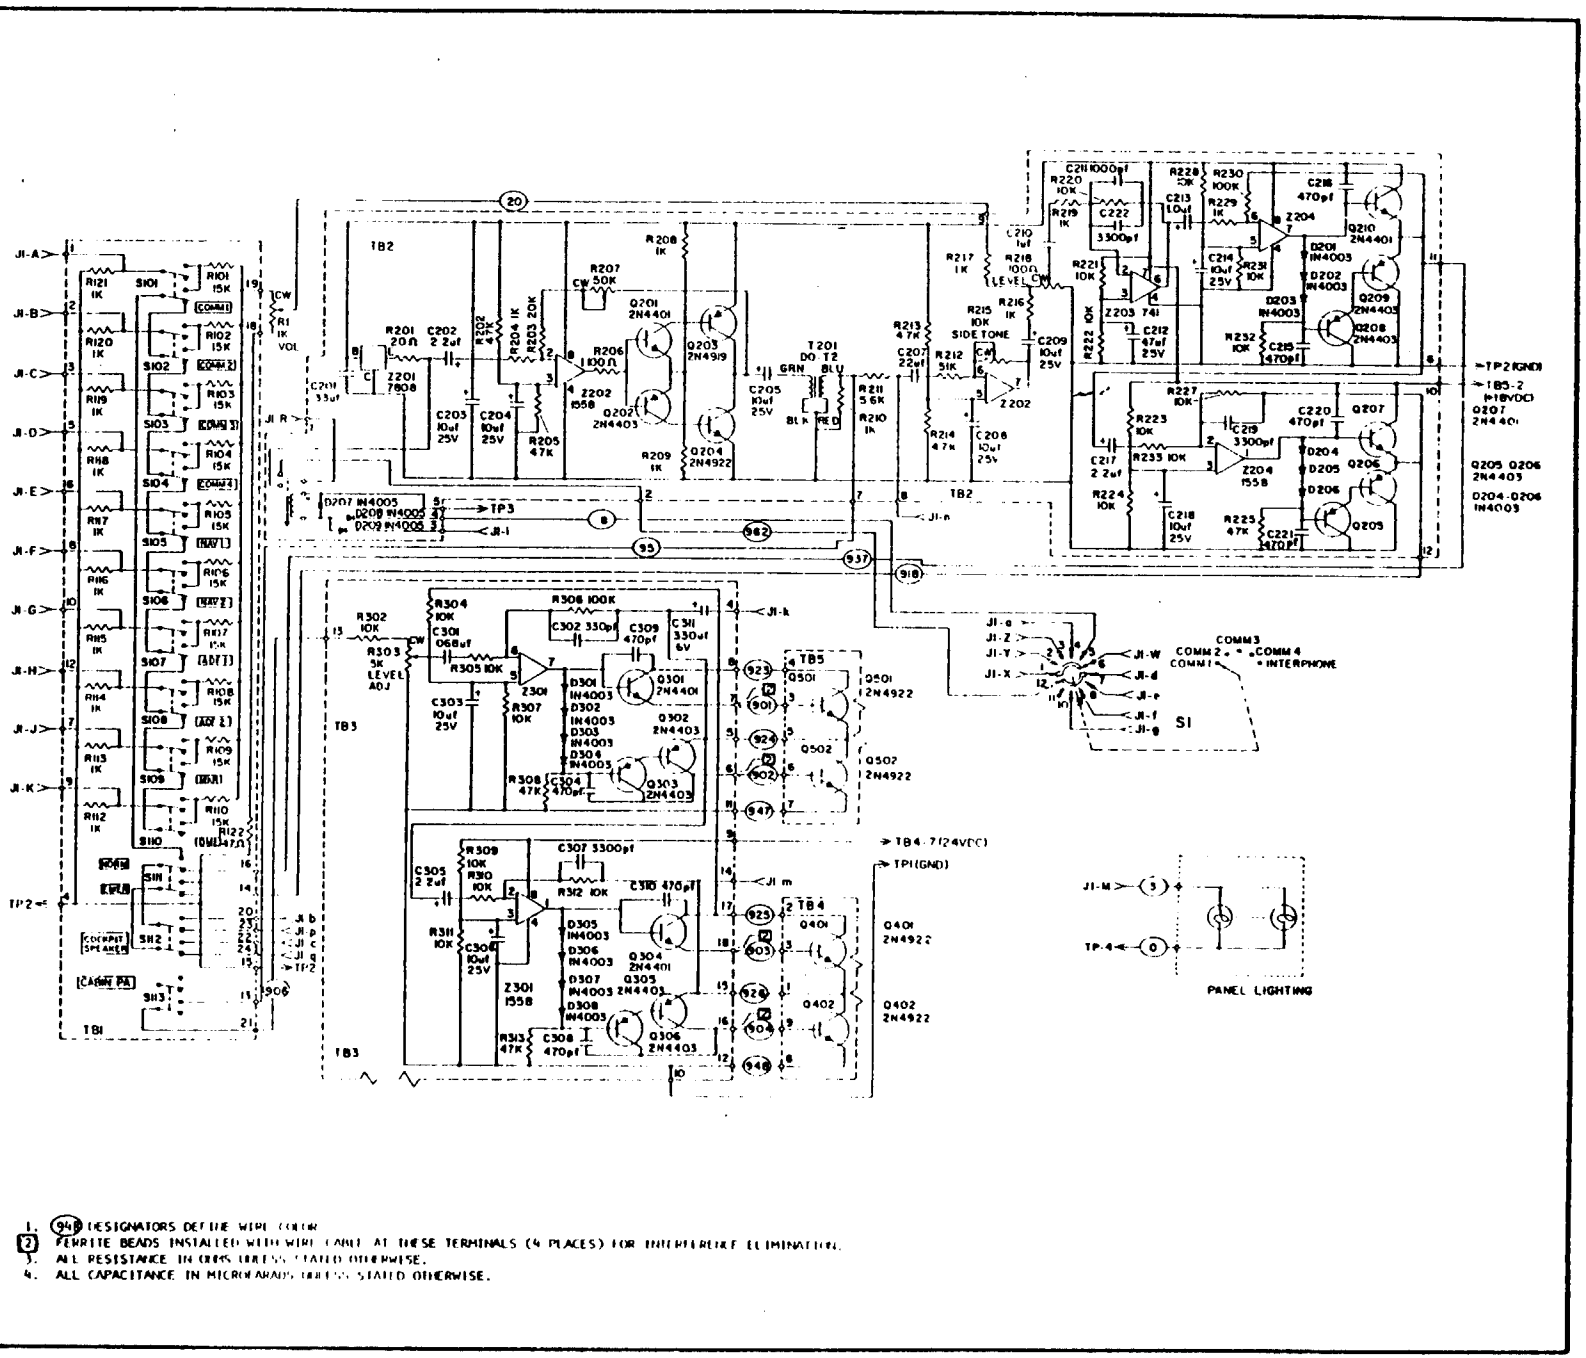
2-2. Correction of a specific malfunction, on the other hand, should isolate and correct the cause of the problem with as little disturbance to the rest of the instrument as possible.

2-3. After a malfunction is ascertained, diagnosed, and corrected by replacement of a faulty component, repeat tests that apply to the trouble to ensure correct functional performance of the equipment.

2-4. TROUBLESHOOTING

2-5. The troubleshooting guide that follows contains items noted by factory technicians that are peculiar to this instrument. It assumes that the technician will be familiar with malfunctions common to an audio selector/amplifier, and that such problems already will have been investigated and corrected.

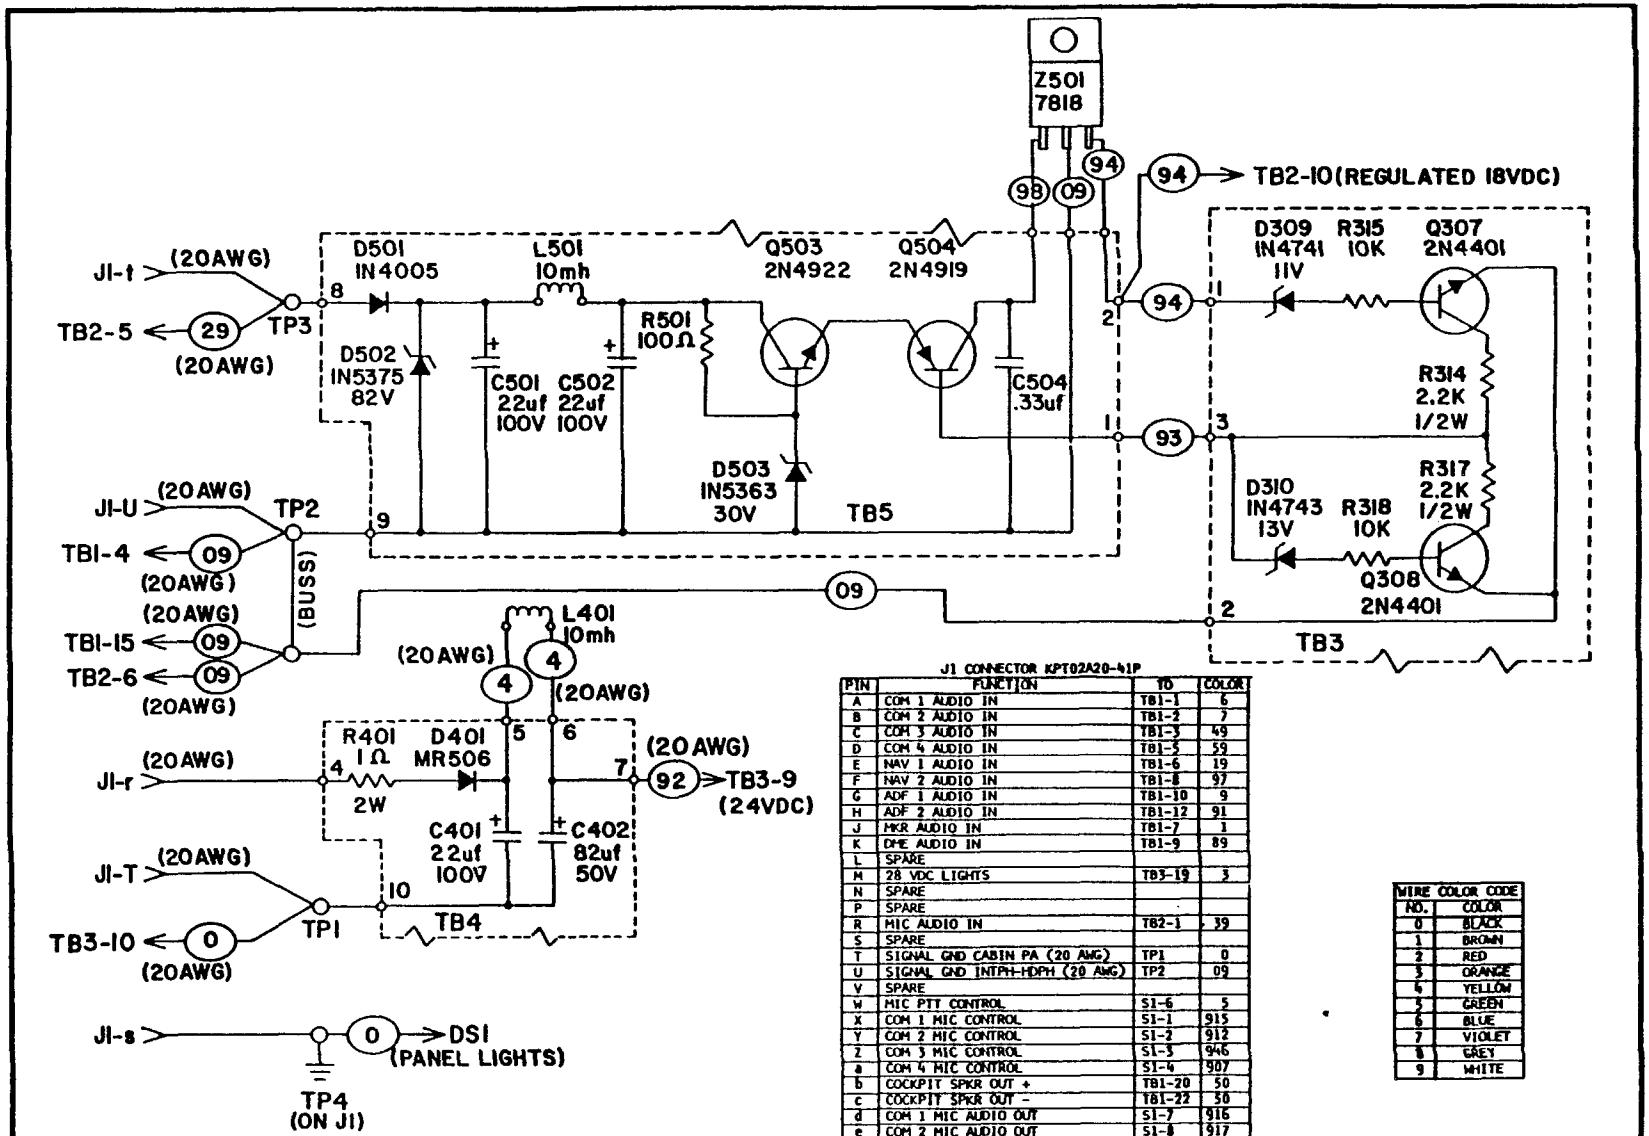
2-6. TROUBLESHOOTING CHART



NOTE

Before consulting the following table, verify that the problem exists with the 1U396-002 Audio Selector/Amplifier and not with associated exterior components, such as headphones, speakers, external amplifiers, microphones, and radio equipment. Make certain that control settings are correct. In the following table, the power input voltage is assumed to be +27.5 vdc.

SYMPTOM	CAUSE	REPAIR
1. Cannot obtain correct continuity measurements	A. Incorrect or loose ground on test setup	Check grounding scheme
	B. Faulty switch board	Replace 1V396-991
	C. Faulty microphone function selector switch	Replace switch, 907053-01
2. Panel lamps do not light	A. Faulty light board	Replace 1V396-980
3. Interphone relay does not energize	A. Faulty interphone relay	Replace 1V396-941
4. No headphone output when using a receiver input	A. Faulty switch board	Check continuity measurements
	B. Faulty volume control	Replace volume control, R1
	C. Faulty Inph/Hdph power supply	Replace 1V396-961 if output is not = 18 vdc = 5%
	D. Faulty Inph/Hdph board	Replace 1V396-941
5. Volume of headphone output too low or too high with a receiver input	A. Headphone level pot not adjusted correctly	Adjust headphone level pot per paragraph 2-43
	B. Faulty volume control	Replace volume control R1
	C. Faulty Inph/Hdph board	Replace 1V396-941



TROUBLESHOOTING CHART (CONTINUED)

SYMPTOM	CAUSE	REPAIR
6. Inadequate headphone frequency response with receiver input	A. Faulty Inph/Hdph board supply	Replace 1V396-941
7. Excessive headphone distortion with receiver input	A. Faulty Inph/Hdph power supply	Replace 1V396-961 if output is not = 18 vdc ± 5%
	B. Faulty Inph/Hdph board	Replace 1V396-941
8. No headphone output when using a microphone input	A. Faulty Inph/Hdph power supply	Replace 1V396-961 if output is not = 18 vdc ± 5%
	B. Faulty Inph/Hdph board	Replace 1V396-941
9. Inadequate headphone frequency response with microphone input	A. Faulty Inph/Hdph board	Replace 1V396-941
10. Excessive headphone distortion with microphone input	A. Interphone level pot adjusted for too much gain	Adjust Interphone level pot per paragraph 2-41
	B. Faulty Inph/Hdph power supply	Replace 1V396-961 if output is not = 18 vdc ± 5%
	C. Faulty Inph/Hdph board	Replace 1V396-941
11. No headphone output with an interphone input from another unit (there is a headphone output with a microphone input)	A. Broken or loose interphone line	Check interphone line in wire harness for broken or loose connection
	B. Problem exists in other unit	Check unit that originated signal for symptom #8
12. No PA output with microphone input	A. Check for symptom #8 Faulty PA power supply	Check symptom #8 Replace 1V396-971 if output is not = 26 vdc ± 5%
	B. Faulty PA Amplifier output transistors	Check voltage between pins J1-m (+) and J1-T (-) with no input signal to PA amplifier. If voltage is not = 13 vdc ± 1 vdc, replace 1V396-971 Check voltage between terminal .5 (TB3) and J1-T with no input signal to PA amplifier. Replace 1V396-961 if voltage is not = 13 vdc ± 1 vdc
	C. Faulty PA amplifier board	Replace 1V396-951
13. Inadequate PA amplifier frequency response	A. Check for symptom #9 faulty PA amplifier board	Check symptom #9 Replace 1V396-951
14. Excessive Pa output distortion	A. Check for symptom #10 faulty PA amplifier board	Check symptom #10 Replace 1V396-951

1. (948) DESIGNATORS DEFINE WIRE COLOR

2-7. TEST EQUIPMENT

2-8. Table 2-1 lists the test equipment required to perform the procedures described in this section of the manual. Test equipment, other than that listed in table 2-1 under REPRESENTATIVE TYPE, can be substituted if their specifications fulfill those requirements listed under CHARACTERISTICS REQUIRED.

CAUTION

Do not short headphone or PA outputs to ground, as this will damage the output transistors. Place ground isolation plugs on all test equipment, except power supply.

ITEM	DESCRIPTION	COMMON NAME	CHARACTERISTICS REQUIRED	REPRESENTATIVE TYPE
1	Audio Oscillator	Audio Oscillator	100 through 20,000 cps. At least 11 vrms maximum output	Hewlett-Packard Model 3310B
2	AC Vacuum-Tube Voltmeter	ac vtvm	At least ± 5% accuracy at any point on the scale	Hewlett-Packard Model 400D
3	Output Power Meter	output power meter	Measures power up to 12 w for 8 ohm load; up to 200 mw for 600 ohm load	General Radio Model 583A
4	Distortion Analyzer	distortion analyzer	Measures and indicates percent of audio distortion; incorporates vtvm with decibel scale	Hewlett-Packard Model 331A
5	Power Supply	power supply	0 through 30 vdc variable output, up to 1.4 amps	Power/Mate Corp. Model BP-40D
6	Digital Multimeter	DMM	Measures voltages and resistances, at least 1 Meg ohm input impedance	Hewlett-Packard Model 3476B

Table 2-1. Test Equipment

2-9. To establish that the unit meets minimum performance requirements, the bench tests in this section should be performed. If the unit under test fails to meet the results required for proper operation, that section of the audio selector/amplifier should be investigated using the troubleshooting chart (see paragraph 2-6).

2-10. To assist in the performance of the following tests, it is suggested that a test jig be fabricated for connection to the control so that contact with each terminal pin on the unit's rear connectors will be accessible on a terminal strip. The test jig should use a cable harness terminated at one end with a terminal strip, and at the other end with an electrical connector. Use a type KPT06E20-41S Cannon connector or equivalent to mate with J1 at the rear of the 1U396-002 Audio Selector/Amplifier.

2-11. TESTING

2-12. Testing of the 1U396-002 Audio Selector/Amplifier consists primarily of checking each board which should function according to specifications. Refer to figure 3-1.

2-13. TEST PROCEDURES

2-14. The 1U396-002 Audio Selector/Amplifier consists primarily of three different amplifier sections which are described in detail in the following paragraphs.

2-15. BENCH TESTS AND ADJUSTMENTS

2-16. INITIAL CONTROL SETTINGS

2-17. Set the 1U396-002 Audio Selector/Amplifier controls as shown in table 2-2.

CONTROLS	CONTROL DESIGNATION	POSITION

Table 2-3. Resistance Chart

2-20. LIGHTS

2-21. Apply 27.5 vdc to pin J1-M; ground power supply to pin J1-s. Panel lamps should light.

2-22. INTERPHONE RELAY

2-23. Apply 27.5 vdc to pin J1-t, momentarily ground power supply to pin J1-i. Relay K201 should energize.

2-24. *HEADPHONE AMPLIFIER TEST

NOTE

The internal headphone amplifier gain adjustment has been preset by the manufacturer. If the gain is not adequate, it can be changed as described in the Level Potentiometer Adjustments section (see paragraphs 2-39 through 2-46).

A. Set all controls as shown in table 2-2.

B. Connect the power meter and distortion analyzer to pins J1-p and J1-q (see figure 2-1). Set the impedance of the power meter to 600 ohms.

C. Connect the audio oscillator and the vtvm to pin J1-A. Set the oscillator to 1000 cps, 10 vrms.

D. Ground the power supply to pins J1-T and J1-u.

E. Apply 27.5 vdc to pins J1-r and J1-t.

F. Place COM 1 switch in the on (up) position. The power meter should indicate an output of 150 mw, and the distortion should be less than 5%.

G. Slowly tune the audio oscillator to 300 cps ensuring that the oscillator output remains 10 vrms. The power meter indication should not change more than ± 3 db from 150 mw. The distortion should remain below 5%.

H. Slowly tune the audio oscillator to 3000 cps ensuring that the oscillator output remains 10 vrms. The power meter indication should not change more than ± 3 db from 150 mw. The distortion should remain below 5%.

2-25. *INTERPHONE AMPLIFIER TEST

NOTE

The internal interphone and sidetone gain adjustments have been preset by the manufacturer. The interphone level should require no further adjustment. The sidetone gain will require adjustment, dependent on the number of audio panels interconnected in the system. For the purpose of this test, the sidetone gain has been preset for a two unit system (no load on J1-n). Refer to the Level Potentiometer Adjustment section (see paragraph 2-44) for readjusting gains.

A. Set all controls as shown in table 2-2.

B. Connect the power meter and distortion analyzer to pins J1-p and J1-g (see figure 2-1). Set the impedance of the power meter to 600 ohms.

C. Connect audio oscillator and vtvm to the RC network as shown in figure 2-1. Set the oscillator to 1000 cps, 125 vrms.

D. Ground the power supply to pins J1-T and J1-U.

E. Apply 27.5 vdc to pins J1-r and J1-t.

F. Ground pin J1-i to the power supply. The power meter should indicate an output of 120 mw, and the distortion should be less than 5%.

G. Slowly tune the audio oscillator to 300 cps ensuring that the oscillator output remains 125 mvrms. The power meter indication should not change more than ± 3 db from 120 mw. The distortion should remain below 5%.

H. Slowly tune the audio oscillator to 2850 cps ensuring that the oscillator output remains 125 mvrms. The power meter indication should not change more than ± 3 db from 120 mw. The distortion should remain below 5%.

2-26. *PA AMPLIFIER TEST

NOTE

The internal PA amplifier gain adjustment has been preset by the manufacturer. To readjust gain, refer to the Level Potentiometer Adjustment section (see paragraph 2-45).

A. Set all controls as shown in table 2-2.

B. Connect the power meter and distortion analyzer to pins J1-k and J1-m (see figure 2-1). Set the impedance of the power meter to 8 ohms.

C. Connect the audio oscillator and vtvm to the RC network as shown in figure 2-1. Set the oscillator to 1000 cps, 125 mvrms.

D. Ground the power supply to pins J1-T and J1-U.

*See CAUTION on page 2-5.

E. Apply 27.5 vdc to pins J1-r and J1-t.

F. Ground pin J1-i to the power supply.

G. Place PA switch on (up). The power meter should indicate an output of 10 watts, and the distortion should be less than 5%.

H. Slowly tune the audio oscillator to 300 cps ensuring that the oscillator output remains 125 mvrms. The power meter indication should not change more than ± 3 db from 10 watts. The distortion should remain below 5%.

J. Slowly tune the audio oscillator to 3000 cps ensuring that the oscillator output remains 125 mvrms. The power meter indication should not change more than ± 3 db from 10 watts. The distortion should remain below 5%.

2-27. CLEANING

2-28. When deemed necessary (depending upon the environment to which the equipment is exposed, and the intensity the instrument is used) periodic inspection and cleaning should be performed.

CAUTION

Exercise care when inspecting or cleaning the interior of the control unit so that none of the critically positioned components, wires, and adjustments are accidentally disturbed.

2-29. RECOMMENDED CLEANING PROCEDURES

CAUTION

Some cleaning agents will attack and deform plastic parts. Carefully use least amount of cleaning agent required to do the job.

2-30. The exterior of the control unit should be wiped with a lint-free cloth. Remove any foreign matter from the interior of control unit with a soft, clean camel-hair brush and/or a clean, forced-air stream (30 psi maximum). For dirt or other foreign matter that cannot be removed in this manner from surfaces difficult to reach, the equipment may require partial disassembly to clean with a stiff bristle brush. If switch contacts are noticeably dirty and the wafer is suspected of having failed, replace switch.

2-31. DISASSEMBLY

2-32. Disassembly of the 1U396-002 Audio Selector/Amplifier is straightforward and generally obvious. The following steps are to be used as an aid to break down the audio selector/amplifier into more workable assemblies.

2-33. Unless service time or other factors dictate a complete overhaul, disassemble the audio selector/amplifier no further than necessary to make a specific repair.

A. Remove four flat head screws and remove top dust cover.

B. Loosen four set screws and remove both knobs (see figure 2-2).

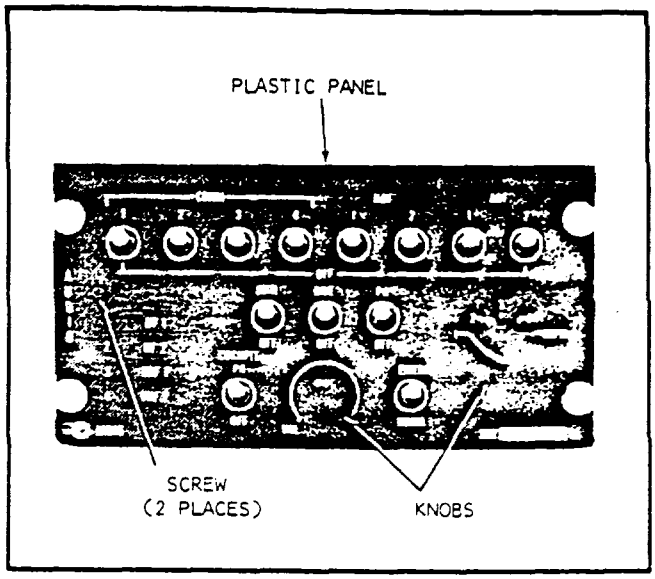

Figure 2-2. Plastic Panel Removal

C. Remove two screws and two lockwashers and lift plastic panel from the unit.

D. Unsolder terminals and remove panel lighting assembly.

E. Unscrew four flat head screws and remove two round posts (see figure 2-3).

F. Remove eight flat head screws and remove two square posts to detach subpanel.

G. Unscrew nut and remove rotary switch from subpanel.

H. Unscrew nut and remove potentiometer from subpanel.

J. Remove two flat head screws from bottom dust cover to release two PCB standoffs (see figure 2-4).

K. Remove four pan head screws, four hex nuts, and four lockwashers to disassemble interphone/headphone amp assembly. Two PCB standoffs and power amp assembly will come apart.

L. Remove two flat head screws, two hex nuts, and two lockwashers to release mounting bracket from bottom dust cover.

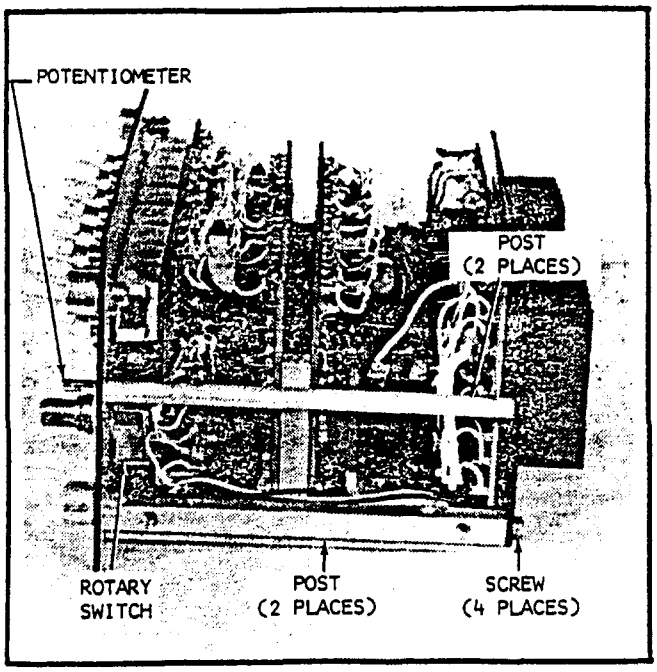

Figure 2-3. Subpanel and Switch Board Assembly Removal

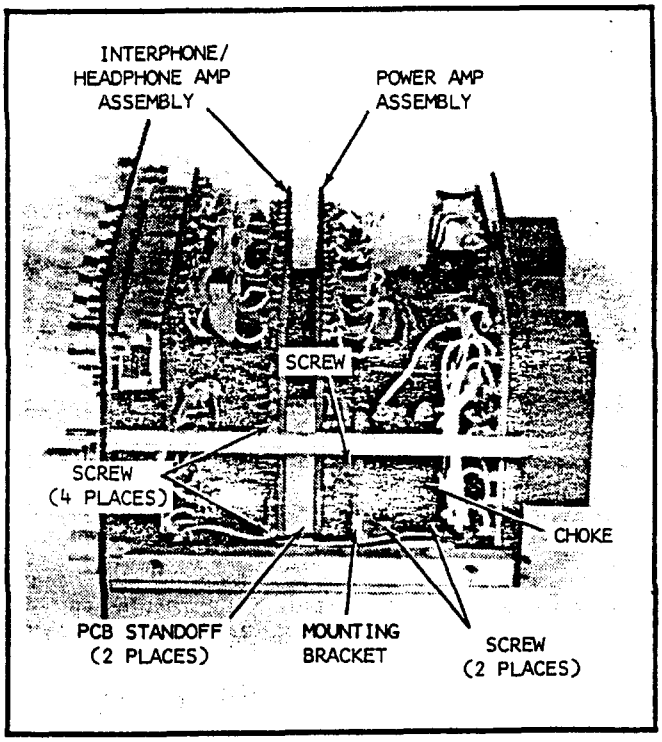

Figure 2-4. Interphone/Headphone Amp and Power Amp Assemblies Removal

M. Remove one pan head screw, one hex nut, and one lockwasher to remove choke from mounting bracket.

NOTE

Unsolder two wires to completely detach choke.

N. Remove one flat head screw from bottom dust cover to detach regulator.

O. Remove two pan head screws and remove PA supply assembly (see figure 2-5).

P. Remove two pan head screws and remove interphone/ headphone assembly.

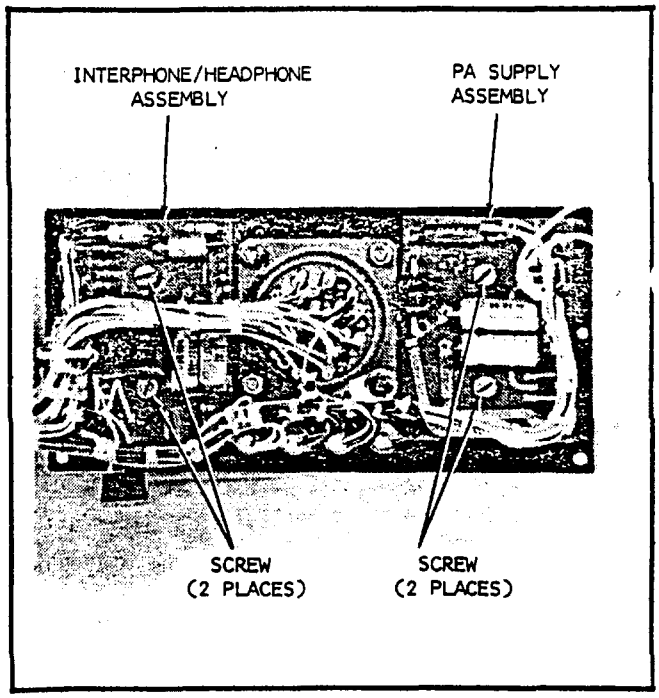

Figure 2-5. PA Supply Assembly and Interphone/Headphone Assembly Removal

Q. Remove four flat head screws and two heatsinks from connector plate assembly (see figure 2-6).

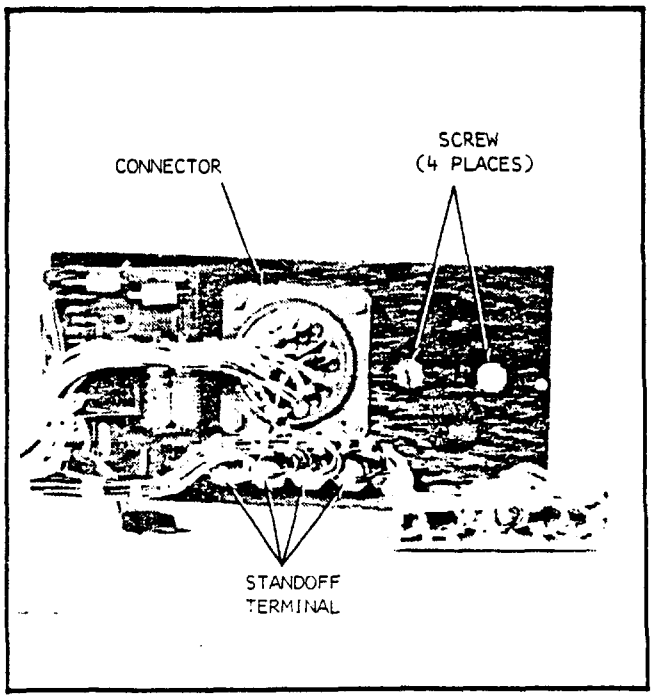

Figure 2-6. Heatsink Removal

R. Remove four flat head screws, four hex nuts, three lockwashers, and one solder lug and slide connector from connector plate assembly (see figure 2-7).

S. Remove four flat head screws and remove four standoff terminals from connector plate assembly.

2-34. INSPECTION AND REPAIR

2-35. GENERAL

2-36. With disassembly completed, there should be easy access to areas for inspection and repair. All parts should be thoroughly examined for any evidence of damage prior to reassembly. Repair of damaged parts is recommended only when it can be done economically and without adversely affecting the proper operation of instrument. If any doubt exists as to the operating condition of any component parts or assembly, refer to the parts list section of this manual, and order replacement parts directly from Edo-Aire through their parts sales department.

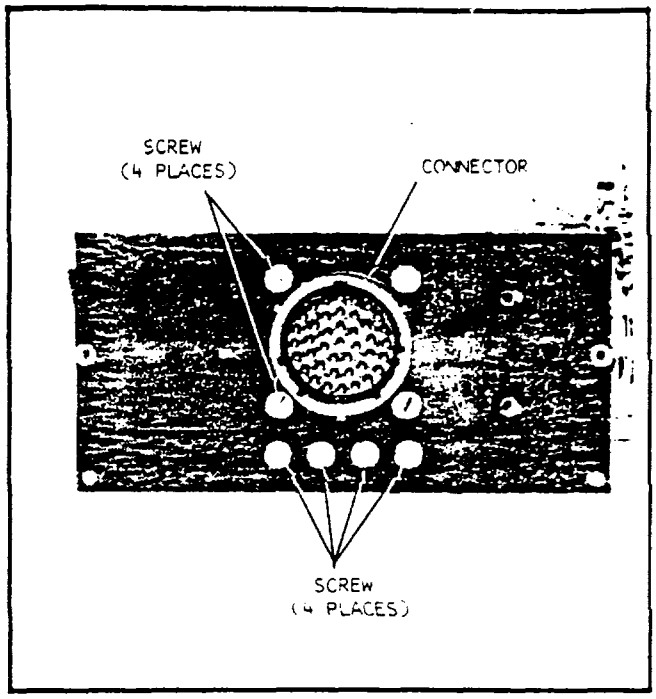

Figure 2-7. Connector Plate Assembly Removal

2-37. REASSEMBLY ROUTINE

2-38. Assembly of the 1U396-002 Audio Selector/Amplifier is straightforward and generally obvious. In general, assembly should be accomplished in the reverse order of disassembly (paragraphs 2-31 through 2-33). For detailed assembly information, use the appropriate exploded-view illustrations provided in the ILLUSTRATED PARTS BREAKDOWN section of this manual.

2-39. LEVEL POTENTIOMETER ADJUSTMENTS

2-40. There are four gain adjustment potentiometers within the audio selector/amplifier. The adjustment of these potentiometers will depend on the equipment used in conjunction with each audio selector/amplifier and on personal taste. When adjusting these level potentiometers, it is best to use the following sequence. This sequence will help avoid any confusing interaction between two or more gain adjustments. Refer to figures 2-8 and 2-9 when adjusting the level potentiometers.

CAUTION

Do not short headphone or PA outputs to ground, as this will damage the output transistors. Place ground isolation plugs on all test equipment, except power supply.

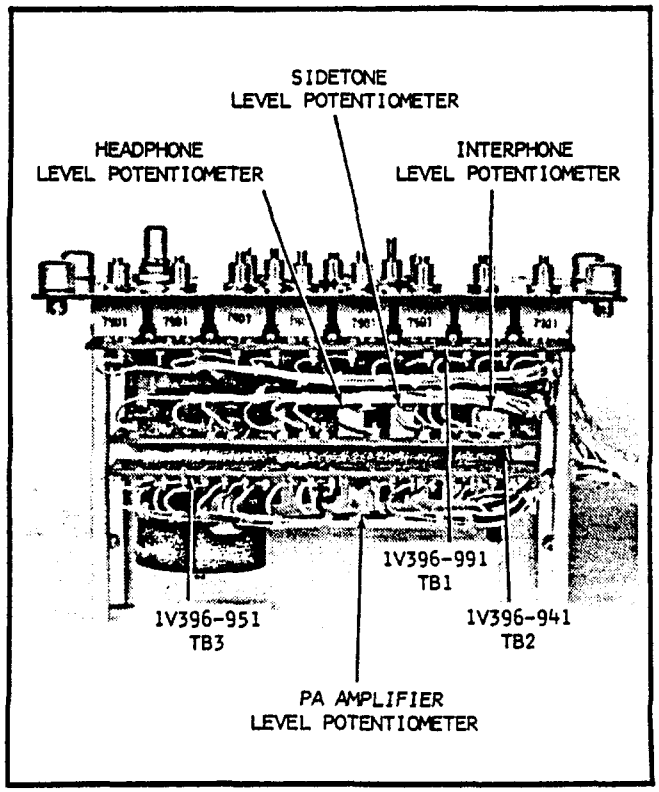

Figure 2-8. Level Potentiometer Locations

2-41. INTERPHONE LEVEL POTENTIOMETER

2-42. This potentiometer is preadjusted and should require no further adjustment. Adjusting this potentiometer for more output than specified may result in a large amount of distortion. If readjustment is necessary, use the following method.

A. Place a 150 ohm, one watt resistor across the microphone input and signal ground (simulates microphone load).

CAUTION

Do not short headphone or PA outputs to ground, as this will damage the output transistors. Place ground isolation plugs on all test equipment, except power supply.

B. Apply a 1000 Hz sine wave to the microphone input (use a 100 uf capacitor between the generator and the microphone input for ac coupling). The amplitude of the input signal will be dependent on the type of microphone used with the audio selector/amplifier. A typical amplitude is 125 mvrms.

C. With no load on the interphone output (adjust each audio selector/amplifier separately with no interconnecting interphone line), adjust the interphone level potentiometer for 9.0 vrms interphone output. A large amount of distortion may result if the output is adjusted for more than 9.0 vrms.

2-43. HEADPHONE LEVEL POTENTIOMETER

A. Apply a 1000 Hz sine wave to any one of the radio inputs (amplitude is dependent on equipment used in conjunction with the audio selector/amplifier, 10 vrms nominal).

B. Adjust the headphone level potentiometer for desired output (150 mw into 600 ohms, nominal with volume control set at maximum, cw).

2-44. SIDETONE LEVEL POT

A. Interconnect all audio selector/amplifiers to be used in the system.

B. Using the same procedure as stated in paragraph 2-42, A, and B, adjust each unit's sidetone level potentiometer for the desired headphone output (120 mw into 600 ohms, nominal).

2-45. PA LEVEL POTENTIOMETER

2-46. Using the same procedure as stated in paragraph 2-42, A, and B, switch on the PA amplifier and adjust the PA amplifier level potentiometer for the desired output (10 watts into eight ohms, nominal).

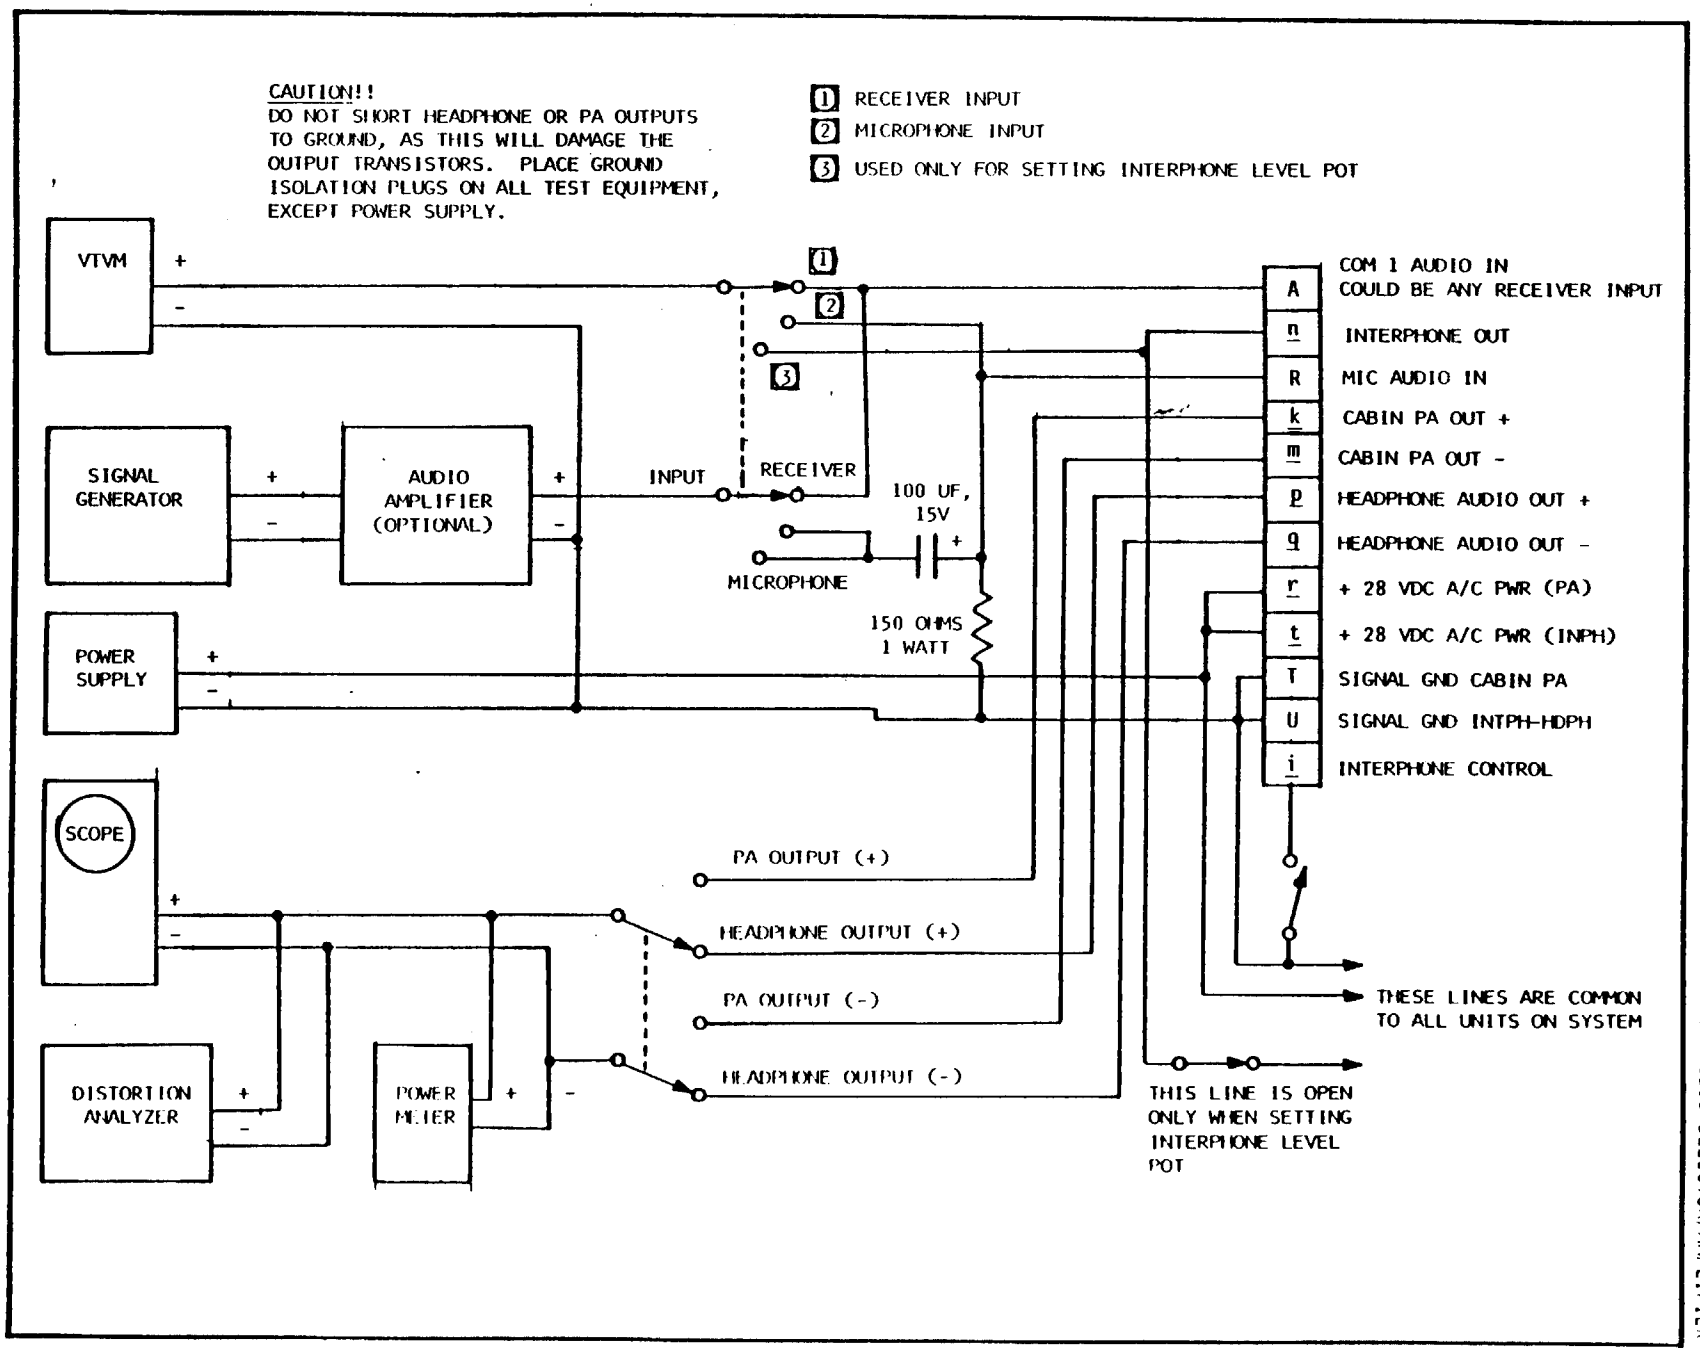

Figure 2-9. Test Equipment Diagram

SECTION III

ILLUSTRATED PARTS BREAKDOWN

3-1. The illustrated parts breakdowns, figures 1 through 3 and their accompanying lists, are arranged in disassembly sequence. Where assemblies can be broken down, the breakdown is indicated by indention in the nomenclature column. If the complete assembly is wanted, order by the assembly part number. When ordering only individual parts in an assembly, order by the individual part numbers. Assemblies that are permanently joined, or for some reason should not be disassembled, are listed and sold only as assemblies.

3-2. Where parts have been changed in production but the new parts are interchangeable with the old in both fit and function, only the current part number is listed and the current part illustrated, since only these items will be supplied as spares. The old part number may be shown as obsolete for clarity. If a new part is not fully interchangeable, the correct part number combinations are explained in notes at the end of each figure.

3-3. Assemblies or parts that are applicable to a specific series or modification (MOD) are identified in the EFF CODE column. The effective code is listed at the end of the text for each figure. When no code is listed, it is assumed that all of the parts or assemblies shown in the illustrated parts breakdown may be used on all of the models or series covered by the manual. The EFF CODE column may also be used to denote any peculiarities about listed assemblies or parts. The codes are unique to each individual figure (code "A" in figure 3-1 has no relationship to code "A" of figure 3-2).

3-4. Fasteners and standard purchased parts are listed by their Edo-Aire part numbers and may be purchased from Edo-Aire; however, the descriptions of these items are adequate for local or distributor purchase as well. Bulk items, such as sealers, are included with either their Edo-Aire part numbers for special materials or sufficient description for local purchase. These items should be kept in stock, and substitutions should be avoided to prevent risking the performance of an untested material.

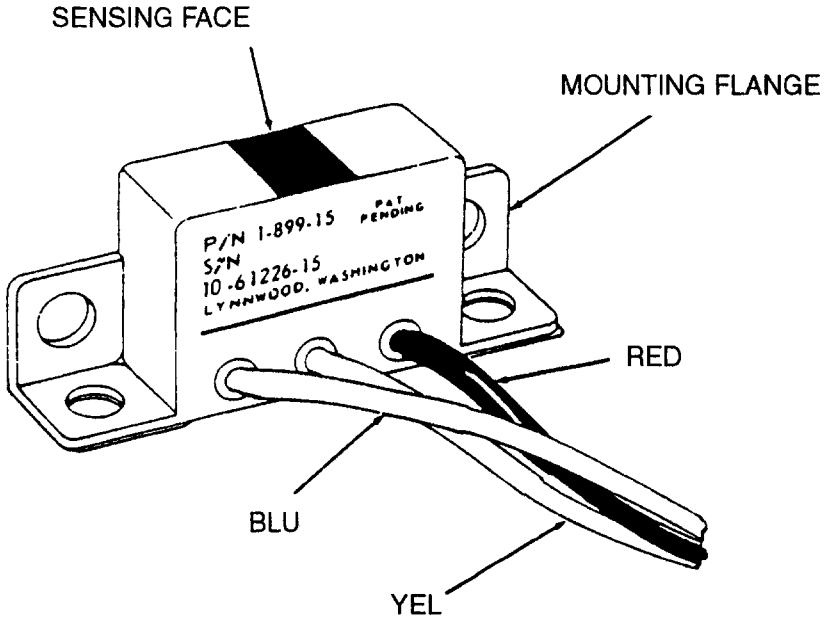
DESCRIPTION AND OPERATION

1. General

Proximity systems use sensors and targets to find the position of parts of an aircraft, such as doors and landing gear. When metal targets come near, the electrical properties of the sensor change. The change in sensor inductance (or impedance) controls the operation of a remote electronic switch.

A. Description



The Proximity Sensors (PN 1-899-15, -29, -28, and -83 shown in Figure 1) are variable reactance sensors. The proximity sensor is an inductor and a temperature compensation resistor contained in a stainless steel case. These remotely installed sensors detect the presence or absence of magnetically permeable targets. Each sensor is an integral part of a proximity switch system. Sensor specifications are shown in Table 1.

B. Theory of Operation

In the system, the sensor is electrically connected to a solid state proximity switch circuit. Figure 2 illustrates the elements of the basic system. Figure 3 shows the sensor schematic diagrams. The sensor forms two legs of a bridge circuit. One leg is a coil; the other is a temperature-compensating resistor. Alternating current flowing through the sensor coil produces a magnetic field around the sensing surface. When a ferromagnetic target is brought near the sensing surface, the magnetic field is intensified, which produces an impedance change across the coil.

Regulated direct current is converted to alternating current by an oscillator and applied across the bridge. When the target is within the actuation range of the sensor, the impedance change unbalances the bridge circuit. The resulting signal is demodulated and compared with a reference voltage. When the signal exceeds the reference, it triggers a flip-flop circuit to change its state. The output of the flip-flop is amplified by a driver stage and applied as a gate voltage to a high current transistor switch.

TESTING AND FAULT ISOLATION

NOTE: ELDEC approved technical data and its referenced test equipment can be used as an alternative to the Testing and Fault Isolation procedures in this section. Only the latest released revision of this data shall be used.

1. General

This section gives the instructions needed to test ELDEC sensors. Sensors are tested in the repair shop with special ELDEC test equipment. Sensors that fail on-aircraft tests must be tested again in the repair shop before they are removed from service. Replace the sensor if it fails the required repair shop tests.

A. Related Publications

(1) ELDEC ATA 32-60-04 – ELDEC Sensor Test System (PN 38-841-01)

(2) ELDEC document 011-2920-603 – Sensor Test Gauge Kit (PN 8-758-01)

B. Test Procedures

There are two methods to test sensors. Method 1 is a return-to-service test that is done on a test bench and uses special ELDEC test equipment. Method 2 uses a commercially available L/C/R meter. This test method is useful on the aircraft as a confidence test. Hi-Pot tests are required to find internal component deterioration.

C. Required Test Equipment

Table 2 shows a list of test equipment needed to test the proximity sensors.

NOTE: Equipment with equivalent specifications can be used.

Required Test Equipment (Continued)

NOMENCLATURE	MODEL/PN	MFR/VENDOR
Test Method 2		
Sensor Test Gauge Kit (Preferred)	8-758-01	ELDEC Corporation 16700 13th Ave W. Lynnwood, WA 98046-9727 (V08748)
L/C/R Meter	878 or 848	BK Precision Maxtec International Corp. 6470 Cortland St. Chicago, IL 60635-4011 (V0CE78)

D. ELDEC Test Equipment

The Proximity Switch Card, PN 8-060-02CP (see Table 2), has the electronic circuits required to energize a sensor and monitor operation. A lamp is used to show sensor conditions target near and target far. Jacks are used to connect the sensor and 28 V dc operating power.

The Test Stand, PN 3-445-16 (Figure 3) has a target mounted on a movable slide. Slide travel is measured by a dial gauge on the Test Stand. The difference in distance between target on the sensor face (target near) and target far sensor conditions must fall within a go/no-go range.

1-899\XXT0011.TIF

Figure 3
Test Stand 3-455-16

E. Hi-Pot Test

WARNING: Hi-POT VOLTAGES CAN BE LETHAL. BE CAREFUL.

CAUTION: ALTHOUGH HI-POT TESTS ARE POTENTIALLY DESTRUCTIVE, THIS TEST IS REQUIRED TO IDENTIFY INTERNALLY DAMAGED UNITS. MARGINAL OR INTERMITTENT UNITS CAN ESCAPE DETECTION IF NOT TESTED.

CAUTION: DO NOT TEST SENSOR PN 1-899-28 WITH HI-POT. THIS SENSOR HAS AN INTERNAL HARD-WIRED GROUND (SEE FIGURE 4).

NOTE: Units are tested at the maximum specified Hi-Pot during production. Hi-Pot tests gradually degrade the UUT insulation. Reduced voltages are used during return-to-service tests to minimize damage.

(1) Slowly apply 500 V ac, 60 Hz between the yellow lead and case. Keep the voltage on for at least 60 seconds.

(2) If current leakage is greater than 1.0 milliamp during test, the sensor is faulty. If electrical breakdown is heard or seen, the sensor is faulty. Replace any faulty sensor.

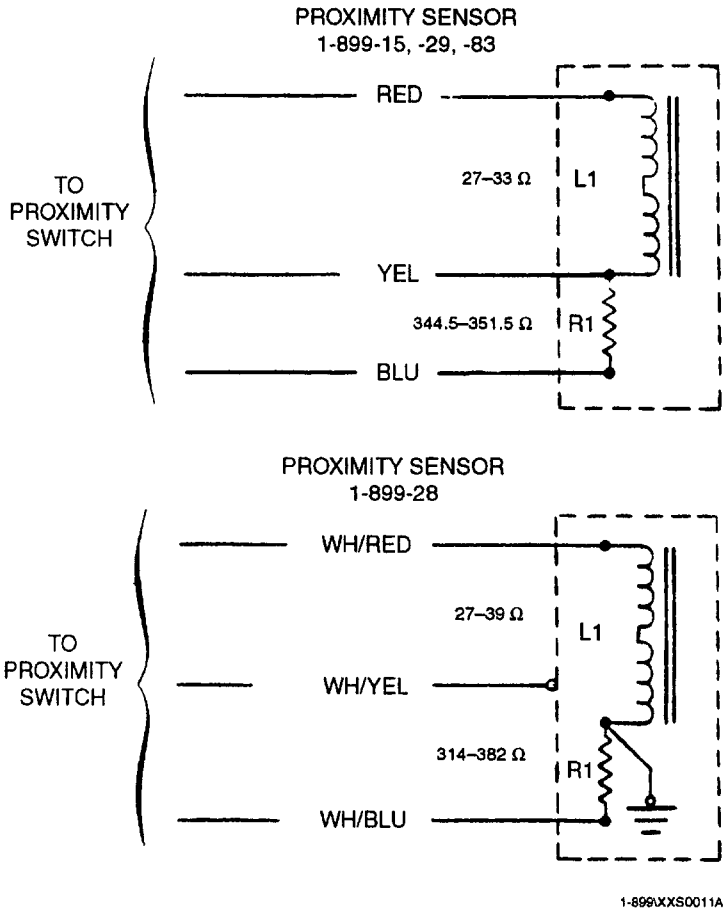

Figure 4
Proximity Sensor Schematics

F. Functional Test – Method 1

Figure 5 shows the test equipment setup to functionally test the sensor for return-to-service.

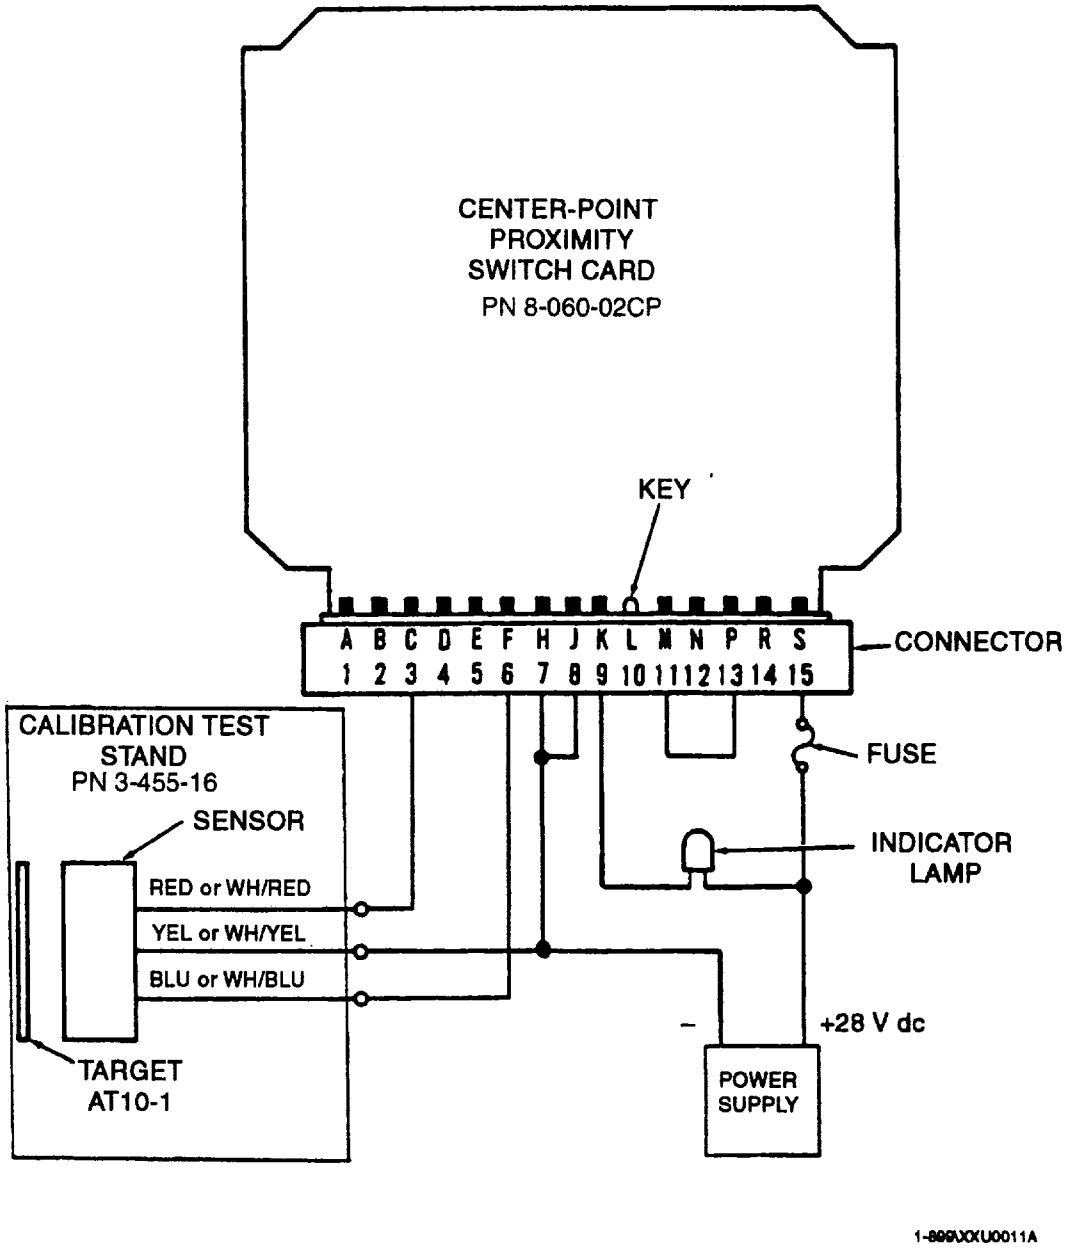

Figure 5
Test Setup, Functional Test – Method 1

CAUTION: DO NOT INSERT OR REMOVE SWITCH CARD FROM CONNECTOR WITH POWER ON. SENSOR MAY BE CONNECTED OR DISCONNECTED WITH POWER ON.

(1) Connect the equipment as shown in Figure 5.

(2) Energize the power supply and adjust output to 28 ± 1 V dc.

(3) Adjust the test stand target position to contact the sensor face.

(4) Adjust the test stand dial indicator to zero.

(5) Make sure the indicator lamp is on.

(6) Adjust the stand to move the target away from sensor.

(7) Record the dial scale indication when the indicator lamp goes off.

(8) Adjust the target toward sensor until the indicator lamp turns on. The dial scale indication must be as shown in Table 3.

(9) Subtract the adjusted dial scale indication in step (8) from the recorded value in step (7). The result must be within the limits shown in Table 3.

Table 3
Functional Test Limits – Method 1

SENSOR	DIAL SCALE INDICATION IN STEP (8)	VALUE OF STEP (8) MINUS STEP (7) MUST BE . . .
1-899-15, -29, -83	0.300 ± 0.015	0.010 to 0.030 inch
1-899-28	0.228 ± 0.010	0.005 to 0.015 inch

(10) If the sensor under test fails any test step, do Paragraph H., Fault Isolation.

G. Functional Test – Method 2

This method uses an L/C/R meter (see Table 2) to check the health of a sensor. Figure 6 shows the Test Method 2 test equipment setup.

NOTE: The sensor to be tested may have specific aircraft interface cables or connectors. A suitable adapter cable to connect the red and blue wires may be required.

(1) On the L/C/R meter, push the POWER button to turn the meter on.

(2) Push the 1 kHz/120 kHz button to select the 1 kHz meter excitation frequency.

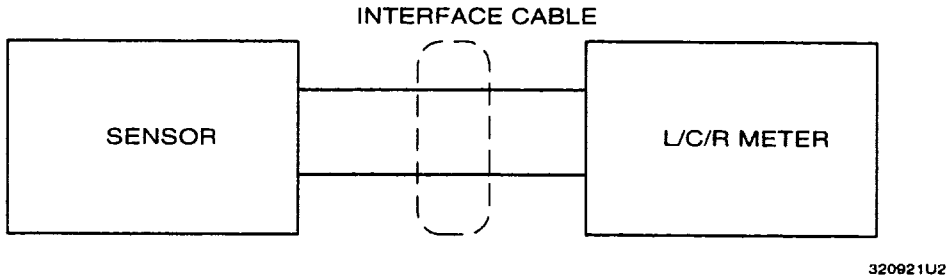

Figure 6
Test Setup, Functional Test – Method 2

(3) Push the L/C/R button to select the H (Henries) measurement mode.

(4) Connect the meter to the red (wht/red) and yellow (wht/yellow) sensor leads of the sensor to be tested.

(5) The meter will show the series inductance of the sensor and associated wires. Write down this value as Target Far. See Table 4 for correct sensor values.

(6) Place the appropriate test gauge from Sensor Test Gauge Kit 8-758-01 directly on the face of the sensor.

(7) The meter will show the series inductance of the sensor and associated wires. Write down this value as Target Near. See Table 4 for correct sensor coil values.

(8) Measure the series resistance of the sensor coil with the instructions below.

(a) Push the L/C/R mode switch to set the L/C/R meter in R (resistance mode).

(b) Push the L/C/R meter DATA HOLD button once.

(c) Push and hold the L/C/R meter D/Q button until the meter changes to the series mode (Ser appears in the upper right corner of the display).

(d) Write down this value. See Table 4 for correct sensor coil resistance values.

(9) Measure the resistance of the fixed resistor with the instructions below.

(a) Connect the meter to the blue (white/blue) and yellow (white/yellow) leads of the sensor under test.

(b) Push the L/C/R mode switch to set the L/C/R meter in R (resistance mode).

(c) Push the L/C/R meter DATA HOLD button once.

(d) Push and hold the L/C/R meter D/Q button until the meter changes to the series mode (Ser appears in the upper right corner of the display).

(e) Write down this value. See Table 4 for correct fixed resistor values.

(10) To check another sensor, push the L/C/R meter DATA HOLD button once, then push the L/C/R button until the desired measurement mode is displayed.

(11) If the sensor under test fails any test step, do Fault Isolation, paragraph H.

Table 4
Functional Test Limits – Method 2

NOMINAL VALUE		SENSOR CONDITION
36.20 mH		Target FAR
38.20 mH		Target NEAR
27–33 Ω	(1-899-15, -29, -83 coil)	Target FAR
27–39 Ω	(1-899-28 coil)	Target FAR
344.5–351.5 Ω	(1-899-15, -29, -83 resistor)	–
314–382 Ω	(1-899-28 resistor)	–

H. Fault Isolation

If Functional Test – Method 1 shows a faulty sensor, degauss the sensor and retest. Make sure that the switch card is correct and in calibration. Make sure the card is operative. Detailed fault isolation is not given because the sensors are not repairable.

Replace any sensor that fails Functional Test – Method 1 or Functional Test – Method 2.

DISASSEMBLY

1. General

Disassembly is not applicable. The proximity sensor is a sealed unit and cannot be disassembled.

CLEANING

1. General

WARNING: VENTILATE WORK AREA WHEN USING SOLVENT. AVOID CONTACT WITH SKIN. WEAR RUBBER GLOVES. OBSERVE ALL SAFETY AND FIRE REGULATIONS.

Clean dirt, oil, or grease from sensor with a commercial degreaser such as Degreasol F99 (Kleer-Flo Company).

CHECK

1. General

Inspect the proximity sensor for damage, wear, corrosion, broken leads, or cracked face surface.

REPAIR

1. General

The proximity sensor is a sealed unit. Replace the sensor if it is defective.

ASSEMBLY

1. General

Assembly is not applicable since the proximity sensor cannot be disassembled. Package the sensor in a polyethylene bag. Seal in a commercial carton and store in a cool, dry place.

FITS AND CLEARANCES

1. General

Special fits and clearances are not required.

SPECIAL TOOLS, FIXTURES, AND EQUIPMENT

1. General

See Table 5 for special tools, fixtures, and equipment. Equivalent replacements can be used for listed items.

Table 5
Special Tools, Fixtures, and Equipment

1. INTRODUCTION

A. Description

EDC Proximity Switch Model 899 is an all solid-state system that changes state (switches) when a movable metal target comes within a particular distance of the fixed sensor. The proximity switch performs the same function as a mechanical switch but without physical contact (no moving parts to bend, break, or wear out). EDC switches can be either normally open or normally closed (selected by jumpers at the switch card connector), and they may be connected in parallel or in series (up to six).

B. Operation

Figure 1 illustrates the elements of the basic system. The sensor (located remotely from the switch card) appears as an inductance to the switch card. A change of inductance, caused by the proximity of a metal target, is sensed by the switch card. The switch card then completes (or, in the case of a normally closed switch, interrupts) the circuit to an external load. For specific test actuation distances and other leading particulars of the system, see Figure 2.

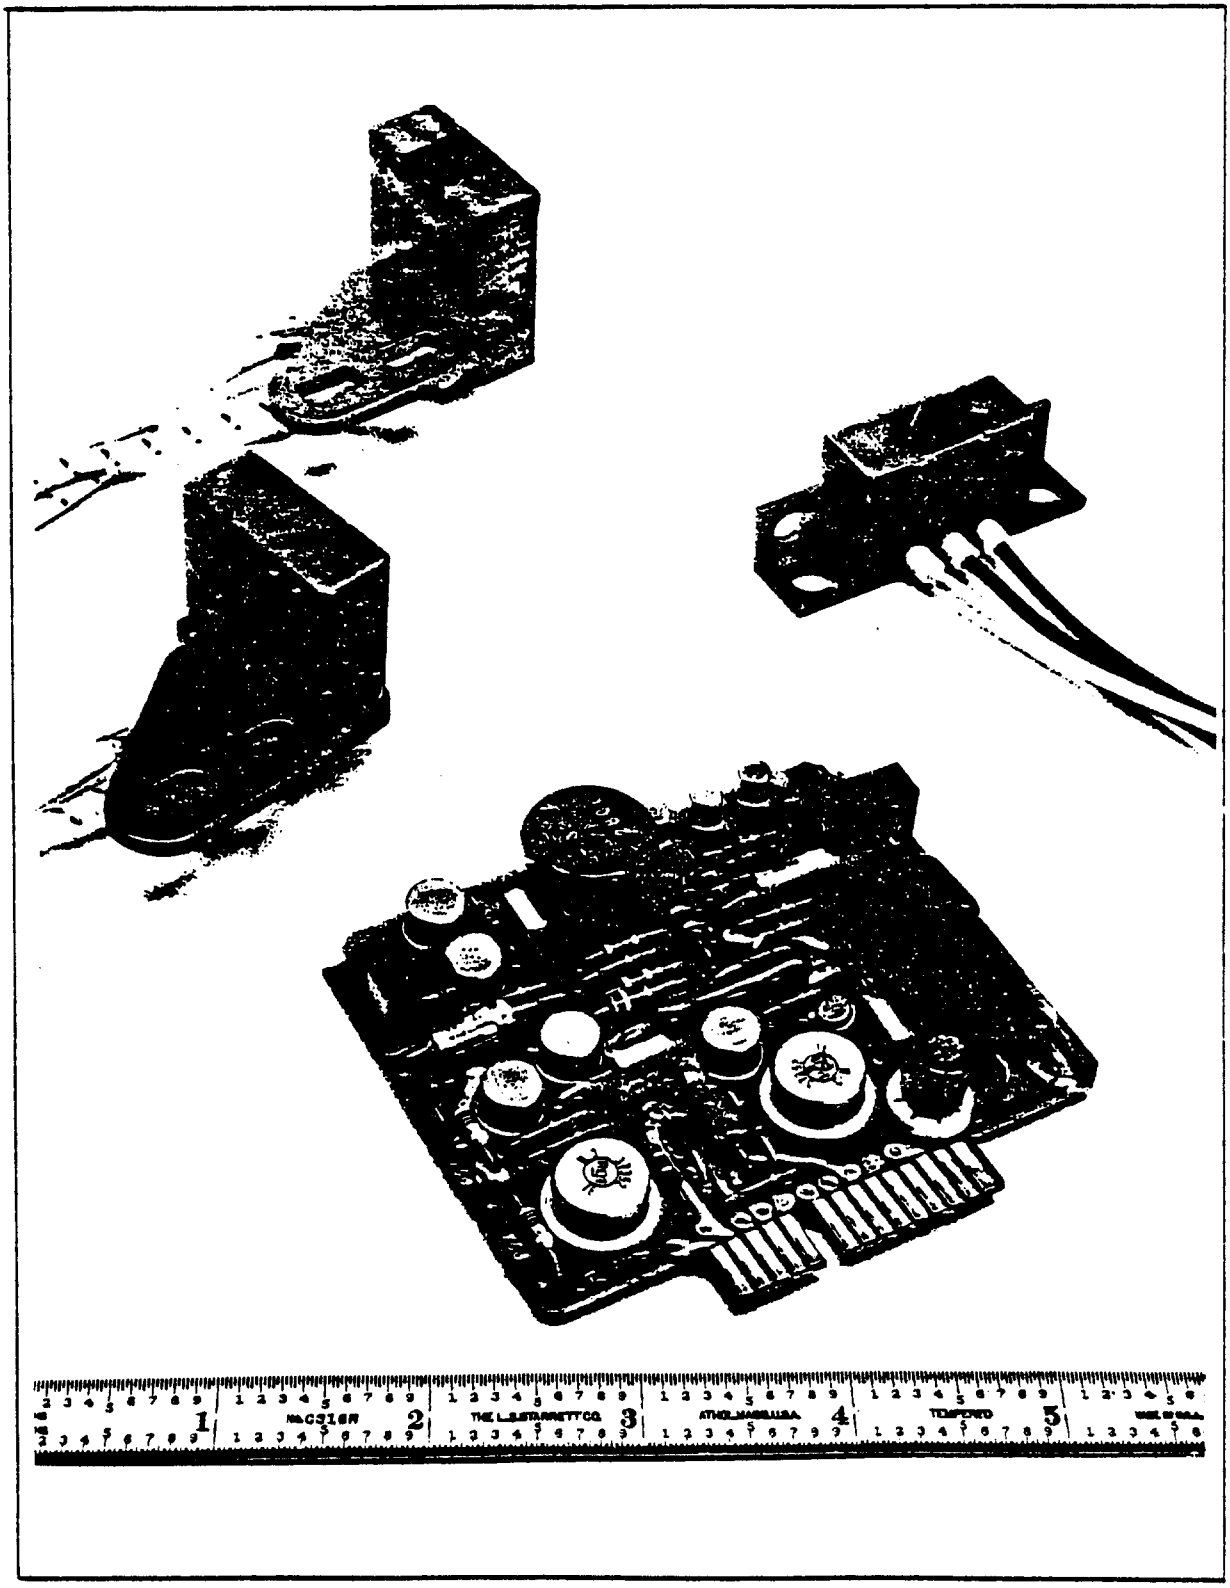
TABLE OF LEADING PARTICULARS

FIGURE 2

1. INTRODUCTION (Cont.)

C. Interchangeability



For a given card/sensor system (e.g., 2-899-111/1-899-15) any -111 card will operate with any -15 sensor. A particular pair will have a specific actuation point, but the actuation point of any pair will fall within the test limits specified in Figure 2.

D. Failsafe

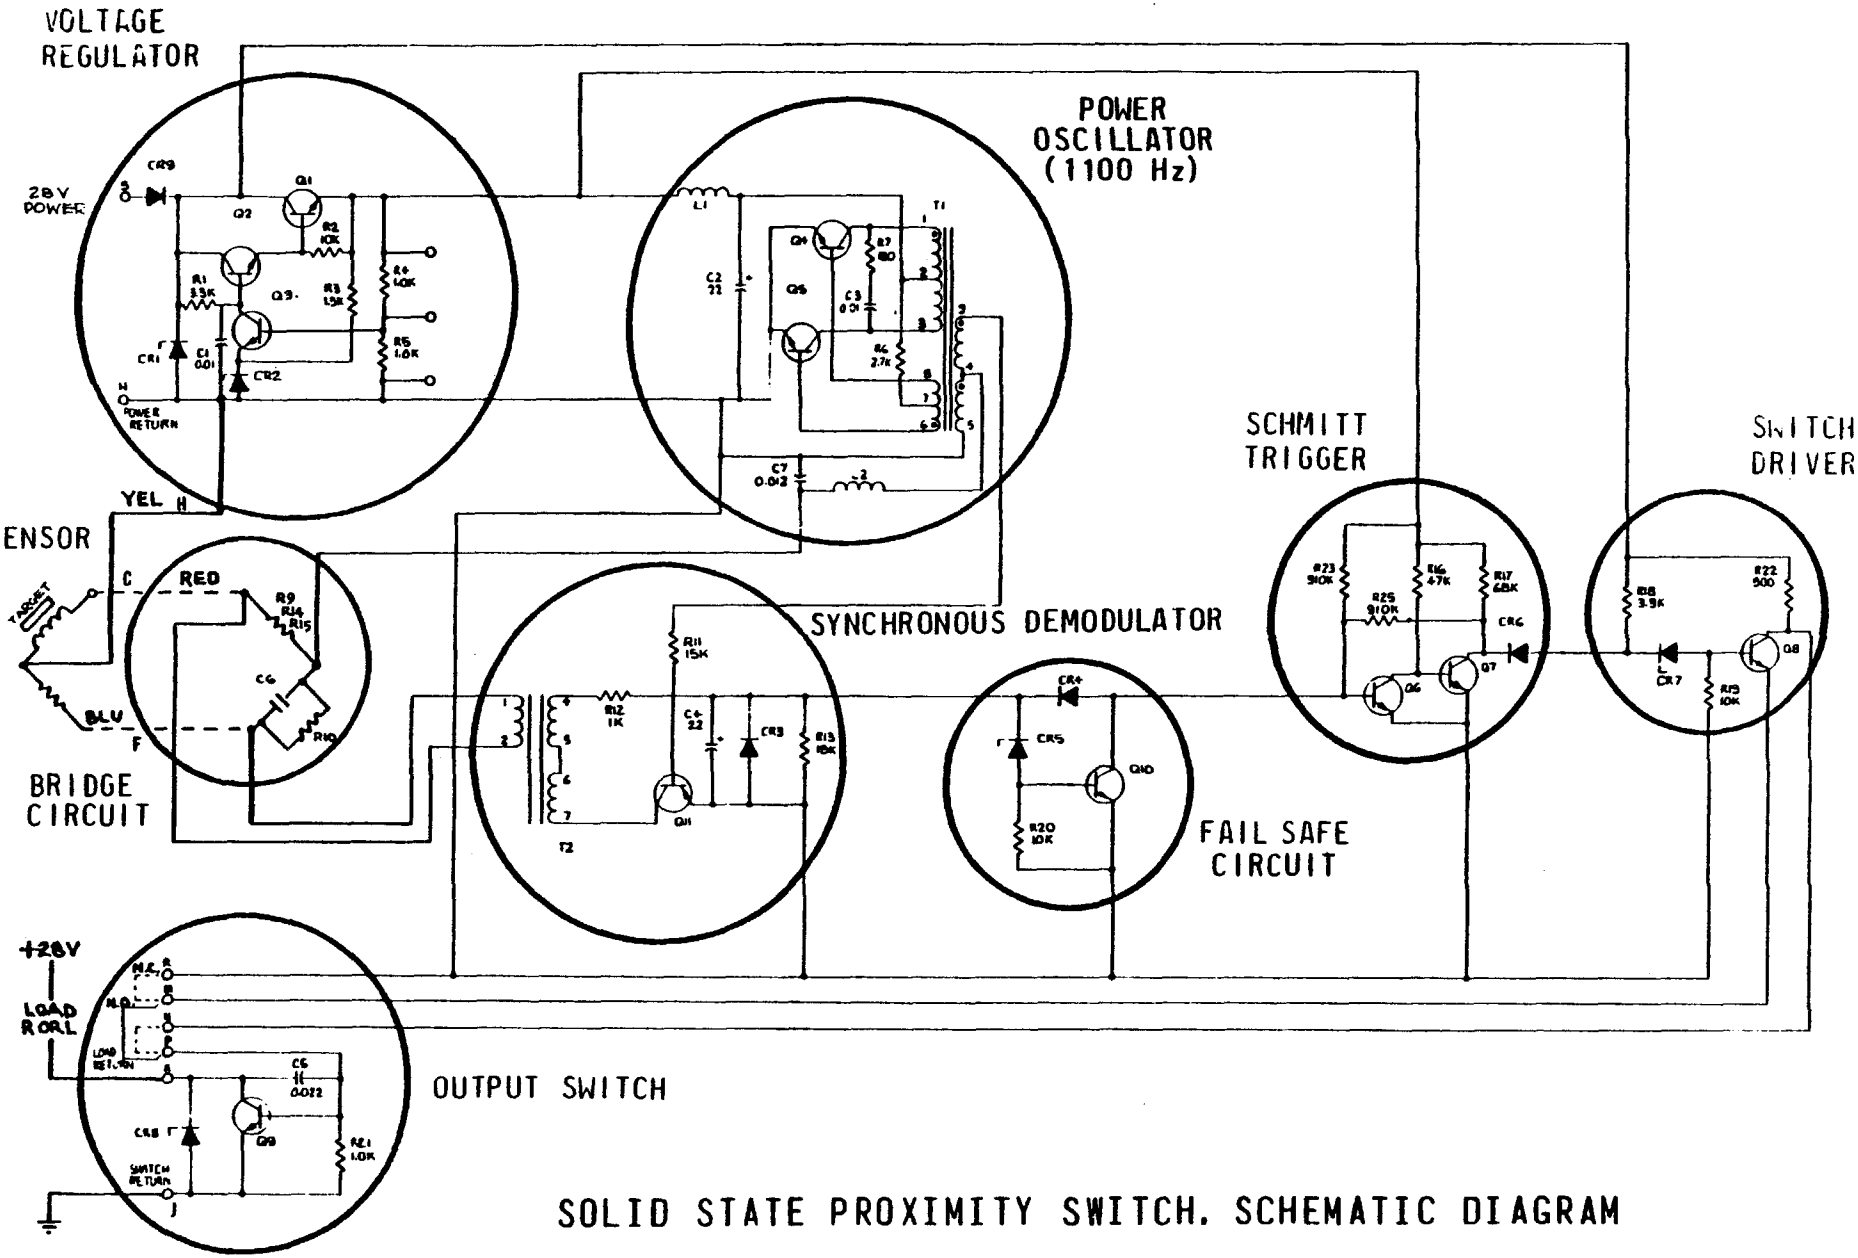
The proximity switch was designed so that open or shorted sensor leads will inhibit the actuation of the switch, regardless of the position of the target. Loss of power will cause the output switch to fail open.

E. Illustration

Figure 3 portrays the actual physical construction of the basic elements of the system.

Proximity Switch Model 899
Figure 3

2. THEORY OF OPERATION



A schematic of the proximity switch, divided into sections, is shown in Figure 4. The sections relate to the following discussion.

(a) Voltage Regulator

The voltage regulator portion of the circuit provides the necessary stable voltage, free of large transient variations, to the other switch circuitry. Diodes CR1 and CR9 provide input protection to the regulator. CR9 protects against a reverse voltage connection while CR1 is a high voltage transient protecting zener. The error voltage amplifier Q3 senses the difference between the output voltage divider (R4, R5) and reference diode CR2. Q3 delivers an error signal to Q2 which provides the current gain necessary to drive series regulator Q1. Fine adjustment of the output voltage is made by placing trimming resistors in parallel with R4 or R5 as required. The combination of L1 and C2 prevents large current spikes from being impressed on the DC line by the oscillator circuit.

(b) Power Oscillator (1100 Hz)

Sensor excitation is provided by a single-transformer

SOLID STATE PROXIMITY SWITCH. SCHEMATIC DIAGRAM

FIGURE 4

2. THEORY OF OPERATION (Cont.)

(b) Power Oscillator (1100 Hz) (Cont.)

Royer oscillator including Q4, Q5, T1 and associated parts. Transistors Q4 and Q5 switch the supply current in opposite directions through the primary winding 1-2-3 of T1. Secondary winding 6-7-8 provides feedback to the bases of switching transistors Q4 and Q5. Secondary winding 4-5-9 provides the drive to the sensor and synchronous detector. The bridge circuit is fed through the waveshaping filter L2, C7 which removes many of the high frequency components from the transformer output.

(c) Bridge Circuit

The bridge circuit includes internally arm R9, R15, R14, and arm R10, C6. The other two arms of the bridge are located remotely in the sensor. The red and blue leads which are attached to the sensor, are also connected to the primary side of transformer T2. An unbalance of the bridge circuit is reflected as a change in voltage between the red and blue leads.

(d) Synchronous Demodulator

The use of T2 as a balanced input to the synchronous

2. THEORY OF OPERATION (Cont.)

(d) Synchronous Demodulator (Cont.)

demodulator greatly increases the common mode rejection of unwanted signals on the sensor lines. The demodulator (Q11, C4, CR3, R12, and R13) samples the bridge unbalance every half cycle of the sensor excitation. The drive signal for the demodulator is taken off a secondary tap on T1 through R11. Capacitor C4 is charged every half cycle by the bridge output signal, but is charged and discharged randomly by any non-synchronous noise. C4 is protected from reverse voltages by diode CR3. The voltage level developed across R13 is sensed through isolation diode CR4. CR4 becomes back-biased when the threshold of the Schmitt Trigger circuit is exceeded, thus the demodulator is isolated from loading effects of the Schmitt Trigger.

(e) Failsafe Circuit

A failsafe circuit is included and is made up of CR5, R20, and Q10. In the event of a failure resulting in a high voltage across R13, CR5 conducts and turns on Q10, which in turn clamps off the Schmitt Trigger.

(f) Schmitt Trigger and Switch Driver

The Schmitt Trigger operates as a high gain feedback

2. THEORY OF OPERATION (Cont.)

(f) Schmitt Trigger and Switch Driver (Cont.)

amplifier circuit with the bias point set by biasing resistor R23 and feedback resistor R25. Exceeding the threshold of the circuit causes Q6 to saturate, which turns off Q7. The Schmitt Trigger is isolated from the switch driver by diode CR6. R18, R19, and CR7 are biasing components for drive transistor Q8.

(g) Output Switch

The output switch Q9, R21, C5, and CR8 is externally jumpered for normally open or normally closed operation. With the connector wired for normally open operation, emitter current of Q8 will provide base drive for Q9.

In the normally closed condition, Q9 is driven through R22. The zener CR8 across Q9 protects against transients. Capacitor C5 is for EMI suppression.

3. DISASSEMBLY

CAUTION: POWER TO THE PROXIMITY SWITCH SYSTEM MUST BE OFF BEFORE REMOVAL OF SWITCH CARD FROM SYSTEM. FAILURE TO DO SO MAY RESULT IN DAMAGE TO UNIT.

A. Sensor

The sensor is a nonrepairable unit and cannot be disassembled.

B. Switch, Component Removal

The switch is disassembled only to the extent necessary to remove defective components. (Component identification is shown in Figure 12.)

(1) Remove plastic coating only from circuit pads requiring replacement.
(2) Touch pad area lightly with soldering iron to remove coating.

CAUTION: USE HEATSINK ATTACHMENT WHEN APPLYING SOLDERING HEAT TO DIODES. USE MINIMUM HEAT REQUIRED TO REMOVE PARTS.

(3) Unsolder part leads from pad.
(4) Apply side pressure to loosen part from circuit board.

4. CLEANING

A. See Figure 5 for required cleaning materials.

CLEANING MATERIAL	SPECIFICATION
Solvent	Stoddard, Commercial
Brush	Small size with soft, nonmetallic bristles

Materials Required for Cleaning Switch

Figure 5

B. Clean printed circuit board with vacuum cleaner (preferred method) or low-pressure compressed air (optional method). Use the small brush to dislodge foreign particles from crevices and surfaces. Dip brush in solvent and wash parts as necessary to remove oily film. Dry with low-pressure compressed air.

WARNING: VENTILATE WORK AREA THOROUGHLY WHEN USING SOLVENT. AVOID CONTACT OF SOLVENT WITH SKIN. OBSERVE ALL SAFETY AND FIRE PRECAUTIONS.

5. INSPECTION

A. Sensor

Inspect sensor for damage, wear, corrosion, and deterioration.

B. Switch Card

Inspect switch card for damage from overheating, cracks, distortion, oxidation, deterioration, displacement, loose mounting, broken leads, and unacceptable solder connections.

NOTE: Switch cards are coated with a conformal coating. Dark brown color of the coating on transistor Q1 and Resistor R22 is acceptable and not cause for rejection.

6. REPAIR

A. Sensor

The sensor is not repairable.

B. Switch Card

The switch card may be repaired by replacement of defective

B. Switch Card (Cont.)

components and/or restoration of damaged solder connections. Defective components are detected by inspection (Section 5) or trouble shooting (Section 10). Remove switch components per Section 3 and install per Section 7.

7. ASSEMBLY

A. Sensor

The sensor cannot be disassembled or assembled.

B. Switch

(1) See Figure 6 for required material.

NAME	SPECIFICATION
Urelane 8267	Furane Plastics, Los Angeles, California
Toluene	Commercially Available

Materials Required for Reassembly

Figure 6

B. Switch (Cont.)

(2) Clean pad areas from which components have been removed. Use toluene.

NOTE: Avoid contamination of gold-plated areas of circuit board.

(3) Install new component using standard commercial practices.

CAUTION: USE HEATSINK ATTACHMENT WHEN APPLYING SOLDERING HEAT TO DIODES. USE MINIMUM HEAT REQUIRED TO SOLDER PARTS.

(4) Dry in oven at 50°C to 60°C for 20 minutes.

(5) Brush coating on uncoated area and air-cure for 30 - 40 minutes. Dry in oven at 50° to 60°C for 2 hours.

8. FITS AND CLEARANCES

No special fits or clearances are required.

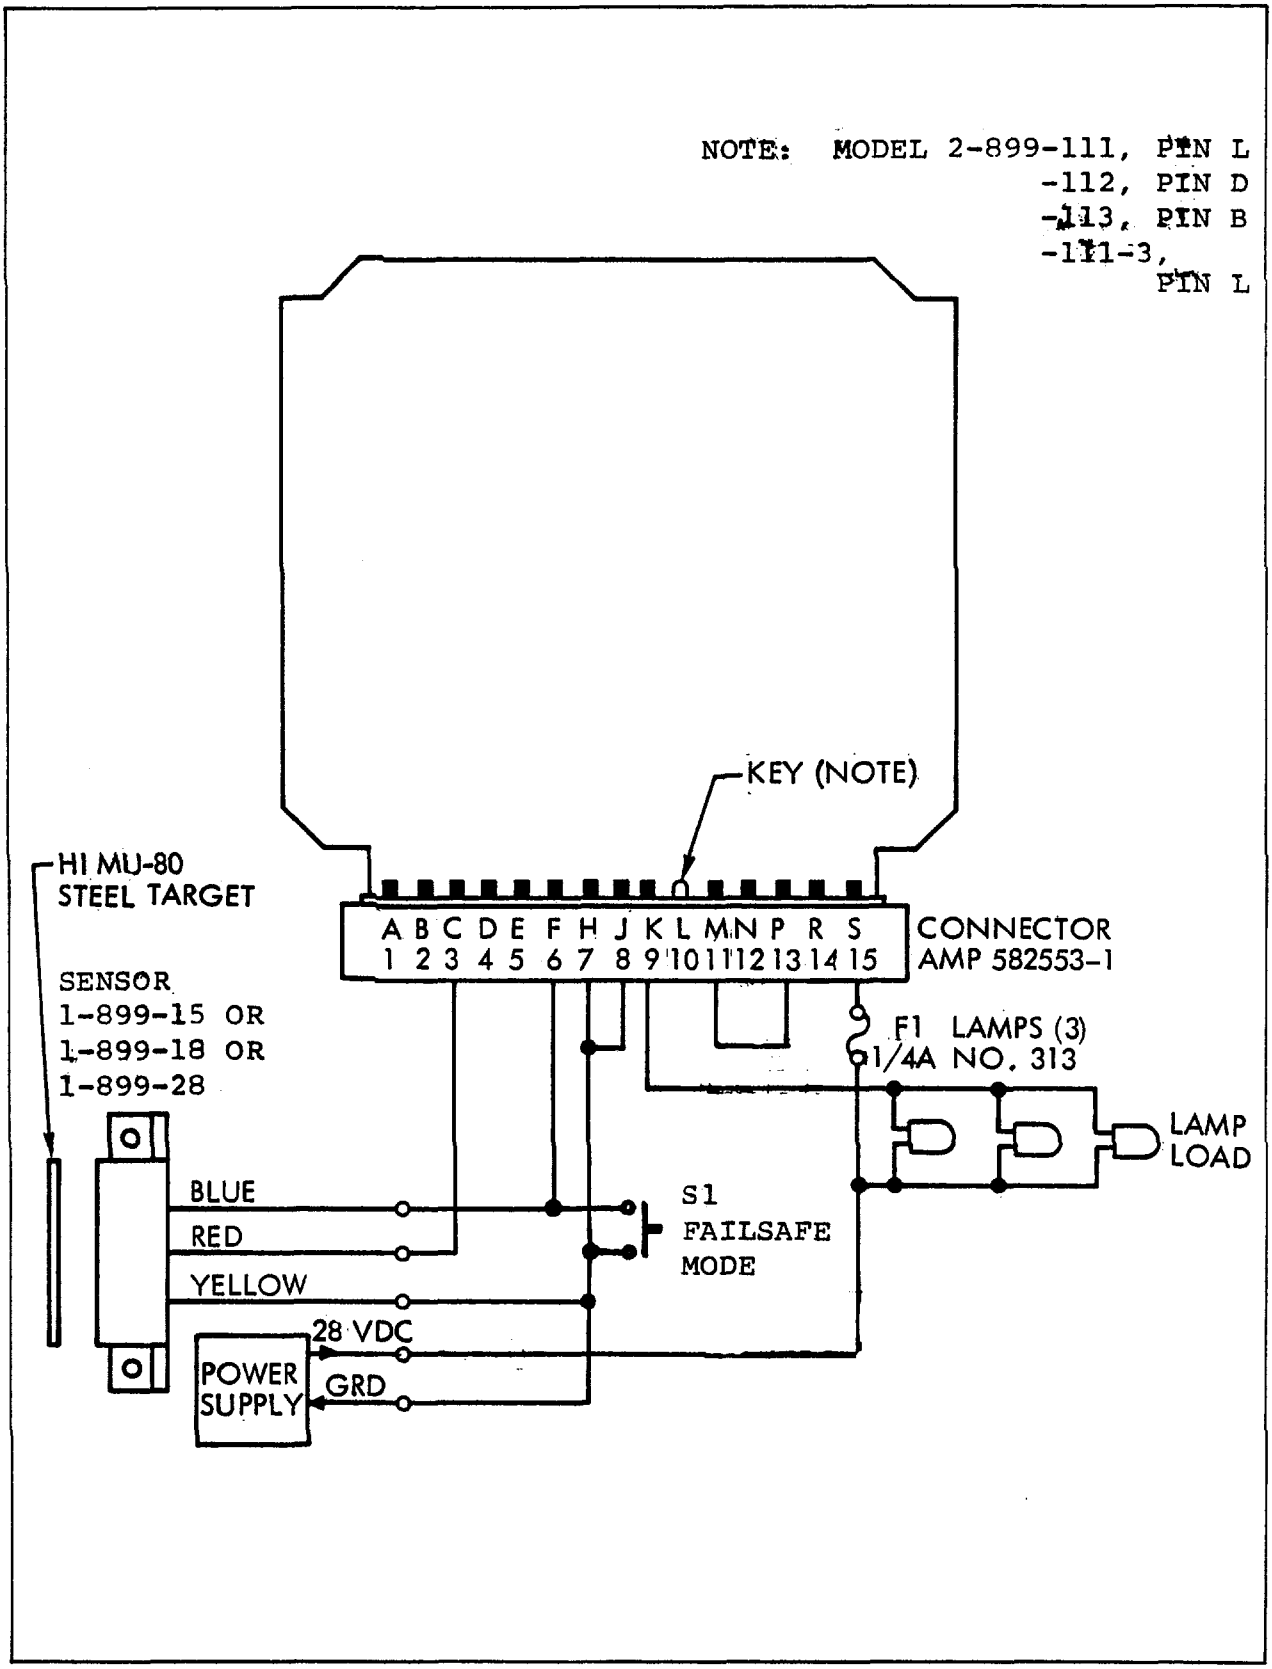
9. TESTING

A. Test Setup

This section covers testing of the sensor and switch.

A. Test Setup (Cont.)

Figure 7 shows a test setup.



B. Test Equipment

(1) Test set, EDC P/N 8-005-01 (see Appendix), or equivalent (see Figure 7).
(2) Test gage, select the proper test gage from Figure 2.
(3) Actuator Test Target Assembly, EDC P/N 8-005101-02 or equivalent (see Figure 10).

C. Testing Sensors 1-899-15, 1-899-18 and 1-899-28.

CAUTION: DO NOT INSERT OR REMOVE SWITCH CARD FROM CONNECTOR WITH POWER ON. COMPONENT SIDE OF THE SWITCH CARD MUST BE AS NOTED ON THE TEST SET. SENSORS MAY BE CONNECTED OR DISCONNECTED WITH POWER ON.

(1) Insert a known good 2-899-xxx (see Figure 2 for the correct part number) switch card in the connector on the test set.
(2) Plug the line card into 115 VAC 60 to 400 Hz or connect 28 ± 1 VDC to the jacks on the test set.
(3) Insert the sensor to be tested in the mounting clips on the test set (-15 only) or place on non-magnetic surface.
(4) Connect the blue, red and yellow sensor to the binding posts marked BLU, RED and YEL respectively.

TEST SET-UP
FIGURE 7

C. Testing Sensors 1-899-15, 1-899-18 and 1-899-28 (Cont.)

(5) Switch ON/OFF power switch to the applicable ON position. Indicator light should be "OFF".

(6) Select the correct test gage from Figure 2. Place test gage on the sensor with the "ON" side down. Indicator light should go "ON".

(7) Place test gage on the sensor with the "OFF" side down. The indicator shall be "OFF".

D. Testing Switch, All Models

(1) Insert the switch card to be tested in the connector on the test set.

(2) Select a known good sensor, 1-899-xxx, (see Figure 2 for the correct part number).
Connect the blue, red and yellow sensor leads to the binding posts marked BLU, RED and YEL respectively.

(3) Apply power to the test set by means of the line card provided, 110 VAC 60 to 400 Hz, or connect 28 ± 1 VDC to the jacks on the test set.

(4) Switch ON/OFF power switch to the applicable ON position. Indicator light should be "OFF".

(5) Select the correct test gage from Figure 2. Place test gage on the sensor with the "ON" side down. Indicator light should go "ON".

(6) Place test gage on the sensor with the "OFF" side down. The indicator shall be "OFF".

D. Testing Switch, All Models (Cont.)

NOTE: Remove Test Gage.

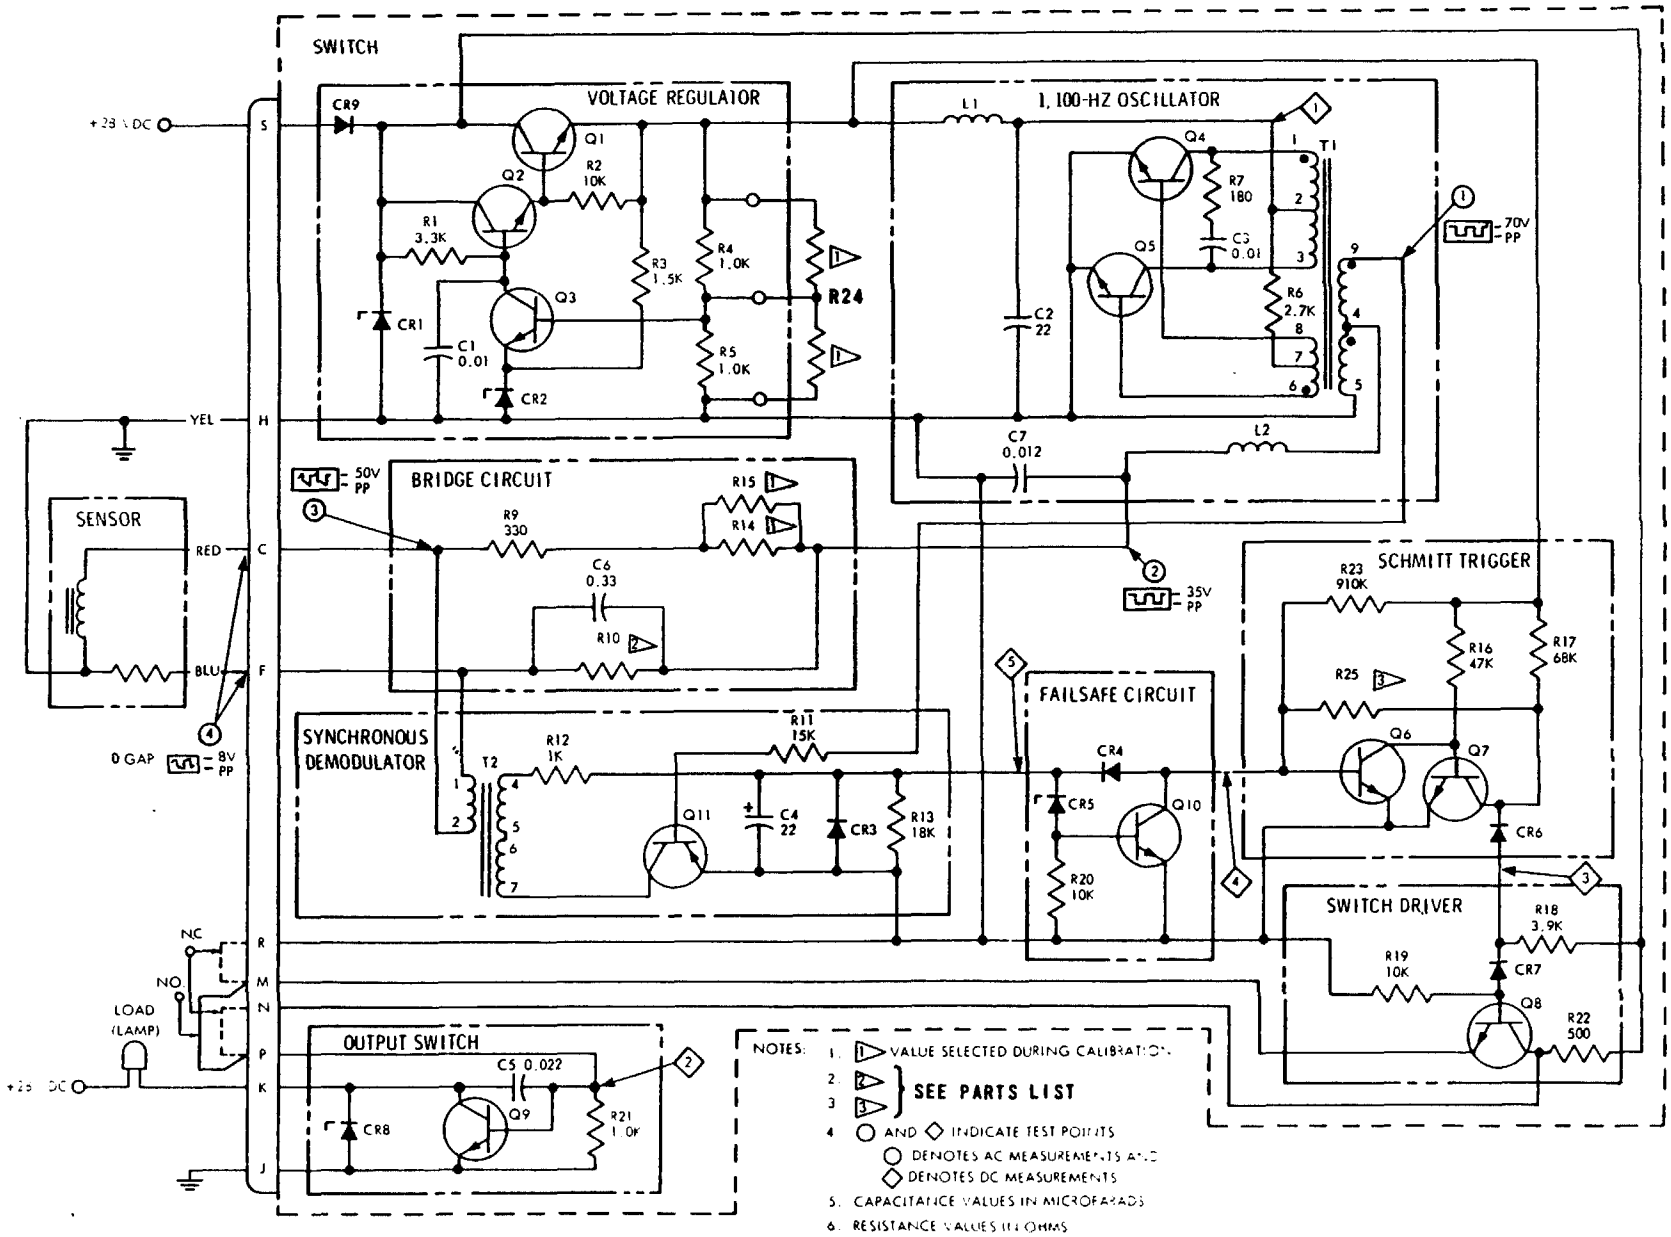
(7) Press FAILSAFE MODE push button. Indicator light should go "OFF". A brief blink of the indicator light is acceptable.

(8) Place the actuator test target (EDC P/N 8-005101-02) against sensitive face of sensor (zero gap). The light should be on.

NOTE: If switch fails this test, analyze in accordance with procedures in Section 10.

10. TROUBLE SHOOTING

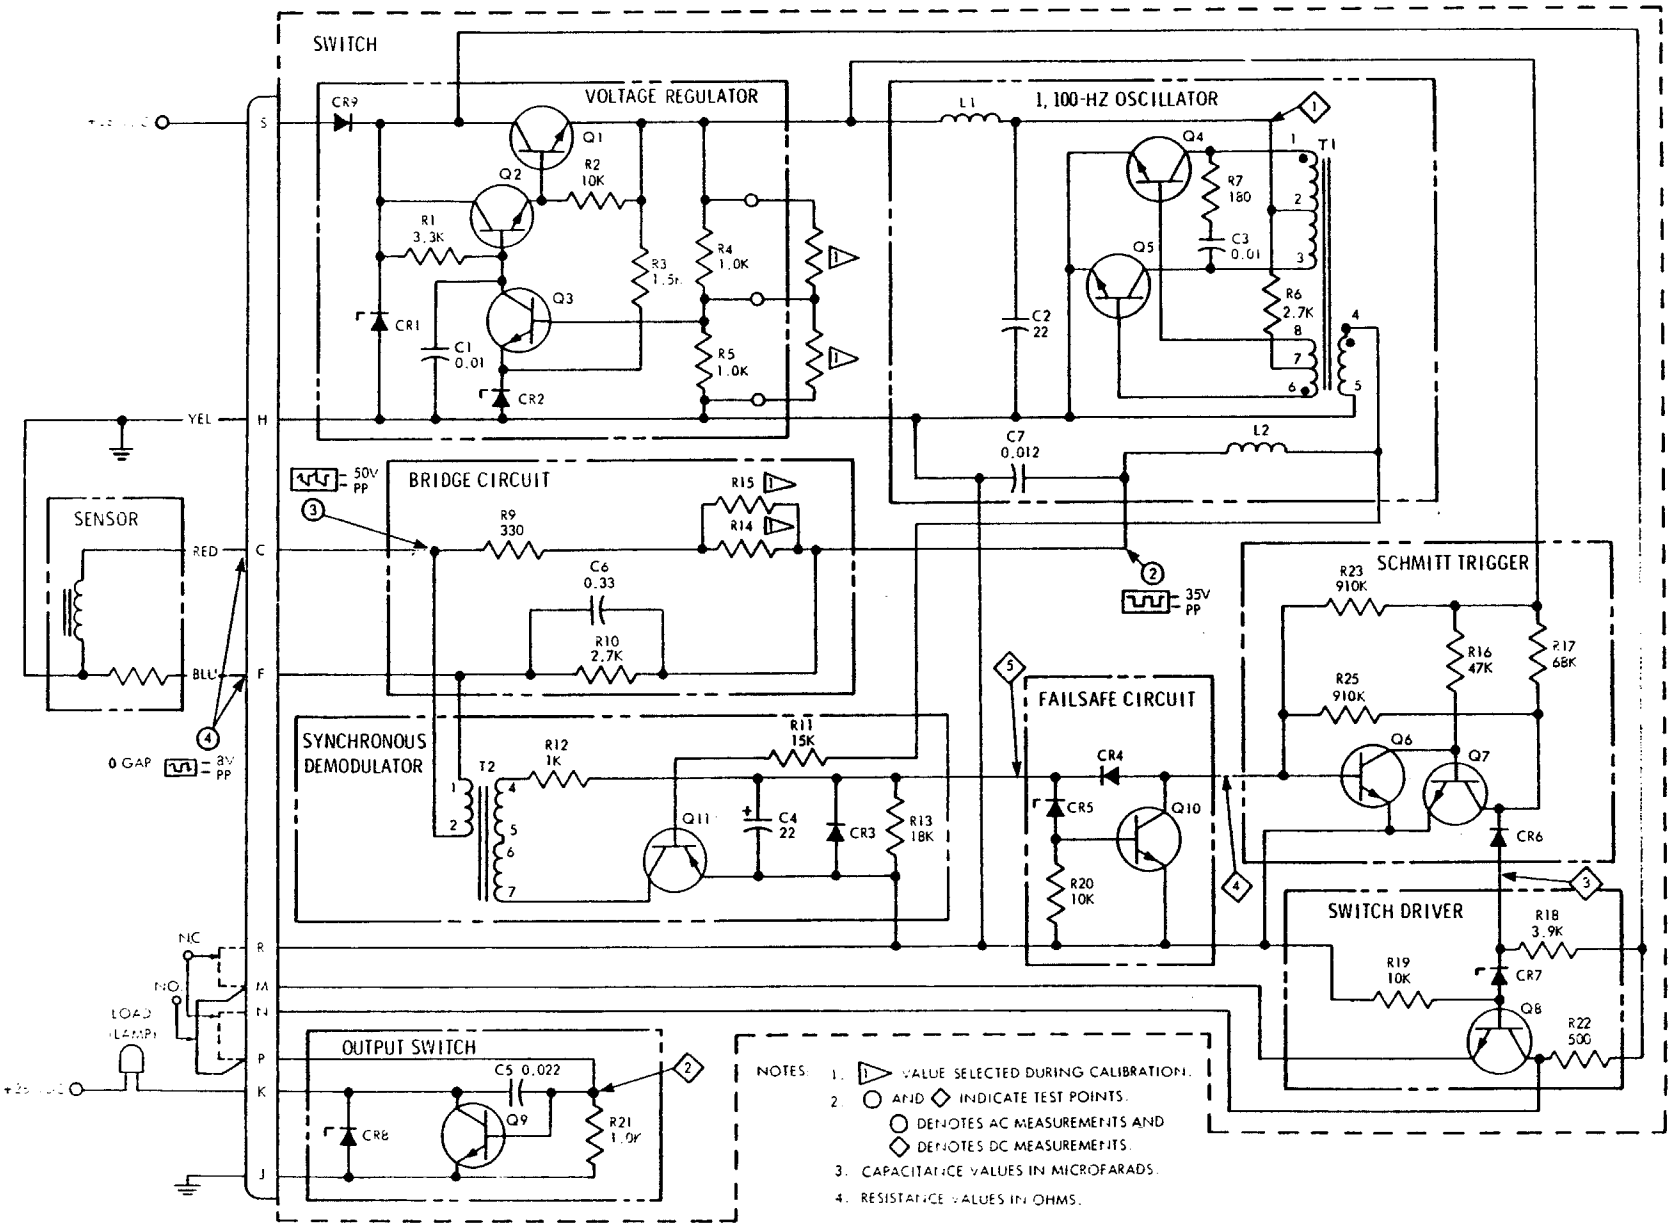
A. General



(1) Test Equipment

(a) DC differential voltmeter, John Fluke Model 801 or equivalent.

(b) Oscilloscope, Tektronix type 503 or equivalent.

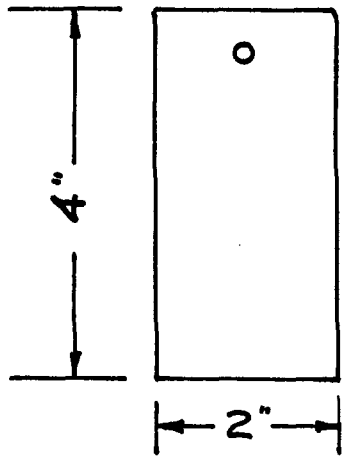


(c) Actuator test target, EDC P/N 8-005101-02 or equivalent (see Figure 10).

(2) Switch troubles can be analyzed and isolated by standard procedures. This section describes the switch circuit in detail. Figures 8 and 9 provide functional block system schematics with waveform and test point data.

Proximity Switch (2-899-111, Serial No. 401 and On, 2-899-111-3, 2-899-112, and 2-899-113) Schematic Diagram

Figure 8



Proximity Switch (2-899-111, Serial No. 1 Through 400 Only), Schematic Diagram

Figure 9

A. General (Cont.)

Actuator/Deactuator Test Target Assembly

P/N 8-005101-01 consists of (1) 8-005101-02 and (1) 8-005101-03

1. 8-005101-02 (Actuator) is made from stainless steel type 430, cold rolled strip, No. 2 bright annealed finish. Thickness = 0.023 ± 0.003 inches.
2. 8-005101-03 (Deactuator) is made from 6061-T6 aluminum per QQ-A-327, and black anodized per MIL-A-8625 after fabrication. Thickness = 0.040 ± 0.003 inches.

FIGURE 10

NOTE: The Deactuator Test Target (8-005101-03) is used to deactuate an 899 switch when a target is within the actuate range. When the test target is inserted between a target and a sensor, the switch should always deactuate.

The term "actuates" denotes a particular change of state in the switch, and should not be confused with closed or open. The switch card circuitry always "actuates" when a target moves through the specified actuation point and is moving toward the sensor. Conversely, the switch "deactuates" when the target is moved away from the sensor. If the switch is jumpered for normally open operation, it will close when the card "actuates". If the switch is jumpered for normally closed operation, it will open when the card "actuates".

B. Switch 2-899-111 Circuit Description (See Figures 8 and 9)

Refer to Section 2 for theory of operation.

C. Switch Trouble Isolation

(1) There are only two major symptoms and one minor symptom that occur with the proximity switch. These symptoms are:

(a) Switch never actuates. (light "OFF")

(b) Switch always actuated. (light "ON")

(c) Switch actuates properly but deactuates at zero gap.

(2) When the system test indicates that the switch never actuates, make the following checks (see Figures 8 or 9). Target not required for (a) through (c).

NOTE: ◯ indicates alternating-current measurements.
◇ indicates direct-current measurements.
Figure 13 defines test points on the circuit. Voltages indicated are approximate and variations from unit to unit are to be expected.

C. Switch Trouble Isolation (Cont.)

(2) (Continued)

card with relation to points on the schematic (see Figures 8 and 9).

(a) Test point ◇1◇ +14.0 (±0.1) VDC. If not 13.9 to 14.1 VDC, the trouble is in the regulation circuit.

(b) Test point (1) is a square wave: 70v peak-to-peak (35 vrms) at 1,100 (±75) Hz. If not, the oscillator circuit is faulty.

(c) Test point (2) is a 30v peak-to-peak version of (b). If not, the L2-C7 filter is faulty or shorted.

NOTE: (1) If the previous tests are normal, place actuate test target EDC P/N 8-005101-02 on the sensor at zero gap and make the following checks.

(2) All voltages referred to GRD (Black banana jack on test set) except test point (3) :

(d) Test point ◇2◇ . +0.8 VDC indicates the output switch is faulty and 0.0 VDC indicates the output switch is not at fault.

C. Switch Trouble Isolation (Cont.)

(2) (Continued)

(e) Test point ◇3◇ . +7 to +8 VDC indicates the fault is in the switch driver; +1 to +2 VDC indicates the switch driver is not at fault.

(f) Test point ◇4◇ . +0.6 VDC indicates the fault is in the Schmitt Trigger; ± 0.1 VDC indicates the Schmitt Trigger is not at fault.

(g) Test point ◇5◇ . +6 to +10 VDC indicates the fault is in the failsafe circuit; -0.3 to -0.5 VDC indicates the failsafe circuit is not at fault. +11 volts would indicate a failsafe fault exists.

(h) Test point (3) . If the voltage across the blue and red binding post on the test set is 6 to 8V peak-to-peak square wave, the trouble is in the detector circuit. If it is near zero, the trouble is in the bridge circuit.

(3) When the system indicates that the switch is always actuated, the same checks as steps (d) through (h) of paragraph 10 C (2) are to be made except that the target is to be greater than 1.0 inch away and the voltage at the test points that indicated a fault would now be normal operation and those that indicated normal operation would now be a fault.

(4) Symptom C (1) (c) is most likely caused by pre-zener leakage of CR5 (activating the failsafe circuit). CR5 must be replaced.

11. CALIBRATION, SWITCH (ALL MODELS)

A. Sensor

The sensor cannot be calibrated.

B. Switch Card Calibration Equipment

(1) Calibration Fixture

NOTE: A special fixture is required to calibrate 2-899-111-3, 2-899-111, 2-899-112 and 2-899-113 switch cards. An example of a suitable fixture is shown in Figure 11. The fixture must be constructed so that the sensor is mounted on a nonmetallic surface with sensing face of the sensor a minimum of .75 inches from any nonmagnetic metal (aluminum) and a minimum of 2 inches from any magnetic material other than the target. The movable target must be parallel to sensing face and cover 100% of sensing face. Target must be able to move from zero gap to a minimum of 1 inch from sensing face.

(2) Standard Sensor

NOTE: Calibrating the switch card with a 1-899-15 sensor selected at random potentially broadens the actuation

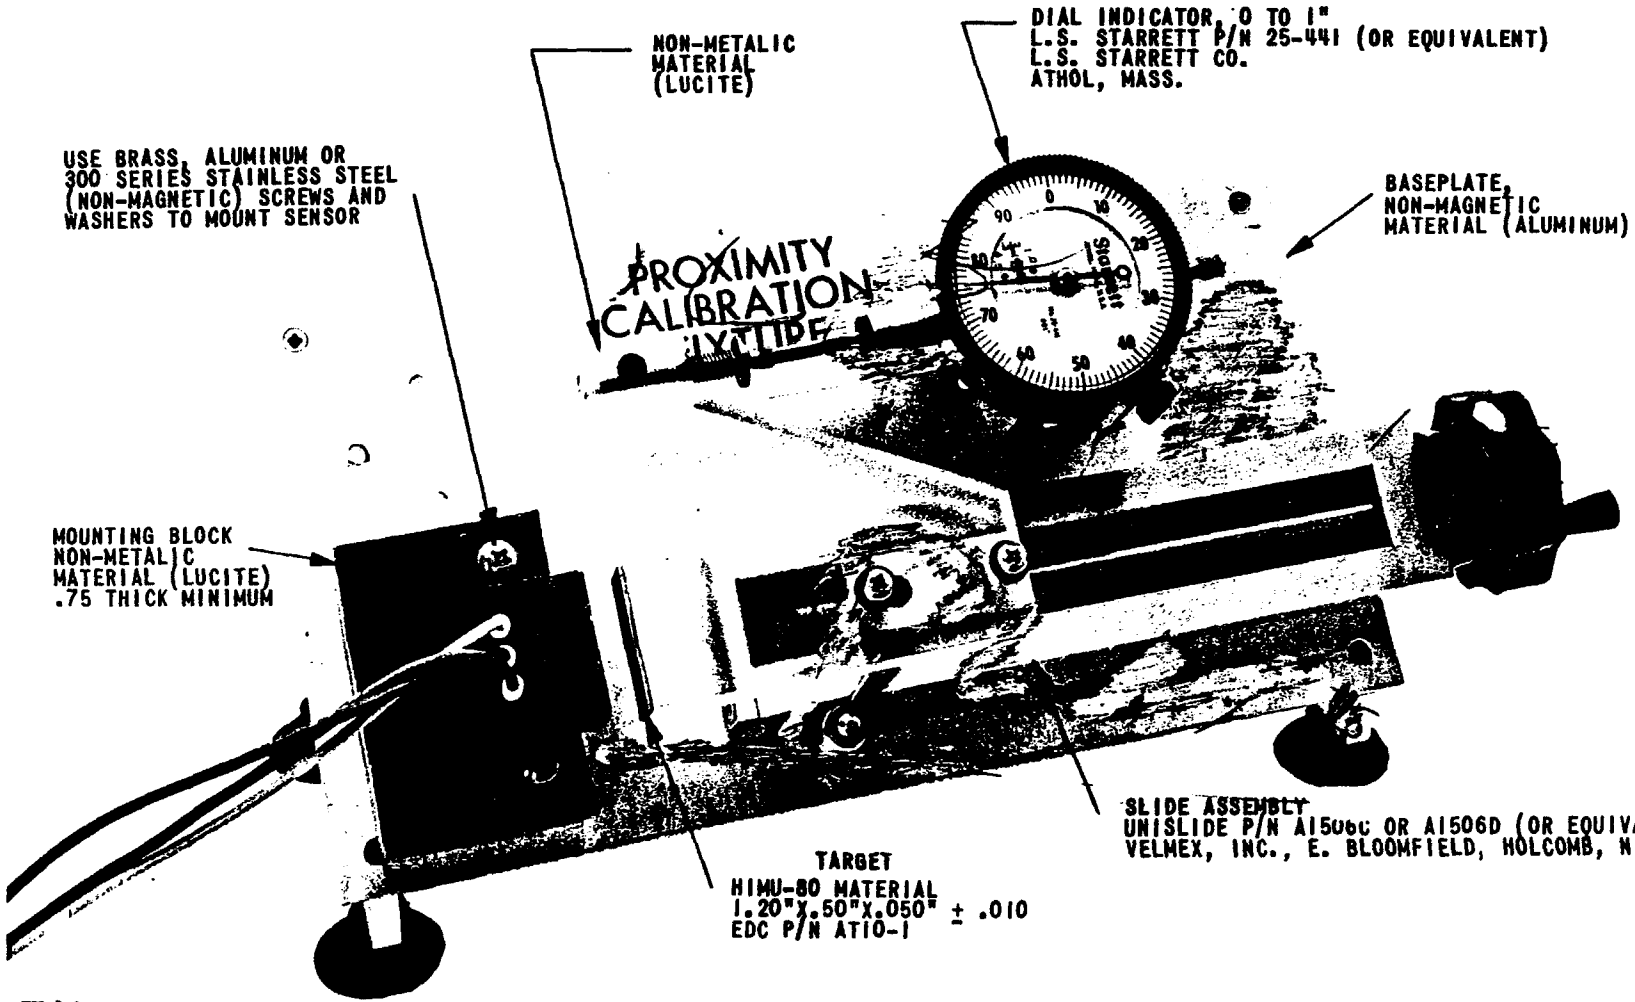


FIGURE 11
PROXIMITY CALIBRATION FIXTURE

B. Switch Card Test Equipment (Cont.)

(2) Standard Sensor (Cont.)

tolerance by a factor of two because of tolerance build up. Therefore it is recommended that a "standard" 1-899-15 sensor be used or the switch card should be returned to manufacturer for calibration.

(3) Test Set, EDC P/N 8-005-01 (see Appendix), or Equivalent (see Figure 7)

(4) Decade Resistor, General Radio Type 1434-N or Equivalent

C. Calibration Test Set-Up

(1) Install standard 1-899-15 sensor in test fixture.

(2) Connect sensor leads to binding posts on test set.

(3) Install switch card to be calibrated in connector on test set.

(4) Target not required for regulator calibration.

D. Regulator Voltage

(1) Apply power, connect the differential voltmeter across C2 of the switch card.

D. Regulator Voltage (Cont.)

(2) If the voltage is below 13.9 VDC, remove any resistors shunting R4 or R5 and select a resistor that (when shunted across R5) will cause a voltage of 14.0 (±0.1) VDC. If the voltage is above 14.1 VDC, remove any resistors shunting R4 or R5 and select a resistor that (when shunted across R4) will cause a voltage of 14.0 (±0.1) VDC. Install the proper resistor onto the board.

E. Gap Calibration

Remove R14 and R15 from switch card. Connect the decade resistor across the R14 terminals.

(1) R14 Selection

(a) Move target to the nominal gap specified in Figure 12.

(b) Adjust decade resistor to 100 ohms or greater. Light should be off. Carefully decrease the decade resistor until the light turns on.

(c) Select a standard resistor value (see parts list for type) that is equal to or greater than the decade resistor setting.

E. Gap Calibration (Cont.)

(1) R14 Selection (Cont.)

(d) Temporarily install the resistor in the R14 position. Adjust the decade box to 10K.

(e) Move target away from sensor beyond deactuation point.

(f) Slowly move target toward sensor until light goes on.

(g) Measure distance of target from sensor's sensing face. If gap is greater than the nominal specified in Figure 12. use the next higher value of resistor for R14, and proceed to Paragraph E.2.a. If the gap is nominal, select a 10K resistor and proceed to Paragraph E.2.d. If the gap is less than nominal, proceed to Paragraph E.2.a.

SWITCH CARD	NOMINAL SWITCH POINT WITH STANDARD 1-899-15 SENSOR	SWITCH POINT DIFFERENTIAL
2-899-111	0.300	0.005 to 0.030
2-899-111-3	0.300	0.004 to 0.010
2-899-112	0.115	0.005 to 0.015
2-899-113	0.145	0.005 to 0.015

Gap Calibration Data

Figure 12

E. Gap Calibration (Cont.)

(2) R15 Selection

(a) Increase this target gap until the light goes out. Move the target to the nominal gap. Light should be off.

(b) Adjust the decade resistor for actuation at the nominal actuation point.

(c) Select a resistor that is closest to the decade box value. (See parts list for type)

(d) Temporarily install selected resistor in parallel with R14 and disconnect decade box.

NOTE: If the actuation point is not within ±0.003 of nominal, select another resistor for R15. When the calibration is within ±0.003, install both R14 and R15 into the card. When the above steps have been performed, calibration is complete.

(3) After calibration, retest per paragraph 9.D.

(4) Apply conformal coating to calibration resistors and solder areas per paragraph 7.B.

12. STORAGE INSTRUCTIONS

Package solid-state switch and sensor in polyethylene bags. Seal in commercial carton and store in dry place.

13. SPECIAL TOOLS, FIXTURES AND EQUIPMENT

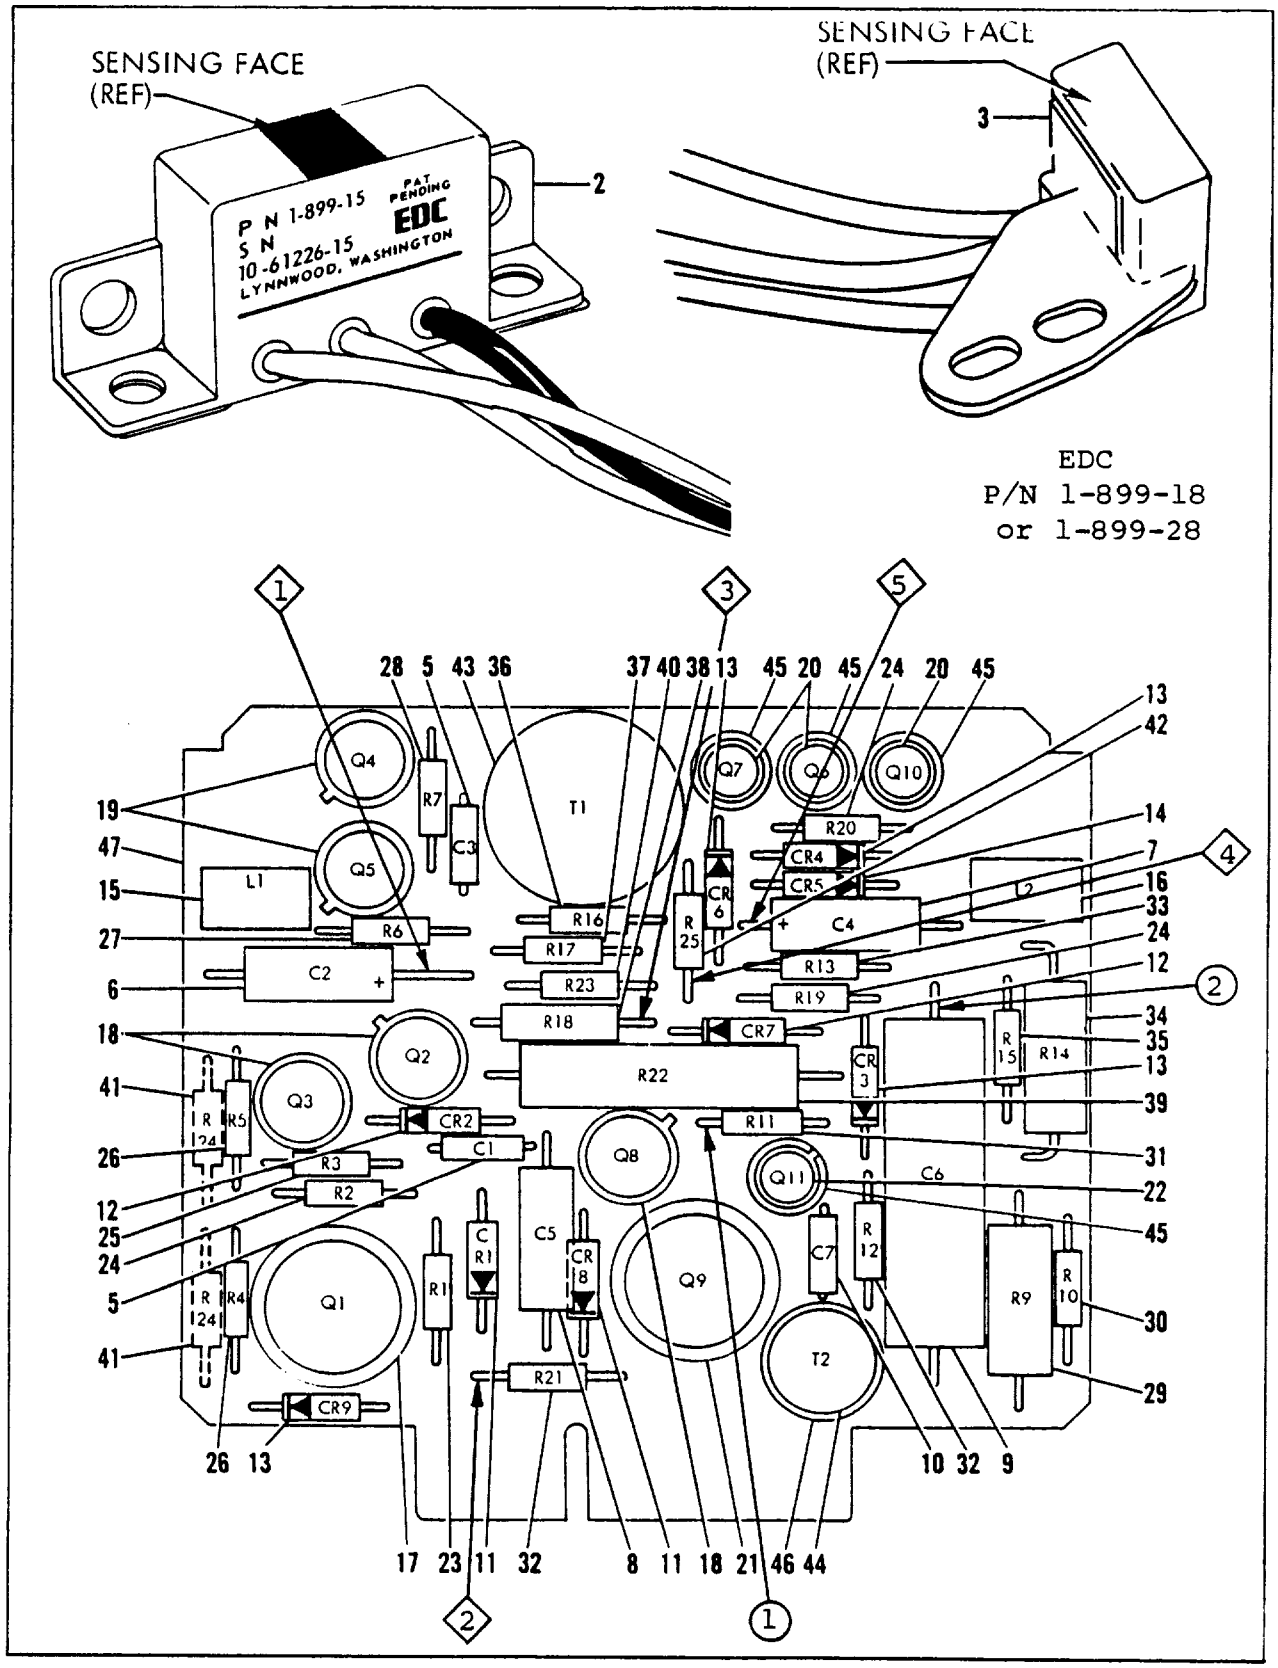
A. Test Gages: (See Figure 2)

B. Test Set: EDC P/N 8-005-01 (see Appendix), or equivalent (see Figure 7).

C. Calibration Test Fixture: See Figure 11 (or equivalent)

D. Actuator/Deactuator Test Target Assembly:
EDC P/N 8-005101-01 or equivalent (see Figure 10)

14. ILLUSTRATED PARTS LIST



A. Introduction

(1) The Illustrated Parts List provides a breakdown of the Proximity Switch Model 899. All parts are identified by corresponding index number on exploded view illustration, Figure 13.

A. Introduction (Cont.)

(2) All items are assigned an index number. Items listed but not illustrated are identified by a - preceding the index number.

(3) For identification of detail parts and assemblies, the nomenclature column employs the indenture system. Each assembly is listed with its detail parts listed in the next indenture to the right. Conversely the next higher assembly of any detail part may be determined by its location in the indenture to the left.

Proximity Switch Model 899, Component Location

A. Introduction (Cont.)

(4) Vendors' Codes*

CODE	VENDOR'S NAME AND ADDRESS
V07047	ROSS MILTON COMPANY Hatboro, Pennsylvania
V56289	SPRAGUE ELECTRIC COMPANY North Adams, Massachusetts
V96733	SAN FERNANDO ELECTRIC MFG. CO. San Fernando, California

*Unless otherwise indicated by a vendor's code number in parentheses following the part name in the parts list, all parts are either standard military items, registered JEDEC type numbers, or Electro Development Corporation parts. Where there are no optional parts to the EDC parts, the parts are either screened from commercial items by EDC, or produced to an EDC specification. We recommend the customer do not attempt substitution on those parts.

B. Reference Designation Index

The Reference Designation Index contains the reference designations for components shown in the schematic diagrams (ref. Figures 8 & 9). These designations are arranged in alpha-numerical order.

FIG. ITEM	PART NUMBER	1 2 3 4 5 6 7 NOMENCLATURE	EFFECT FROM TO	UNITS PER ASSY

General Information

1.1 Introduction

This instruction manual has been prepared to provide information on installation, performance, operation, identification of parts, and maintenance of the Flite-Tronics Model PC14 and PC14A Power Inverters.

1.2 Purpose of Equipment

The PC14 and PC14A shown in figure 1.1 is a transistorized inverter designed to supply 115 VAC at 400 cycles per second. The input power voltage is 28.0 VDC.

The unit is capable of delivering a current overload of 150% for a minimum duration of 5 minutes at full rated output. This permits the PC14 and PC14A to power equipment that requires momentary surges of power during turns on.

1.3 Specifications

Input Voltage.....27.5 VDC
Input Current...
a) 5.2 amperes for PC14 delivering 100 VA.
b) 3.2 amperes for PC14A delivering 60 VA.
c) .75 amperes for PC14 and PC14A with no load.
Input Voltage Range.....26 to 30 VDC normal, will operate down to 20 VDC.

Input Overvoltage..Withstands 130% input overvoltage for 5 minutes while supplying full rated 100 VA output power. Output voltage under this condition 115 VAC +5% -7%.

Output Voltage...115 AC rms +5% -7%

Output Frequency.....400 cps ± 1%

Output Power...100 VA, Model PC14
60 VA, Model PC14A

Output Waveform.....Sine Wave, Single Phase

Harmonic Distortion..Typically 3%

Overload Capacity...Withstands 150% output current overload for at least 5 minutes.

Power Factor..... .8 to 1.0

Input Voltage Protection...
Unit withstands transient of 88 volts lasting 1 millisecond on the 27.5 VDC input line.

Excessive Overload and Output Short Circuit...
Withstands without damage or degradation loads exceeding 150% nominal to an output short circuit. Unit delivers rated output on removal of above condition.

Altitude.....45,000 feet

Efficiency.....72% typical

Temperature..-65° F. to 160° F.

Emission RFI...90 KC to 1000 MC
None measurable

Weight.....4.75 lbs., PC14
4.25 lbs., PC14A

Size: PC14 and PC14A
Width 5"
Length 7"
Height 2-3/4"

Humidity...
Greater than 95% for ten days, temperature cycled between 75° F. to 160° F.

Vibration...
To withstand at least 10 G's from 10 to 500 cycles per second in three directions for 90 minutes each direction.

Shock...
To withstand at least 10 G's for 11 milliseconds in three directions.

1.4 Description

The PC14 and PC14A are transistorized airborne static power inverters. The unit operates from 27.5 VDC aircraft power source and delivers 115 VAC at 400 cps.

An L/C tuned 400 c/s oscillator operating in a class B push-pull mode is used to generate the output voltage.

This signal is amplified by 3 stages of class B push-pull emitter follower amplifiers. Protective circuits for output regulation, output overload, thermal runaway and input voltage transient are incorporated to make the PC14 and PC14A an extremely reliable equipment.

Frequency and output voltage are adjustable. However, once set at the factory they should not require readjusting for the life of the equipment.

SECTION II

INSTALLATION

2.1 General

The PC14 and PC14A 400 c/s Inverters are ready to install when delivered from the factory.

To determine that the unit is operating satisfactorily, a bench test may be made. The external hook-up for such a test is illustrated in figure 4.1.

The PC14 will deliver 100 VA of power to a load having a power factor between .8 lag to 1.0. The PC14 will operate into loads which are more reactive, however, external correcting capacitor will be required.

The capacitance value may be determined by noting what value causes a null in the input current reading. This, of course, should be determined with the equipment the PC14 delivers power to.

2.2 Installation Procedure

The PC14 and PC14A are environmentally designed to mount on a rack with other equipment, or in any suitable location in the aircraft.

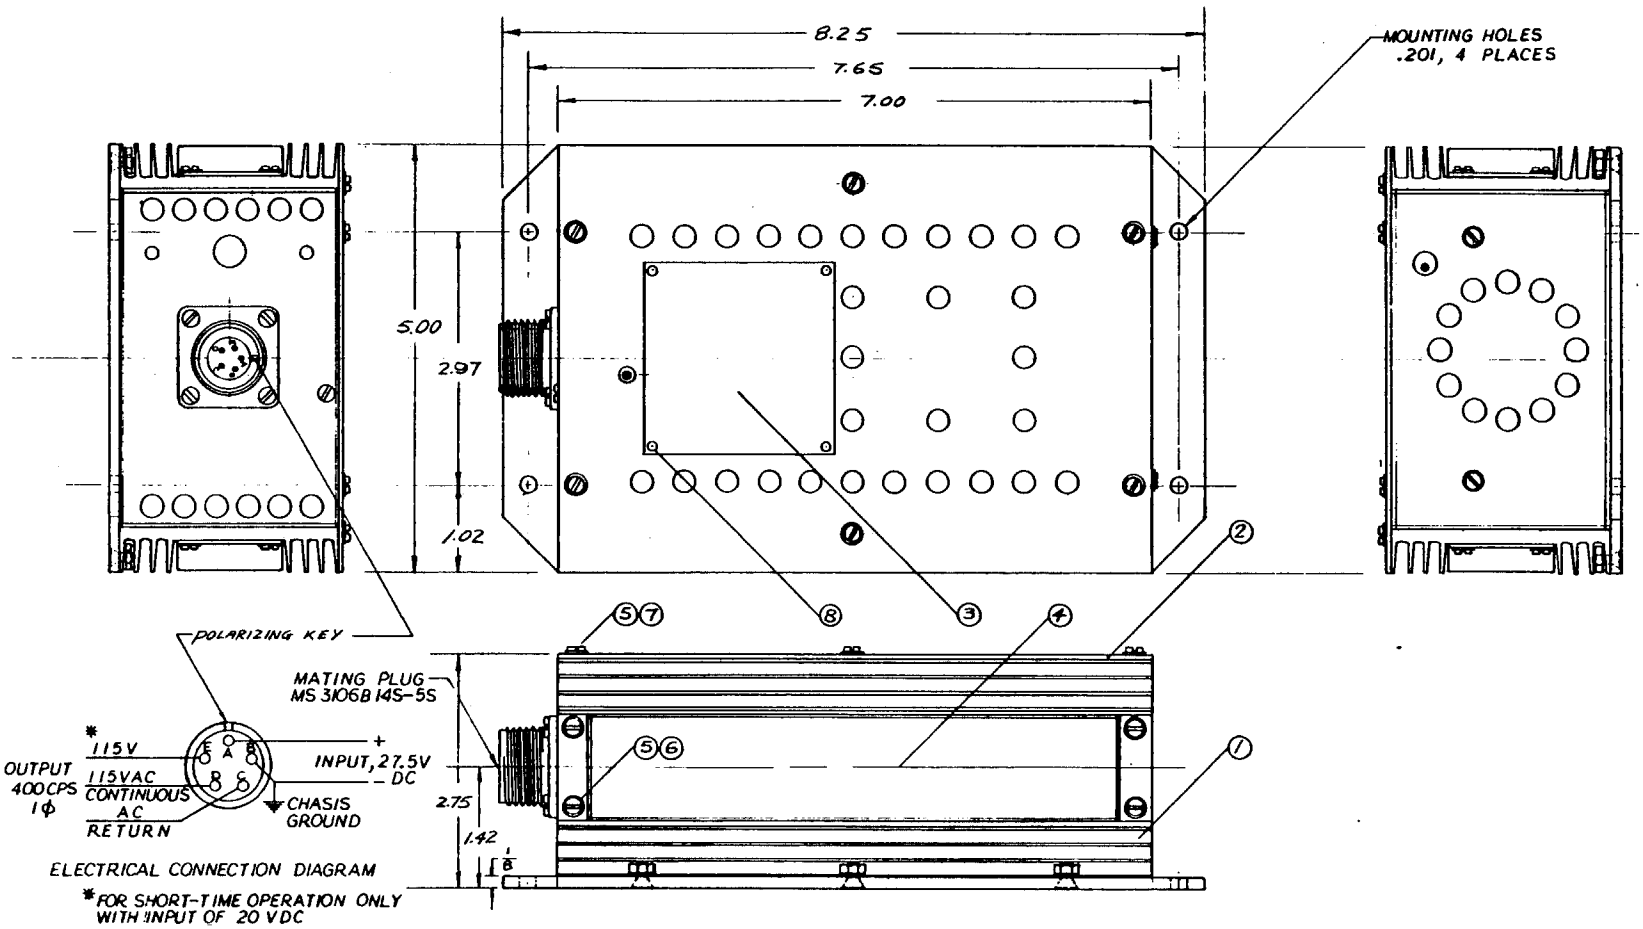

Figure 2.1 illustrates the installation dimensions and mounting centers. Mounting hardware is not normally supplied with the unit. The screw size should be 10-32 and length long enough to have 1-1/2 threads exposed after installing the necessary hardware.

The mating connector plug to the PC14 and PC14A receptacle is MS3106B14S-5S.

A wire size AWG #14 is suggested for the low voltage D.C. input and an AWG size #22 for the A.C. output leads. The low voltage input to the PC14 should be protected with a 12 amp circuit breaker and the PC14A with a 7 amp circuit breaker.

CAUTION

The PC14 and PC14A should not be installed in an area where the ambient air temperature exceeds 172° F. under all weather and operating conditions.

SIZE C DWG. NO. 85000

SECTION III

Principles of Operation

3.1 General

The PC14 converts D.C. energy to A.C. electrical energy.

The nominal output is 115 VAC on pin D for an input of 28 VDC ± 2 VDC. However, in an emergency battery condition of 20 VDC input the output from pin E is 115 VAC working into a 90 VA load. The 400 cps is generated by an L/C tuned push-pull oscillator. The sine wave source is amplified by two stages of class B push-pull amplifier. The final power output stage is also class B, but the transistors are cascoded. This increases the operating temperature and also decreases the collector to emitter operating voltage in half, i.e., eliminates the possibility of an 88 volt peak transient on the 27.5 VDC bus destructing the transistors. A schematic of the PC14 and PC14A are illustrated in figures 3.1 and 3.2 respectively.

3.2 Block Diagram

Figure 3.3 illustrates the PC14 operation in a block diagram form. The block diagram illustrates the time tested and proven circuitry for power amplification of a low level A.C. signal. All the stages are class B push-pull emitter follower configuration. The emitter follower circuitry having inherent negative feedback introduces very little amplitude and phase distortion.

The output signal is sampled by current and voltage transformer. These components yield a signal to operate the output overload and output voltage level circuitry.

They in turn control the push-pull 400 cps oscillator amplitude.

The output overload reduces the output current and voltage when a load excess of 160% is applied to the output. This same circuitry operates in the event of a short circuit on the output.

The automatic level control maintains the output voltage constant for load and temperature variation.

3.3 400 cps Sine Wave Oscillator

Inductor-transformer T1 is the feedback, output and resonant tuning transformer. The center tapped primary winding is 1-2-3. Feedback winding is 4-5-6. The output and resonant tuning winding is 7-8-9.

Capacitor C10 (.47 ufd) resonants with the inductance of the output winding at 400 cps.

Transformer T1 has a tuning slug which is adjusted at the factory for an oscillator frequency of 400 cps.

Transistors Q1 and Q2 are the class B push-pull amplifier to sustain oscillation. Resistors R2 and R3 biases the transistors to cause oscillation to start. Capacitor C9 suppresses any tendency for high frequency mode oscillation. Resistor R4 is the degenerating resistor.

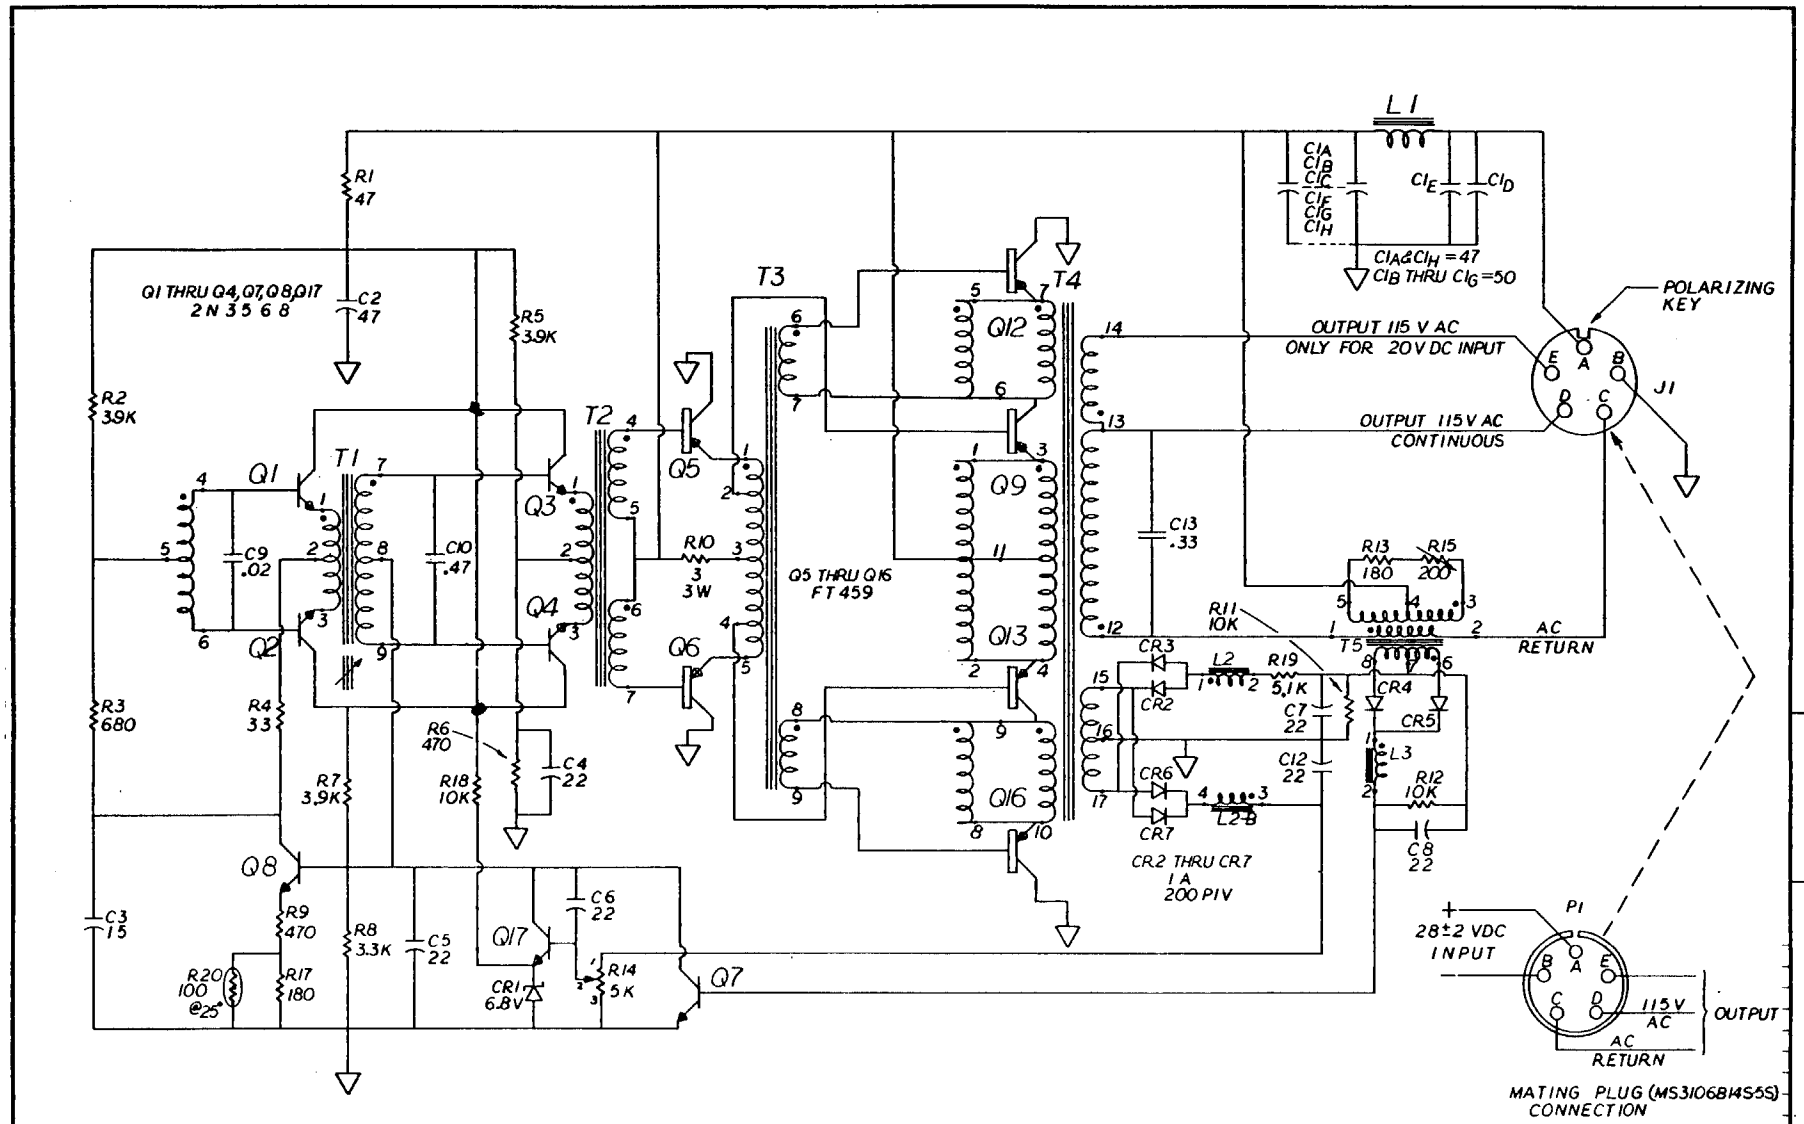

FIGURE 3.2

NOTES

1. RESISTORS IN OHMS: 1/2 W UNLESS OTHERWISE NOTED
2. CAPACITORS IN μF:

The output winding 7-8-9 drives the bases of Q3 and Q4 in opposite phase.

3.4 Low Level Amplifiers

Between the sine wave oscillator and power amplifiers there are two stages of class B push-pull emitter follower amplifiers.

The first stage consists of transistors Q3 and Q4 and the interstage transformer T2. Resistors R5 and R6 biases these transistors operating point.

The output from the transformer T2 drives the bases of Q5 and Q6. Resistor R10 is the emitter degenerating resistor. T3 is a tapped primary and two isolated secondary winding transformer. The unusual configuration is necessitated by the cascaded power output transistor connection.

3.5 Power Amplifier

The power amplifier consists of power transistors connected in cascaded pairs for the PC-14. For the PC14, transistors Q11, Q12, Q9, Q10 and Q13, Q14, Q15, Q16 are driven in alternate half cycles. The multiple winding primary of transformer T4 divides the 27.5 VDC input so the transistors supports only 13.75 peak A.C. signal.

These power transistors are controlled to Flite-Tronics' specification FT459. These devices are inspected for certain minimum breakdown voltage, gain and recovery time. The minimum test for breakdown voltage Vcex is 105 volts. Therefore, an 88 volt peak transient on the 27.5 VDC input will not cause a collector to emitter voltage to exceed 88 volt peak. The primary of the transformer forces this voltage division.

The secondary of T4 has a tapped winding for the 115 VAC output and a center tapped winding for control of output voltage and output current.

The output from terminal 13 of T4 is connected to pin D of connector J1. This output is 115 VAC when the input is 28 VDC ± 2 VDC. To get 115 VAC and up to 90 VA output when the input is 20 VDC emergency condition the load should be connected to pin E of J1. There will exist, however, slight squaring of the peaks of the sine wave in this condition.

Capacitor C13 is the phase compensating capacitor to permit the unit to operate efficiently with a load power factor between .8 lag to 1.0.

3.6 Output Voltage Control

The output voltage sample is realized from the center tapped winding 15-16-17 of T4. Rectifiers CR6 and CR7 converts the A.C. signal to a D.C. output. Filter consisting of L2-B and C12 is the L section choke input to give an average D.C. output which is proportional to the 115 VAC level.

This D.C. output is also applied across a variable resistor R14. The variable portion of the resistor is connected to the base of Q17. In essence this output voltage sample is compared with the zener CR1 in the emitter of Q17. Resistor R18 is the bleeder resistor to the zener to permit operating this zener on its flat portion of its transfer characteristics.

The variable resistor R14 is adjusted for an output of 115 VAC. The load resistor R7 is connected to the collector of Q17. The D.C. current passing these R7 determines the bias

point to transistor Q8. Transistor Q8 is the variable D.C. source for the push-pull 400 cps oscillator.

The push-pull oscillator represents an impedance to the collector circuit of Q8. Hence, the conduction of Q8 will determine the magnitude of D.C. voltage across the oscillator circuit. This in turn determines the voltage amplitude of oscillation, which of course controls the A.C. output level. Resistor R9 and R17 are the degenerating resistors for transistor Q8.

Thermistor R20 is a temperature compensating resistor.

Resistor R8 is the starting resistor for transistor Q8 until the oscillator amplitude builds up sufficiently for the automatic level control circuitry to take over.

Capacitor C6 is a low frequency feedback capacitor to prevent the automatic level control circuitry from motor boating. Capacitor C3 and C5 are simply by-pass capacitors.

3.7 Current Overload Control

The output A.C. current is sampled by the transformer T5. The current flowing thru the winding 1-2 causes a voltage to be developed across the center tapped winding 6-7-8. The magnitude of voltage across this winding is controlled by the variable resistor R15 across the center tapped winding 3-4-5.

The A.C. voltage from winding 6-7-8 is rectified by CR4 and CR5. The averaging choke input filter consisting of L3 and C8 cause a D.C. voltage to be developed across R12 which is proportional to the output current. The D.C. voltage is proportio: to the output current.

To realize an overload action that causes quenching the overload current D.C. voltage is compared with the output D.C. voltage. This tends to give a trigger like action when an overload condition is sustained.

The output voltage sample is taken from winding 15-16-17 of transformer T4. CR2 and CR3 rectifies this voltage. The L section choke input filter consisting of L2 and C7 places across resistor R11 a ripple free D.C. voltage. The voltage across R11 is a negative polarity with respect to ground.

The D.C. voltage across R12 which is proportional to the output current is compared with the voltage across resistor R11. When the output current causes a voltage across R12 to exceed the compared voltage across R11, transistor Q7 will start conducting. The extent of overload determines the magnitude of current Q7 will conduct. As Q7 conducts this tends to cut off Q8 which in turn decreases the voltage across the 400 cps oscillator circuit.

When the load is in excess of 150% of normal the oscillator circuit will exhibit anything from low frequency quenching to almost a complete shut down.

During output short circuit the current overload circuitry will reduce the voltage across the push-pull oscillator until a feeble oscillation is maintained until the overload is removed.

Of course on removal of this condition, the unit will immediately return to normal operating condition.

3.8 Input Filtering and Blower

The input is filtered by a pi section consisting of capacitors C1A thru C1H and choke L1.

Additional filtering for the low level stage is done by the RC filter consisting of R1 and C2.

Blower motor M1 is used only in the PC14, the 100 VA unit. The blower motor turns on when the heat sink temperature has reached 165° fahrenheit.

In normal installation where thermal conduction by the aircraft structure is adequate the blower motor may never come on. Resistor R16 simply reduces the speed slightly.

The PC14A does not use a blower since the heat sink can more than adequately handle the thermal dissipation.

SECTION IV

MAINTENANCE

4.1 General

This section covers the bench check of the PC14 and PC14A to determine conformance to manufacturers specification. Periodic preventative maintenance is not necessary since no moving parts are employed to realize functional electrical performance.

For safety feature only, a thermostatically controlled blower motor is used. It will come on only when the heat sink temperature exceeds 165° F.

The instructions on table 4.2 will aid in localizing the cause of defective operation should any component fail.

4.2 Test Equipment

Table 4.1 lists the components and test equipment recommended to be employed in conducting electrical test per manufacturers test procedures.

Figure 4.1 illustrates the PC14 and PC14A bench test interconnection diagram. The Flite-Tronics Test Set TS14-1 is a unit for readily conducting the test in table 4.2.

4.3 Performance Test and Localizing Trouble Source

Table 4.2 outlines a step by step procedure to performance test the PC14 and PC14A to localize fault source if troubles exist.

It is suggested the technician acquire familiarity of the unit by studying the principles of operation section prior to attempting this section.

NOTE: Step 1 through 13 is for the PC14 and Step 14 through 24 is for the PC14A.

* These meters are required only if the power supply does not contain them.

FIGURE 4.1 BENCH TEST HOOK-UP

TABLE 4.2 PERFORMANCE TEST AND LOCALIZING TROUBLE

STEP	SET-UP	PROCEDURE	PERFORMANCE READING	POSSIBLE CAUSE OF ABNORMAL READING
1	Interconnect unit per bench test hook-up	a) Turn on power supply, keep input voltage set at zero. b) Turn on all measuring equipment for warm-up. c) Check polarity of power supply. d) Set S1 to No. 1 position. e) Set switch S2 in #1 position for PC14. f) Set switches S3 through S10 in the off position.		
2	S3 through S9 in the off position	a) Gradually increase power supply voltage to 27.5 VDC.	Input D.C. current I1 should not exceed 3/4 amps D.C.	Test set-up incorrectly connected. Capacitor C1A thru C1H shorted. Transistors Q11 thru Q16 shorted C2 shorted.
3	S3 thru S9 in the off position	a) Input voltage set at 27.5 VDC b) Adjust R14 as required so V2 reads 117 VAC if necessary.	V2 should read between 107 VAC to 120.7	Check for following likely defective components: CR6, CR7, C12, R14, C6, CR1, Q17, C3, Q8, and R20

STEP	SET-UP	PROCEDURE	PERFORMANCE READING	POSSIBLE CAUSE OF ABNORMAL READING
4	S3 thru S9 in the off position	a) Input voltage set at 27.5 VDC. b) If frequency is out of tolerance adjust tuning slug on transformer T1.	Frequency meter should read 400 c/s ± 4 c/s I1 = 3/4 A	Defective parts likely to cause abnormal reading: Transformer T1, Capacitor C10.
5	S3 thru S9 in the off position	a) Input voltage set at 27.5 VDC. b) Vary input voltage between 28 to 30 VDC.	Distortion meter should read less than 7%. I1 = 3/4 A	Defective parts likely to cause abnormal reading: Transistors Q3 thru Q6 and Q9 thru Q16. Capacitors C3, C5.
6	Switch S5 on for full load output	a) Input voltage set at 27.5 VDC. b) Resistor R14 may require readjusting, however, if adjusted step 3 should be re-tested. c) Vary input voltage between 28 to 30 VDC.	I2 read .81A to .91 amps A.C. V2 should read between 107 to 120.7 VAC. I1 should read approximately 5.2A	Defective parts likely to cause abnormal reading: Diodes CR2, CR3, CR4 and CR5. Transistor Q1 thru Q17.
7	Switch S6 for 150% overload test	a) Input voltage set at 27.5 VDC. b) Resistor R15 may require adjusting if unit tends to motor boat. However, in the event of any adjustment step 3 should be repeated.	I2 should read between 1.25 to 1.4 amp. V2 should read at least 103 VAC. I1 should read approximately 9.0 amps.	Defective parts likely to cause abnormal reading: Diodes CR2, CR3, CR4 and CR5. Transistor Q1 thru Q17.
8	Switch S7 on for 200% overload load test.	a) Input voltage set at 27.5 VDC. b) R15 adjust the overload threshold point. The proper setting is at the 165% overload point the unit should start motorboating. However, any adjustment will require re-testing for step 3, 6, and 7.	I1 should read between 1 to 4½ amps. V2 and I2 should indicate output voltage and current motorboating.	Defective component likely to cause abnormal reading: Diodes CR2, CR3, CR4 and CR5. Capacitors C7 and C8. Transistors Q7 and Q8.

STEP	SET-UP	PROCEDURE	PERFORMANCE READING	POSSIBLE CAUSE OF ABNORMAL READING
9	Switch S9 on for output short circuit test.	a) Input set anywhere between 26 and 28 VDC. b) If I1 exceeds 4 amps at any time, the unit should be turned off.	I1 less than 4 amps. V2 = zero I2 less than ½ amp.	Defective component likely to cause abnormal reading: Diodes CR2, CR3, CR4 and CR5. Capacitors C7 and C8. Transistors Q7 and Q8.
10	Switches S3 thru S6 in the off position switch S8 on 100 VA reactive load and S9 off.	a) Input voltage set at 27.5 VDC. b) Vary input voltage between 28 to 30 VDC.	I2 read .80 to .90 amps A.C. V2 read between 107 to 120.7 VAC.	Defective parts likely to cause abnormal reading: Diodes CR2, CR3, CR4 and CR5. Transistor Q1 thru Q17. Capacitor C13.
11	Switch S5 on S3, S4 and S6 thru S9 off position. Full load test.	a) Input voltage set at 27.5 VDC.	Distortion meter should read less than 7%. Frequency meter should read 400 cps ± 4 cps.	Defective parts likely to cause abnormal reading: Transformer T1, Capacitor C3, C5, and C10. Transistors Q3 thru Q6 and Q9 thru Q16.
12	Switch S3 on S4 thru S9 off.	a) Input voltage between 26.0 to 28 VDC.	V2 read 107 to 120.7 VAC I1 reads 2 amps D.C. I2 reads .27 to .34 amps A.C.	Defective parts likely to cause abnormal reading: Diodes CR6, CR7, C12, R14, C6, CR1, Q17, C3, Q8, and R20.
13	Switch S1 to #2 position S4 on, S3 and S5 thru S9 off position	a) Set Input voltage at 20 VDC.	V2 read 105 to 120.7 VAC. I2 read .73 to .82 amps A.C. I1 read approximately 5.3 amps D.C.	Defective parts likely to cause abnormal reading: Diodes CR2, CR3, CR4 and CR5. Transistor Q1 thru Q17.

FOLLOWING TEST FOR PC14A:

STEP	SET-UP	PROCEDURE	PERFORMANCE READING	POSSIBLE CAUSE OF ABNORMAL READING
14	Switch S1 to #1 position S2 to #2 position. Switches S3 to S9 in the off position.	a) Gradually increase power supply voltage to 27.5 VDC.	Input D.C. current I1 should not exceed 3/4 amps. D.C.	Test set-up incorrectly connected. Capacitor C1A thru C1H shorted. Transistors Q11 thru Q16 shorted. C2 shorted.
15	S3 thru S9 in the off position	a) Input voltage set at 27.5 VDC. b) Adjust R14 as required so V2 reads 117 VAC.	V2 should read between 107 to 120.7 VAC.	Check for following likely defective components: CR6, CR7, C12, R14, C6, CR1, Q17, C3, Q8, & R20
16	S3 thru S9 in the off position.	a) Input voltage set at 27.5 VDC. b) If frequency is out of tolerance adjust tuning slug on transformer T1.	Frequency meter should read 400 c/s ± 4 c/s I1 = 3/4A	Defective parts likely to cause abnormal reading: Transformer T1, Capacitor C10
17	S3 thru S9 in the off position	a) Input voltage set at 27.5 VDC. b) Vary input voltage between 28 to 30 VDC.	Distortion meter should read less than 7%. I1 = 3/4A	Defective parts likely to cause abnormal reading: Transistors Q3 thru Q6 and Q9 thru Q16. Capacitors C3, C5.
18	Switch S5 on for full load test.	a) Input voltage set at 27.5 VDC. b) Resistor R14 may require re-adjusting, however, if adjusted step 15 should be re-tested.	I2 read .49 to .55 amps. V2 should read between 107 to 120.7 VAC I1 read 3.1 amps.	Defective parts likely to cause abnormal reading: Diodes CR2, CR3, CR4, and CR5. Transistors Q1, thru Q9, Q11, Q13, Q15, and Q17.
19	Switch S6 on for 150% overload test.	a) Input voltage set at 27.5 VDC. b) Resistor R15 may require adjusting if unit tends to motor boat. However, in the event of any adjustment step 15 should be re-tested.	I2 read between .73 to .84 amps. V2 should read at least 103 VAC.	Defective parts likely to cause abnormal reading: Diodes CR2, CR3, CR4, and CR5. Transistors Q1, thru Q9, Q11, Q13, Q15, and Q17.

STEP	SET-UP	PROCEDURE	PERFORMANCE READING	POSSIBLE CAUSE OF ABNORMAL READING
20	Switch S7 on for 200% overload test.	a) Input voltage set at 27.5 VDC. b) R15 adjust the overload threshold point. The proper setting is at the 165% overload point the unit should start motor-boating. However, any adjustment will require re-testing for steps 15, 18 and 19.	I1 should read between 3/4 to 3 amps D.C. V2 and I2 should indicate output voltage and current is motor-boating.	Defective component likely to cause abnormal reading: Diodes CR2, CR3, CR4 and CR5. Capacitors C7 and C8. Transistors Q7 and Q8.
21	Switch S9 on for short circuit test.	a) Input set anywhere between 26 and 28 VDC. b) If I1 exceeds 3 amps at any time the unit should be turned off.	I1 less than 3 amps. V2 equal zero. I2 less than ½ amp.	Defective component likely to cause abnormal reading: Diodes CR2, CR3, CR4 and CR5. Capacitors C7 and C8. Transistors Q7 and Q8.
22	Switches S3 thru S7 in the off position and S9 off, switch S8 on (60 VA reactive load).	a) Input voltage set at 27.5 VDC. b) Vary input voltage between 28 to 30 VDC.	I2 read .48 to .54 amps A.C. V2 read between 107 to 120.7 VAC	Defective parts likely to cause abnormal reading: Diodes CR2, CR3, CR4 and CR5. Transistors Q1 thru Q9, Q11, Q13, Q15 and Q17. Capacitor C13.
23	Switch S5 on S3, S4 and S6 thru S9 off position.	a) Input voltage set between 26 to 30 VDC.	Distortion meter should read less than 7%. Frequency meter should read 400 cps to ± 4 cps.	Defective parts likely to cause abnormal reading: Diodes CR2, CR3, CR4 and CR5. Transistors Q1 thru Q9, Q11, Q13, Q15 and Q17.

STEP	SET-UP	PROCEDURE	PERFORMANCE READING	POSSIBLE CAUSE OF ABNORMAL READ
24	Switch S1 to #2 position S3 on, S4 and S5 thru S9 off position.	a) Set input voltage at 20 VDC.	V2 read 105 to 120.7 VAC	Defective parts likely to cause abnormal reading: Diodes CR2, CR3, CR4 and CR5.
			I2 read .44 to .48 amps.	
			I1 read approximately 3.0 amps.	Transistors Q1 thru Q9, Q11, Q13, Q15 and Q17.

4.4 Voltage Measurement

To enable the technicians to effectively service the PC14 and PC14A, table 4.3 tabulates the typical D.C. and/or A.C. voltage to assist in localizing a fault source.

Table 4.2 indicates the possible component for an abnormal reading. If a voltage other than those listed in table 4.3 is measured this will enable the technician to determine which component is possibly faulty.

TABLE 4.3 PC14 AND PC14A VOLTAGE DISTRIBUTION MEASUREMENT

CONDITION

1. Input 27.5 VDC.
2. Full load with Switch S5 on.
3. Switch S1 in the #1 position.
4. PC14 switch S2 in the #1 position.
5. PC14A switch S2 in the #2 position.
6. DC and AC measurement made with a Simpson 270 or equivalent.
   (Note: Make AC measurement in the output connection to this meter.)

CIRCUIT REF.	TEST POINT	VOLTAGE MEASUREMENT D.C.	VAC RMS	CIRCUIT REF.	TEST POINT	VOLTAGE MEASUREMENT D.C.	VAC RMS

* These voltages are load dependent.

4.5 Servicing Practice and Replacement

Section 5.0 lists the table of replaceable parts. Figures 5.1 thru figure 5.5 illustrates the location of these components.

When installing or removing transistors, semiconductor diodes and heat sensitive components, grasp the lead between the solder joint and the component with a thermal dissipator, such as a spring loaded copper clip or long nose pliers. This will bleed off the heat being applied at the solder joint.

A temperature controlled soldering iron is recommended for such use. The wattage rating of the iron should not be greater than 35 watts. Always work with an iron that the tip is well thinned so the soldering can be done quickly and cleanly.

Power transistors Q9, Q10, Q13 and Q14 are insulated from ground. This insulating is done by means of insulating washers made of fiber and mica. When replacing these transistors, be sure washers are replaced in proper order and coating the washers with a film of silicone fluid is recommended.

After such replacement, check with an ohmmeter to see that the insulation is effective.

SECTION V - TABLE OF REPLACEABLE PARTS

5.1 General

This section illustrates and lists components that can be replaced for repair purposes. It is recommended that parts requiring replacement that are not listed in table 5.1, the unit be returned to the factory for service.

Figures 5.1 through 5.5 illustrates the location of all the components that are listed in the table of replaceable parts.

5.2 Manufacturer's Code

WARRANTY

Flite-Tronics Co., Inc. warrants each item of new equipment manufactured by it to be free from defects in material and workmanship under normal service use for which intended. Flite-Tronics obligates itself under this warranty to replace or repair (at Flite-Tronics' discretion), at its factory, any Flite-Tronics' equipment which shall within one year or 1,000 hours of service, whichever comes first, be returned, transportation charges collect to Flite-Tronics with a statement from an authorized Flite-Tronics Dealer establishing the date equipment was placed in service, which Flite-Tronics examination shall disclose to have been defective in manufacture. This warranty shall not apply to any equipment which, in the judgment of Flite-Tronics, has been repaired or altered in any way so as adversely to affect its performance or reliability, or which has been subject to misuse, negligence or accident. This warranty is in lieu of all other guaranties or warranties expressed or implied. The obligation and responsibility of Flite-Tronics for or with respect to defective equipment shall be limited to that expressly provided herein and Flite-Tronics shall not be liable for consequential or other damage or expense whatsoever therefor or by reason thereof. Flite-Tronics reserves the right to make changes in design or additions to or improvement in its equipment without obligation to install such additions or improvements in equipment theretofore manufactured.

HOW TO ORDER REPLACEMENT PARTS

When ordering replacement parts, you should direct your order as indicated below and furnish the following information insofar as applicable.

ADDRESS: Flite-Tronics Co., Inc., Sales Service Department
3314 Burton Avenue
Burbank, California

INFORMATION NEEDED:

1. Quantity required.
2. Part Number (Obtain from parts list or schematic diagram.)
3. Type number and serial number of equipment.

HOW TO RETURN MATERIALS OR EQUIPMENT

If, for any reason, you should wish to return material or equipment, whether under warranty or otherwise, you should notify us, giving full particulars including the details listed below, insofar as applicable. Upon receipt of such notice, Flite-Tronics Co., Inc. will promptly advise you respecting the return. Failure to secure our advice prior to the forwarding of the goods, or failure to provide full particulars, may cause unnecessary delay in handling of your returned material.

ADDRESS: Flite-Tronics Co., Inc., Sales Service Department
3314 Burton Avenue
Burbank, California

INFORMATION NEEDED:

1. Date of delivery of equipment.
2. Date placed in service.
3. Number of hours in service.
4. Part number (obtain from parts list or schematic diagram.)
5. Type number and serial number of equipment.
6. Nature and cause of failure.
7. Remarks

FLITE-TRONICS STATIC INVERTERS
UNDER MODEL PC-15( ) and
MODEL PC-15B( ) SERIES

MODEL SERIES	DESCRIPTION
PC-15	Basic 250VA, 400HZ, 115VAC output inverter 5 pin or 7 pin connectors This model series superseded by Model PC-15B
PC-15A	250VA, 400HZ, 115V & 26VAC outputs, Osc. Sync. output. 7 pin connector This model series superseded by Model PC-15B.
PC-15A with M1 after Serial No.	PC-15A with field modification per Flite-Tronic's Service Bulletin No.1/PC-15A. This model series superseded by Model PC-15B
PC-15A with A after Serial No.	PC-15A with increased fuse-rupture capability per Flite-Tronic's Service Bulletin No.2/PC-15A. This model series superseded by Model PC-15B.
* PC-15B or PC-15A with B after Serial No.	Currently available basic 250VA, 400HZ Static Inverter 115V & 26VAC outputs, Osc. Sync. output. 7 pin connector Refer to Section VII of this Manual for detail
PC-15C	Not Assigned.
*PC-15D	PC15B with 150VA from 26VAC output 100VA from 115VAC output Osc. Sync. output 7 pin connector Refer to Section VII of this Manual for detail.
*PC-15E	PC-15B with remote on & off feature added 9 pin connector. Refer to Section VII of this Manual for detail.
*PC-15F	PC-15B with DC return isolated from chassis Refer to Section VII of this Manual for detail.
*PC-15G	PC-15F with a MS3102A22-15P connector and 115VAC output only. Refer to Section VII of this Manual for detail.

* Refer to Page ii for Model identification changes.

Model identification change has been made as listed below. This is an identification change of the inverters of current manufacture. Interchangeability of the PC-15B( ) with the PC-15B, effective Serial Number 3178, is not affected and the electrical and mechanical specifications are the same.

The electrical and mechanical specifications of the PC-15B( ) are equal to or superior than the PC-15( ) manufactured previously. PC-15B( ) Serial Number effectivity is 3700 except as noted under Revision No. 7.

NEW IDENTIFICATION		PREVIOUS IDENTIFICATION	
MODEL	SERIAL NUMBER EFFECTIVITY	MODEL	SERIAL NUMBER
PC-15B( )	3700	PC-15B	3178 & Up
PC-15B(D)	25	PC-15D	1 & Up
PC-15B(E)	27	PC-15E	9 & Up

Section I

General Information

1.1 Introduction

This instruction manual has been prepared to provide information in installation, performance, operation, identification of parts, and maintenance of the Flite-Tronics' Model PC-15 and PC-15A Transistorized Power Inverter. PC-15A is identical to PC-15, except it has a 26.0 VAC 400 HZ output.

1.2 Purpose of Equipment

The PC-15 and PC-15A, shown in Figure 1.1, is a transistorized inverter designed to supply AC power at 400 cycles per second.

The unit is capable of delivering a current overload of 150% for a minimum duration of 5 minutes at full rated output. This permits the PC-15 and PC-15A to power equipment that requires momentary surges of power during turn on. When the 26 VAC output from the PC-15A is not used, the PC-15A is identical in performance to the PC-15.

1.3 Specifications for PC-15 and PC-15A

Input Voltage.....: 28.0 VDC

Input Current: Steady state @ 28 VDC

a) 14.2 amperes for PC-15s delivering 250 VA.

b) .75 amperes typical no load.

Input Voltage Range:

22 to 30 VDC
Operate down to 20 VDC

Input Overvoltage:

Withstands 130% input overvoltage for 5 minutes, while supplying full rated 250 VA output power. Output voltage under this condition, +5%, -7%.

Output Voltage:
(PC-15 and PC-15A)
115 VAC rms +5%, -7% 22 to 30 VDC, Greater than 100 VAC down to input of 20 VDC

Pin E Output @ 20 VDC input:
115 VAC @ 90% load.

Output Voltage: (PC-15A only)

26.0 VAC rms +5%, -7%

Output Frequency: 400 HZ ± 1%

Total Maximum Continuous Output Power..... 250 VA

Output Power, PC-15A
26.0 VAC..... 75 VA

Output Waveform:

Weight. 8.2 lbs. for PC-15B( ).
7.5 lbs. for PC-15BC( ).

Size:

Width	6"
Length	9-3/8" (not incl. mounting flange)
Height	3-3/16"

*See Page A0 for output fault clearance capability

Humidity:

Greater than 95% for ten days, temperature cycled between 75° F. to 160° F.

Vibration:

To withstand in three directions

.08 DA	5-15 HZ
.036 DA	15-70 HZ
10 G's	70-500 HZ

Shock:

To withstand at least 10 G's for 11 milliseconds in three directions.

1.4 Description

The PC-15 and PC-15A is a transistorized airborne static power inverter. The unit operates from 28.0 VDC aircraft power source and delivers 115 VAC at 400 HZ. The Model PC-15A has a 26.0 VAC output. The total continuous power drawn from the two outputs should not exceed 250 VA for the PC-15A.

An L/C tuned 400 HZ oscillator operating in a class B push-pull mode is used to generate the 400 HZ signal.

This signal is amplified by 4 stages of class B push-pull emitter follower amplifiers. Protective circuits for output overload, thermal runaway and input voltage transient are incorporated to make the PC-15s an extremely reliable equipment.

Frequency and output voltage are adjustable. However, once set at the factory, they should not require readjusting for the life of the equipment.

Statement by Test Lab.; Cornell-Dublier Electronics Division.

Summary of Results for Radiated and Conducted RFI:

The Static Inverter M/N PC-15, S/N 100, was subjected to an electromagnetic interference investigation test program per R.T.C.A. Paper 120-61/DO-108, Appendix A. Upon evaluation of the test data, it was found that the above referenced static inverter generated interference which was below the specification limits of R.T.C.A Paper 120-61/DO-108, Appendix A.

Section II

Installation

2.1 General

The Model PC-15 and PC-15A (hereinafter referred to as PC-15s) is a 400 HZ Inverter, ready to install when delivered from the factory.

To determine that the unit is operating satisfactorily, a bench test may be made. The external hook-up for such a test is illustrated in Figure 4.1 page22.

The PC-15s will deliver 250 VA of power to a load having a power factor between .8 lag to 1.0. The PC-15s will operate into loads which are more reactive; however, an external phase correcting capacitor will be required.

The capacitance value may be determined by noting what value causes a null in the input current reading. This, of course, should be determined with the load the PC-15 or PC-15A delivers power to. A poly-carbonate type capacitor having a rating of 300 volts or greater may be used for this phase correcting.

Installation where more than 250 VA of continuous power is required, the PC-15s may be paralleled, as necessary, to double, triple, or even quadruple the power of a single unit.

2.2 Installation Procedure

The PC-15s are environmentally designed to mount on a rack with other equipment, or in any suitable location in the aircraft.

Figure 2.1 illustrates the installation dimensions and mounting centers; see page 8 for PC-15 and page 9 for PC-15A. Mounting hardware should be 10-32 and length long enough to have 1-1/2 threads exposed after installing the necessary hardware.

The mating connector plug to the PC-15s' receptacle is MS3106B18-9S.

A wire size AWG #10 or #12 is suggested for the low voltage DC input and an AWG size #12 for the AC output leads. The low voltage input to the PC-15s should be protected with a 25 amp circuit breaker.

Figure 2.3 page10 illustrates the electrical connection to operate units in parallel for greater output power capability.

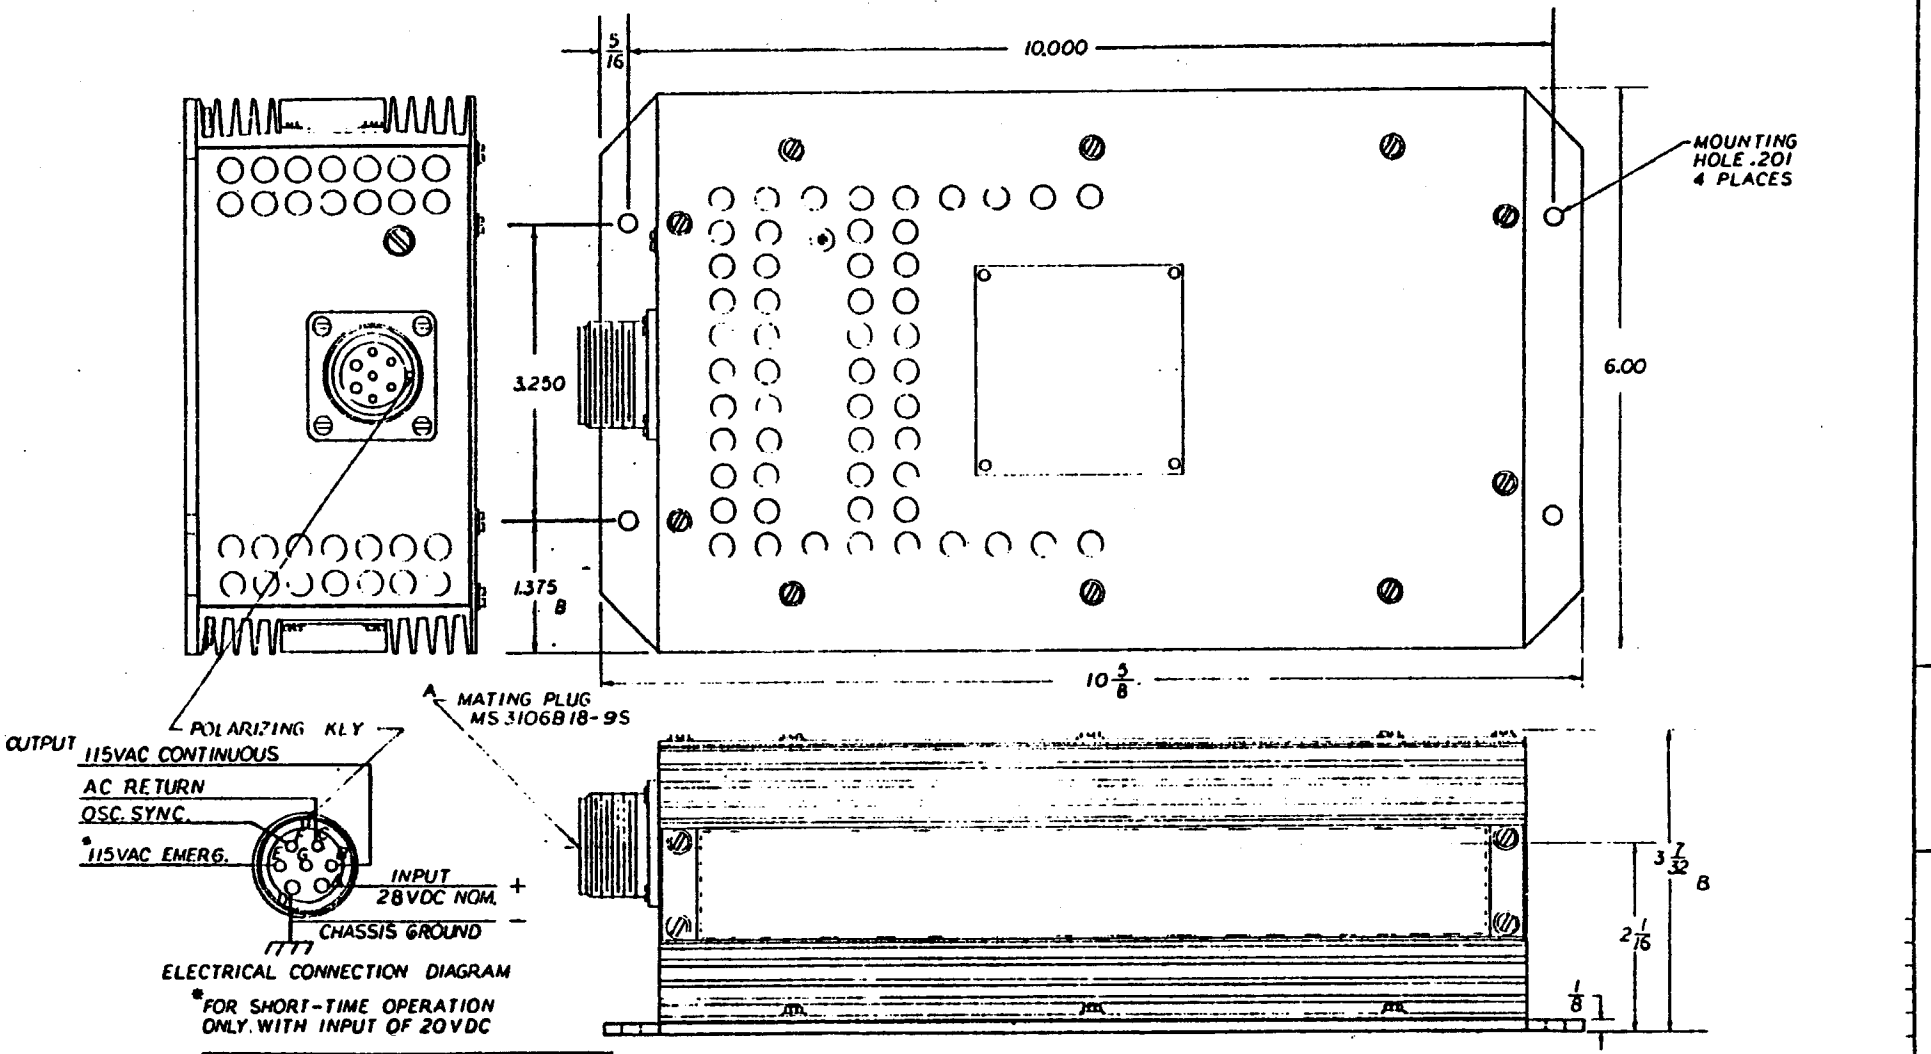
Figure 2.4 page11 illustrates the electrical connection to operate units in parallel, not only for greater power, but also switching the PC-15s for parallel or independent operation remotely.

Units operating in parallel must have oscillators phase locked. This is

accomplished by connecting pin F together. To frequency lock the PC-15s to other 400 HZ ± .5%, 115 VAC source, R25 is changed .0047 ufd and pin F is connected to that source.

Frequency locking of PC-15s is only necessary when other 400 HZ ± 2 HZ power sources are in an aircraft and resulting in an undersirable beating effect.

CAUTION



THE PC-15S SHOULD NOT BE INSTALLED IN AN AREA WHERE THE AMBIENT AIR TEMPERATURE EXCEEDS 172° F. UNDER ALL WEATHER AND OPERATING CONDITIONS. THE UNIT MAY BE MOUNTED IN ANY POSITION. IN AN INSTALLATION THE VENT HOLES SHOULD NOT BE RESTRICTED. ALSO, THE PC-15S SHOULD BE MOUNTED DIRECTLY TO METALLIC PLATES OR SUPPORTS.

WHEN PC-15S ARE CONNECTED IN PARALLEL, ALL UNITS MUST BE TURNED ON. OTHERWISE THE PARALLEL CONNECTION SHOULD BE DISCONNECTED TO OPERATE INDEPENDENTLY.

WHEN THE PC-15S ARE OPERATED IN THE FREQUENCY LOCKED MODE TO OTHER 115 VAC 400 HZ ± 2 HZ SOURCE, THE OUTPUT, OF COURSE, SHOULD NOT BE PARALLELED.

WARNING

THE BLOWER MOTOR SHOULD BE INSPECTED AND OVERHAULED EVERY 1000 HOURS OF MOTOR OPERATION.

Section III

Principles of Operation

3.1 General

The PC-15 and PC-15A (referred to as PC-15s) convert DC energy to AC electrical energy.

The nominal output is 115 VAC on pin B and 26 VAC output from pin G, for Model PC-15A only. However, in an emergency battery condition of 20 VDC input, the output from pin E is 115 VAC working into 90% of full rated load. The output from pin G, the 26 VAC output, will follow the input DC voltage variation below 24.0 VDC. The 400 HZ is generated by an L/C tuned push-pull oscillator. The sine wave signal is amplified by four stages of class B push-pull amplifier. The final power output stage is also class B, but the transistors are cascaded. This permits operating at higher temperature and also decreases the collector to emitter operating voltage in half; i.e., eliminates the possibility of an 88 volt peak transient on the 28.0 VDC buss destructing the transistors. A schematic of the PC-15s is illustrated in Figure 3.2 and 3.3.

3.2 Block Diagram

Figure 3.1 shows the PC-15s' operation in a block diagram form. The block diagram illustrates the time tested and proven circuitry for power amplification of a low level AC signal. All the stages are class B push-pull emitter follower configuration. The emitter follower circuitry having inherent negative feedback introduces very little amplitude and phase distortion.

The output signal is sampled by current and voltage transformers. These components deliver a signal to operate the output overload and output voltage level circuitry.

This output, in turn, controls the push-pull 400 HZ oscillator amplitude.

The output overload reduces the output current and voltage when a load excess of 160% is applied to the output. This same circuitry operates in the event of a short circuit on the output.

The automatic level control maintains the output voltage constant for load and temperature variation.

3.3 400 HZ Sine Wave Oscillator

Inductor-transformer T1 is the feedback, output and resonant tuning transformer. The center tapped primary winding is 1-2-3. Feedback winding is 4-5-6. The output and resonant tuning winding is 7-8-9.

Capacitor C10 (.47 ufd) resonates with the inductance of the output winding at 400 HZ.

Transformer T1 has a tuning slug which is adjusted at the factory for an oscillator frequency of 400 HZ.

Transistors Q1 and Q2 are the class B push-pull amplifier to sustain oscillation. Resistors R2 and R3 biases the transistors to cause oscillation to start. Capacitor C9 suppresses any tendency for high frequency mode oscillation. Resistor R4 is the degenerating resistor.

The output winding 7-8-9 drives the bases of Q3 and Q4 in opposite phase.

3.4 Low Level Amplifiers

Between the sine wave oscillator and power amplifiers, there are three stages of class B push-pull emitter follower amplifiers.

The first stage consists of transistors Q3 and Q4 and the interstage transformer T2. Resistors R5 and R6 biases the transistors operating point.

The output from the transformer T2 drives the bases of Q5 and Q6. Resistors R24 and R23 biases transistors Q5 and Q6. Transistors Q5 and Q6 emitters drive the matching autotransformer T3. By using an autoformer connection for T3, the unit is designed compactly and yet permits proper step-up to drive transitors Q9 and Q10. Capacitor C22, a selected value connected across 4 and 6 of T2, is used to suppress ringing.

Capacitor C21 connected to the base of Q9 and Q10 suppresses parasitic oscillation. The emitter of Q9 and Q10 drives transformer T4. Transformer T4 delivers proper voltage and current to the final power output transistors.

Decoupling network for the oscillator stage and first low level amplifier is R1 and C2. Decoupling network for the intermediate stage is R10.

Zener CR8 clips transient voltage above 43 VDC.

3.5 Power Amplifier

The power amplifier consists of power transistors connected in cascaded pairs. Transistors Q11 through Q16 and Q18 through Q23 are driven in alternate half cycles. The multiple winding primary of transformer T5 divides the 28.0 VDC input, so the transistors support 26.75 peak AC signal.

These power transistors are controlled to Flite-Tronics' specifications. These devices are inspected for certain minimum breakdown voltage, gain and recovery time. Therefore, an 88 volt peak transient on the 28.0 VDC input will not cause a collector to emitter voltage to exceed the minimum breakdown voltage. The primaries of the transformer forces this voltage division. In spite of the unusual connection of transistors Q11 through Q23, they are connected for class B push-pull amplifier.

The tapped secondary of T5 delivers 26 VAC from terminal 13, and 115 VAC from terminal 8. (Model PC-15A only)

The output from terminal 9 is 115 VAC working into 90% of rated load, during an input of 20 VDC on the A+ line.

This output is to be used only during emergency 20 VDC input condition and the load should be connected to pin E of J1. There will exist, however, a slight squaring of the peaks of the sine wave in this condition.

Capacitor C13 is the phase compensating capacitor to permit the unit to operate efficiently with a load power factor between .8 lag and 1.0.

3.6 Output Voltage Control

The output voltage sample is realized from the center tapped winding 10-11-12 of T5. Rectifiers CR6 and CR7 converts the AC signal to a DC output. Filter consisting of L2-B and C12 is the L section choke input to give an average DC output which is proportional to the 115 VAC level.

This DC output is also applied across a variable resistor R14 in series with R22. The variable portion of the resistor is connected to the base of Q17. In essence, this output voltage sample is compared with the zener CR1 in the emitter of Q17. Resistor R18 is the bleeder resistor to the zener to permit operating this zener on its flat portion of its transfer characteristics curve.

The variable resistor R14 is adjusted for an output of 115 VAC. A common load resistor R7 is connected to the collector of Q7 and Q17. The DC current passing through R7 determines the bias point for transistor Q8. Transistor Q8 is the variable DC source for the push-pull 400 HZ oscillator.

The push-pull oscillator represents an impedance to the collector circuit of Q8. Hence, the conduction of Q8 will determine the magnitude of DC voltage across the oscillator circuit. This, in turn, determines the amplitude of oscillation, which controls the AC output level. Resistor R9 and R17 are the degenerating resistors for transistor Q8.

Thermistor R20 is a temperature compensating resistor.

Resistor R8 is the starting resistor for transistor Q8 until the oscillator amplitude builds up sufficiently for the automatic level control circuitry to take over.

Capacitor C6 is a low frequency feedback capacitor to prevent the automatic level control circuitry from motor boating. Capacitor C3 and C5 are simply by-pass capacitors.

3.7 Output Overload Control

The output AC current is sampled by the transformer T6. The current flowing through the winding 1-2 causes a voltage to be developed across the center tapped winding 3-4-5. The magnitude of voltage across this winding is controlled by the variable resistor R15 in series with R13.

The AC voltage from winding 3-4-5 is rectified by CR4 and CR5. The averaging choke input filter, consisting of L3 and C8, develops a DC voltage across R12, which is proportional to the output AC current. For the Model PC-15A, the 26 VAC output current is sampled by winding 6-7 of transformer T6.

To realize an overload that causes quenching action, the overload current resulting in DC voltage across R12 is compared with the output DC voltage across R11. This tends to give a trigger-like action when an overload condition is sustained.

The output voltage sample is taken from winding 10-11-12 of transformer T5. CR1 and CR3 rectifies this voltage. The L section choke input filter, consisting of L2 and C7, places across resistor R11 a ripple-free DC voltage. The voltage across R11 is a negative polarity with respect to ground.

The DC voltage across R12, which is proportional to the output current, is compared with the voltage across resistor R11. When the output current causes a voltage across R12 to exceed the compared voltage across R11, transistor Q7 will start conducting. The extent of overload determines the magnitude of current Q7 will conduct. As Q7 conducts, this tends to cut off Q8, which, in turn, decreases the voltage across the 400 HZ oscillator circuit.

When the load is in excess of 165% of 250 VA, the oscillator circuit will exhibit anything from low frequency quenching to almost a complete shut down.

During output short circuit, the current overload circuitry will reduce the voltage across the push-pull oscillator until a feeble oscillation is maintained.

Of course, on removal of the short circuit condition, the unit will immediately return to normal operating condition.

3.8 Input Filtering and Blower

The input is filtered by a pi section filter, consisting of capacitors C1A, C14 through C17 and choke L1.

Additional filtering for the low level stage is done by the RC filter, consisting of R1, C2, and R10, C1B, C11, C18 through C20.

Blower motor M1 is thermostatically controlled and used for protection only. The blower motor turns on when the heat sink temperature exceeds 165° Fahrenheit.

In normal installation where thermal conduction by the aircraft structure is adequate, the blower motor may never come on. Resistor R16 simply reduces the speed slightly to measurably increase the life of the blower.

F1 fuses the intermediate amplifier stages.

3.9 Transient Protection

To eliminate deleterious effects of voltage transients, zener and diodes are used.

Transient voltage passing through the A+ input filter section and exceeding 43 volts are clipped by the zener diode CR8.

Transient voltage occuring at the junctions of the power output transistors exceeding the input voltages are clipped by diodes CR9 and CR10.

3.10 Phase & Frequency Locking

When the PC-15s are paralleled together, it is necessary to phase synchronize the output voltage. Resistor R25 is the coupling resistor to phase lock the oscillator together through pin F of J1.

When the PC-15s are paralleled, it is necessary to have all the parallel units operating. The loading effect of the non-operating unit causes the other parallel unit or units to shut down. Refer to page 11 for remotely disconnecting non-operating unit.

To frequency lock the PC-15s to other 115 VAC sources, resistor R25 is changed to C23. Typically .0047 ufd, as shown in the bill of material may be used.

When PC-15s are frequency locked, the output should not be paralleled to the 115 VAC source.

Section IV

Maintenance

4.1 General

This section covers the bench check of the PC-15s to determine conformance to manufacturers specification. Periodic preventative maintenance is not necessary, since no moving parts are employed to realize functional electrical performance.

For safety feature only, a thermostat is used to control the blower motor. It will come on only when the heat sink temperature exceeds 165°F.

Table 4.2, page 23, is used to functionally check the PC-15s to manufacturers performance.

The instructions on table 4.3 will aid in localizing the cause of defective operation, should any component fail.

4.2 Test Equipment

Table 4.1 lists the recommended components and test equipment to be employed in conducting electrical test per manufacturers test procedures.

Figure 4.1 illustrates the bench test inter-connection diagram. The Flite-Tronics Test Set TS15-1 is a unit for readily conducting the test in table 4.2 and 4.3. Table 4.2 indicates the readings and step-by-step procedure to test PC-15s operating normally. Table 4.3 notes test procedure and possible cause of abnormal reading.

4.3 Performance Test and Localizing Trouble Source

Table 4.3 outlines a step-by-step procedure to performance test the PC-15s to localize fault source, if troubles exist.

It is suggested the technician acquire familiarity of the unit by studying the principles of operation section prior to attempting this section.

In table 4.3, test 1 through 14 is valid for the Models PC-15 and PC-15A. Test 15 and 16 are for the Model PC-15A only.

*These meters are required only if the power supply does not contain them.
**Emergency output at 20 VDC input only.

FIGURE 4.1 BENCH TEST SET AND HOOK-UP

4.4 Check Procedure for PC-15 and PC-15A

To functionally test Flite-Tronics Static Inverter connect the PC-15 or PC-15A to the test rack TS-PC15-1.

A. Model PC-15: 1 output; 115 VAC, 400 Hz, 250 VA Max.
B. Model PC-15A: 2 outputs; 115 VAC, 400 Hz, *250 VA Max.
26 VAC, 400 Hz, *75 VA Max.
C. Frequency: 400 Hz ± 4 Hz, both Models.
D. Amplitude Distortion: 7% or less under normal operating conditions, both Models.
E. Tests for 115 VAC output of PC-15 and PC-15A are identical.
*Sum of powers from the 115 VAC and 26 VAC outputs should not exceed 250 VA.

*Table 4.2 Test Conditions and Typical Readings

Model	Condition	Switch	Position	** Typical Readings			
				DC Input		AC Output	
				Voltage	Current	Voltage	Current
PC-15 or PC-15A	No load	S1 S2 thru S10 S11 S12 & S13	#1 Off PC15 115 VAC	Set to 28 VDC	.75 Amps or less	120.7 VAC maximum	C Amp
PC-15 or PC-15A	4% load	S1 S2 S3 thru S10 S11 S12 & S13	#1 On Off PC15 115 VAC	Set to 28 VDC	2.0 Amps maximum	Between 115 VAC and 120.7VAC	.1 Amps maximum
PC-15 or PC-15A	33% load	S1 S3 S2 & S4 thru S10 S11 S12 & S13	#1 On Off PC15 115 VAC	Set to 28 VDC	5.0 Amps typical	Between 115 VAC and 120.7VAC	.72 Amps typical
PC-15 or PC-15A	100%	S1 S5 S2 thru S4 & S6 thru S10 S11 S12 & S13	#1 On Off PC15 115 VAC	Set to 28 VDC	14 Amps typical	Between 108 VAC and 120.7VAC	2.17Amps typical
PC-15 or PC-15A	150% overload	S1 S6 S2 thru S5 & S7 thru S10 S11 S12 & S13	#1 On Off PC15 115 VAC	Set to 28 VDC	22 Amps typical	At least 107 VAC	3.3 Amps typical
PC-15 or PC-15A	165% overload	S1 S7 S2 thru S6 & S8 thru S10 S11 S12 & S13	#1 On Off PC15 115 VAC	Set to 28 VDC	24 Amps typical	At least 100 VAC	3.6 Amps typical
PC-15 or PC-15A	175% overload	S1 S8 S2 thru S7 & S9 & S10 S11 S12 & S13	#1 On Off PC15 115 VAC	Set to 28 VDC	Between 5.0 Amps and 13 Amps	Output voltage & current motor-boating typically @ 60 VAC and @ 2.2 Amps	

*Table 4.2 additions for Pc-15B
See page A2

** Readings shown are steady state values unless otherwise noted

4.4 Check Procedure for PC-15 and PC-15A (Continued)

Model	Load Condition	Switch	Position	Typical Readings			
				DC Input		AC Output	
				Voltage	Current	Voltage	Current
PC-15 or PC-15A	100% Reactive Load	S1 S9 S2 thru S8&10 S11 S12 & S13	#1 On Off PC15 115 VAC	Set to 28 VDC	14 Amps typical	Between 107 VAC and 120 VAC	Between 2.2 Amps and 2.5 Amps
PC-15 Only	Output Short Circuit	S1 S10 S2 thru S9 S11 S12 & S13	#1 On Off PC15 115 VAC	Set to 28 VDC	3 Amps or less	0 VAC	1 Amp or less
PC-15 or PC-15A	Pin E Output @20 VDC Input	S4 S1 S5 thru S10 S11 S12 & S13	On #2 Off PC15 115 VAC	Set to 20 VDC	15 Amps typical	Between 107 VAC and 115 VAC	1.95Amps typical
PC-15A Only	*Full load 175 VA @115 VAC	S1 S2 thru S10 S11 S12 & S13	#1 Off PC15A 115 VAC	Set to 28 VDC	14 Amps typical	Between 107 VAC and 120 VAC	1.5 Amps typical
	75 VA @26 VAC	S1 S2 thru S10 S11 S12 & S13	#1 Off PC15A 26 VAC	Set to 28 VDC	14 Amps typical	Between 24.2VAC and 27.3VAC	2.9 Amps typical
	Output Short Circuit Test 26 VAC	S1 S2 thru S10 S11 S12 & S13 S10	#1 Off PC15A 26 VAC On	Set to 28 VDC	3 Amps or less	0 VAC	8 Amps initial transient, 2Amp typical
	115 VAC	S1 S2 thru S10 S11 S12 & S13 S10	#1 Off PC15A 115 VAC On	Set to 28 VDC	3 Amps or less	0 VAC	1 Amp or less

* S11 in PC-15A position, 175 VA resistive load is connected to 115 VAC output and 75 VA resistive load is connected to 26 VAC output.

4.4.1 Switch Nomenclature:

S1 115 VAC normal and emergency output selector switch; position #1 normal, position #2 emergency, when input power is 20 VDC
S2 4% Resistive load switch
S3 33% " " "
S4 90% " " "
S5 100% (250VA) Resistive load switch
S6 150% Resistive load switch
S7 165% " " "
S8 175% " " "
S9 100% Reactive load switch
S10 Output short circuit switch for 115 VAC or 26 VAC - the AC voltmeter indicates output being shorted
S11 PC-15 and PC-15A output selector switch
S12 Output voltage selector switch. 115 VAC or 26 VAC
S13 Output current selector switch. 115 VAC or 26 VAC current

Table 4.3 Performance Test and Localizing Trouble Procedures

STEP	SET-UP	PROCEDURE	PERFORMANCE READING	POSSIBLE CA OF ABNORMAL READING
1	Interconnect unit per bench test hook-up	a) Turn on power supply, keep input voltage set at zero. b) Turn on all measuring equipment for warm-up. c) Check polarity of power supply. d) Set S1 to No. 1 position. e) Set switches S2 through S10 in the Off position.		
2	S2 through S10 in the Off position S11 in the PC-15 position S12 & S13 in the 115V position	a) Gradually increase power supply voltage to 27.5 VDC	Input DC current I1 should not exceed 3/4 amps DC	Test set-up incorrectly connected. Capacitor C1A, C1B, C11, and C14 through C20 may be shorted. Transistors Q9 through Q23 shorted. C2 or CR8 shorted.
3	S2 through S10 in the Off position S11 in the PC-15 position S13 in the 115V position	a) Input voltage set at 27.5 VDC b) Adjust R14 as required, so V2 reads 117 VAC if necessary	V2 should read between 107 VAC to 120.7, with S12 in the 115 VAC position. V2 should read between 24.2 to 27.3 VAC with S12 in the 26.0 VAC position for the PC-15A only.	Check for following likely defective components: CR6, CR7, C12, R14, C6, CR1, Q17, C3, Q8, and R20

STEP	SET-UP	PROCEDURE	PERFORMANCE READING	POSSIBLE CAUSE OF ABNORMAL READING
4	S2 through S10 in the Off position S11 in the PC-15 position S12 and S13 in the 115V position	a) Input voltage set at 27.5 VDC. b) If frequency is out of tolerance, adjust turning slug on transformer T1.	Frequency meter should read 400 HZ ± 4 HZ I1=3/4 A	Defective parts likely to cause abnormal reading: Transformer T1, Capacitor C10 or C9
5	S2 through S10 in the Off position S11 in the PC-15 position S12 and S13 in the 115V position	a) Input voltage set at 27.5 VDC. b) Vary input voltage between 26 to 30 VDC.	Distortion meter should read less than 7%. I1=3/4 A	Defective parts likely to cause abnormal reading: Transistors Q3 through Q6 and Q9 through Q23. Capacitors C3, C5.
6	Switch S5 on for full load output S11 in the PC-15 position S12 and S13 in the 115V position	a) Input voltage set at 27.5 VDC. b) Resistor R14 may require readjusting; however, if adjusted, step 3 should be re-tested. c) Vary input voltage between 26 to 30 VDC.	I2 read 2.17 amps AC V2 should read between 107 to 120.7 VAC. I1 should read approximately 14.2 A. Frequency should be 400 HZ ± 4 HZ Distortion less than 7%.	Defective parts likely to cause abnormal reading: Diodes CR2, CR3, CR4 and CR5. Transistor Q1 through Q17.

STEP	SET-UP	PROCEDURE	PERFORMANCE READING	POSSIBLE CAUSE OF ABNORMAL READING
7	Switch S6 for 150% overload test. S11 in the PC-15 position S12 and S13 in the 115V position	a) Input voltage set 27.5 VDC. b) Resistor R15 may require adjusting if unit tends to motor boat. However, in the event of any adjustment, step 3 should be repeated.	I2 should read approximately 3.25 amp. V2 should read at least 107 VAC. I1 should read approximately 22.0 amps.	Defective par. likely to cause abnormal reading: Diodes CR2, CR3, CR4 and CR5. Transistor Q1 through Q17.
8	Switch S7 on for 165% overload test S11 in the PC-15 position S12 and S13 in the 115V position	a) Input voltage set at 27.5 VDC. b) R15 adjust the overload threshold point. The proper setting is at the 165% overload point; the unit should almost start motorboating.	I1 should read 24 amps. V2 should read at least 95 VAC. I2 should read approximately 3.6 amps.	Defective components likely to cause abnormal reading: Diodes CR2, CR3, CR4 and CR5. Capacitors C7 and C8. Transistors Q7 and Q8.
9	Switch S8 on for 175% overload test S11 in the PC-15 position S12 and S13 in the 115V position	a) Input set at 27.5 VDC. b) R15 adjust the overload threshold point. The proper setting at 175% overload point, the PC-15 should be in the motorboating mode.	I1 should be motorboating between 1.0 to 10 amps. I2 and V2 should indicate output current and voltage is motorboating.	Defective components likely to cause abnormal reading: Diodes CR2, CR3, CR4 and CR5. Capacitors C7 and C8. Transistors Q7 and Q8.
10	Switch S10 on for output short circuit test S11 in the PC-15 position S12 and S13 in the 115V position	a) Input set anywhere between 26 and 28 VDC. b) If I1 exceeds 6 amps at anytime, the unit should be turned off.	I1 less than 6 amps. V2 = zero I2 less than 1 amp.	Defective components likely to cause abnormal reading: Diodes CR2, CR3, CR4 and CR5. Capacitors C7 and C8. Transistors Q7 and Q8.

STEP	SET-UP	PROCEDURE	PERFORMANCE READING	POSSIBLE CAUSE OF ABNORMAL READING
	Switches S2 through S8 in the Off position Switch S9 on 250 VA S10 in Off position S11 in the PC-15 position S12 and S13 in the 115V position	a) Input voltage set at 27.5 VDC. b) Vary input voltage between 28 to 30 VDC.	I2 read 2.0 to 2.3 amps AC. V2 read between 107 to 120.7 VAC.	Defective parts likely to cause abnormal reading: Diodes CR2, CR3, CR4 and CR5. Transistor Q1 through Q17. Capacitor C13.
12	Switch S3 on and S4 through S10 in Off position for 33% load test S11 in the PC-15 position S12 and S13 in the 115V position	a) Input voltage set at 27.5 VDC.	I1 read 5.0 amps. I2 read .72A V2 read between 117 to 120.7 VAC. Distortion meter should read less than 7%. Frequency meter should read 400 HZ ± 4 HZ.	Defective parts likely to cause abnormal reading: Transformer T1. Capacitor C3, CR5 and C10. Transistors Q3 through Q6 and Q9 through Q16.
13	Switch S2 on. Switch S3 through S10 in Off position S11 in the PC-15 position S12 and S13 in the 115V position	a) Input voltage between 26.0 to 28 VDC	Distortion less than 7%. Frequency 400 HZ ± 4 HZ. V2 read 115 to 120.7 VAC. I1 read 2 amps DC. I2 read .20 to .35 amps AC.	Defective parts likely to cause abnormal reading: Diodes CR6, CR7, C12, R14, C6, CR1, Q17, C3, Q8 and R20.

STEP	SET-UP	PROCEDURE	PERFORMANCE READING	POSSIBLE CAUSE OF ABNORMAL READING
14	Switch S1 to #2 position. S4 on, and S5 through S10 in Off position S11 in the PC-15 position S12 and S13 in the 115V position	a) Set input voltage at 20 VDC.	V2 read 107 to 120.7 VAC. I2 read 1.93 to 2.12 amps AC. I1 read approximately 15.0 amps DC.	Defective part likely to cause abnormal reading: Diodes CR2, CR3, CR4 and CR5. Transistor Q1 through Q17.
15	Switch S1 to #1 position Switch S11 in the PC-15A position	a) Input voltage set at 28.0 VDC.	I1 should read approximately 14.2 amps. I2 read 1.52 amps, S13 in 115V position. I2 read 2.9 amps, S13 in 26V position. V2 should read between 107 to 120.7 VAC with S12 in 115V position. V2 should read between 24.2 to 27.3 VAC with S12 in 26V position. Distortion for 26 VAC and 115 VAC output should be 7% or less.	Defective parts likely to cause abnormal reading: Diodes CR2, CR3, CR4 and CR5. Transistor Q1 through Q17.

STEP	SET-UP	PROCEDURE	PERFORMANCE READING	POSSIBLE CAUSE OF ABNORMAL READING
	Switch S11 in the PC-15A position for output short circuit test S12 in the 26V position S13 in the 26V position	a) S10 switched on after unit is operating normally. b) If I1 exceeds 6.0 amps at anytime, the unit should be turned off.	I1 less than 6.0 amps. V2 reads zero. I2 less than 1.5 amps.	Defective components likely to cause abnormal reading: Diodes CR2, CR3, CR4 and CR5. Capacitors C7 and C8. Transistor Q7 and Q5. Resistor R15.

4.5 Voltage Measurement

To enable the technicians to effectively service the PC-15's table 4.4 tabulates the typical D.C. and/or A.C. voltage to assist in localizing a fault source.

Table 4.3 indicates the possible component for an abnormal reading. If a voltage other than those listed in table 4.4 is measured this will enable the technician to determine which component is possibly faulty.

TABLE 4.4 PC-15's VOLTAGE DISTRIBUTION MEASUREMENT CONDITION

1. Input 27.5 VDC.
2. Full load with Switch S5 on.
3. Switch S1 in the #1 position.
4. DC and AC measurement made with a Simpson 270 or equivalent.
   (Note: Make AC measurement in the output connection to this meter.)

CIRCUIT REF.	TEST POINT	VOLTAGE MEASUREMENT D.C.	VAC RMS
Q1 and Q2	Emitter	8 to 20*	6
	Base	8 to 20*	6
	Collector	26	0
Q3 and Q4	Emitter	8.2	10
	Base	8.2	10
	Collector	26	0
Q5 and Q6	Emitter	.5	16
	Base	1.0	16
	Collector	26	0
Q9, Q10	Emitter	.7	16
	Base	1.2	17
	Collector	26	0
Q11, Q12, Q13	Emitter	27	8
Q21, Q22, Q23	Base	26.5	8
	Collector	14	0 to 5
Q14, Q15, Q16	Emitter	1	8
	Base	1	8
Q18, Q19, Q20	Collector	14	0 to 5
Q17	Emitter	6 to 7.5	0

*These voltages are load dependent.

CIRCUIT REF.	VOLTAGE MEASUREMENT POINT	D.C.	VAC RMS	CIRCUIT REF.	TEST VOLTAGE MEASUREMENT POINT	D.C.	VAC RMS
Q7	Emitter	0	0	Q17	Base	6 to 7.5	0

	Collector	8 to 20	0	CR4, CR5	Anodes	0	0 to 9*
					Cathode	-9 to +1	6 to 0

*These voltages are load dependent.

4.6 Servicing Practice and Replacement

Section 5.0 lists the table of replaceable parts. Figures 5.1 thru figure 5.7 illustrates the location of these components.

When installing or removing transistors, semiconductor diodes and heat sensitive components, grasp the lead between the solder joint and the component with a thermal dissipator, such as a spring loaded copper clip or long nose pliers. This will bleed off the heat being applied at the solder joint.

A temperature controlled soldering iron is recommended for such use. The wattage rating of the iron should not be greater than 35 watts. Always work with an iron that the tip is well tinned so the soldering can be done quickly and cleanly.

Power transistors Q5, Q6, Q9, thru Q16 and Q18 thru Q23 are insulated from ground. The insulating is done by means of insulating washers made of fiber and mica. When replacing these transistors, be sure washers are replaced in proper order and coating the washers with a film of silicone grease is recommended.

After such replacement, check with an ohmmeter to see that the insulation is effective.

NOTE TO SECTION V

N5.1 Component changes, additions, and relocations due to revisions and introduction of new model series are listed under each revision number and model series in the addenda section.

Following pages should be consulted for above informations.

REV. NO/MODEL SERIES	PAGE
Rev. 1, 2, 3	Incorporated
Rev. 4	53, 54, 56
Rev. 5	Incorporated
Rev. 6	58, 59, 60, 62
PC-15B	A1, A4, A8
PC-15D	A10
PC-15E	A12
PC-15F	A13, A15
PC-15G	A13, A17

N5.2 Addition to N5.1

Rev. 7	63
PC-15B( ) Series	63

N5.3 Any reference to PC-15 or PC-15A in this section is applicable to Model PC-15B( ) unless otherwise noted under PC-15B.

N5.4 Table 5.1 "Table of Replacable Parts" is updated as to manufacturer and part No. for equivalent or superior parts. Component changes and deletions due to revisions are not made to Table 5.1 in order to retain information on earlier units. Consult the serial number effectivity in the revision section for applicable changes.

Section V

Table of Replaceable Parts

5.1 General

This section illustrates and lists components that can be replaced for repair purposes. It is recommended that PC-15s requiring replacement of parts that are not listed in table 5.1, be returned to the factory for service.

Figures 5.1 through 5.7 illustrates the location of all the components that are listed in the Table of Replaceable Parts.

5.4 HOW TO ORDER REPLACEMENT PARTS

When ordering replacement parts, you should direct your order as indicated below and furnish the following information insofar as applicable.

ADDRESS: Flite-Tronics Co., Inc., Sales Service Department
3314 Burton Avenue
Burbank, California

INFORMATION NEEDED:

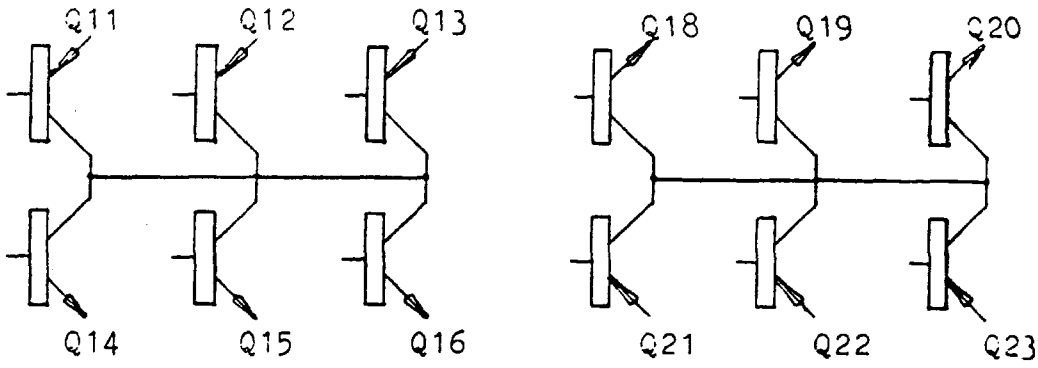
1. Quantity required.
2. Part Number (Obtain from parts list or schematic diagram.)
3. Type number and serial number of equipment.

5.5 HOW TO RETURN MATERIALS OR EQUIPMENT

If, for any reason, you should wish to return material or equipment, whether under warranty or otherwise, you should notify us, giving full particulars including the details listed below, insofar as applicable. Upon receipt of such notice, Flite-Tronics Co., Inc. will promptly advise you respecting the return. Failure to secure our advice prior to the forwarding of the goods, or failure to provide full particulars, may cause unnecessary delay in handling of your returned material.

ADDRESS: Flite-Tronics Co., Inc., Sales Service Department
3314 Burton Avenue
Burbank, California

INFORMATION NEEDED:



1. Date of delivery of equipment.
2. Date placed in service.
3. Number of hours in service.
4. Part number (obtain from parts list or schematic diagram).
5. Type number and serial number of equipment.
6. Nature and cause of failure.
7. Remarks.

SECTION VI REVISIONS

6.1 Revision No. 1

DESCRIPTION OF CHANGE — PAGE NO.

6.1.1 Electrical connection omission in the original manual. 14

Effectivity All Units

6.1.2 Note 4 Added 14

Resistor R25, Fuse F1
Effectivity
Serial number 312 and up.
Also including nos. 107, 120, 146, 155, 194, 201, 202, 225, 226, 229, 259, 261, 262, 276, 285 & 292.

6.1.3 Note 5 Added 14

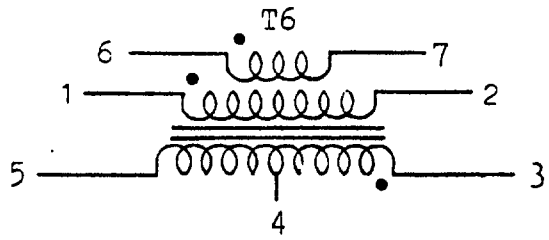
Semiconductor diodes CR9 and CR10.
Effectivity
Serial number 349 and up.
Also including nos. 107, 120, 146, 155, 194, 201, 202, 225, 226, 229, 259, 261, 262, 285 & 292.

6.1.4 Note 6 Added 14

Use capacitor to frequency lock.
To other 115 VAC, 400 HZ line.
(C23 typically .0047 uf, 600V)
Phase lock with R25.

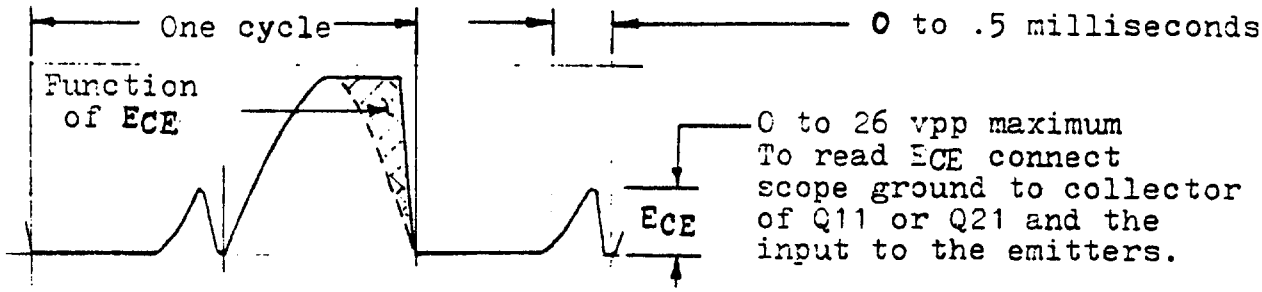
6.1.5 Note 7 Added 14

5 pin connector shown on Revision no. 1-5 Pin.



DESCRIPTION OF CHANGE	PAGE NO.

6.1.6 Revised: Call out of transistor type 2N3713 (Q14, Q15, Q16, Q18, Q19 & Q20) changed to FT501. (PC 15s may use either type.) When FT501 is used as a replacement or original installation, transistors Q14, Q15, Q16, Q18, Q19 & Q20 should all be the same device type. Also T4 is replaced with a FT91030B and connected per paragraph 6.1.10. — 14

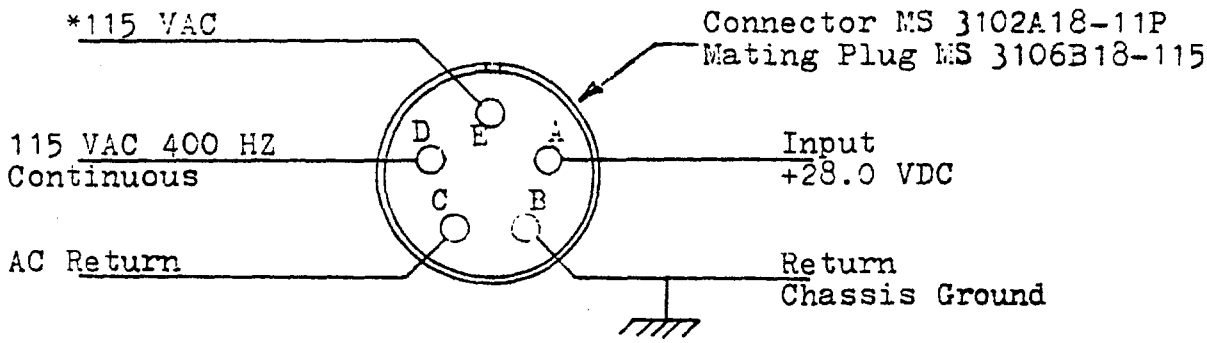


6.1.7 Revised: Call out of transistor type 2N3714 (Q9 & Q10) changed to FT500. (PC 15s may use either type.) When FT500 is used as a replacement or original installation, transistors Q9 & Q10 should be the same device type. — 14

6.1.8 Semiconductor type call out for CR2 thru CR7 deleted. — 14

6.1.9 Added: Schematic for secondary winding 6-7 to T6. Transformer FT91136 is a universal transformer and can be installed in place of FT91061. Winding 6-7 is used to sample the overload current for the 26.0 VAC output for the PC 15A. — 14

6.1.10 Added: Taps 2A and 4A to transformer T4 and designated FT91030B. This tap addition changes this transformer to a universal type. Taps 2A and 4A are used when the h_{FE} of transistors Q14, Q15, Q16, Q18, Q19 & Q20 are high. i.e. greater than 100 @ 2.0 Amps with VCE 2.0 VDC. Tap is selected electrically to give the following collector to emitter (E_{CE}) wave shape across Q11 and Q21. — 14, 39



If E_{CE} is greater than 26.0 vpp it is recommended that the tap 2A and 4A be connected. PC 15s using transistor type FT501 will probably require the 2A and 4A connection. E_{CE} is the reading of importance the balance of the waveshape should not exceed 30 VPP.

	DESCRIPTION OF CHANGE	PAGE NO.
6.1.11	Added: Resistor R19, 10 to 47 ohms, ½ watt ± 20%. Optional.	14, 38
6.1.12	Updated regarding installation	7
	Added 1.375 DIM. Note: Correction 3 7/32 was 3 3/16.	8
	Added New Page	9, 10
	" " "	11, 15
	Updated	16, 17
	"	19, 20, 21
	Corrected to include testing of PC 15A	22
	Added New Page	23, 24
	Updated	25, 26
	"	27, 28
	Added Step 15 and Updated	29
	Added Step 16 and Updated	30
	Updated	34, 35, 36
	"	37, 38
	Changed: FT 91030B, KGS 715T-1 (Universal type for FT 91030, KGS 715T)	39
	Changed: FT 91135, KGS 849T (Universal type for FT 91031, KGS 716T)	39
	Changed: FT 91136, KGS 850T (Universal type for FT 91060, KGS 717T)	39
	Updated	41, 42
	Updated - R4 and C9 identification corrected	44
	Added - CR9, CR10, F1 and R19	45

6.2 PC-15 Revision No. 1 - 5 Pin

6.2.1 Electrical connection for the PC-15 having 5 pin. (5 pin connector units do not have paralleling capability)

* For emergency operation only 115 VAC output into a load of 225 VA at an input of 20 VDC.

ELECTRICAL CONNECTION DIAGRAM

6.2.2 Serial Number Effectivity

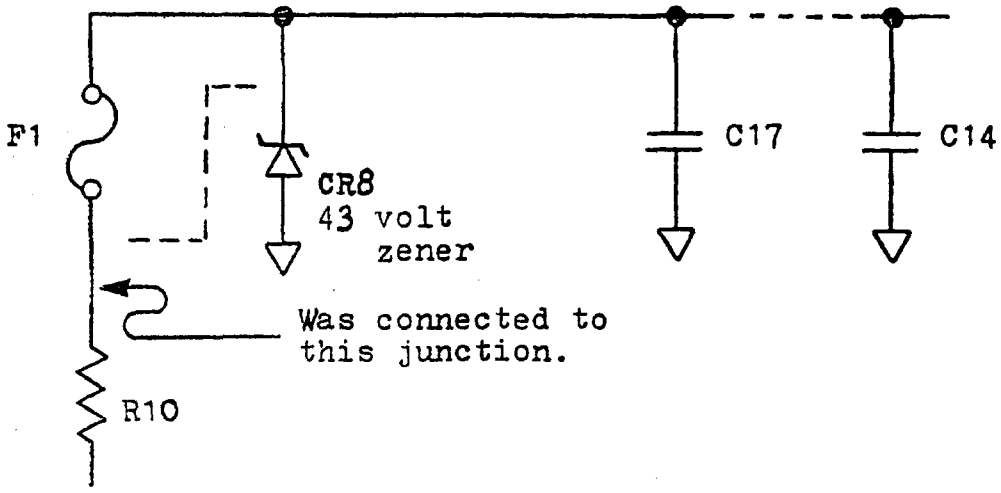
All PC-15 with serial numbers through 311 have the five pin connectors as shown in 6.2.1. Except units noted in paragraph 6.2.3 seven pin connector revision, which have been converted from five to seven pin.

Also the following units have five pin connectors. Serial Numbers: 423 thru 434, 498, 499, 502 thru 516, 552 thru 568, 498 and 592 thru 599.

6.2.3 Electrical connection for the seven pin connector are shown in the mounting details and schematics on pages 8, 9, 14 and 15 respectively.

PC-15 units with serial number 312 and up are seven pin connectors except those serial numbers shown in paragraph 6.2.2. Also the following units preceding serial number 312 have been converted to seven pin connectors. Serial Numbers: 201, 202, 226, 229, 261, 262 and 292.

6.3 Revision No. 2



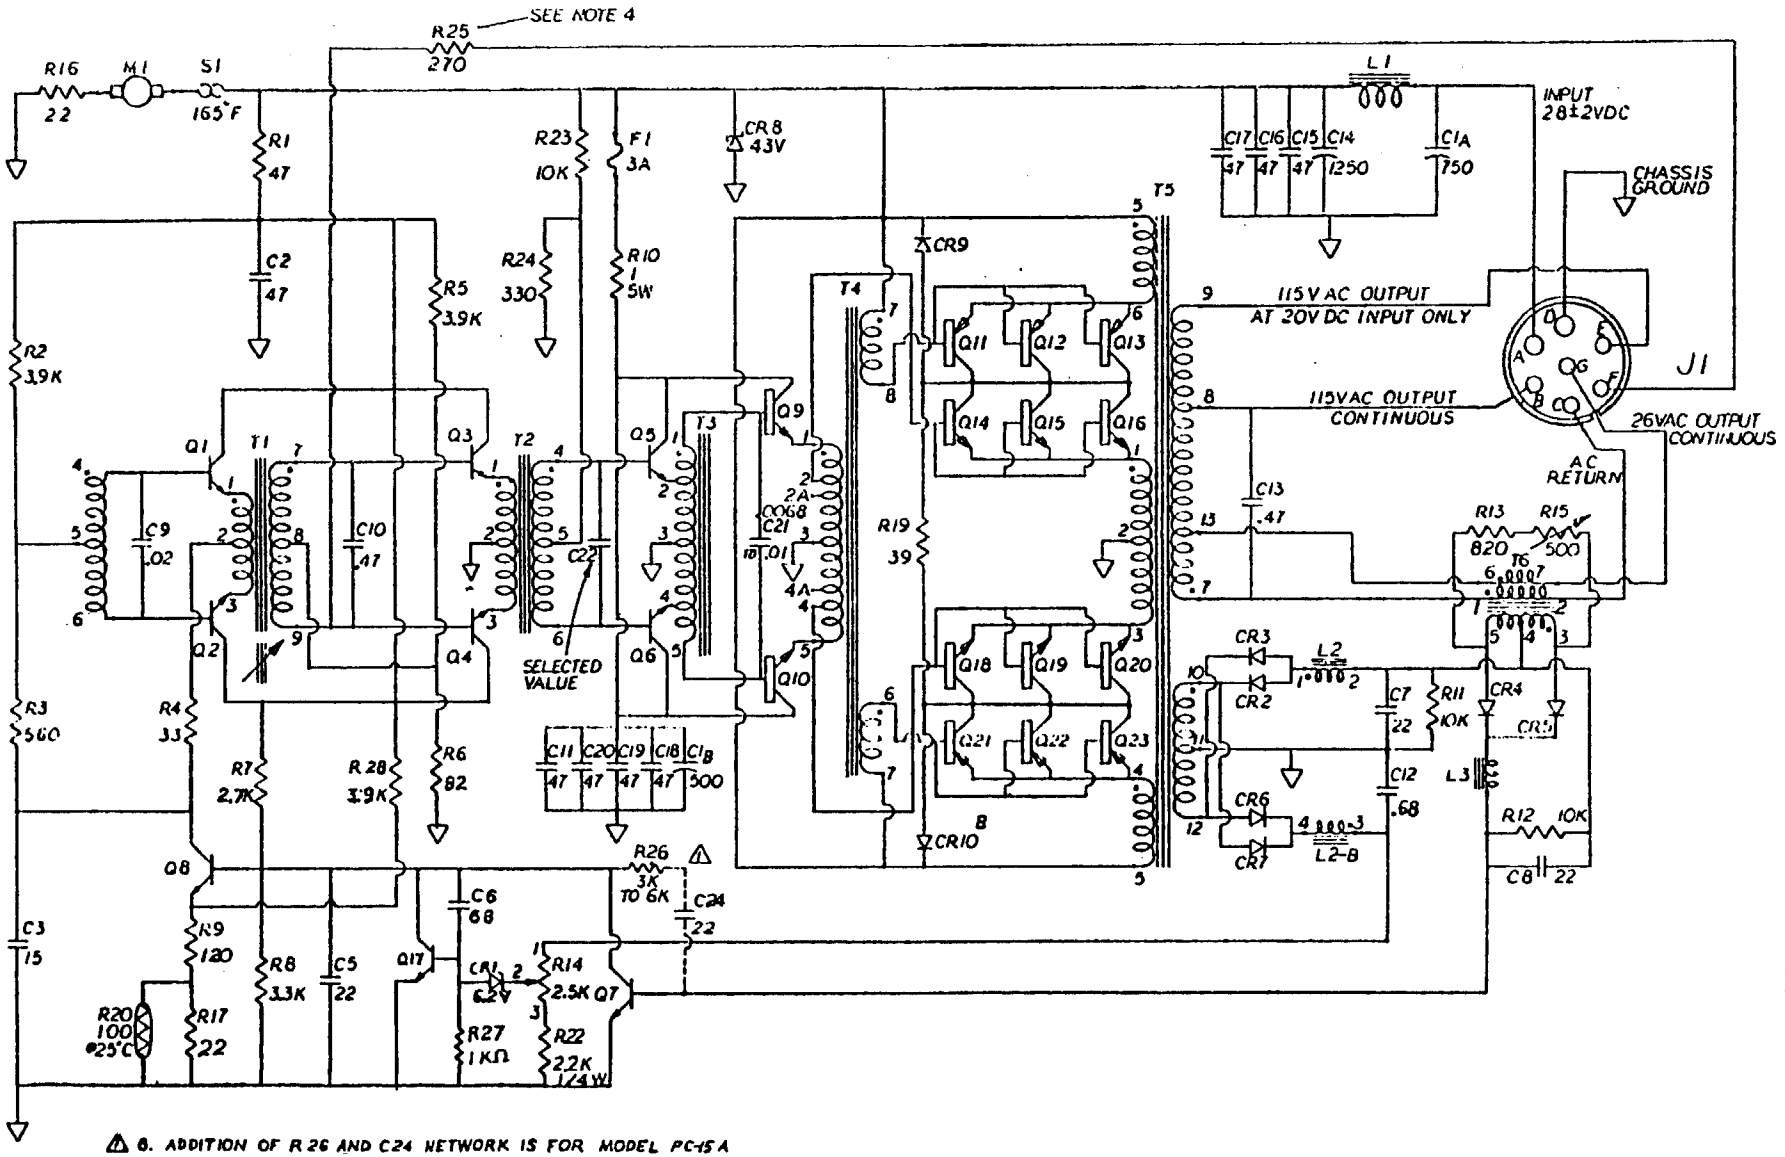
DESCRIPTION OF CHANGE	PAGE NO.
Effective on serial number 1471 and up. Transistors Q11, Q12, Q13, Q21, Q22 and Q23 can be type FT 459 or FT 460.	37

CAUTION: The use of either device type should not be mixed in a given PC-15( ).

6.4 Revision No. 3

Effective immediately and all units manufactured after serial number 1934.

Description of change: Connect zener CR8 as shown.



Reason for change: To prevent undesired rupturing of fuse F1 when zener CR8 is forced into conduction by a transient voltage exceeding 43 volts.

6.5 Revision No. 4

6.5.1 The Revision No. 4 applies to static inverter model PC-15( ) Series manufactured starting with serial number 2779. (Refer to Flite-Tronic's supplementary list of lower serial number units corrected to Revision 4). The purpose of this revision is to maintain a minimum output of 115 VAC -7% down to an input of 22 VDC and 100 VAC output down to an input of 20 VDC.

The following Rev. 4 changes are also shown in schematic on page 54 and in Figure 5.4A on page 56.

	DESCRIPTION OF REV. 4 CHANGES	AFFECTED PAGE NO.
6.5.1.1	C4 is deleted was 22 uf 25 VDC	14, 15, 36
6.5.1.2	C6 is 68 uf 6 VDC CL65BB680-UP3 was 33 uf 15 VDC	14, 15, 36
6.5.1.3	C12 is .68 uf 35 VDC A684K035 was 22 uf 25 VDC T310A684Ko35-AS	14, 15, 36
6.5.1.4	CR1 is 1N753A in base of Q17 was 1N4735 1W in emitter of Q17	14, 15, 3
6.5.1.5	R3 is 560 ohms was 680 ohms	14, 15, 37
6.5.1.6	R6 is 82 ohms was 390 ohms	14, 15, 37
6.5.1.7	R7 is 2.7 K ohms was 3.9 K ohms	14, 15, 37
6.5.1.8	R9 is 120 ohms was 560 ohms	14, 15, 38
6.5.1.9	R17 is 22 ohms was 180 ohms	14, 15, 38
6.5.1.10	R18 is deleted was 10 K ohms	14, 15, 38
6.5.1.11	R27 is 1 K ohm, ½ W added	
6.5.1.12	R28 3.9 K ohm, ½ W added	
6.5.1.13	Gray (8) lead wire from T1 is connected to junction of R5 and R6 was connected to the base of Q8	14, 15
6.5.1.14	Terminal 2 of T2 is grounded was connected to junction of R5 and R6	14, 15
6.5.1.15	Emitter of Q17 is grounded was connected to CR1 cathode	14, 15

⚠ 6. ADDITION OF R 26 AND C24 NETWORK IS FOR MODEL PC-15 A WITH LETTER A AFTER SERIAL NUMBER ONLY.

5. REVISION 4 CHANGE: SERIAL NO. EFFECTIVITY, SN 2779.

4. USE CAPACITOR C23 (TYPICALLY .0047 μF, 600V) TO FREQ. LOCK TO OTHER 115VAC 400HZ LINE, PHASE LOCK TO OTHER PC15A WITH R25

⚠ MATING PLUG FOR J1: MS 3106 B 18-9S.

2. CAPACITORS IN μF: C22 SELECTED AMONG VALUES BETWEEN .002 AND .0068 μF

1. RESISTORS IN OHMS: 1/2 W UNLESS OTHERWISE NOTED

6.5.2 Description of changes and additions to the manual for Revision 4 modification to the PC-15( )

6.5.2.1 Add the following paragraph under Emergency Output Connections of Sec. II on page 7

The AC voltage from the normal output (Pin B) of the PC-15( ) after serial number 2779 shall be greater than 115 VAC -7% at 22 VDC input and greater than 100 VAC delivering up to 90% of rated load for an input battery condition of 20 VDC.

6.5.2.2 The second paragraph and the first sentence in the third paragraph Sec. 3.5 on page 17 is:
The output from terminal 8 (Pin B) shall be greater than 100 VAC working into 90% of rated load, during an input of 20 VDC and at least 115 VAC -7% with 22 VDC input. The output from terminal 9 is 115 VAC +5% -7% working into 90% of rated load, during an input between 19 VDC and 20 VDC on the A+ line.

This output, if needed, can be used only during emergency 20 VDC input condition and the load should be connected to Pin E of J1.

6.5.2.3 The second and third sentence in the second paragraph Sec. 3.6 is:
The variable portion of the resistor is connected to the base of Q17 via CR1. In essence, this output voltage sample is compared with zener CR1 in the base of Q17. "Resistor R18" of the next sentence is "Resistor R27"

6.5.2.4 Check procedure for Pin E output for Table 4.2, Sec. 4.4, on page 24, is as follows under each heading.

Model: PC-15( )
Load condition:Pin B output at 20 VDC input
Switch position:S4 on; S1 to #1; S5 thru S10 off; S11 to PC-15; S12 and S13 to 115 VAC
Input Voltage:Set to 20 VDC
Input Current:12 Amps typical
Output Voltage: 100 VAC minimum
Output Current: 1.72 Amps typical

6.5.2.5 Step 14, Table 4.3, page 29, is changed as follows:

6.5.2.5.1 Under Set Up
is "Switch S1 to #1"
was "Switch S1 to #2"

6.5.2.5.2 Under Reference reading
is "V2 read 100 VAC minimum"
was "V2 read 107 to 120.7 VAC"

6.5.2.6 DC voltage measurement changes for Q3 and Q4 Sec. 4.5, page 31
is "Emitter .1 to .4" was "Emitter 8.2"
is "Base .55" was "Base 8.2"

6.5.2.7 DC voltage measurement change for Q7, page 32
is "Collector 2.5 to 4" was "Collector 8 to 10"

6.5.2.8 DC voltage measurement change for Q17 page 31 and 32
is "Emitter 0" was "Emitter 6 to 7.5"
is "Base .5 to .7" was "Base 6 to 7.5"
is "Collector 2.5 to 4" was "Collector 8.2 to 9.2"

6.5.2.9 DC voltage measurement change for Q8 page 32
is "Emitter 2 to 3.5" was "Emitter 8 to 9"
is "Base 2.5 to 4" was "Base 8.2 to 9.2"

6.5.2.10 Figure 5.4 on page 42 is Figure 5.4A as shown below

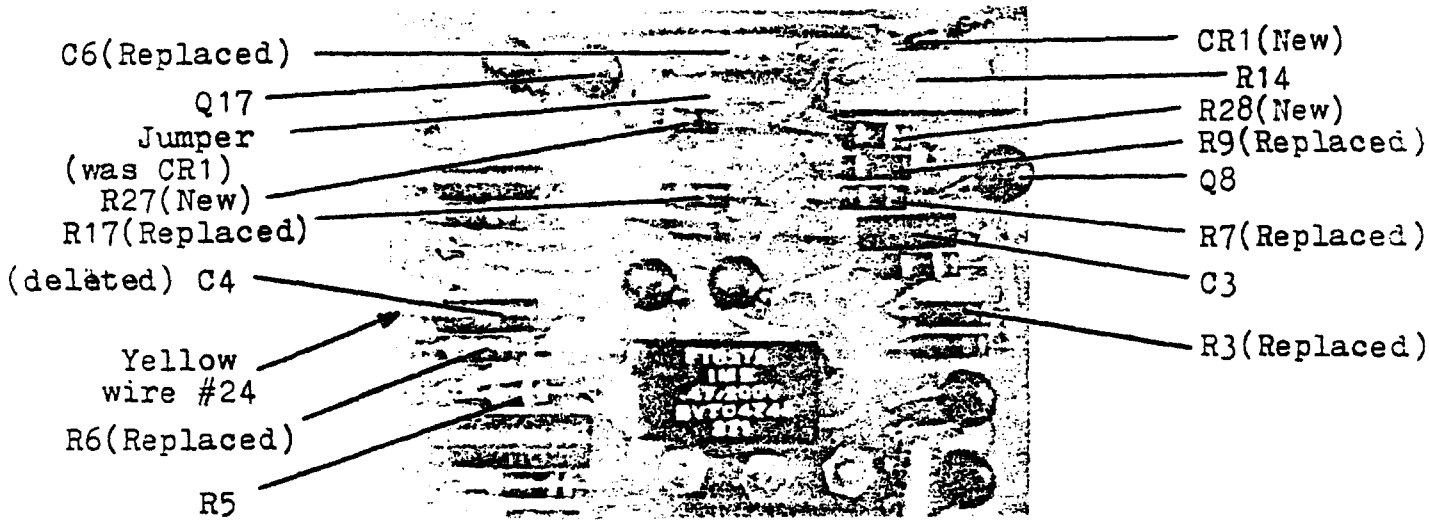

Figure 5.4A component layout changes reflecting Rev. 4

6.6 Revision No. 5

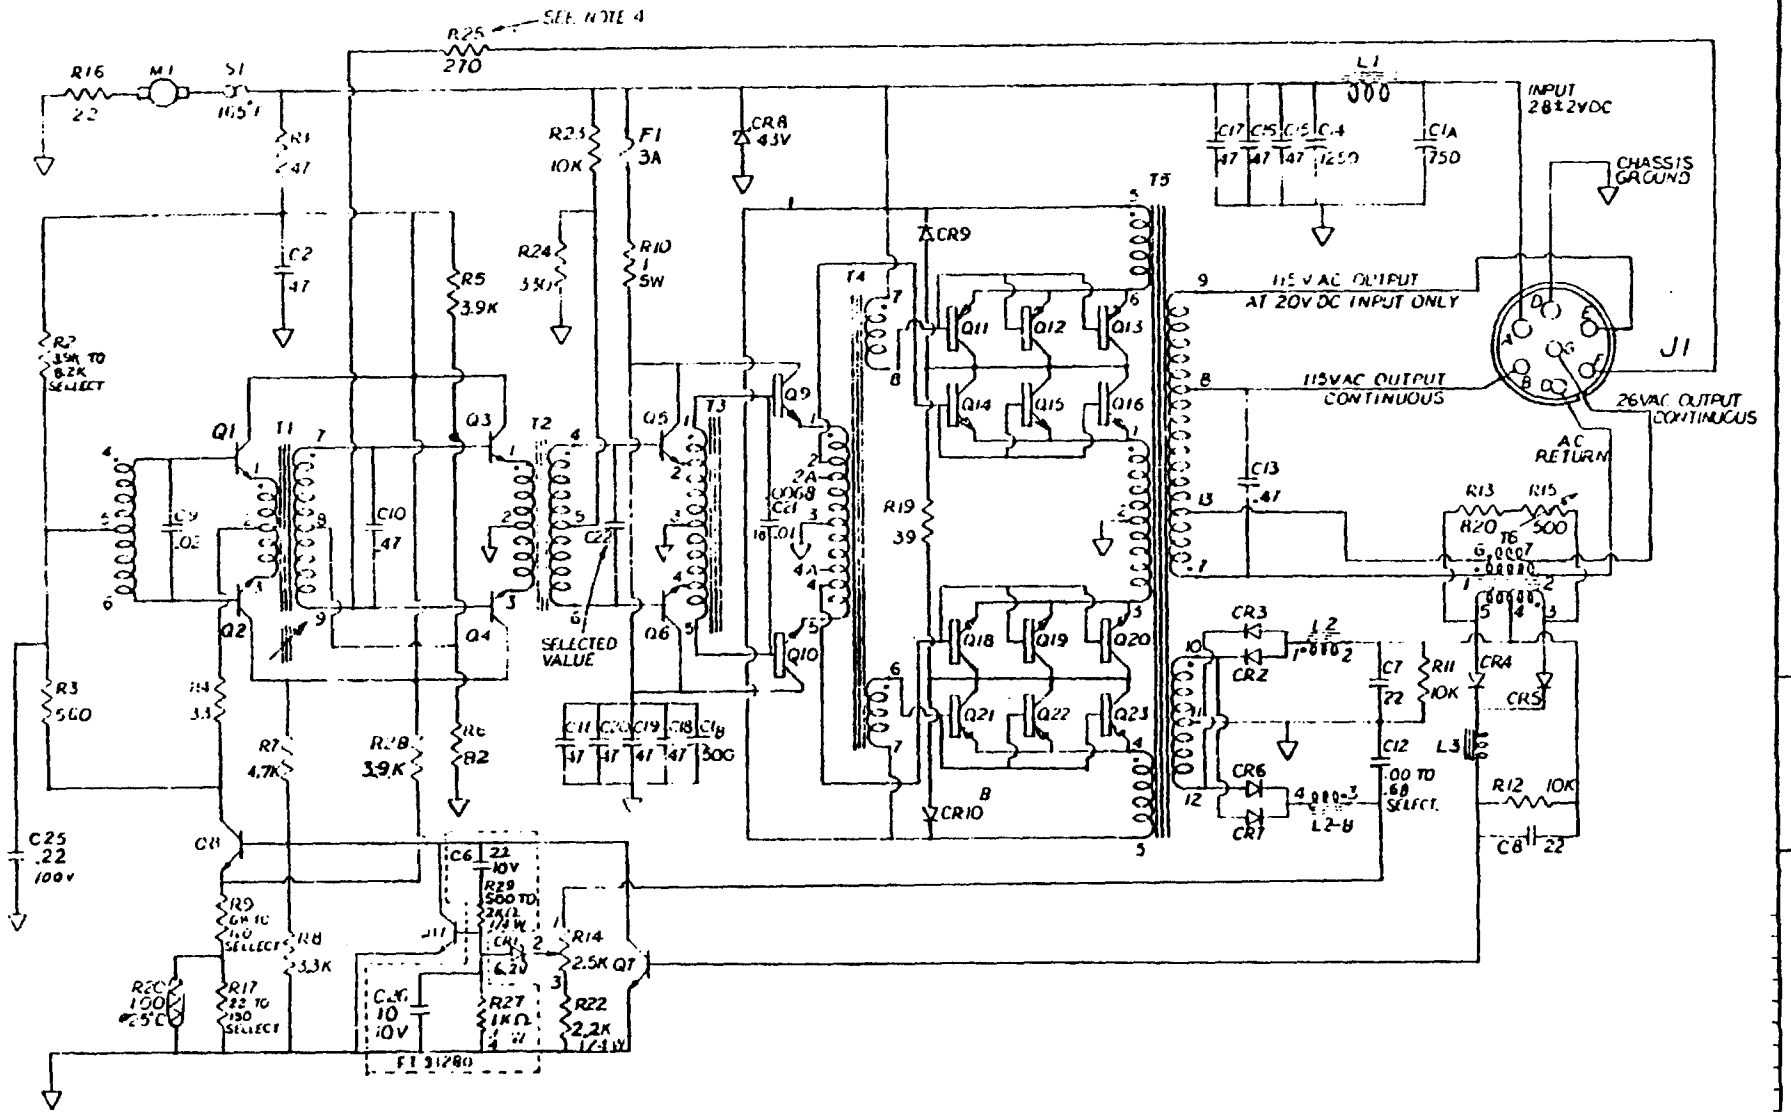
6.6.1 Heading "Service Bulletin" on page 51 is changed to read "Revision". The change is to improve classification.

6.6.2 Heading "PC-15 Service Bulletin No. 1" in Sec. 6.2 is changed to read "PC-15 Revision No. 1-5 Pin". The change is to improve classification.

6.6.3 R22 is 2.2 K ohms was 2.7 K ohms on pages 14, 15 and 38. Typographic error.

6.6.4 R13 is 820 ohms was 560 ohms on page 38. Typographic error.

6.6.5 R1 on page 21 and 22 is 1.16K ohms for 4% load was 1.2K ohms. Serial number effectivity: None



6.7 Revision No. 6

6.7.1 The Revision No. 6 applies to all static inverter model PC-15( ) Series manufactured starting with Serial number 3174 except 3176 and 3177. (Refer to Flite-Tronic's supplementary list of lower serial number units corrected to Revision No. 6)
The purpose of this revision is to improve the frequency response of the unit to decrease the effect of low frequency ripple and transient on the 28VDC bus from appearing on 115VAC output.

The changes for Revision No. 6 are shown in the schematic on page 59 and 60. Figure 5.4B on page 62 is component layout.

6.7.2 Description of Rev. 6 Changes	Affected Page No.
6.7.2.1 C_3 is deleted, was 15uf 50VDC	14, 15, 36, 42, 56 A8, A9, A10, A12
6.7.2.2 C_5 is deleted, was 22uf 25VDC	14, 15, 36, 42, 54, 56, A8, A9, A10, A12
*6.7.2.3 C_6 is 22uf 10Vdc, CS13BC226K CCL-010-226	14, 15, 36, 42, 54, 56, A8 A9 A10, A12
6.7.2.4 C12 is selected between 0 and .68uf, 35VDC, was .68uf 35VDC	14, 15, 36, 42, 54, 56, A8, A9, A10, A12
6.7.2.5 C25, .22uf 100VDC, BA2B224K added DA2B224K	
6.7.2.6 C26 10uf 10VDC. CS13BC106K added CCM-010-106	
6.7.2.7 R_2 is 5.6K ohms selected was 3.9K ohms	14, 15, 37, 42, 54, 56, A8, A9, A10, A12
6.7.2.8 R_7 is 4.7K ohms selected was 2.7K ohms	14, 15, 37, 42, 54, 56, A8, A9, A10, A12
6.7.2.9 R_9 is 82 ohms selected, was 120 ohms	14, 15, 38, 42, 54, 56, A8, A9, A10, A12
6.7.2.10 R_{17} is 75 ohms selected, was 22 ohms	14, 15, 38, 42, 54, 56, A8, A9, A10, A12
*6.7.2.11 R_{29}, $\frac{1}{4}$W 500 ohms to 2K ohms selected, added in series with C_6	
*6.7.2.12 R_{27} is $\frac{1}{4}$W, was $\frac{1}{2}$W	53, 54, 56, A8, A9, A10, A12

*These Components are encapsulated in a module identified as FT 91280 in Model PC-15( ) with serial numbers between 3174 and 3261 inclusive except 3176 and 3177.

5. REV G CHANGE: S/N EFFECTIVITY 3174, 3175, 3178 AND UP.
4. USE CAPACITOR C43 (TYPICALLY .0047 μF, 600V) TO FREQ LOCK TO OTHER 115VAC 400HZ LINE, PHASE LOCK TO OTHER PC15A WITH R25
3. MATING PLUG FOR J1: MS 3106B 18-9S
2. CAPACITORS IN μF. C22 SELECTED AMONG FOUR VALUES FROM .02 TO .0068 μF
1. RESISTORS IN OHMS: 1/2 W UNLESS OTHERWISE NOTED

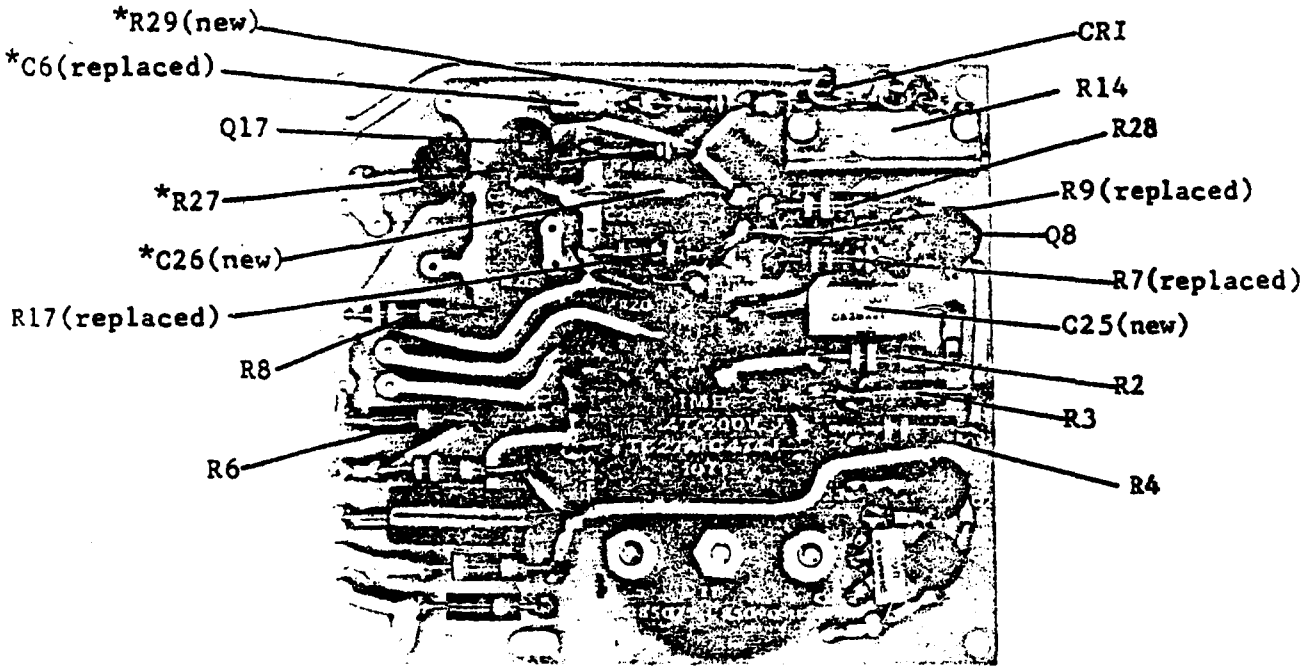
6.7.3 Description of Changes and Additions to the Manual for Revision No. 6 Modifications to the PC-15( ).

6.7.3.1 Add the following sentence at the end of 4th paragraph under Sec. 3.3, Page 16.
Capacitor C25 suppresses any tendency for low frequency motor boating.

6.7.3.2 Add the following sentence at the end of the second paragraph under Sec. 3.6. (Refer also to Rev. 4 changes under Sec. 6.5.2.3, Page 55)
RC network formed by C6, R29 and C26 at the base of Q17 compensate the closed loop circuit gain over operating temperature range and prevents the automatic level control circuitry from motor boating.



6.7.3.3 Delete the entire seventh paragraph under Sec. 3.6, Page 17.

6.7.3.4 AC voltage measurement change for Q7, Sec. 4.5, Page 32.
is "collector .1 to .2" was "Emitter 0"

6.7.3.5 AC voltage measurement change for Q8, Page 32
is "Emitter .1 to .2" was "Emitter 0"

6.9 Revision No. 8

6.9.1 The Revision No. 8 applies when applicable(shown by *) to all 250 VA static inverter model series manufactured starting with following serial numbers.

MODEL	*SERIAL NUMBER EFFECTIVITY
PC-15B( )	4101
PC-15B(D)	40
PC-15B(E)	82
PC-15B(F)	4101
PC-15B(G)	4101

The purpose of this revision is to incorporate improvement changes and correct printing errors.

* Changes are shown in schematics on Page 68 for PC-15B( ) and on Pages A10, A12, A15 and A17 for other model series.

	DESCRIPTION OF REV. 8 CHANGES	AFFECTED PAGE NO.
* 6.9.1.1	CR9 and CR10 deleted	14,15,36,45,48 50,54,59,60,65 A8,A9,
* 6.9.1.2	R14 is 2K to 2.5K ohms was 2.5K	14,15,38,42,56 54,59,60,62,65 A8,A9
* 6.9.1.3	PC-15D schematic on Page A10 is replaced by PC-15B(D) schematic	A0, A6
* 6.9.1.4	PC-15E schematic on Page A12 is replaced by PC-15B(E) schematic	A0, A6
* 6.9.1.5	PC-15F schematic on Page A15 is replaced by PC-15B(F) schematic	A0, A13
* 6.9.1.6	PC-15G schematic on Page A17 is replaced by PC-15B(G) schematic	A0, A13
6.9.1.7	Warranty page deleted from manual, was on page 46	46
6.9.1.8	Step 6, Table 4.3, page 26	
6.9.1.8.1	Under performance reading is: I_2 read typically 2.17 Amps AC was: I_2^2 read 2.17 Amps AC	

6.9.1.9 Step 8, Table 4.3, page 27 under performance reading
is: I_1 should read approximately 24 Amps.
was: I_1 should read 24 Amps

6.9.1.10 Step 10, Table 4.3 page 27 under performance reading
is: I_2 less than 1.4 Amps, was: I_2 less than 1 amp.

6.9.1.11 Step 11, Table 4.3, page 28, under procedure b)
is: 26 to 30VDC
was: 28 to 30 VDC

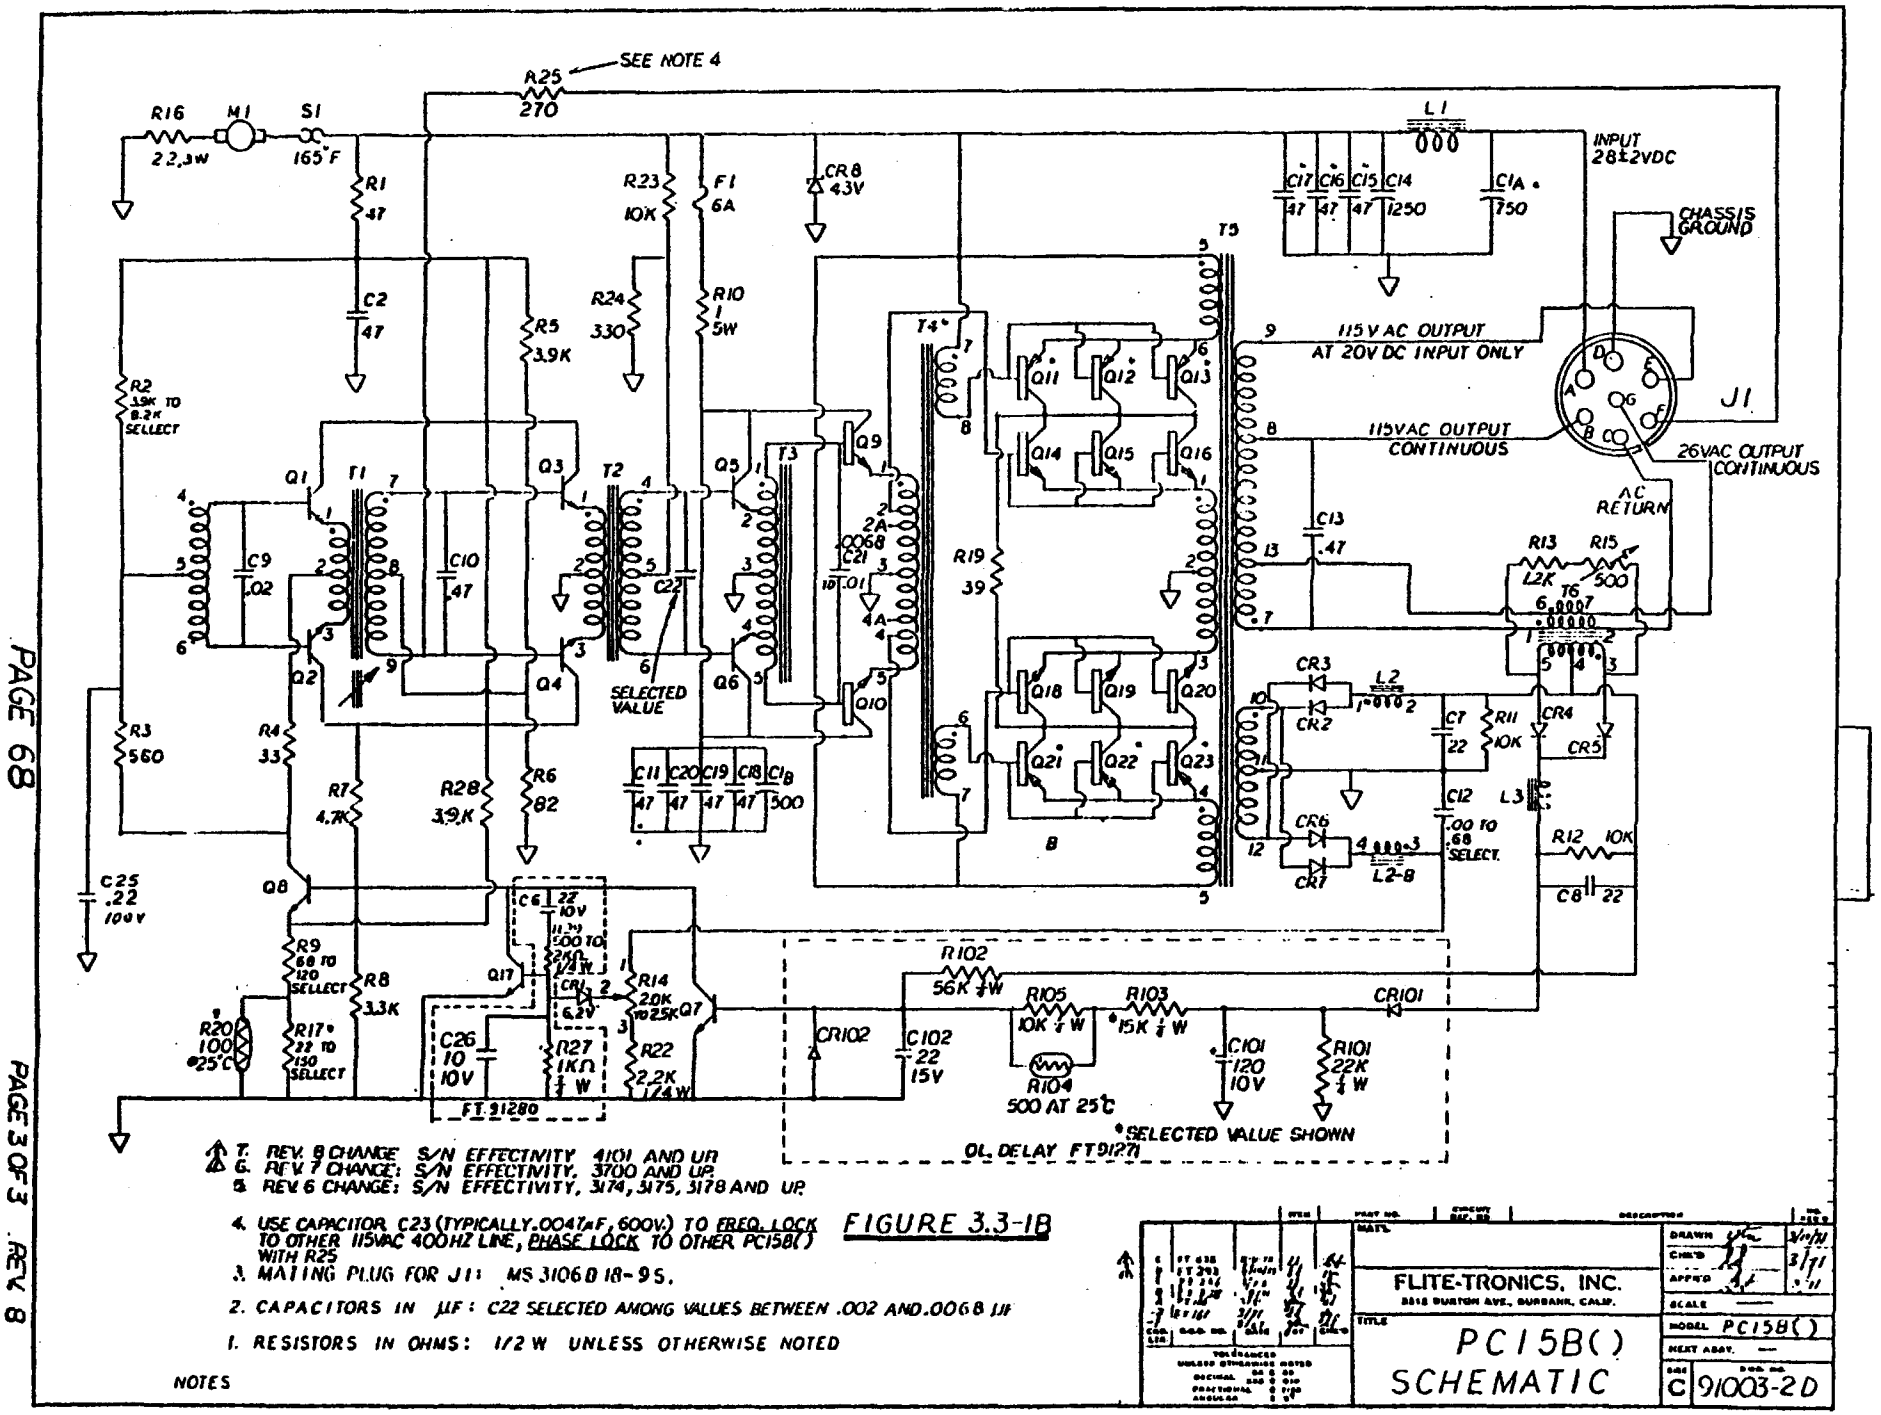
6.9.1.12 Step 12, Table 4.3, page 28, under performance reading
is: I_1 read 5.5 Amps
was: I_1 read 5.0 Amps

6.9.1.13 Step 14 Table 4.3, page 29 under performance reading
is: I_2 should read 1.80 to 2.12 Amps AC
was: I_2 should read 1.93 to 2.12 Amps AC

6.9.1.14 Paragraph 6.5.2.4 of Rev. 4, page 55 is revised to read as follows:

Check procedure for pin E output for Table 4.2, Sec. 4.4, on page 24 is changed as follows under each heading.

Model:	PC-15( ) after serial number 2779
Load Condition:	Pin B output at 20 VDC and at 22 VDC input
Switch Position:	S4 on; S1 to #1; S5 thru S10 off; S11 to PC-15; S12 and S13 to 115VAC
Input Voltage:	Set to 20VDC and then to 22VDC
Input Current:	Approximately 15Amps @20V and @22VDC
Output Voltage:	100VAC min @20VDC input and 107VAC min at 22VDC input
Output Current:	1.64Amp min. @20 VDC input and 1.80 amp min. at 22VDC input



6.9.1.15 Add following to paragraph 6.5.2.5 of Rev. 4, page 55 as paragraph 6.5.2.5.3:

6.5.2.5.3 a) After 20VDC input voltage check is made set input voltage to 22 VDC

b) V_2 should read 107.0 to 120.7VAC

c) I_2 should read 1.8A to 2.12A

d) I_1 should read approximately 14A

⚠7. REV. 8 CHANGE S/N EFFECTIVITY 4101 AND UP.
⚠6. REV 7 CHANGE: S/N EFFECTIVITY, 3700 AND UP.
⚠5. REV 6 CHANGE: S/N EFFECTIVITY, 3174, 3175, 3178 AND UP.

4. USE CAPACITOR C23 (TYPICALLY .0047μF, 600V.) TO FREQ. LOCK TO OTHER 115VAC 400HZ LINE, PHASE LOCK TO OTHER PC15B() WITH R25
3. MATING PLUG FOR J1: MS 3106B 18-9S.
2. CAPACITORS IN μF: C22 SELECTED AMONG VALUES BETWEEN .002 AND .0068 μF
1. RESISTORS IN OHMS: 1/2 W UNLESS OTHERWISE NOTED

6.10 Revision No. 9 is applicable to Model PC-15BC( ). The serial number effectivity for the PC-15BC( ) is 5100 and up. The purpose of this revision is to maintain the reliability using currently available state of the art components. The changes are shown in the schematic on Page 71 and listed below. This change was also necessitated due to the fact that germanium devices are now extremely difficult to purchase and as a result the manufacturers are reluctant to supply these devices to our stringent specifications FT460.

6.10.1 The following components are deleted:

			AFFECTED PAGE NO.
C1B	Capacitor	500 ufd	36,45
C15, C16, C17	Capacitor	47 ufd	36,45
R17	Resistor	75 ohms	38,42,58
R20	Thermistor	100 ohms @ 25°C	38,42
Q11, Q12, Q13 Q21, Q22, Q23	Germanium Transistor	FT 460	37,41,52
T4	Transformer	FT 91030C	39,40

6.10.2 The following components are changed:

	IS	WAS	
C1 Capacitor	1800 ufd, 40 VDC SPG #602D182G040AA2A SAN #100182U040AA2A	750 ufd, 50 VDC	36,45
C14 Capacitor	1800 ufd, 40 VDC SPG #602D182G040AA2A SAN #100182U040AA2A	1250 ufd, 50 VDC	36,45
R19 Resistor	1.2 Kilohms ± 10% ¼W	39 ohms	38,45
R22 Resistor	1 to 2 Kilohms Selected ¼ W	2.2 Kilohms	38,42
Q8 Transistor	FT602	FT600	37,42
T3 Transformer	FT91329	FT91029	39,40

6.10.3 The following components are added:

R18	Resistor	1.2 Kilohms ± 10% ¼ W
R21	Resistor	22 ohms ± 10% ½ W
R38	Resistor	10 ohms ± 10% ¼ W
R39	Resistor	1.8K to 2.2 Kohms ± 10% ¼ W
R40	Thermistor, 25KEI GUL., 1D15 CR	500 ohms 10% @ 25°C
R41, R42	Resistor	100 ohms ± 10% ¼ W
CR11, CR12	Diode	FT100

7. DESCRIPTION OF ADDENDUMS

7.1 Model PC-15B

7.1.1 Refer to page A7 for PC-15B mounting detail

7.1.2 Refer to page A8 for PC-15B schematic

7.1.3 Refer to figure 7.1.1 on page A4 for FT91271 overload delay module schematic

7.1.4 Refer to figure 7.1.2 on page A4 for FT91271 overload delay module layouts

7.1.5 R13 is 1.2K ohms, was 820 ohms

7.1.6 F1 is 6A, GKN 6

7.1.7 C101 is 120 uf, 10 VDC, CS13BC127K, K22J15KS

7.1.8 C102 is 22 uf, 15 VDC, CS13BD226K, K120J10KS

7.1.9 CR1 is 1 amp, 200 VDC, IN5393 or equiv.

7.1.10 CR2 is same as CR1

7.1.11 R101 is 22K ohms, ¼w, 10%

7.1.12 R102 is 33K to 82K ohms selected, ¼w, 10%

7.1.13 R103 is 10K to 27K ohms selected, ¼w, 10%

7.1.14 R104 is 500 ohms @ 25 °C, 25KE1 ,GUL, or equiv.

7.1.15 R105 is 10K ohms, ½w, 10%

7.1.16 The second sentence of the 4th paragraph, sec. 3.7, on page 18 is "when the output current causes a voltage across R12 to exceed the compared voltage across R11, transistor Q7 will start conducting after a time delay introduced by the overload delay module FT91271.

7.1.17 The DC voltage of base of Q7, Table 4.4, page 32 is -.2 to -.5 , was -1.5 to -6*

7.1.18 The 175% overload and output short-circuit tests of Table 4.2, page 23 and 24 are changed as follows

Table 4.2 Test Conditions and Typical Readings

MODEL	CONDITION	SWITCH	POSITION	TYPICAL READINGS			
				DC INPUT		AC OUTPUT	
				VOLTAGE	CURRENT	VOLTAGE	CURRENT
PC-15B Only	175% Overload	S1 S8 S2-S7 S9&S10 S11 S12&S13 S14&S15	#1 on off off PC-15 115 VAC off	Set to 28 VDC	Meter Deflection Between 0 and 25 amp motorboating	Meter Deflection Between 0 and full scale motorboating	Meter Deflection Between 0 and full scale motorboating
PC-15B See Note 1	Output short CKT 115 VAC Output only Loaded	S1 S2-S9 S11 S12&S13 S14&S15 S10(For Short)	#1 off PC-15 115 VAC on on	Set to 28 VDC	See Note 3 Page A3		
	Full Load 175 VA on 115 VAC and 75 VA on 26 VAC	S1 S2-S10 S11 S12&S13 S14&S15 S12&S13	#1 off PC-15A 115 VAC off 26 VAC	Set to 28 VDC	14 Amps Typical	Between 107 VAC and 120 VAC Between 24.2 VAC and 27.3 VAC	1.5 Amps Typical 2.9 Amps Typical
	26 VAC Ouput Short CKT	S1 S2-S9 S11 S12&S13 S14&S15 S10(For Short)	#1 off PC-15A 26 VAC on on	Set to 28 VDC	See Note 3 Page A3		

Notes: 1. Modify TS-PC-15-1 as follows for the output short circuit test only.

a. Refer to figure 7.1.3, page A5, for TS-PC-15-1 modified per this note 1 for output short circuit test.

b. Add S14 directly across terminals of current meter I_1

c. Add S15 directly across terminals of current meter I_2

d. Replace a wire between low side of S10 and AC return with a resistor R11 2 ohms, 200 watts

e. Above modifications prevent any damage to test-set meters, but effectively test the output short circuit performance of PC-15B

2. For output short circuit test close S10 so that 115 VAC or 26 VAC output is shorted to ground through R11

3. The initial output short circuit current burst is relatively long in duration and high in amplitude. The second and subsequent burst will normally settle down to exhibit anything from quenching burst to motorboating. Refer to reference short circuit wave shape shown in Figure 7.1.4 page A6.

7.1.19 Changes in step 9 of Table 4.3, page 27, are as follows

7.1.19.1 Under procedure; add c) Check that the PC-15B is in a motorboating mode at 175% overload before proceeding to step 10.

7.1.19.2 Under Reference Reading
I_1 will be pulsating from 0 to 25 amps

7.1.19.3 Under Possible Cause of Abnormal Readings; add all the components in the FT91271 overload delay module.

7.1.20 Changes in step 10 of Table 4.3, on page 27, are as follows

7.1.20.1 Under Set-Up
add S14 and S15 position "on"

7.1.20.2 Under Procedure
"b" is deleted

7.1.20.3 Under Reference Reading
I_1 and I_2 both indicate motorboating

7.1.20.4 Under Possible Cause of Abnormal Reading; add all components in FT91271 overload delay module

7.1.21 Changes in step 14 of Table 4.3, on page 29, for PC-15B are the same as changes per paragraph 6.5.2.5 on page 55

7.1.22 Changes in step 16 of Table 4.3 on page 30 are as follows

7.1.22.1 Under Set-Up
Add S14 and S15 position "on"

7.1.22.2 Under Procedure
"b" is deleted

7.1.22.3 Under Reference Reading
I_1 and I_2 both indicate motorboating

7.1.22.4 Under Possible Cause of Abnormal Reading add, all components in FT91271 overload delay module

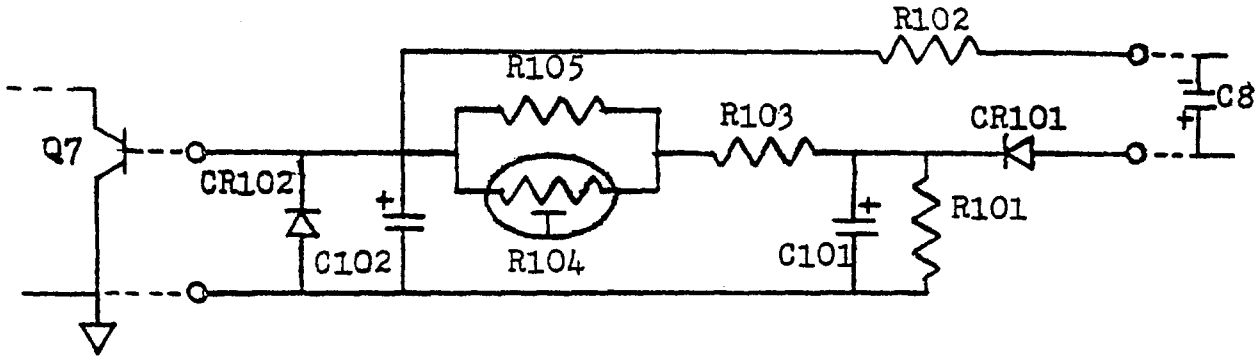

Figure 7.1.1 Overload Delay Module
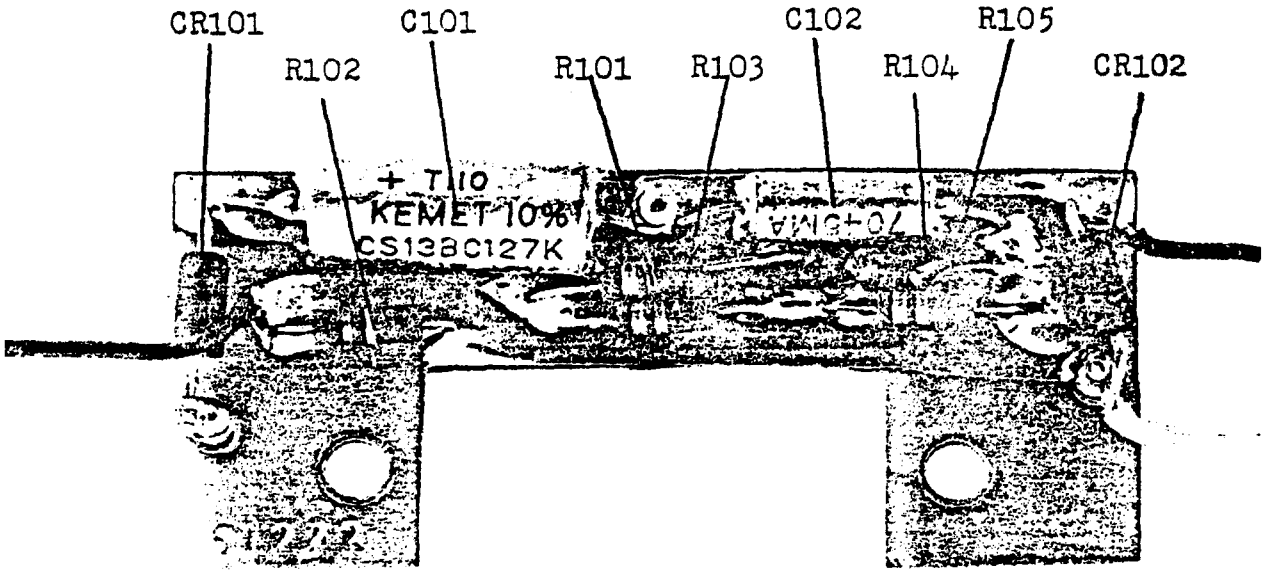
FT91271 Schematic



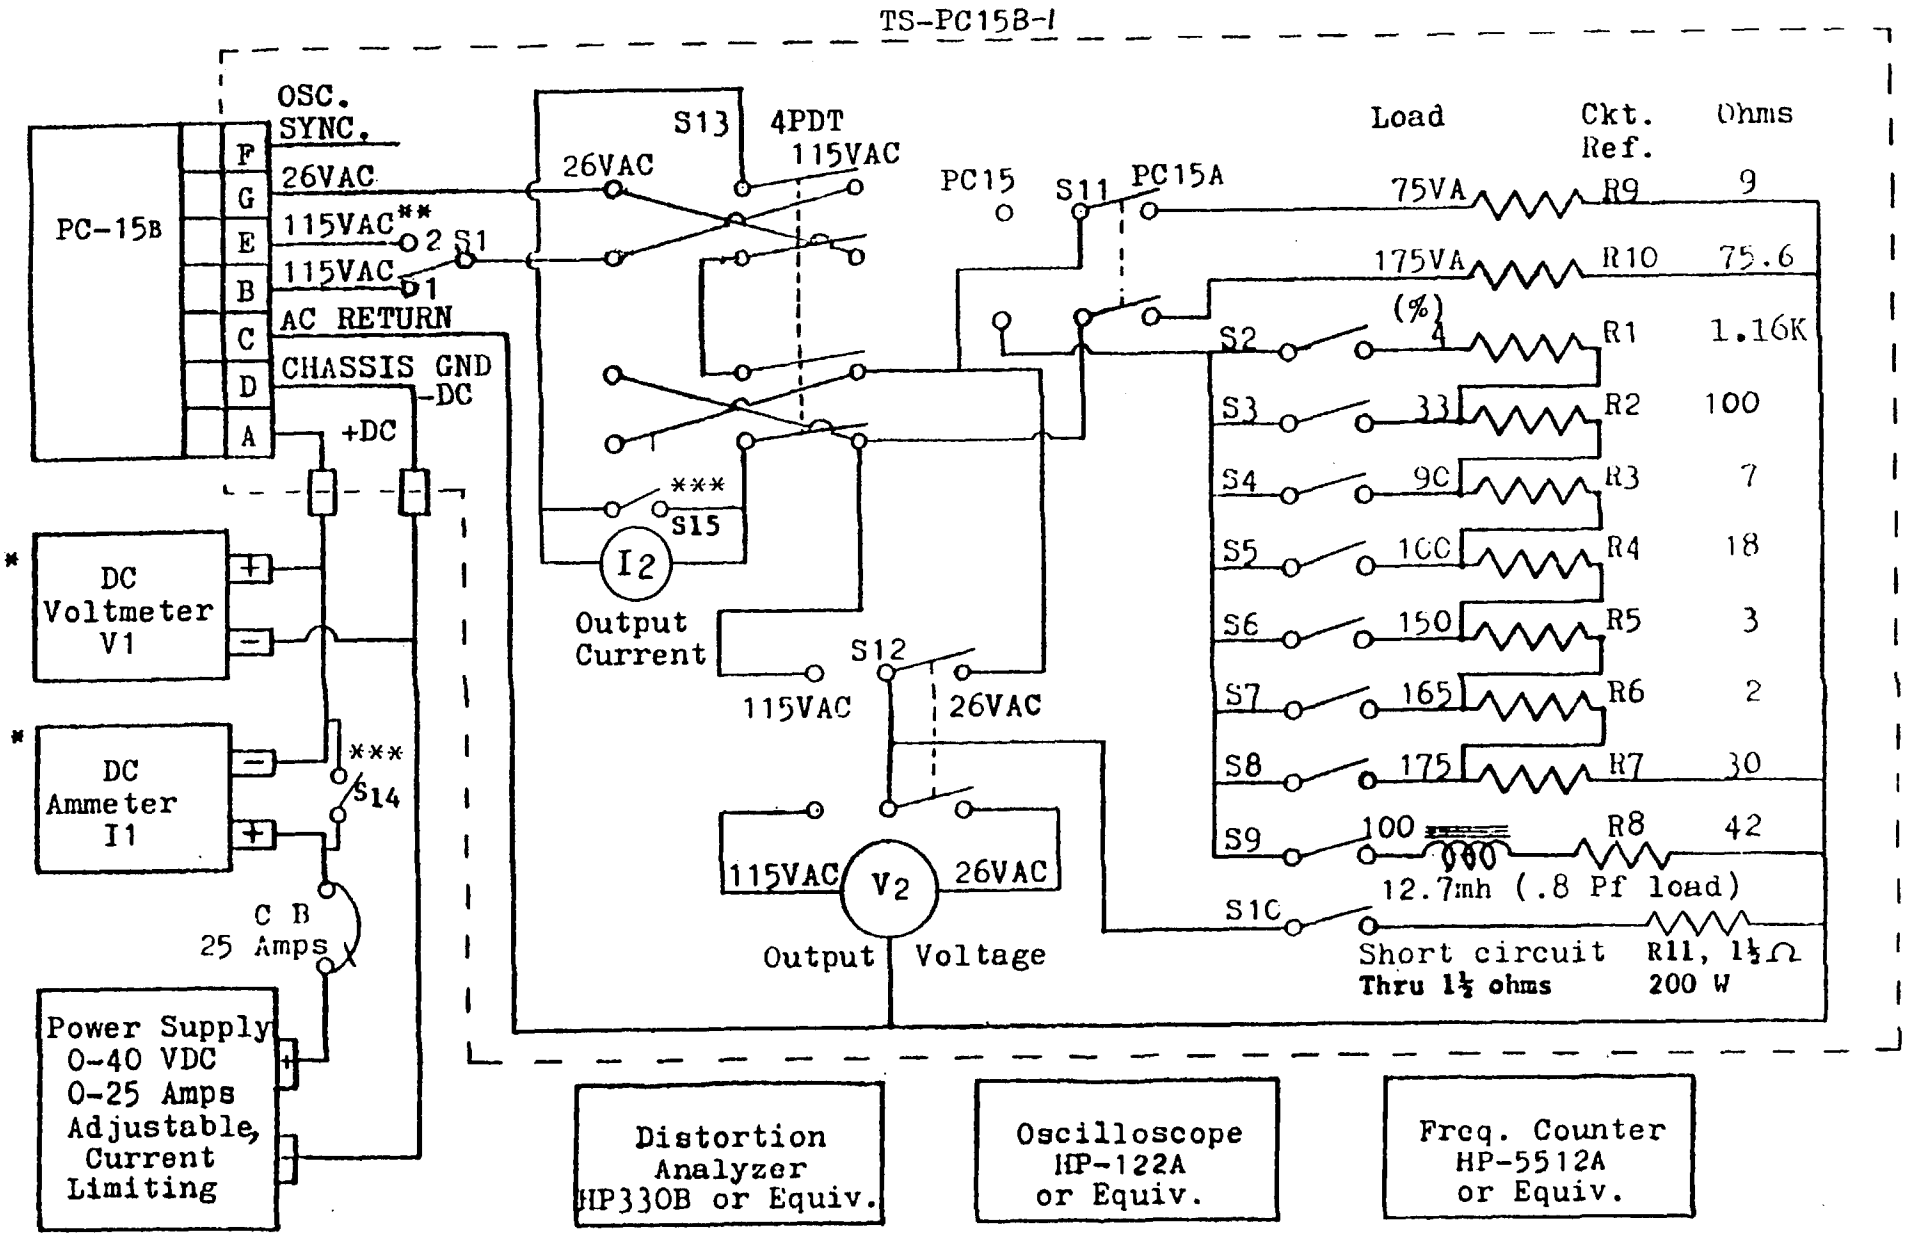


Figure 7.1.2 Overload Delay Module
FT91271 Layouts

*These meters are required only if the power supply does not contain them.

**Emergency output at 20 VDC input only.

***S14 and S15 are closed only during output short circuit test.

The original publication is kept intact and all changes with serial number effectivity when applicable are compiled under revision section as they occur.

MODEL SERIES	DESCRIPTION
PC-15BC( )	Basic 250 VA, 400 HZ, static inverter; 115 VAC and 26 VAC outputs, oscillator synchronization output, 7 pin connector. This unit supersedes Model PC-15B( ) commencing with serial number 5100.
PC-15BC(D)	Modified PC-15BC( ) with 150 VA from 26 VAC output and 100 VA from 115 VAC output commencing with serial number 500.
PC-15BC(E)	Modified PC-15BC( ) with remote ON and OFF feature. Connector used is MS3102A20-16P.
PC-15BC(H)	Modified PC-15BC( ) with the connector KPT02E18-11P.

Information for PC-15B( ) and earlier models refer to the Instruction Manual for PC-15( ), PC-15B( ) and PC-15BC( ) Series. Its latest issue is the 11th printing dated Feburary, 1976.

Section I

General Information

1.1 Introduction

This instruction manual has been prepared to provide information on installation, performance, operation, identification of parts, and maintenance of the Flite-Tronics' Model PC-15BC( ) Series Transistorized Power Inverter.

1.2 Purpose of Equipment

The PC-15BC( ) Series shown in Figure 1.1, is a transistorized inverter designed to supply AC power at 400 HZ.

The unit is capable of delivering a current overload of 150% for a minimum duration of 5 minutes at full rated output. This permits the PC-15BC( ) to power equipment that require momentary surges of power during turn on.

1.3 Specifications for PC-15BC( )

Input Voltage..... 28.0 VDC

Input Current: Steady state @ 28 VDC
a) 13.2 amperes typical delivering 250 VA.
b) .75 amperes typical no load.

Input Voltage Range:
22 to 30 VDC
Operate down to 20 VDC

Input Overvoltage:
Withstands 130% input overvoltage for 5 minutes, while supplying full rated 250 VA output power. Output voltage under this condition +5%, -7%.

Output Voltage:
115 VAC rms +5%, -7% 22 to 30 VDC. Greater than 100 VAC down to an input of 20 VDC

Output Voltage: 75 VA maximum
26.0 VAC rms +5%, -7%.

Pin E Output @ 20 VDC Input:
115 VAC +5%, -7%

Output Frequency: 400 HZ ±1%

Total Maximum Continuous Output Power..... 250 VA
(Sum of 115 VAC and 26 VAC outputs)

Output Waveform:
Sine wave, single phase

For Higher Power Output:
Units may be paralleled for higher power output. (Refer to installation section.)

Amplitude Distortion
Both outputs..... 3% (Typ.)
26-30 VDC input

Overload Capacity:
Withstands 150% output current overload for at least 5 minutes.

Power Factor.... .8 to 1.0

Input Voltage Protection:
Unit withstands transient of 88 volts lasting 1 millisecond on the 28.0 VDC input line.

Excessive Overload and Output Short Circuit:
Withstands without damage or degradation loads exceeding 150% nominal to an output short circuit. Unit delivers rated output on removal of above condition. See Page 205 for output fault clearance capability.

Altitude..... 45,000 feet

Efficiency..... 70% typical

Temperature: -65°F to 160°F

Weight: 7.5 lbs.

Size:
Width 6"
Length 9-3/8" (not incl. mounting flange)
Height 3-3/16"

1.3A Specifications for PC-15BC(D)

Input Voltage..... 28.0 VDC

Input Current: Steady state @ 28 VDC
a) 13.2 amperes typical delivering 250 VA.
b) .75 amperes typical no load.

Input voltage range:
22 to 30 VDC
Operate down to 20 VDC

Input Overvoltage:
Withstands 130% input overvoltage for 5 minutes, while supplying full rated 250 VA output power. Output voltage under this condition +5%, -7%.

Output Voltage:
115 VAC rms +5%,-7% 22 to 30 VDC. Greater than 100 VAC down to an input of 20 VDC

Output Voltage:
26.0 VAC rms +5%, -7%

Pin E Output @ 20 VDC Input:
115 VAC +5%, -7%

Output Frequency: 400 HZ ±1%.

Total Maximum Continuous Output Power..... 250 VA
150VA from 26VAC output plus 100VA from 115VAC output

Output Waveform:
Sine wave, single phase.

For Higher Power Output:
Units may be paralleled for higher power output. (Refer to installation section.)

Amplitude Distortion
Both outputs..... 3% (Typ.)
26-30 VDC input

Overload Capacity:
Withstands 150% output current overload for at least 5 minutes.

Power Factor.... .8 to 1.0

Input Voltage Protection:
Unit withstands transient of 88 volts lasting 1 millisecond on the 28.0 VDC input line.

Excessive Overload and Output Short Circuit:
Withstands without damage or degradation loads exceeding 150% nominal to an output short circuit. Unit delivers rated output on removal of above condition. See Page 205 for output fault clearance capability.

Altitude..... 45,000 feet

Efficiency..... 70% typical

Temperature: -65°F to 160°F

Weight: 7.5 lbs.

Size:
Width 6"
Length 9-3/8" (not incl. mounting flange)
Height 3-3/16"

1.3B Specifications for PC-15BC(E)

Input voltage..... 28.0 VDC

Input Current: Steady state @ 28 VDC
a) 13.2 amperes typical delivering 250 VA.
b) .75 amperes typical no load.

Input voltage Range:
22 to 30 VDC
Operate down to 20 VDC

Input Overvoltage:
Withstands 130% input overvoltage for 5 minutes, while supplying full rated 250 VA output power. Output voltage under this condition +5%, -7%.

Output Voltage:
115 VAC rms +5%, -7% 22 to 30 VDC. Greater than 100 VAC down to an input of 20 VDC

Output Voltage: 75 VA maximum
26.0 VAC rms +5%, -7%.

Pin E Output @ 20 VDC Input:
115 VAC +5%, -7%

Output Frequency: 400 HZ ±1%

Total Maximum Continuous Output Power..... 250 VA
(Sum of 115 VAC and 26 VAC outputs)

Output Waveform:
Sine wave, single phase

For Higher Power Output:
Units may be paralleled for higher power output. (Refer to installation section.)

Amplitude Distortion
Both outputs..... 3% (Typ.)
26-30 VDC input

Overload Capacity:
Withstands 150% output current overload for at least 5 minutes.

Power Factor.... .8 to 1.0

Input Voltage Protection:
Unit withstands transient of 88 volts lasting 1 millisecond on the 28.0 VDC input line.

Excessive Overload and Output Short Circuit:
Withstands without damage or degradation loads exceeding 150% nominal to an output short circuit. Unit delivers rated output on removal of above condition. See Page 205 for output fault clearance capability.

Altitude..... 45,000 feet

Efficiency..... 70% typical

Temperature: -65°F to 160°F

Remote-On-Off:
Complete circuit from Pins A to D to turn unit on.

Weight: 7.5 lbs.

Size:
Width 6"
Length 9-3/8" (not incl. mounting flange)
Height 3-3/16"

1.3C Specifications for PC-15BC(H)

Input voltage..... 28.0 VDC

Input Current: Steady state @ 28 VDC
a) 13.2 amperes typical delivering 250 VA.
b) .75 amperes typical no load.

Input Voltage Range:
22 to 30 VDC
Operate down to 20 VDC

Input Overvoltage:
Withstands 130% input overvoltage for 5 minutes, while supplying full rated 250 VA output power. Output voltage under this condition +5%, -7%.

Output Voltage:
115 VAC rms +5%, -7% 22 to 30 VDC. Greater than 100 VAC down to an input of 20 VDC.

Output Voltage: 75 VA maximum
26.0 VAC +5%,-7%.

Output Frequency: 400 HZ ±1%

Total Maximum Continuous Output Power..... 250 VA
(Sum of 115 VAC and 26 VAC outputs)

Output Waveform:
Sine wave, single phase

For Higher Power Output:
Units may be paralleled for higher power output. (Refer to installation section.)

Amplitude Distortion
Both outputs..... 3% (Typ.)
26-30 VDC input

Overload Capacity:
Withstands 150% output current overload for at least 5 minutes.

Power Factor.... .8 to 1.0

Input Voltage Protection:
Unit withstands transient of 88 volts lasting 1 millisecond on the 28.0 VDC input line.

Excessive Overload and Output Short Circuit:
Withstands without damage or degradation loads exceeding 150% nominal to an output short circuit. Unit delivers rated output on removal of above condition. See Page 205 for output fault clearance capability.

Altitude..... 45,000 feet

Efficiency..... 70% typical

Temperature: -65°F to 160°F

Weight: 7.5 lbs.

Size:
Width 6"
Length 9-3/8" (not incl. mounting flange)
Height 3-3/16"

1.3.1 Environmental Specifications Applicable to All Model Series

Emission RFI:
Radiated & Conducted... 90 KC to 1000 MC.
Far below levels specified in Appendix A of RTCA Paper 120-61/DO-108 Category "A", see pages 4 and 5.

Humidity:
Greater than 95% for ten days, temperature cycled between 75°F to 160°F.

Vibration:
To withstand in three directions

.08 DA	5-15 HZ
.036 DA	15-70 HZ
10 G's	70-500 HZ

Shock:
To withstand at least 10 G's for 11 milliseconds in three directions.

1.4 Description

The PC-15BC( ) is a transistorized airborne static power inverter. The unit operates from 28.0 VDC aircraft power source and delivers 115 VAC and 26 VAC @ 400 HZ. The total continuous power drawn from the two outputs should not exceed 250 VA.

An L/C tuned 400 HZ oscillator operating in a class B push-pull mode is used to generate the 400 HZ signal.

This signal is amplified by 3 stages of class B push-pull emitter follower amplifiers. Protective circuits for output overload, thermal runaway and input voltage transient are incorporated to make the PC-15s an extremely reliable equipment.

Frequency and output voltage are adjustable. However, once set at the factory, they sould not require readjusting for the life of the equipment.

Statement by Test Lab.; Cornell-Dublier Electronics Division.
Summary of Results for Radiated and Conducted RFI:
The Static Inverter M/N PC-15, S/N 100, was subjected to an electromagnetic interference investigation test program per R.T.C.A. Paper 120-61/DO-108, Appendix A. Upon evaluation of the test data, it was found that the above referenced static inverter generated interference which was below the specification limits of R.T.C.A Paper 120-61/DO-108, Appendix A.

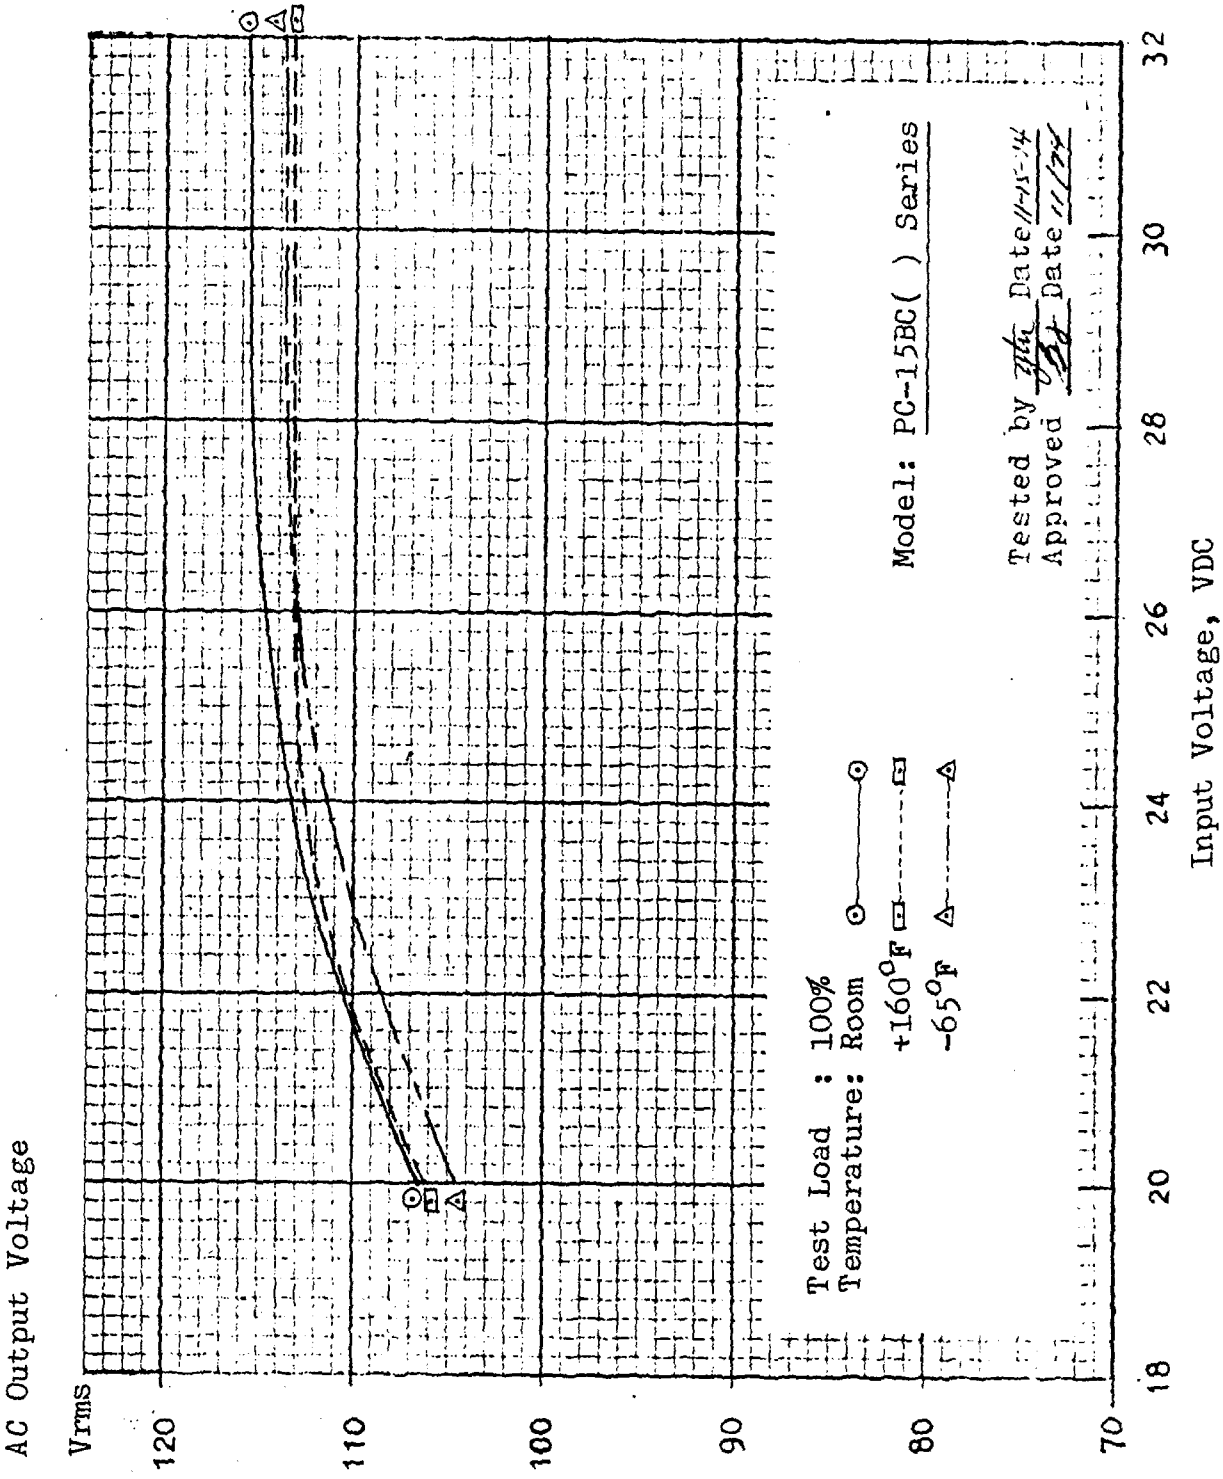

Figure 1.4 Typical Output Performance Curve

Section II

Installation

2.1 General

The Model PC-15BC( ) Series (hereinafter frequently referred to as PC-15s) is a 400 HZ Inverter, ready to install when delivered from the factory.

To determine that the unit is operating satisfactorily, a bench test may be made. The external hook-up for such a test is illustrated in Figure 4.1 page 203.

The PC-15s will deliver 250 VA of power to a load having a power factor between .8 lag to 1.0. The PC-15s will operate into loads which are more reactive; however, an external phase correcting capacitor will be required.

The capacitance value may be determined by noting what value causes a null in the input current reading. This, of course, should be determined with the load the PC-15BC( ) delivers power to. A poly-carbonate type capacitor having a rating of 300 volts or greater may be used for this phase correcting.

Installation where more than 250 VA of continuous power is required, the PC-15s may be paralleled, as necessary, to double, triple, or even quadruple the power of a single unit.

2.2 Installation Procedure

The PC-15s are environmentally designed to mount on a rack with other equipment, or in any suitable location in the aircraft.

Figure 2.1( ) Page 9( ) illustrates the installation dimensions and mounting centers. Mounting hardware should be 10-32 and length long enough to have 1-1/2 threads exposed after installing the necessary hardware.

The mating connector plug to the PC-15s' receptacle is MS3106B18-9S or equivalent.

A wire size AWG #10 or #12 is suggested for the low voltage DC input and an AWG size #18 for the AC output leads. The low voltage input to the PC-15s should be protected with a 25 amp circuit breaker.

Figure 2.2 page 10 illustrates the electrical connection to operate units in parallel for greater output power capability.

Units operating in parallel must have oscillators phase locked. This is

accomplished by connecting pin F together. To frequency lock the PC-15s to other 400 HZ ± .5%, 115 VAC source, R25 is changed .0047 ufd and pin F is connected to that source.

Frequency locking of PC-15s is only necessary when other 400 HZ ± 2 HZ power sources are in an aircraft and resulting in an undersirable beating effect.

CAUTION

THE PC-15s SHOULD NOT BE INSTALLED IN AN AREA WHERE THE AMBIENT AIR TEMPERATURE EXCEEDS 172° F. UNDER ALL WEATHER AND OPERATING CONDITIONS. THE UNIT MAY BE MOUNTED IN ANY POSITION. IN AN INSTALLATION THE VENT HOLES SHOULD NOT BE RESTRICTED. ALSO, THE PC-15s SHOULD BE MOUNTED DIRECTLY TO METALLIC PLATES OR SUPPORTS.

WHEN PC-15s ARE CONNECTED IN PARALLEL, ALL UNITS MUST BE TURNED ON. OTHERWISE THE PARALLEL CONNECTION SHOULD BE DISCONNECTED TO OPERATE INDEPENDENTLY.

WHEN THE PC-15s ARE OPERATED IN THE FREQUENCY LOCKED MODE TO OTHER 115 VAC 400 HZ ± 2 HZ SOURCE, THE OUTPUT, OF COURSE, SHOULD NOT BE PARALLELED.

CAUTION

THE BLOWER MOTOR SHOULD BE INSPECTED AND OVERHAULED EVERY 1000 HOURS OF MOTOR OPERATION.

Section III

Principles of Operation

3.1 General

The PC-15BC( ) converts DC energy to AC electrical energy.

The nominal output is 115 VAC on pin B and 26 VAC output from pin G. The AC output will follow the input DC voltage variation below 24.0 VDC. The 400 HZ is generated by an L/C tuned push-pull oscillator. The sine wave signal is amplified by three stages of class B push-pull amplifier. The final power output stage is also class B. To minimize the possibility of an 88 volt peak transient on the 28.0 VDC buss destructing the transistors the FT500 are tested to 175 VDC VCEX prior to installation. Schematics of the PC-15s are illustrated in Figure 3.2( ) page 13( ).

3.2 Block Diagram

Figure 3.1 shows the PC-15s' operation in a block diagram form. The block diagram illustrates the time tested and proven circuitry for power amplification of a low level AC signal. All the stages are class B push-pull emitter follower configuration. The emitter follower circuitry having inherent negative feedback introduces very little amplitude and phase distortion.

The output signal is sampled by current and voltage transformers. These components deliver a signal to operate the output overload and output voltage level circuitry.

This output, in turn, controls the push-pull 400 HZ oscillator amplitude.

The output overload reduces the output current and voltage when a load excess of 170% is applied to the output. This same circuitry operates in the event of a short circuit on the output.

The automatic level control maintains the output voltage constant for load and temperature variation.

3.3 400 HZ Sine Wave Oscillator

Inductor-transformer T1 is the feedback, output and resonant tuning transformer. The center tapped primary winding is 1-2-3. Feedback winding is 4-5-6. The output and resonant tuning winding is 7-8-9.

Capacitor C10 (.47 ufd) resonates with the inductance of the output winding at 400 HZ.

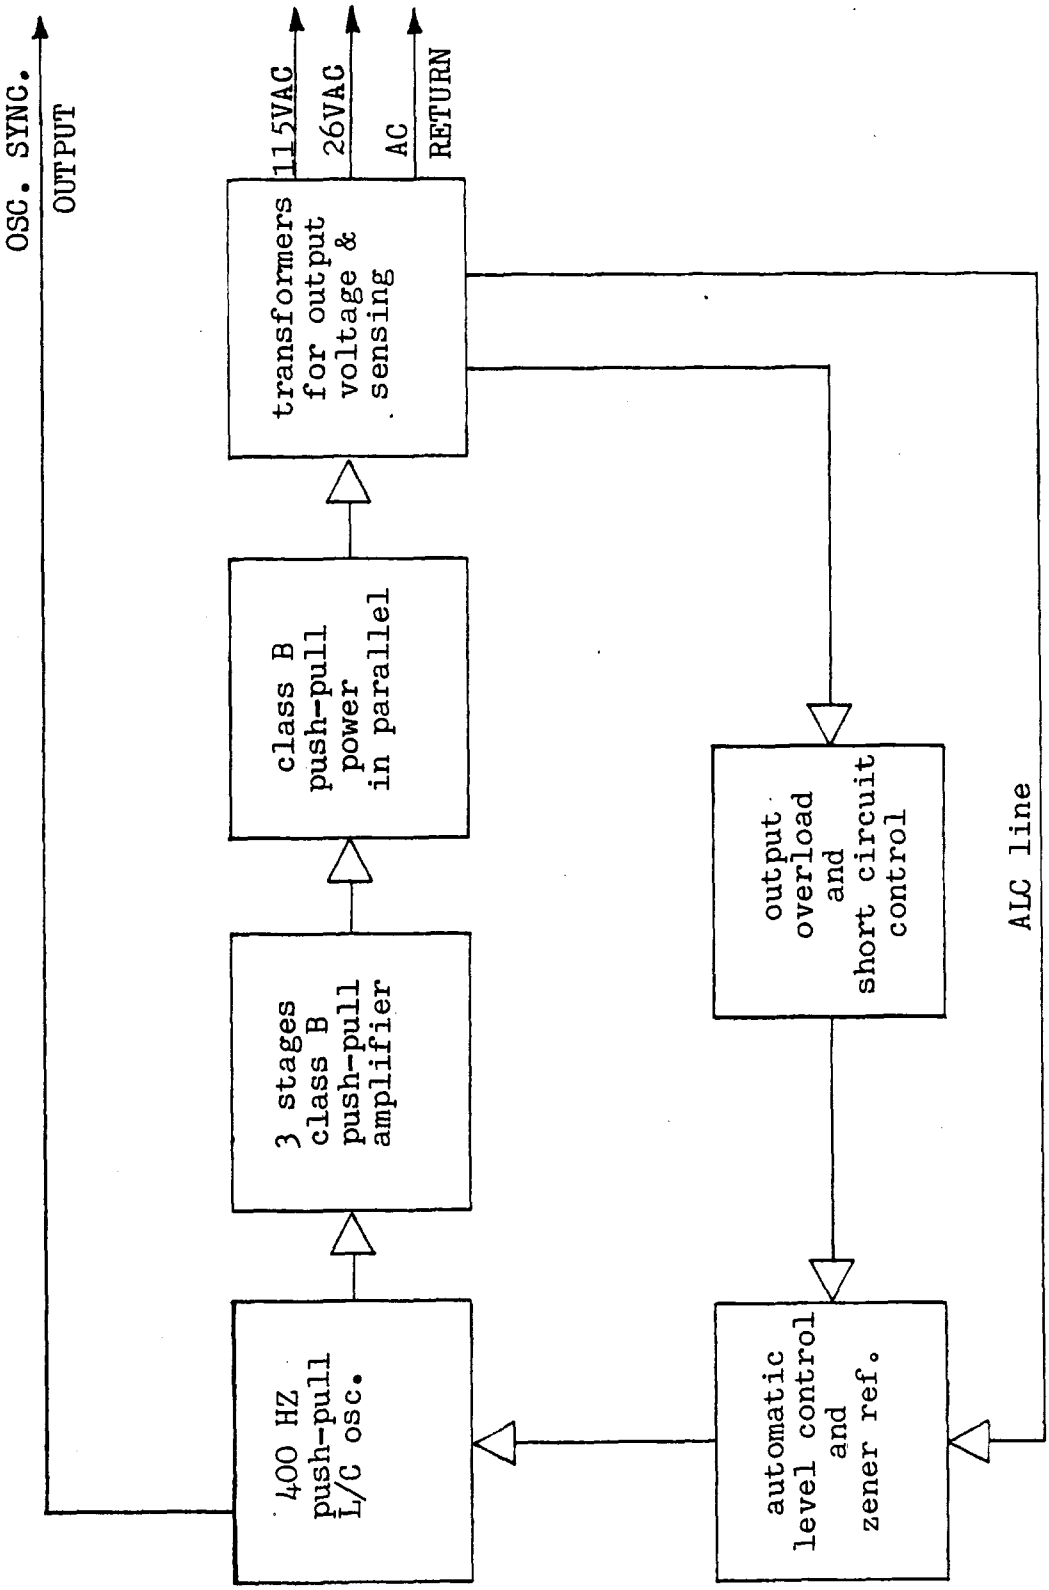

FIGURE 3.1 BLOCK DIAGRAM

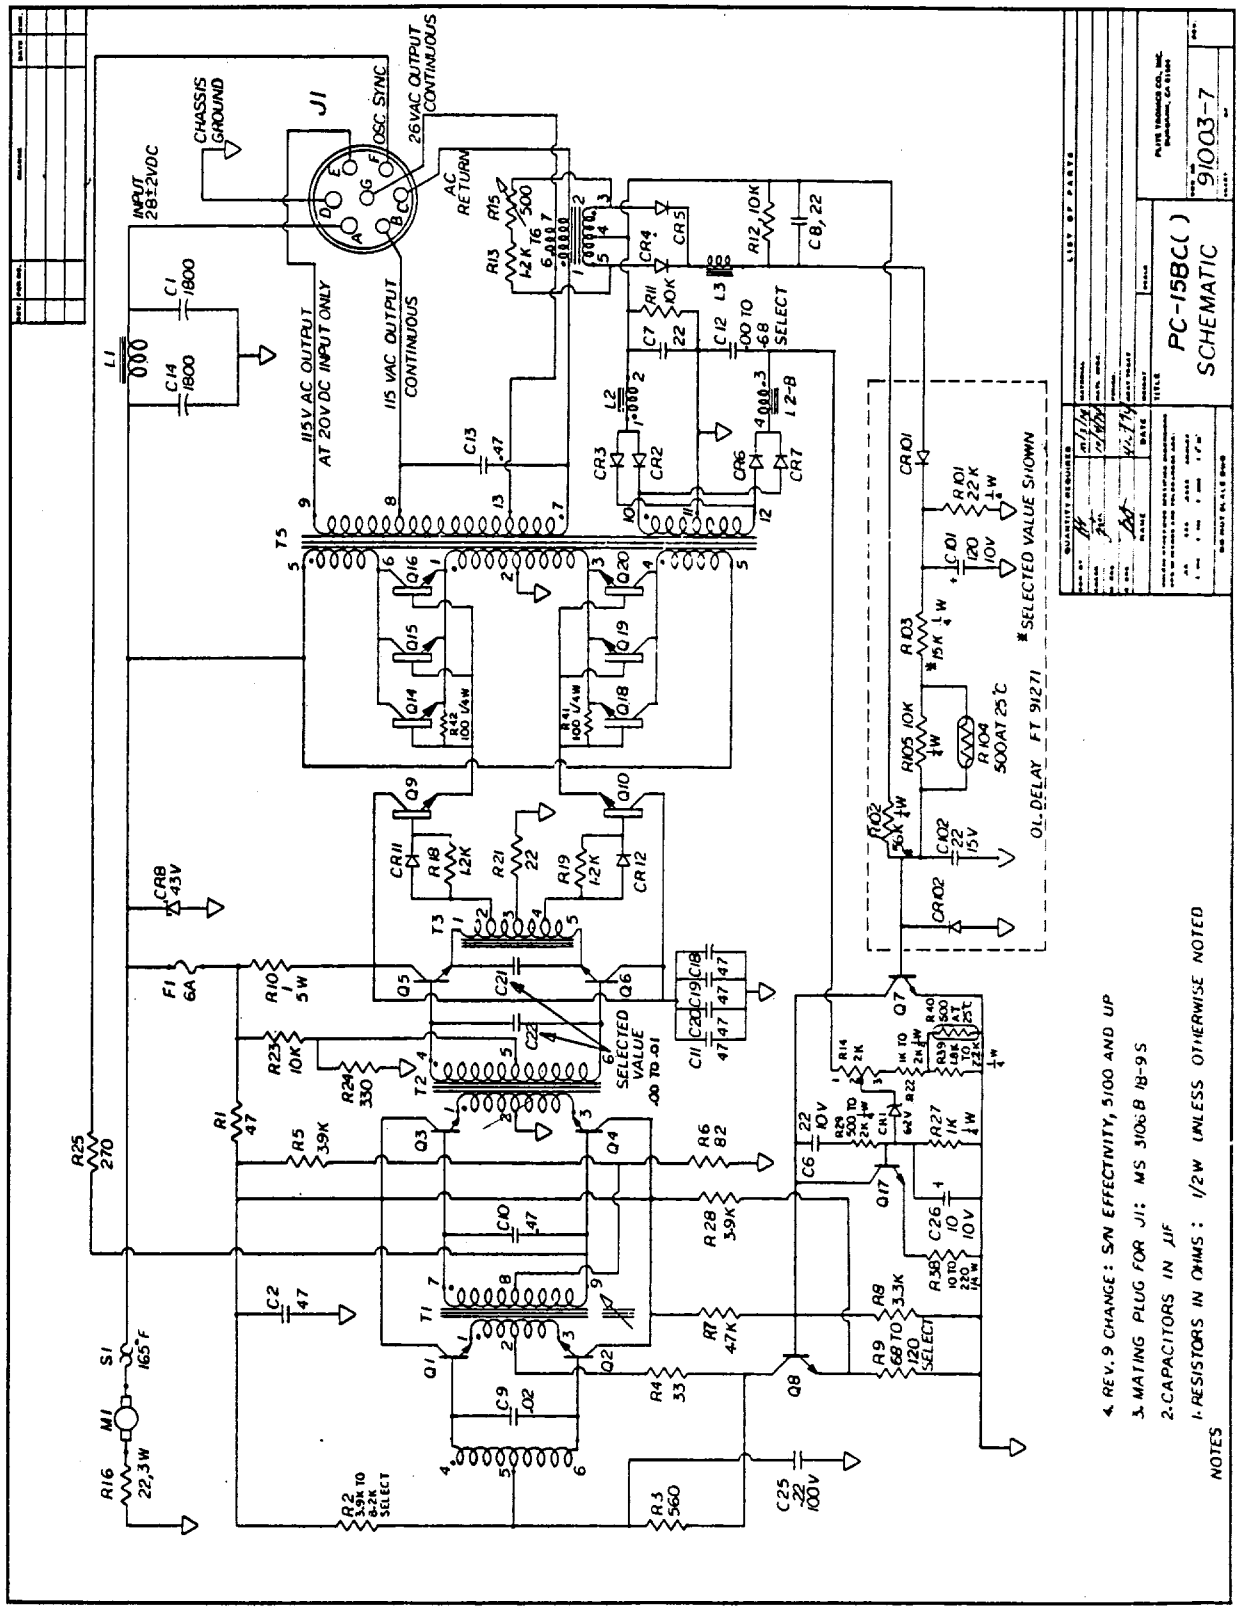

Figure 3.2 PC-15BC( ) SCHEMATIC

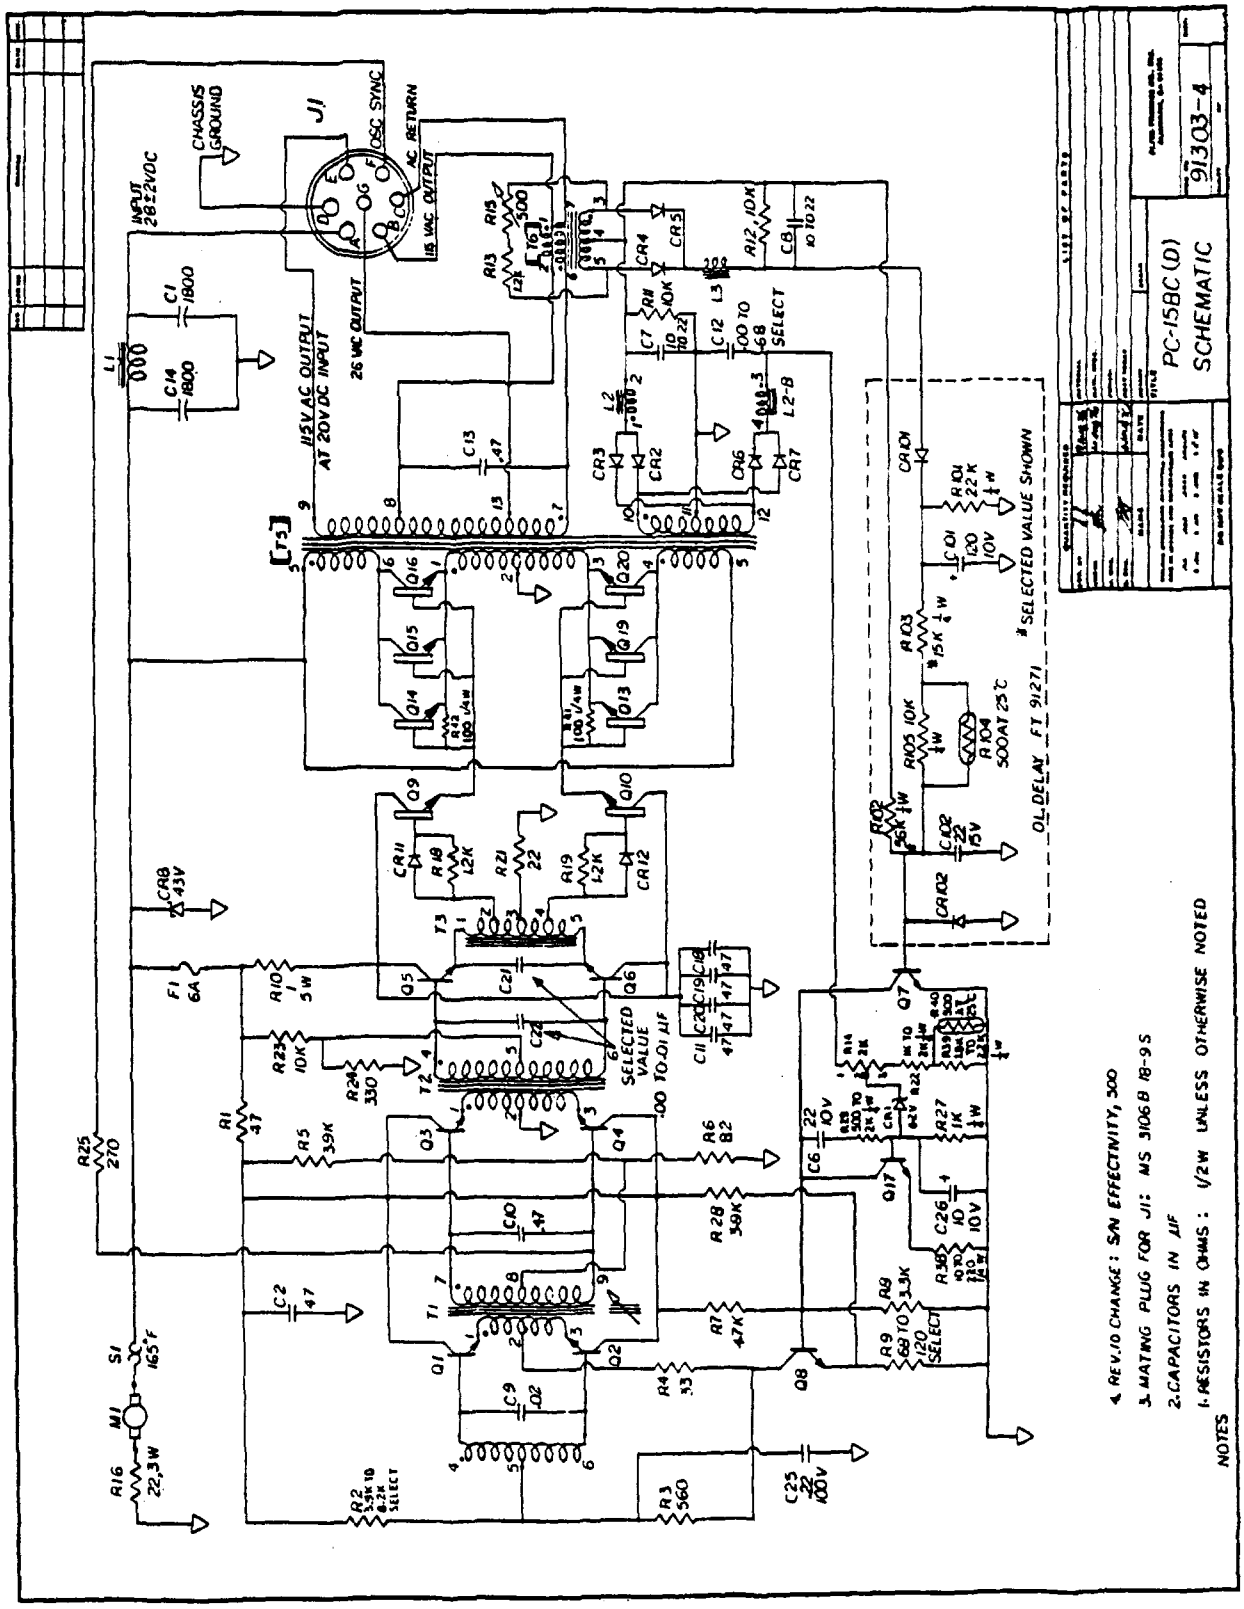

Figure 3.2-1 PC-15BC(D) SCHEMATIC

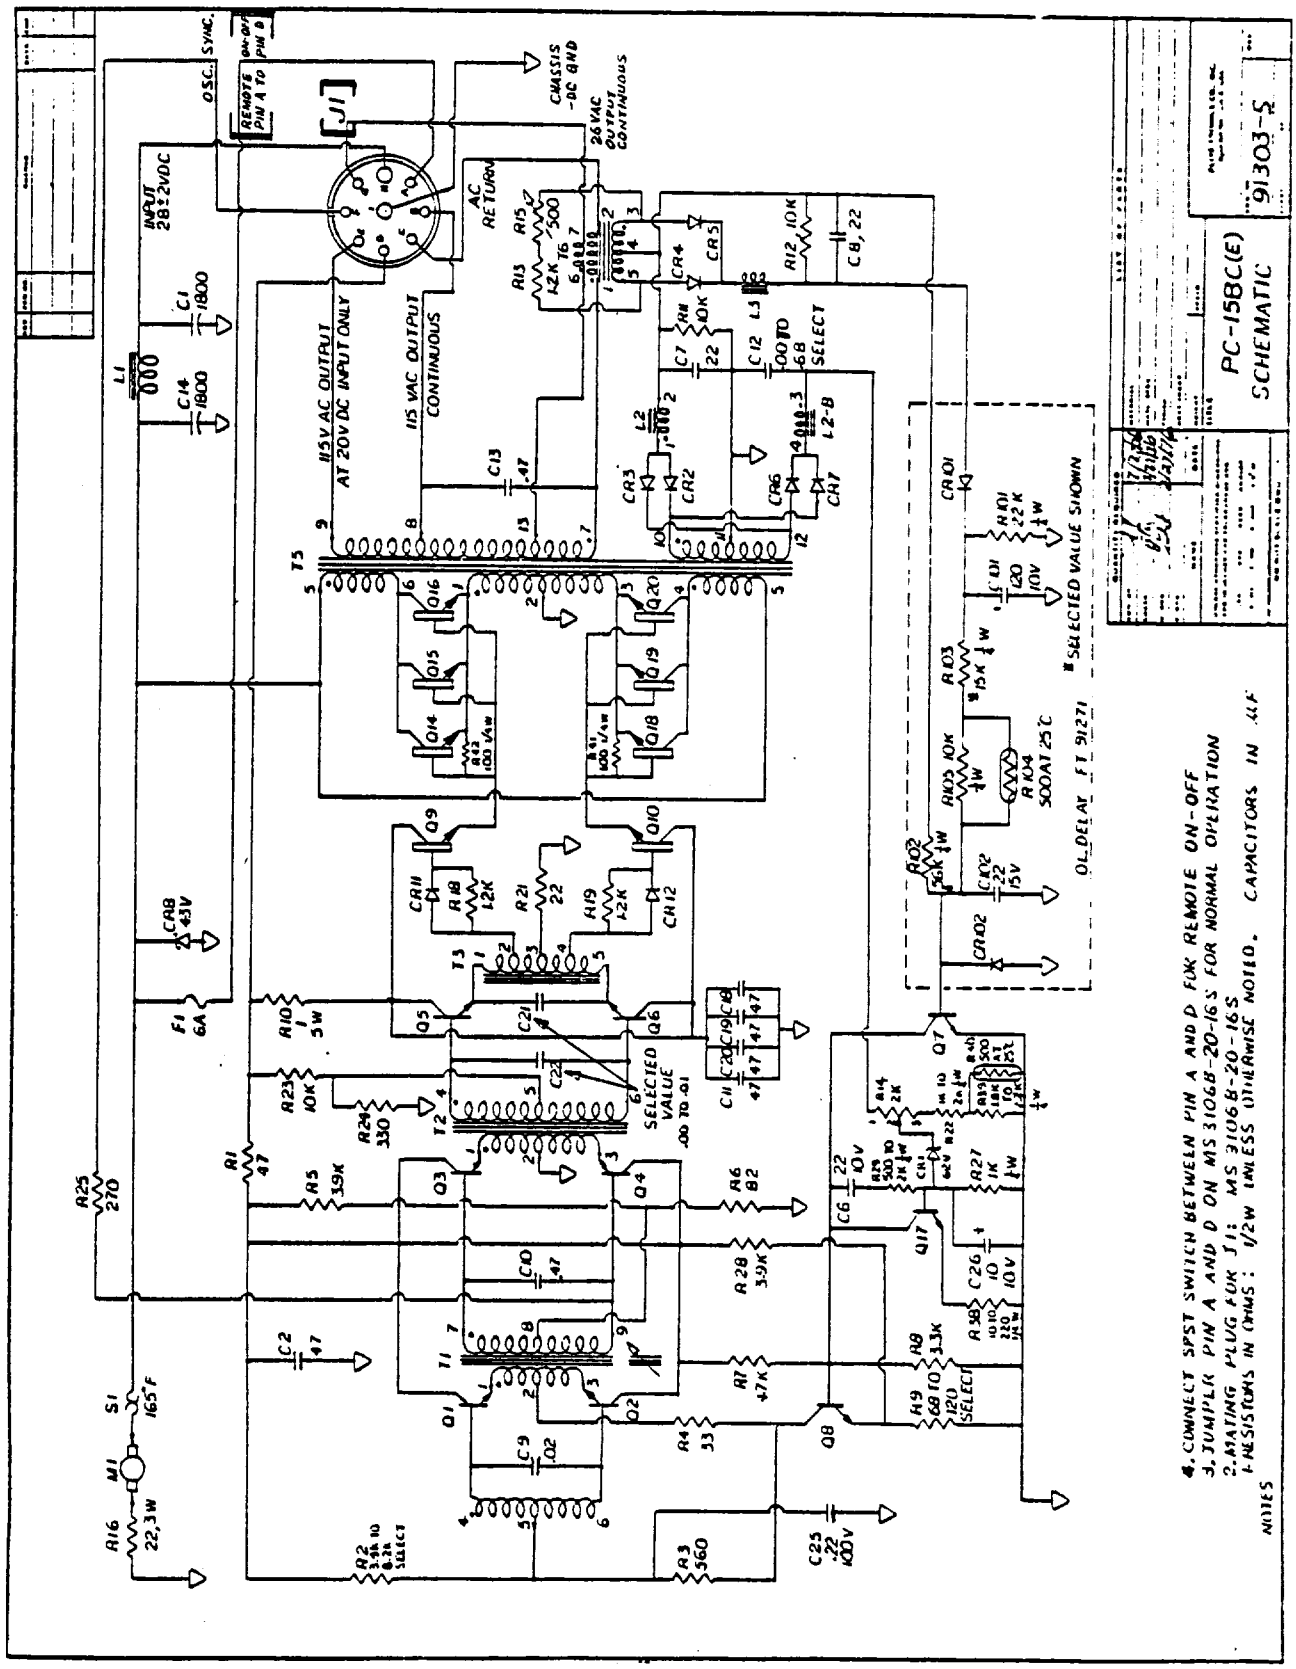

Figure 3.2-2 PC-15BC(E) SCHEMATIC

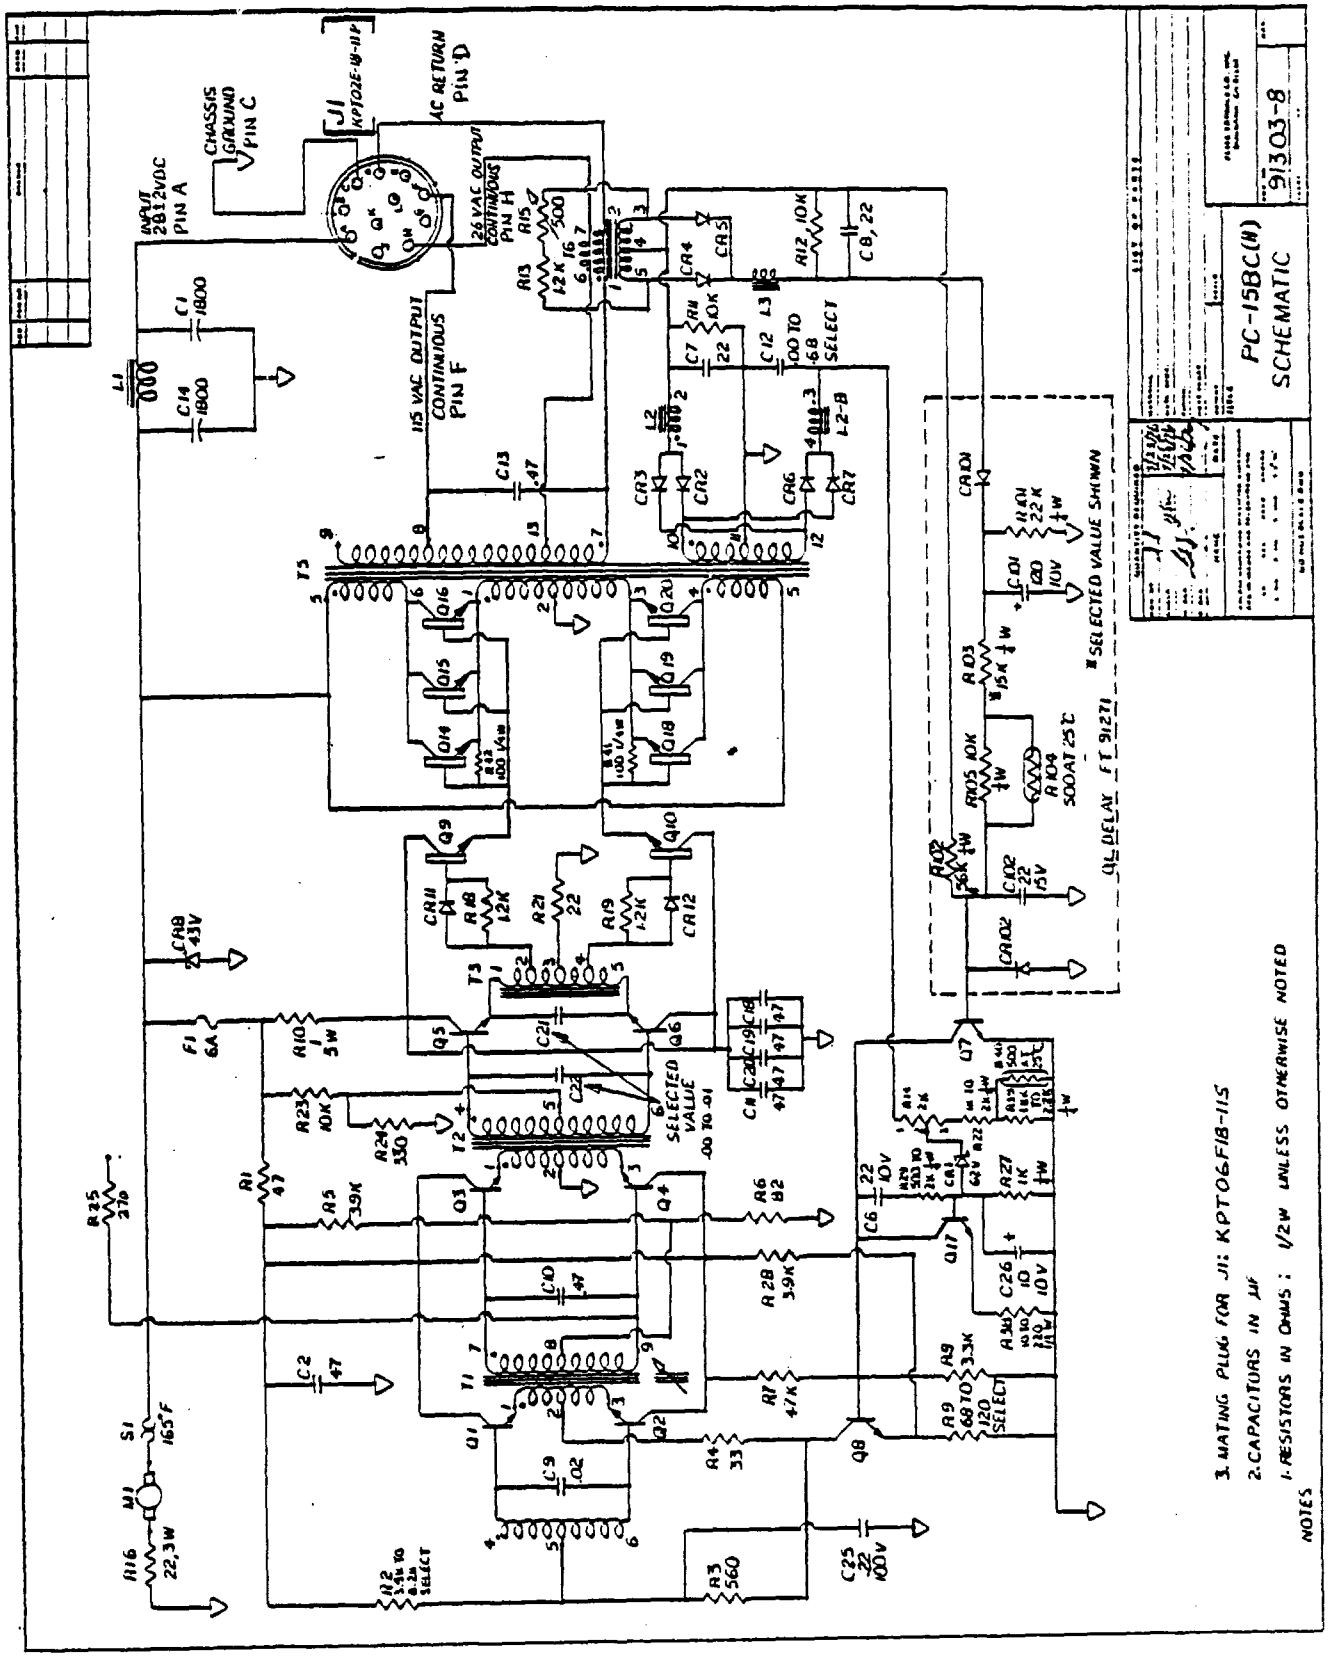

Figure 3.2-3 PC-15BC(H) SCHEMATIC

Transformer T1 has a tuning slug which is adjusted at the factory for an oscillator frequency of 400 HZ.

Transistors Q1 and Q2 are the class B push-pull amplifier to sustain oscillation. Resistors R2 and R3 biases the transistors to cause oscillation to start. Capacitor C9 suppresses any tendency for high frequency mode oscillation. Resistor R4 is the degenerating resistor.

The output winding 7-8-9 drives the bases of Q3 and Q4 in opposite phase.

3.4 Low Level Amplifiers

Between the sine wave oscillator and power amplifiers, there are three stages of class B push-pull emitter follower amplifiers.

The first stage consists of transistors Q3 and Q4 and the interstage transformer T2. Resistors R5 and R6 biases the transistors operating point.

The output from the transformer T2 drives the bases of Q5 and Q6. Resistors R24 and R23 biases transistors Q5 and Q6. Transistors Q5 and Q6 emitters drive the matching autotransformer T3. By using an autoformer connection for T3, the unit is designed compactly and yet permits proper step-down to drive transistors Q9 and Q10. Capacitor C22, a selected value connected across 4 and 6 of T2, is used to suppress ringing.

Capacitor C21 connected to the emitter of Q5 and Q6 suppresses parasitic oscillation. Transformer T3 delivers proper voltage and current to the final power output transistors thru logic network consisting of CR11, R18 and CR12, R19.

Decoupling network for the oscillator stage and first low level amplifier is R1 and C2. Decoupling network for the intermediate stage is R10.

Zener CR8 clips transient voltage above 43 VDC.

3.5 Power Amplifier

The power amplifier consists of silicon power transistors. Transistors Q14 through Q16 and Q18 through Q20 are driven in alternate half cycles. The multiple winding primary of transformer T5 divides the 28.0 VDC input, so the transistors operate in a hybrid grounded emitter and grounded collector configuration.

These power transistors are controlled to Flite-Tronics' specifications. These devices are inspected for certain minimum breakdown voltage, gain and recovery time. Therefore, an 88 volt peak transient on the 28.0 VDC input will not cause a collector to emitter voltage to exceed the minimum breakdown voltage. The primaries of the transformer forces this voltage division.

The tapped secondary of T5 delivers 26 VAC from terminal 13, and 115 VAC from terminal 8.

The output from terminal 9 is 115 VAC working into 90% of rated load, during an input of 20 VDC on the A+ line. There will exist, however, a slight squaring of the peaks of the sine wave in this condition.

Capacitor C13 is the phase compensating capacitor to permit the unit to operate efficiently with a load power factor between .8 lag and 1.0.

3.6 Output Voltage Control

The output voltage sample is realized from the center tapped winding 10-11-12 of T5. Rectifiers CR6 and CR7 converts the AC signal to a DC output. Filter consisting of L2-B and C12 is the L section choke input to give an average DC output which is proportional to the 115 VAC level.

This DC output is also applied across a variable resistor R14 in series with R22 and temperature compensating network R39 and R40 in parallel. The variable portion of the resistor is connected to the base of Q17 thru zener 6.2 VDC CR1. In essence, this output voltage sample is compared with the zener CR1.

The variable resistor R14 is adjusted for an output of 115 VAC. A common load resistor R7 is connected to the collector of Q7 and Q17. The DC current passing through R7 determines the bias point for transistor Q8. Transistor Q8 is the variable DC source for the push-pull 400 HZ oscillator.

The push-pull oscillator represents an impedance to the collector circuit of Q8. Hence, the conduction of Q8 will determine the magnitude of DC voltage across the oscillator circuit. This, in turn, determines the amplitude of oscillation, which controls the AC output level. Resistor R9 is the degenerating resistor for transistor Q8.

Resistor R8 is the starting resistor for transistor Q8 until the oscillator amplitude builds up sufficiently for the automatic level control circuitry to take over.

Capacitor C6 is a low frequency feedback capacitor to prevent the automatic level control circuitry from motor boating. Capacitor C25 and C26 are simply by-pass capacitors.

3.7 Output Overload Control

The output AC current is sampled by the transformer T6. The current flowing through the winding 1-2 causes a voltage to be developed across the center tapped winding 3-4-5. The magnitude of voltage across this winding is controlled by the variable resistor R15 in series with R13.

The AC voltage from winding 3-4-5 is rectified by CR4 and CR5. The averaging choke

input filter, consisting of L3 and C8, develops a DC voltage across R12, which is proportional to the output AC current. The 26 VAC output current is sampled by winding 6-7 of transformer T6.

To realize an overload that causes quenching action, the overload current resulting in DC voltage across R12 is compared with the output DC voltage across R11. This tends to give a trigger-like action when an overload condition is sustained.

The output voltage sample is taken from winding 10-11-12 of transformer T5. CR2 and CR3 rectifies this voltage. The L section choke input filter, consisting of L2 and C7, places across resistor R11 a ripple-free DC voltage. The voltage across R11 is a negative polarity with respect to ground.

The DC voltage across R12, which is proportional to the output current, is compared with the voltage across resistor R11. When the output current causes a voltage across R12 to exceed the compared voltage across R11, transistor Q7 will start conducting when this signal is coupled thru overload (OL) delay network shown as FT91271. The extent of overload determines the magnitude of current Q7 will conduct. As Q7 conducts, this tends to cut off Q8, which, in turn, decreases the voltage across the 400 HZ oscillator circuit.

When the load is in excess of 170% of 250 VA, the oscillator circuit will exhibit anything from low frequency quenching to almost a complete shut down.

During output short circuit, the current overload circuitry will reduce the voltage across the push-pull oscillator until a feeble oscillation is maintained.

Of course, on removal of the short circuit condition, the unit will immediately return to normal operating condition.

3.8 Input Filtering and Blower

The input is filtered by a pi section filter, consisting of capacitors C1, C14 and choke L1.

Additional filtering for the low level stage is done by the RC filter, consisting of R1, C2, and R10, C11, C18, C19 and C20.

Blower motor M1 is thermostatically controlled and used for protection only. The blower motor turns on when the heat sink temperature exceeds 165° Fahrenheit.

In normal installation where thermal conduction by the aircraft structure is adequate, the blower motor may never come on. Resistor R16 simply reduces the speed slightly to measurably increase the life of the blower.

F1 fuses the intermediate amplifier stages.

3.9 Transient Protection

To eliminate deleterious effects of voltage transients a zener diode is used.

Transient voltage passing through the A+ input filter section and exceeding 43 volts are clipped by the zener diode CR8.

3.10 Phase & Frequency Locking

When the PC-15s are paralleled together, it is necessary to phase synchronize the output voltage. Resistor R25 is the coupling resistor to phase lock the oscillator together through pin F of J1.

When the PC-15s are paralleled, it is necessary to have all the parallel units operating. The loading effect of the non-operating unit causes the other parallel unit or units to shut down. However, instead of paralleling PC-15s we suggest using a higher Flite-Tronics' VA inverter.

To frequency lock the PC-15s to other 115 VAC sources, resistor R25 is changed to C23. Typically .0047 ufd, as shown in the bill of material, may be used.

When PC-15s are frequency locked, the output should not be paralleled to the 115 VAC source.

Section IV

Maintenance

4.1 General

This section covers the bench check of the PC-15s to determine conformance to manufacturers specification.

For safety feature only, a thermostat is used to control the blower motor. It will come on only when the heat sink temperature exceeds 165°F.

Table 4.2, page 204, is used to functionally check the PC-15s to manufacturers performance.

The instructions on table 4.3 will aid in localizing the cause of defective operation, should any component fail.

4.2 Test Equipment

Table 4.1 lists the recommended components and test equipment to be employed in conducting electrical test per manufacturers test procedures.

Figure 4.1 illustrates the bench test inter-connection diagram. The Flite-Tronics Test Set TS-PC-15B-1 is a unit for readily conducting the test in Table 4.2 and 4.3. Table 4.2 indicates the readings and step-by-step procedure to test PC-15s operating normally. Table 4.3 notes test procedure and possible cause of abnormal reading.

Resistor R9	9 ohm 150 watt	Resistive load
Resistor R10	75.6 ohm 350 watt or equiv.	Resistive load
Resistor R11	1.0 ohm 200 watt	Resistive load
Switch S1	SPDT	20 VDC input switch
Switch S2	SPST	4% load switch
Switch S3	SPST	33% load switch
Switch S4	SPST	90% load switch
Switch S5	SPST	100% load switch
Switch S6	SPST	150% load switch
Switch S7	SPST	170% load switch
Switch S8	SPST	185% load switch
Switch S9	SPST	.8 power factor switch
Switch S10	3PST	Short circuit switch
Switch S11	DPDT	115 V or 115/26 V load selector switch
Switch S12	DPDT	Output voltage selector switch
Switch S13	4PDT	Output current selector switch

4.3 Performance Test and Localizing Trouble Source

Table 4.3 outlines a step-by-step procedure to performance test the PC-15s to localize fault source, if troubles exist.

It is suggested the technician acquire familiarity of the unit by studying the principles of operation section prior to attempting this section.

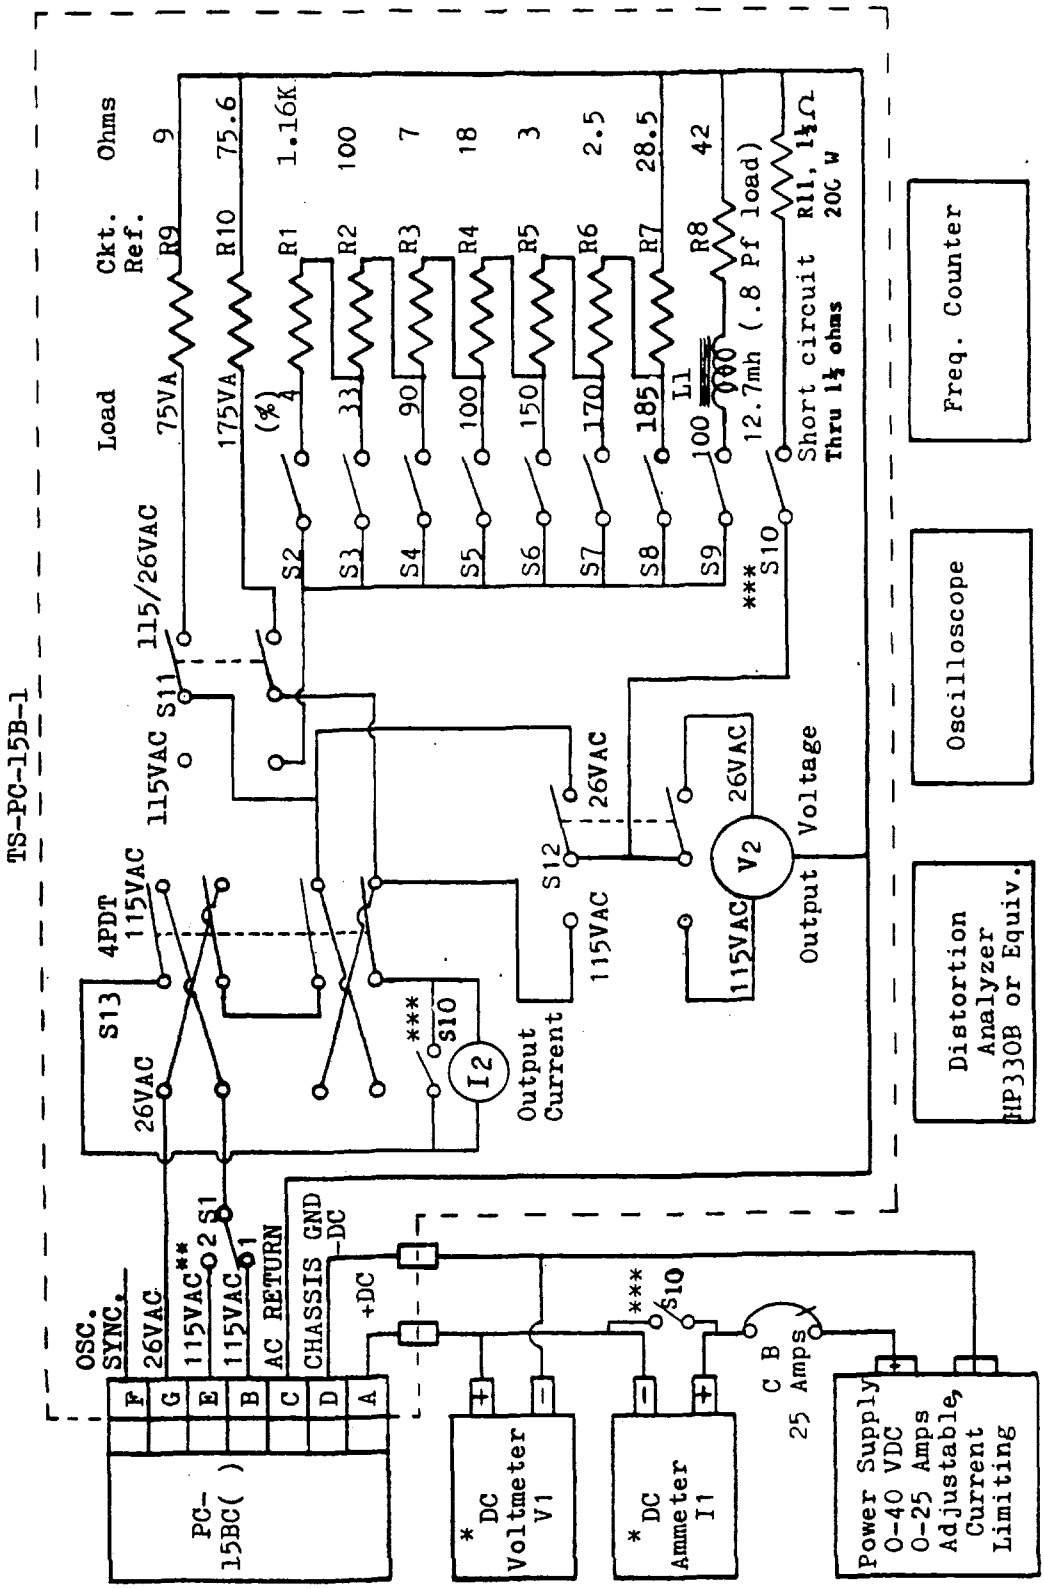

Figure 4.1 BENCH TEST SET AND HOOK-UP TS-PC-15B-1

4.4 Check Out Procedure for PC-15BC( )

To functionally test Flite-Tronics Static Inverter connect the PC-15BC( ) to the test set TS-PC15B-1.

A. Model PC-15BC( ): 2 outputs; 115 VAC, 400 HZ, *250VA Max.
26 VAC, 400 HZ, *75VA Max.

B. Frequency: 400 HZ ± 4 HZ

C. Amplitude Distortion: 7% or less under normal operating conditions.

*Sum of powers from the 115 VAC and 26 VAC output should not exceed 250 VA.

Table 4.2 Test Conditions and Typical Readings

Condition	Switch	Position	** Typical Readings			
			DC Input		AC Output	
			Voltage	Current	Voltage	Current
No load	S1 S2 thru S10 S11 S12 & S13	#1 Off 115 VAC 115 VAC	28 VDC	.75 Amps or less	116 to 120.7 VAC	0 Amp
4% load	S1 S2 S3 thru S10 S11 S12 & S13	#1 On Off 115 VAC 115 VAC	28 VDC	2.0 Amps	Between 115 VAC and 120.7 VAC	.1 Amps
33% load	S1 S3 S2 & S4 thru S10 S11 S12 & S13	#1 On Off 115 VAC 115 VAC	28 VDC	5.0 Amps typical	Between 115 VAC and 120.7 VAC	.72 Amps typical
100%	S1 S5 S2 thru S4 & S6 thru S10 S11 S12 & S13	#1 On Off 115 VAC 115 VAC	28 VDC	14 Amps typical	Between 108 VAC and 120.7 VAC	2.17 Amps Typical
150% overload	S1 S6 S2 thru S5 & S7 thru S10 S11 S12 & S13	#1 On Off 115 VAC 115 VAC	28 VDC	20 Amps typical	At least 107 VAC	3.3 Amps typical
170% overload	S1 S7 S2 thru S6 & S8 thru S10 S11 S12 & S13	#1 On Off 115 VAC 115 VAC	28 VDC	22 Amps typical	At least 100 VAC	3.6 Amps typical

** Readings shown are steady state values unless otherwise noted

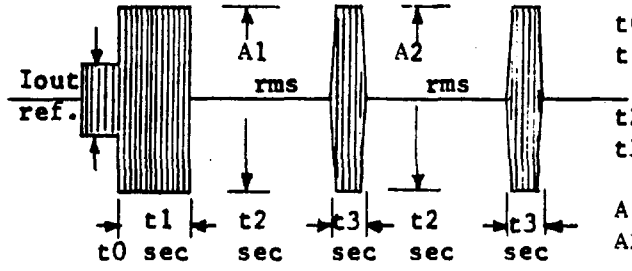

Table 4.2 Test Conditions and Typical Readings (cont'd)

Load Condition	Switch	Position	Typical Readings			
			DC Input		AC Output	
			Voltage	Current	Voltage	Current
185% overload	S1 S8 S2 thru S7 & S9 & S10 S11 S12 & S13	#1 On Off 115 VAC 115 VAC	28 VDC	Between 0 Amps and 23 Amps	Output voltage & current motor-boating	
100 % reactive load	S1 S9 S2 thru S8 &10 S11 S12 & S13	#1 On Off 115 VAC 115 VAC	28 VDC	14 Amps typical	Between 107 VAC and 120 VAC	Between 2.2 Amps and 2.5 Amps
Pin E output @ 20 VDC input	S4 S1 S5 thru S10 S11 S12 & S13	On #2 Off 115 VAC 115 VAC	20 VDC	15 Amps typical	Between 107 VAC and 115 VAC	1.95 Amps typical
See note 1 load 175 VA on 115 VAC	S1 S2 thru S10 S11 S12 & S13	#1 Off 115/26VAC 115 VAC	28 VDC	14 Amps typical	Between 107 VAC and 120 VAC	1.5 Amps typical
75 VA on @ 26 VAC	S1 S2 thru S10 S11 S12 & S13	#1 Off 115/26VAC 26 VAC	28 VDC	14 Amps typical	Between 24.2 VAC and 27.3 VAC	2.9 Amps typical
Output short circuit test: 115 VAC	S1 S2 thru S10 S11 S12 & S13 Turn S10 on	#1 Off 115/26VAC 26 VAC On	28 VDC	See Note 2 Below $A_1=A_2=5$ to 10 amps rms typ $t_1=.35$ to .65 sec typical $t_2=2$ to 3.5 sec typical $t_3=.1$ to .3 sec typical		
26 VAC	S1 S2 thru S10 S11 S12 & S13 Turn S10 on	#1 Off 115/26VAC 115 VAC on	28 VDC	See Note 2 Below for general waveform $A_1=A_2=14$ to 20A rms typ. t_1, t_2, t_3 } Typically same durations as in 115 VAC output short circuit case.		

Note 1. S11 in 115/26 VAC position, 175 VA resistive load is connected to 115 VAC output and 75 VA resistive load is connected to 26 VAC output.

Note 2. The initial output short circuit current burst is relatively long in duration. The second and subsequent bursts keep the same amplitude but less in duration. Typical burst waveform is shown on next page.

Table 4.2 Note 2 (continued)

t0 = Time output fault occurs
t1 = Initial duration of the output current burst
t2 = Duration of no output, repeated
t3 = Duration of second and repeated bursts until fault clears
A1 = Initial rms current burst amplitude
A2 = Second and repeated rms current burst amplitude

4.4.1 Switch Nomenclature:

S1	115 VAC normal and 20 VDC input output selector switch; position #1 normal, position #2, when input voltage is 20 VDC
S2	4% Resistive load switch
S3	33% " " "
S4	90% " " "
S5	100% (250VA) Resistive load switch
S6	150% Resistive load switch
S7	170% " " "
S8	185% " " "
S9	100% Reactive load switch
S10	Output short circuit switch for 115 VAC or 26 VAC- the AC voltmeter indicates output being shorted
S11	115 VAC only and 115/26 VAC output selector switch
S12	Output voltage selector switch. 115 VAC or 26 VAC
S13	Output current selector switch. 115 VAC or 26 VAC current

Table 4.3 Performance Test and Localizing Trouble Procedures

STEP	SET-UP	PROCEDURE	PERFORMANCE READING	POSSIBLE CAUSE OF ABNORMAL READING
1	Interconnect unit per bench test hook-up	a) Turn on power supply, keep input voltage set at zero. b) Turn on all measuring equipment for warm-up c) Check polarity of power supply. d) Set S1 to No. 1 position e) Set switches S2 through S10 in the Off position.		
2	S2 through S10 in the Off position S11 in the 115 VAC only position S12 & S13 in the 115V position	a) Gradually increase power supply voltage to 28 VDC	Input DC current I1 should not exceed 3/4 amps DC	Test set-up incorrectly connected. Capacitor C1, C11,C14 and C18 thru C20 may be shorted. Transistors Q9,Q10,Q14, Q15,Q16,Q18, Q19 & Q20 shorted. C2 or CR8 shorted.
3	S2 thru S10 in the Off position S11 in the 115 VAC only position S13 in the 115V position	a) Input voltage set at 28.0 VDC b) Adjust R14 as required, so V2 reads 117 VAC and then CR1 zener voltage must be checked and confirmed to be 6.2 VDC ±5%.	V2 should read between 107 VAC to 120.7, with S12 in the 115 VAC position and between 24.2 to 27.3 VAC with S12 in 26 VAC position.	Check for following likely defective components: CR6,CR7,C12, R14,C6,CR1, Q17 and Q8.

Table 4.3 (continued)

STEP	SET-UP	PROCEDURE	PERFORMANCE READING	POSSIBLE CAUSE OF ABNORMAL READING
4	S2 through S10 in the Off position S11 in the 115 VAC only position S12 and S13 in the 115V position	a) Input voltage set at 28.0 VDC. b) If frequency is out of tolerance, adjust tuning slug on transformer T1	Frequency meter should read 400 HZ ± 4 HZ I1-3/4 A typical	Defective parts likely to cause abnormal reading: Transformer T1, Capacitor C10 or C9
5	S2 through S10 in the Off position S11 in the 115 VAC only position S12 and S13 in the 115V position	a) Input voltage set at 28.0 VDC. b) Vary input voltage between 26 to 30 VDC.	Distortion meter should read less than 7%. I1-3/4 A typical	Defective parts likely to cause abnormal reading: Transistors Q3 thru Q6,Q9,Q10, Q14,Q15,Q16 Q18 and Q19.
6	Switch S5 on for full load output S11 in the 115 VAC only position S12 and S13 in the 115V position	a) Input voltage set at 28.0 VDC. b) Resistor R14 may require readjusting; however, if adjusted, step 3 should be retested. c) Vary input voltage between 26 to 30 VDC.	I2 read 2.17 amps AC V2 should read between 107 to 120.7 VAC I1 should read approximately 14.2 A. Frequency should be 400 HZ ± 4 HZ Distortion less than 7%.	Defective parts likely to cause abnormal reading: Diodes CR2, CR3,CR4 and CR5. Transistor Q1,Q2,Q8 and Q17.

Table 4.3 (continued)

STEP	SET-UP	PROCEDURE	PERFORMANCE READING	POSSIBLE CAUSE OF ABNORMAL READING
7	Switch S6 for 150% overload test. S11 in the 115 VAC only position S12 and S13 in the 115V position	a) Input voltage set at 28.0 VDC. b) Resistor R15 may require adjusting if unit tends to motor boat. However, in the event of any adjustment, step 3 should be repeated.	I2 should read approximately 3.3 amp. V2 should read at least 107 VAC. I1 should read about 20 amps.	Defective parts likely to cause abnormal reading: Diodes CR2, CR3, CR4 and CR5. Transistor Q1, Q2, Q8 and Q17.
8	Switch S7 on for 170% overload test S11 in the 115 VAC only position S12 and S13 in the 115V position	a) Input voltage set at 28.0 VDC. b) R15 adjusts the overload threshold point. The proper setting at the 170% overload point; the unit should almost start motorboating.	I1 should read about 22 amps. V2 should read at least 100 VAC. I2 should read approximately 3.6 amps.	Defective components likely to cause abnormal reading: Diodes CR2, CR3, CR4 and CR5. Capacitors C7 and C8. Transistors Q7 and Q8. OL delay. FT91271 components.
9	Switch S8 on for 185% overload test S11 in the 115 VAC only position S12 and S13 in the 115V position	a) Input set at 28.0 VDC. b) R15 adjust the overload threshold point. The proper setting at 185% overload point, the PC-15BC( ) should be in the motorboating mode.	I1 should be motorboating between 0 to 20 amps. I2 and V2 should indicate output current and voltage is motorboating.	Defective components likely to cause abnormal reading: Diodes CR2, CR3, CR4 and CR5. Capacitors C7 and C8. Transistors Q7 and Q8.

Table 4.3 (continued)

STEP	SET-UP	PROCEDURE	PERFORMANCE READING	POSSIBLE CAUSE OF ABNORMAL READING
10	Switch S10 on for output short circuit test S11 in the 115 VAC only position S12 and S13 in the 115V position	a) Input set anywhere between 26 and 28 VDC. b) I1 will be pulsating	I1 pulsating. V2≈10 VAC pulsating. I2 bypassed during this test. Scope should measure waveshape shown on page 206.	Defective components likely to cause abnormal reading: Diodes CR2, CR3, CR4 and CR5. Capacitors C7 and C8 Transistors Q7 and Q8.
11	Switches S2 through S8 in the Off position Switch S9 on 250 VA S10 in Off position S11 in the 115 VAC only position S12 and S13 in the 115V position	a) Input voltage set at 28.0 VDC. b) Vary input voltage between 26 to 30 VDC.	I2 read 2.0 to 2.3 amps AC. V2 read between 107 to 120.7 VAC.	Defective parts likely to cause abnormal reading: Diodes CR2, CR3, CR4 and CR5. Transistor Q1, Q2, Q8 thru Q17. Capacitor C13.

Table 4.3 (continued)

STEP	SET-UP	PROCEDURE	PERFORMANCE READING	POSSIBLE CAUSE OF ABNORMAL READING
12	Switch S3 on and S4 through S10 in Off position for 33% load test S11 in the 115 VAC only position S12 and S13 in the 115V position	a) Input voltage set at 28.0 VDC.	I1 read 5.0 amps. I2 read .72A V2 read between 116 to 120.7 VAC Distortion meter should read less than 7%. Frequency meter should read 400 HZ ± 4 HZ.	Defective parts likely to cause abnormal reading: Transformer T1. Capacitor C10. Transistors Q3 thru Q6,Q9,Q10, Q14,Q15,Q16, Q18,Q19 and Q20.
13	Switch S2 on. Switch S3 through S10 in Off position S11 in the 115 VAC only position S12 and S13 in the 115V position	a) Input voltage between 26.0 to 28 VDC	Distortion less than 7%. Frequency 400 HZ ± 4 HZ. V2 read 115 to 120.7 VAC. I1 read 2 amps DC. I2 read .20 to .35 amps AC.	Defective parts likely to cause abnormal reading: Diodes CR6, CR7,C12,R14, C6,CR1,Q17, and Q8

Table 4.3 (continued)

STEP	SET-UP	PROCEDURE	PERFORMANCE READING	POSSIBLE CAUSE OF ABNORMAL READING
14	Switch S1 to #2 position. S4 on, and S5 through S10 in Off position S11 in the 115 VAC only position S12 and S13 in the 115V position	a) Set input voltage at 20 VDC.	V2 read 107 to 120.7 VAC. I2 read 1.93 to 2.12 amps AC. I1 read approximately 15.0 amps DC.	Defective parts likely to cause abnormal reading: Diodes CR2, CR3, CR4 and CR5. Transistor Q1, Q2, Q8 and Q17.
15	Switch S1 to #1 position Switch S11 in the 115/26 VAC position	a) Input voltage set at 28.0 VDC.	I1 should read approximately 14.2 amps I2 read 1.52 amps, with S13 in 115V position. I2 read 2.9 amps, with S13 in 26V position. V2 should read between 107 to 120.7 VAC with S12 in 115V position V2 should read between 24.2 to 27.3 VAC with S12 in 26V position. Distortion for 26 VAC and 115VAC output should be 7% or less.	Defective parts likely to cause abnormal reading: Diodes CR2, CR3, CR4 and CR5. Transistor Q1, Q2, Q8 and Q17.

Table 4.3 (continued)

STEP	SET-UP	PROCEDURE	PERFORMANCE READING	POSSIBLE CAUSE OF ABNORMAL READING
16	Switch S11 in the 115/26 VAC position for output short circuit test S12 in the 26V position S13 in the 26V position	a) S10 switched on after unit is operating normally. b) I1 will be pulsating.	I1 pulsating. V2 20 VAC pulsating. I2 bypassed during this test. Scope should measure waveshape shown on page 206.	Defective components likely to cause abnormal reading: Diodes CR2, CR3, CR4 and CR5. Capacitors C7 and C8. Transistor Q7 and Q8. Resistor R15.

4.5 Voltage Measurement

To enable the technicians to effectively service the PC-15's table 4.4 tabulates the typical D.C and/or A.C. voltage to assist in localizing a fault source.

Table 4.3 indicates the possible component for an abnormal reading. If a voltage other than those listed in table 4.4 is measured this will enable the technician to determine which component is possibly faulty.

Table 4.4 PC-15BC( ) Voltage Distributions

Measurement Condition

1. Input 28.0 VDC.
2. Full load with Switch S5 on.
3. Switch S1 in the #1 position.
4. DC and AC measurement made with a Simpson 270 or equivalent.
   (Note: Make AC measurement in the output connection to this meter.)

Table 4.4 PC-15BC( ) Voltage Distributions

CIRCUIT REF.	TEST POINT	DC VOLTS	AC RMS
Q1 & Q2	Emitter	8 to 20*	6
	Base	8 to 20*	6
	Collector	26	0
Q3 & Q4	Emitter	.2	9
	Base	.5	9
	Collector	26	0
Q5 & Q6	Emitter	.7	15
	Base	.3	15
	Collector	26	0
Q9 & Q10	Emitter	.5	9
	Base	.15	10
	Collector	27	0
Q14,Q15 Q16,Q18 Q19,Q20	Emitter	.1	8.5
	Base	.5	9
	Collector	26	8.5

CIRCUIT REF.	TEST POINT	VDC (VOLTS)	VAC (RMS)
Q7	Emitter	0	0
	Base	-.2 to -.5	0
	Collector	3	0
Q8	Emitter	2.5	0
	Base	3	
	Collector	8 to 20	.4
Q17	Emitter	.04	0
	Base	.65	0
	Collector	3	0
CR2,CR3	Anode	0	10
CR6,CR7	Cathode	8.5	5
R11 & L2	Junction	-8.5	0
CR4,CR5	Anode	0	0 to 15*
	Cathode	-9 to +6*	6 to 0
R12 & L3	Junction	-9 to +5*	0

*These voltages are load dependent.

4.6 Servicing Practice and Replacement

Section 5.0 lists the table of replaceable parts. Figures 5.1 thru figure 5.7 illustrates the location of these components.

When installing or removing transistors, semiconductor diodes and heat sensitive components, grasp the lead between the solder joint and the component with a thermal dissipator, such as a spring loaded copper clip or long nose pliers. This will bleed off the heat being applied at the solder joint.

A temperature controlled soldering iron is recommended for such use. The wattage rating of the iron should not be greater than 35 watts. Always work with an iron that the tip is well tinned so the soldering can be done quickly and cleanly.

Power transistors Q5, Q6, Q9, Q10, Q14, Q15, Q16, Q18, Q19 and Q20 are insulated from ground. The insulating is done by means of insulating washers made of fiber and mica. When replacing these transistors, be sure washers are replaced in proper order and coating the washers with a film of silicone grease is recommended.

After such replacement, check with an ohmmeter or 40 VDC leakage tester to determine that the insulation is effective.

Section V

Table of Replaceable Parts

5.1 General

This section illustrates and lists components that can be replaced for repair purposes. It is recommended that PC-15s requiring replacement of parts that are not listed in Table 5.1, be returned to the factory for service.

Figures 5.1 through 5.7 illustrates the location of all the components that are listed in the Table of Replaceable Parts.

5.2 *Manufacturer's Code

Code	Name and Address
FT	Flite-Tronics Co., Inc. Burbank, California
FD	Fairchild Mountain View, California

T6	1	Transformer FT91136	FT	Output current sense

Model Series Listing Component Changes and/or Substitutions

1. Model PC-15BC(D) has 150 VA power output from the 26 VAC. The total power output, 115 VAC plus 26 VAC, remains the same.

   1.1 Component Change:

	Is	Was
Transformer T5;	FT91143	FT91135
Transformer T6;	FT91144	FT91136

2. Model PC-15BC(E) has remote on-off feature.

   2.1 Connector Change:

	Is	Was
Receptacle J1;	MS3102A20-16P	MS3102A18-9P

3. Model PC-15BC(H) has different connector type.

   3.1 Connector Change:

	Is	Was
Receptacle J1;	KPT02E18-11P	MS3102A18-9P

5.4 How To Order Replacement Parts

When ordering replacement parts, you should direct your order as indicated below and furnish the following information insofar as applicable.

Address: Flite-Tronics Co., Inc.
Sales Service Department
3314 Burton Avenue
Burbank, California, 91504

Infromation Needed:

1. Quantity required.
2. Part Number (Obtain from parts list or schematic diagram.)
3. Type number and serial number of equipment.

5.5 How To Return Materials Or Equipment

If, for any reason, you should wish to return material or equipment, whether under warranty or otherwise, you should notify us, giving full particulars including the details listed below, insofar as applicable. Upon receipt of such notice, Flite-Tronics Co., Inc. will promptly advise you respecting the return. Failure to secure our advice prior to the forwarding of the goods, or failure to provide full particulars, may cause unnecessary delay in handling of your returned material.

Address: Flite-Tronics Co., Inc.
Sales Service Department
3314 Burton Avenue
Burbank, California, 91504

Information Needed:

1. Date of delivery of equipment.
2. Date placed in service.
3. Number of hours in service.
4. Part number (obtain from parts list or schematic diagram.)
5. Type number and serial number of equipment.
6. Nature and cause of failure.
7. Remarks.

DESCRIPTION AND OPERATION

1. Description (See Figure 1)

The 250 VA static inverter, Model PC-250 is an enclosed rectangular unit consisting of a base plate, two heat sinks, two end plates, and a dust cover. Electronic components are mounted on the base plate, the heat sinks, the front and rear end plates, and on a printed circuit board and a bracket assembly that are internally installed. A connector is mounted on the front end plate to provide both input and output connections to the static inverter.

Refer to Table 1 for leading particulars of the basic Model PC-250 static inverter. Table 2 lists the differences in the basic PC-250 and the PC-250 (Mod Level A), PC-250-1A (Mod Level A), PC-250-1B, PC-250-1B (Mod Level A), PC-250-1C, and PC-250-1C (Mod Level A).

250 VA Static Inverter, Model PC-250
Figure 1

TABLE 1 (Sheet 1 of 4)
LEADING PARTICULARS

Dimensions	
Length	238 mm (9.375 in.)
Width	152.4 mm (6.0 in.)
Height	81.0 mm (3.188 in.)
Weight	3.6 Kg (8.1 lb.)
Input Power	
Nominal	28 VDC at 11.4 amp
Normal range	24 VDC to 32 VDC
Total range	20 VDC to 37 VDC
No-load current	1 amp
Output Power	
Continuous operation	250 VA at 115 volts RMS with a DC input voltage of 20 through 35 volts
	150 VA at 26 volts RMS with a DC input voltage of 20 through 35 volts

NOTE: The maximum output power available from a combination of 115V output power and 26V output power is 250 VA.

Short time operation	375 VA at 115 volts with an input voltage of 24 through 32 volts for 5 minutes
Output voltage	115 volts RMS ±3% at any combination of 24 to 32 volts and 0 to 125% output load
Output configuration	Monophase
Frequency	400 Hz ±1% under all operating conditions
Distortion	3.25% THD under nominal operating conditions
	7.0% maximum THD under all normal DC inputs and load configurations
Power factor	0.9 leading to 0.8 lagging

TABLE 1 (Sheet 2 of 4)
LEADING PARTICULARS

Efficiency	79% nominal
Overvoltage Protection	Automatically shuts off the inverter should the output voltage rise from 125 to 138 VRMS
Phase Locking	The PC-250 incorporates all necessary circuitry to phase lock two or more inverters for parallel or polyphase operation (consult factory)
Frequency Monitor	The PC-250 incorporates all necessary circuitry to monitor the inverter frequency including automatic shut-off should the frequency drift below 370 Hz or above 430 Hz
Fault Monitor	Provides 27 VDC output at 100 ma to an annunciator device when the inverter is operating normally. PC-250 series: No power is available to the annunciator under overvoltage or frequency fault and off conditions. PC-250 series, mod level A: No power is available to the annunciator under overvoltage, frequency fault, no output, short circuit, or off conditions.
Soft Start	To avoid high in-rush current, the PC-250 will reach its rated output in approximately 500 milliseconds.
Output Short Circuit Current	
115 volts	PC-250 series: Will trip 2.0 amp circuit breaker in less than 1 minute. Short circuit current approximately 3.5 amperes.
26 volts	Will trip a 7.5 amp circuit breaker in less than 1 minute. Short circuit current approximately 14 amperes.

NOTE: An output short circuit for a duration of one minute or less on the 115 volts or 26 volts line will not damage the inverter.

TABLE 1 (Sheet 3 of 4)
LEADING PARTICULARS

115 volts	PC-250 series, mod level A: The inverter will deliver a short circuit current equal to 200% of rated load current for at least 5 seconds after which automatic control will take place to fold back the current to a safe level.
26 volts	The inverter will deliver a short circuit current of approximately 18 amperes for at least 5 seconds, after which automatic control will take place to fold back the current to a safe level.

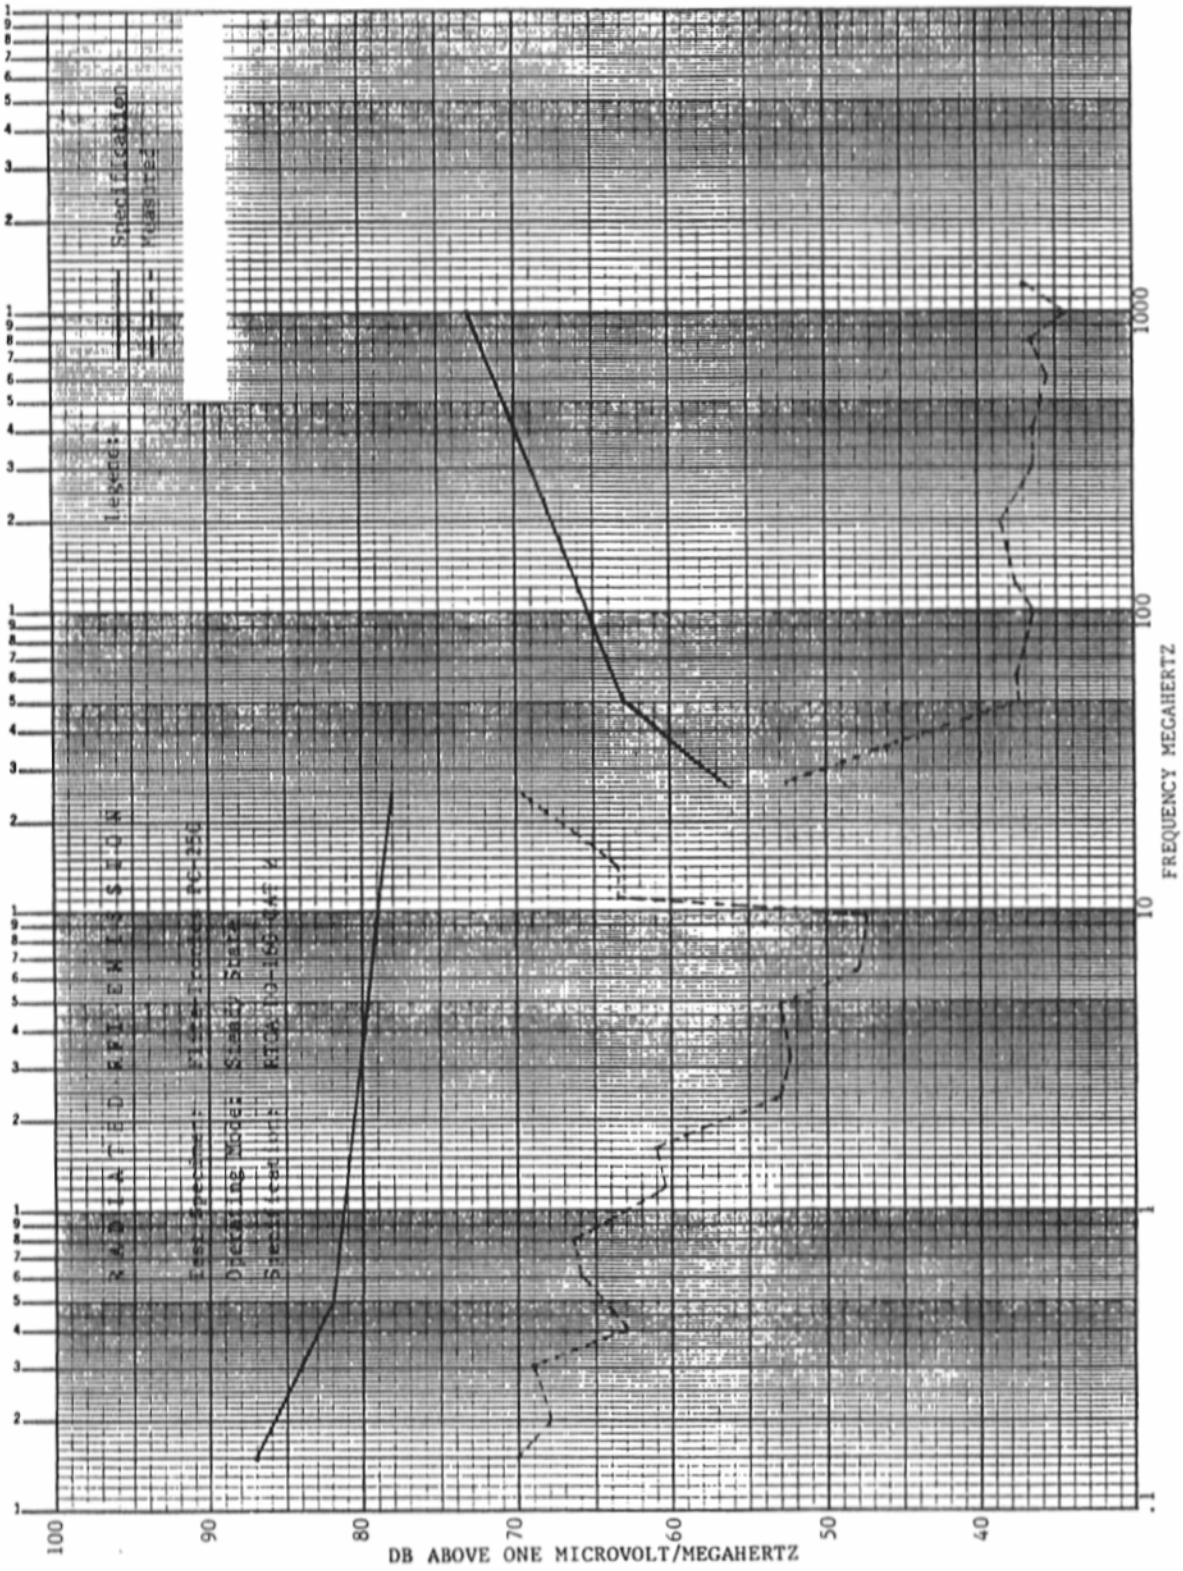
NOTE: There will be no damage to the inverter should the output short circuit not be cleared by the initial current surge and stay on continuously.

Remote ON/OFF	Controllable by standard TTL circuit
Cooling	Free air convection
Qualification Documents	FAA TSO C-73 RTCA DO160 CAT D2B/RV/EXXXXXAZAZZ

TABLE 1 (Sheet 4 of 4)
LEADING PARTICULARS

Environmental Conditions	
Temperature (continuous operation)	-55°C to 71°C (-67°F to 160°F)
Altitude	Up to 15,000 m (50,000 ft)
RFI Emission	Figures 2 and 3 illustrate the RFI emissions generated by a typical inverter, Model PC-250. The plots indicate the broad band radiated and conducted emission levels in the steady state mode. There was no detectable narrow band CW emissions. The specification limits are set forth in RTCA document D0160, Category Z.

2.0 Operation (See Figure 4) PC-250 Series



A. The static inverter converts an unregulated DC electrical power into single phase, sinewave, regulated AC electrical power. The nominal input DC power is 28 volts and the nominal outputs of the inverter are 115 VAC and 26 VAC. The generation of the alternating signal and the regulation are accomplished by a single integrated regulating pulse width modulator circuit. The quasi-square wave output of the integrated circuit is amplified and filtered by a tuned transformer to provide a low distortion sinewave output. The output signal is used for both current and voltage sensing circuits to provide the necessary information to the regulating control circuits of the integrated circuit.

B. The conversion of the non-regulated DC electrical energy to regulated, 400 Hz, sinewave AC electrical energy, is achieved by the following steps:

Input DC filtering
400 Hz frequency and pulse generation
Pulse width modulation
Power amplification
Output filtering
Current sensing
Voltage sensing and regulation
Short circuit control
Over voltage control
Frequency monitor
Phase lock control
Fault monitor

C. Input DC Filtering. (See Figure 201.) The 28 VDC input power is applied to the inverter through a DC filtering network composed of L2, C14, C15, C16, C17, C18 and C19. This network prevents DC supply transients from reaching the internal circuitry of the inverter and, also, prevents the internally generated transients and RF from reaching the DC bus. An additional filter consisting of R8 and zener diode CR2, protects the integrated circuit U5 from any surge or transient higher than 40 volts peak.

D. 400 Hz Frequency and Pulse Generation. (See Figure 201.) Two gates (U1C and U1D) of a CMOS "nor" integrated circuit are connected as an astable multivibrator. CMOS gates display very little change in transfer characteristics over the temperature range of -55°C to 125°C (-67°F to 257°F); therefore, the output frequency depends primarily upon the stability of the RC components. Metal film resistors and mica capacitors have been selected for their extreme stability. The integrated circuit is powered from the 5 volts reference available at the pulse width modulator integrated circuit (U5) assuring a stable input to the gates to enhance frequency stability. The output of the multivibrator at U1D is routed, through a power amplifier (U2D), to a pulse shaping network composed of C8, R30, R31, and CR8. C8 and R30 control the pulse width at the input of U1B and at the collector of Q3. The square wave at the output of comparator U2D is differentiated through capacitor C8 and resistor R30. The differentiated square wave is fed to gate U1B, then to Q3, where it is inverted and routed to U5. The pulse repetition rate equals the frequency of the CMOS astable multivibrator. The pulse at the collector of Q3 thus provides a stabilized clock signal to the integrated circuit U5.

E. Pulse Width Modulation. (See Figure 201.) The pulse width modulation capability of integrated circuit U5 provides a method of controlling and regulating the output voltage of the inverter. In essence, this technique controls the voltage by varying the duration of the output voltage pulses depending upon the requirements for the external load. During a high load condition, a high energy level is fed to the output transformer as the duration of time is close to half a cycle for each transistor pair (Q8, Q9 and Q10, Q11). In a low load condition, the transistors are turned on for a much shorter period of time, thus feeding output transformer T3 with a much lower energy level. The process is identical for compensating for high and low DC bus voltage.

F. Power Amplification. (See Figure 201.) The power amplification is achieved in two stages. The pulse width modulator U5 provides a signal to the first stage composed of the push-pull combination of Q4 and Q5. Transformer T1 couples the output of Q4 and Q5 to power stage Q8, Q9, Q10, and Q11. Q8 and Q9, as well as Q10 and Q11, are essentially connected in parallel to handle the power requirement. The output transformer, the power transistors, and the driver transformer are connected

Functional Block Diagram
Figure 4

in such a way that the transistor base drive is proportional to the collector current and, therefore, to the 400 Hz power requirement at the external load. Following the current path for transistor Q8, we see power coming from terminal 2 of the spillover choke L1 going through current sense transformer T2, then, through winding 2-1 of power transformer T3, continuing on through windings 4-5 of transformer T3 and transistor Q8. The polarity of windings 4-5 and 8-9 of T1 are such that as current flow through winding 4-5 increases, the output voltage at 8-9 increases, thus forcing more base current through R44 to base of Q8. Connections and operation of Q9, Q10 and Q11 are identical. Proper base drive and optimum efficiency is thus assured. Resistors R44, R45, R48 and R50 provide equalization of base current through the transistors. Diodes CR13, CR16, CR18, and CR19 provide reverse current paths for reliable operation with inductive loads.

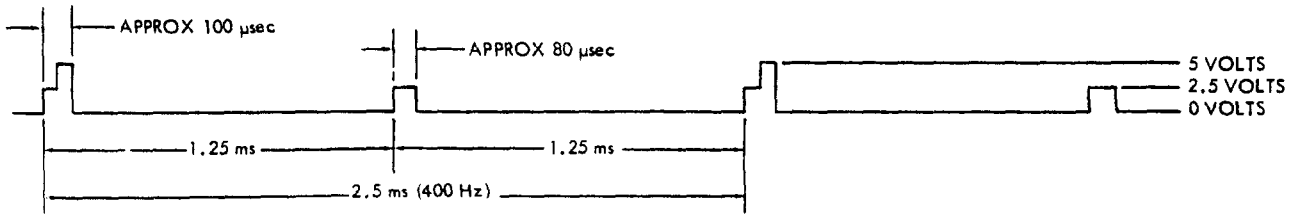
G. Output Filtering. (See Figure 201.) The output of the inverter is required to be a sinewave with less than 7 percent total harmonic distortion. The filtering is accomplished in two steps. Spillover choke (L1) prevents the shorting of the primary of output transformer T2 to the power supply when transistors Q8, Q9, Q10 and Q11 are in saturation, thus allowing tuning of the secondary of output transformer (T3). The tuned secondary of output transformer (T3) provides attenuation of the harmonics commensurate with the system's Q. At low load, the operating Q is higher and the output distortion is lower. L1 also acts as a swinging choke. When the transistors are turned off, current flows through diode CR11, feeding stored power back to the supply and preventing high voltage transients from occuring at the transformer center tap.

H. Voltage Sensing and Regulation. (See Figure 201.) The output voltage is sensed at windings 12-13-14 of output transformer (T3). The 400 Hz signal is rectified in the bridge rectifier (U6). The resultant DC is filtered in RC network R57, R54, R53, R55, C28, and C32, and fed to integrated circuit (U5). The DC voltage at pin 1 is compared to a reference voltage at pin 2 of the integrated circuit (U5) whose comparator circuit regulates the pulse width of the output waveforms at pins 12 and 13 to arrive at a balanced level between the rectified 400 Hz and the reference voltage. A variable resistor, R53, allows calibration of the output voltage to 115 ±1 volts. The R24, C7 network provides frequency compensation to insure stability of the regulation loop.

I. Current Sensing. (See Figure 201.) The current flowing through transistors Q8, Q9, Q10 and Q11, is sensed in current sense transformer (T2). The transformer output is rectified by diodes CR15 and CR16, and the resultant DC is filtered in resistor-capacitor network R49, R51, C27 and fed to pin 1 of integrated circuit (U5). Resistor R46 is selected of such value that the output voltage becomes controlled by the output of the current sensing circuit when the load current increases to more than

160% of rated value. For currents exceeding 160% of rated value, the output voltage of the current sensing circuit exceeds that of the voltage sensing circuit and takes control of the error sensing amplifier within integrated circuit (U5): as the current increases, the output voltage decreases to keep the output power within the limits of safe operation.

J. Short Circuit Control. (See Figure 201.) The center tap of the current sense transformer (T2) is returned to the negative output of the bridge rectifier (U6) connected to the voltage sensing winding of output transformer (T3). Under normal operating conditions, the negative DC output of the bridge rectifier sets a back-bias on diodes CR15 and CR16, and reduces the output voltage of the current sensing circuit such that it does not affect the voltage regulation circuit. Under short circuit conditions, the negative back-bias is removed and the current sensing circuit output voltage is increased substantially at pin 1 of integrated circuit (U5). The high voltage at pin 1 of U5 takes control of the error amplifier circuit, which, in turn, reduces the output pulse width to maintain the power dissipation and the input current to an acceptable and safe level.



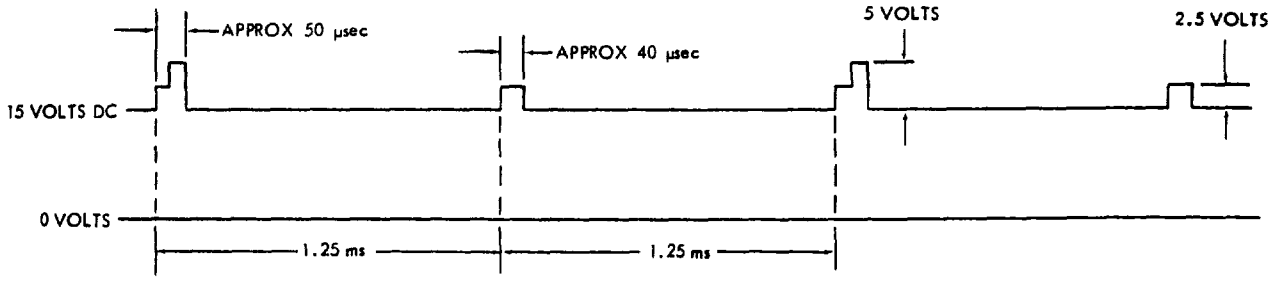
K. Overvoltage Control. (See Figure 201.) The output of rectifier bridge U6 is fed to a resistive divider, R66 and R67. The voltage at the junction of R66 and R67 is compared to a reference voltage into comparator U4D at pins 10 and 9, respectively. In the event of overvoltage from 125 to 138 RMS, the voltage at U4D, pin 10 becomes higher than the reference voltage at U4D pin 9. Voltage at U4D pin 8 and input 12 of OR gate U3C goes high. The U3C (11) and successively U3A (3) go high making transistor Q6 conduct to saturation. U5(9) is grounded and the inverter is turned "off". The high output of comparator U4D at pin 8 is fed back through CR26 and R64 to the positive input at pin 10 and latches the U4D comparator to a high output position keeping the inverter "off" even when the output voltage has dropped to zero. The inverter may be restarted by setting the remote on/off switch to OFF, then ON. Capacitor C30 provides a delay to prevent nuisance activation of the overvoltage circuit when a short overvoltage surge occurs as during sudden unloading of the inverter.

L. Low Voltage Shutoff. (See Figure 201.) The DC power input is fed to U4C pin 6 through a voltage divider R62 and R63. Whenever voltage at U4C pin 6 is lower than the reference voltage applied at U4C pin 5, the output of U4C pin 7 is high. OR gate outputs U3B(4) and U3A(3) are high keeping transistor Q6 conducting to saturation, driving U5 pin 9 to ground and the inverter to the "off" state. Whenever the DC input reaches approximately 15 volts, the output of U4C goes low, gates outputs U3B(4) and U3A(3) go low, Q6 is turned off and the voltage at U5 pin 9 goes high through R28 letting the inverter go through the soft start mode.

M. Frequency Monitor (See Figure 201.) The frequency control circuit monitors the inverter frequency whether it is driven from its own internal oscillator or from an outside source. The master pulse at the collector of Q3 drives pulse width modulator U5 and is also routed through resistor R35 to an active filter composed of operational amplifier U4A, resistors R37, R36,and capacitors C10 and C11. Metal film resistors and mica capacitors are used for their excellent stability over a wide range of temperatures. The filter is tuned at 800 Hz and has a Q of approximately 12. When the pulse repetition rate is between 740 and 860 Hz, the output U4A pin 14 is of high enough amplitude that after rectification through CR9, it will maintain pin 3 of U4B at a lower level than the reference voltage applied at pin 2 of U4B. When U4B pin 3 is low, U4B pin 1 is low and the outputs of OR gates U3C pin 11 and U3A pin 3 are low. Q6 is then turned "off" and the inverter operates. When the pulse repetition rate is outside of the frequency limit of 740-860 Hz, the output at U4A pin 14 is low, the output at U4B pin 1 is high driving U3C pin 11 and U3A pin 3 to the high state. Q6 becomes conductive, maintaining U5 pin 9 to ground potential and the inverter in the "off" mode. R30 is selected to obtain the desired bandwidth.

N. Phase Lock Control (See Figure 201.) The PC-250 may be phase-locked to one or more additional PC-250's for parallel operation, or to an external source for polyphase operation. The phase locking is achieved by means of a multi-level signal fed to the inverter at J1 pin F.

(1) Parallel operation. For a parallel mode of operation, the system will automatically lock onto the highest pulse repetition rate present on the lock line. The lock signal appears on the lock line as shown in Figure 5. To insure proper load distribution, the output voltage of all inverters to be paralleled must be within .20 volt of each other. (Consult factory).



Phase Lock Control Parallel Operation
Figure 5

(2) Polyphase operation. For a polyphase mode of operation, the inverter is phase-locked to a signal generated from an external source such as the three phase adapter PC-3Ø, providing the required waveform and sequencing. A typical signal fed to the lock line of one inverter of a polyphase system is shown in Figure 6.

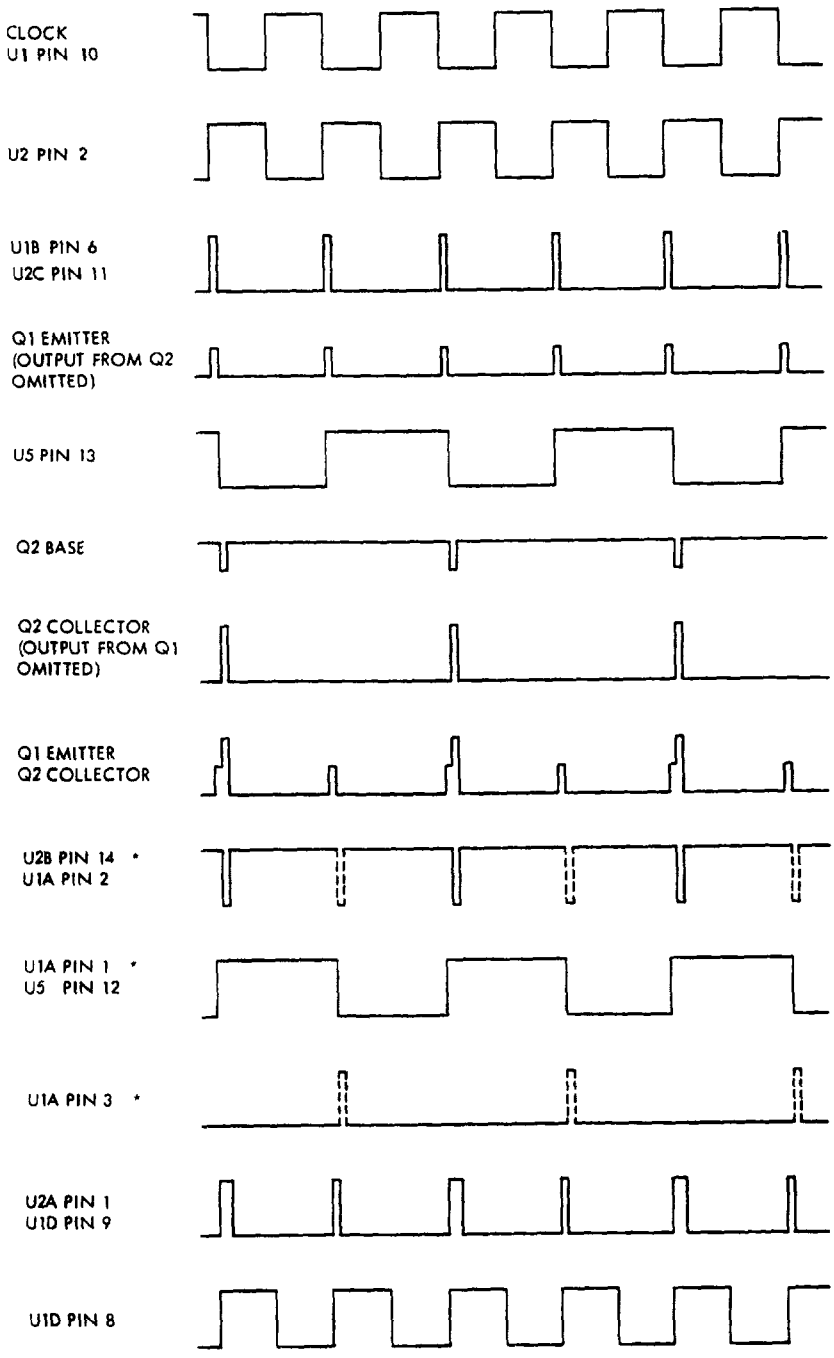
(3) Phase lock operation. The principle of operation of phase-locking is similar in both parallel and polyphase operation, with the exception that in a polyphase operation, the internal multivibrator of each inverter is inhibited by the 15 volts DC present in the lock signal. The DC signal is divided into R4 and R5 and fed to pin 13 of "NOR" gate U1C where it inhibits the multivibrator action of U1C and U1D, whereas, in the parallel mode, the multivibrator is not inhibited, but synchronizes to the highest repetition rate present on the lock line.

The lock signal entering J1 pin F goes through DC blocking capacitor C1 to a first comparator U2A pin 7. The reference level at pin 6 of U2A is 1.7 volts DC delivered from the voltage divider R22, R23, R25, and R27. All the pulses present on the lock line will appear at pin 1 of U2A, then inverted at pin 10 of "NOR" gate U1D, inverted again at pin 2 of U2D, differentiated through C8 and R30 and on through the normal path to pin 3 of U5. These pulses provide the desired frequency for synchronization, but do not carry phase information.

The lock signal at the negative end of C1 also goes to a second comparator U2B pin 8. The reference level at pin 9 of U2B is 3.75 volts DC. Therefore, only the pulses with a 5 volt amplitude will appear inverted at pin 14 of the comparator U2B. These pulses are fed to pin 2 of "NOR" gate U1A. The 400 Hz signal drive at pin 12 of U5 is fed to pin 1 of "NOR" gate U1A. Whenever

Phase Lock Control Polyphase Operation
Figure 6

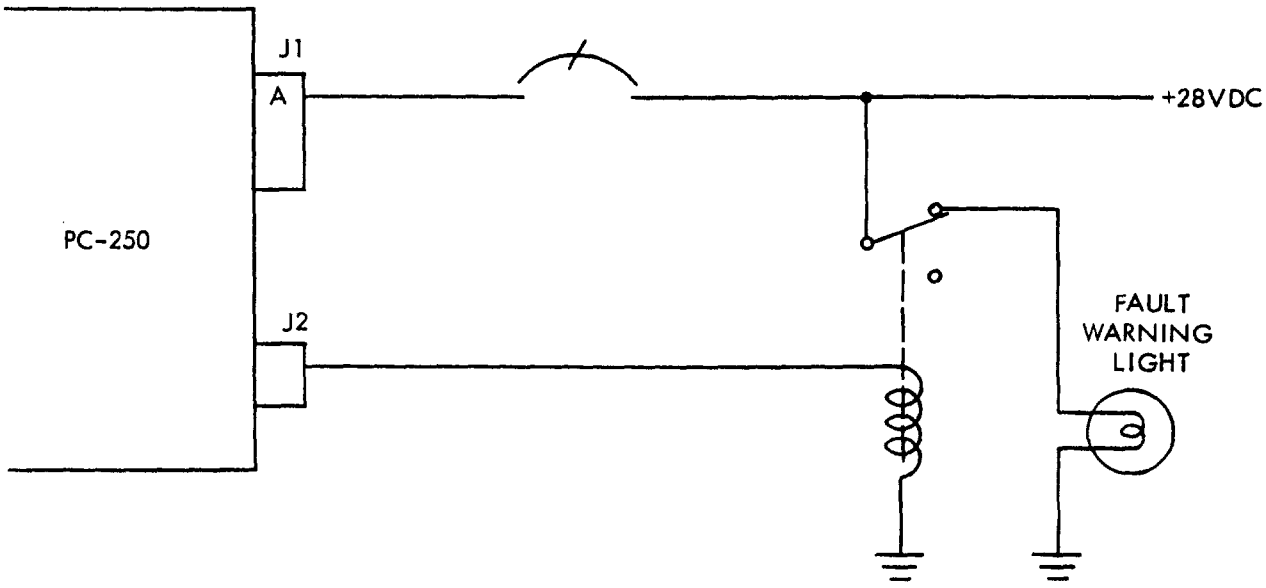
the signals at pins 1 and 2 of U1A are such that there are no simultaneous zero levels, the output at pin 3 stays at ground level. If, however, simultaneous zeros appear at pins 1 and 2 of U1A, a pulse will appear at U1A pin 3, then at U1B pin 4, and finally, at U5 pin 3. This pulse, additional to the regular clock pulse, will generate a phase reversal in the pulse width modulator U5 and no more pulse will appear at U1A pin 3.



For parallel operation, the lock signal is generated in the inverter as follows: the clock signal at 800 Hz is differentiated through C8 and R30, then fed to comparator U2C pin 11. At the comparator output the pulse is limited to approximately 3 volts amplitude and routed to J1 through emitter follower amplifier Q1 and capacitor C1. Also, the 400 Hz drive signal at pin 13 of U5 is differentiated through C2, R14, R13, and CR4, amplified to a 5 volt level through Q2 and "ANDED" with the pulse from Q1 to form a complete lock signal, then routed to J1 through C1. It should be noted that when lock is achieved, the pulses coming to J1 pin F from the external source and the pulses going out from J1 pin F are coincidental; therefore, one set of pulses only can be seen on an oscilloscope. A timing diagram of the phase lock operation is shown in Figure 7.

O. Fault Monitor (See Figure 201.) Under normal operating conditions, transistor Q6 collector is at 5 volts DC. Gate U3D pin 10 is high causing transistor Q12 to conduct to saturation. 27 volts DC at 100 ma is then available at the collector of Q13 to power an annunciator device. If the frequency of the inverter shifts beyond the preset limits of 370 and 430 Hz, the outputs of gates U3C and U3A go high driving Q6 to saturation and the output of gate U3D goes low, turning transistors Q12 and Q13 "off". No power is then available to the annunciator.

In the event of an overvoltage condition, pin 8 of comparator U4D goes high, driving U3C output pin 11 high and, as in above paragraph, turning transistors Q12 and Q13 "off". Again, no power is then available to the annunciator.



A typical fault warning light installation is shown in Figure 8.

P. Soft Start Control (See Figure 201.) The error amplifier within the integrated U5 is of a transconductance design. The output is a very high impedance and can deliver a limited amount of current (approximately 200 microamps). At first start, C9 maintains the error amplifier. output at pin 9 to ground potential which keeps output at pins 12 and 13 at a high state. As the capacitor charges, the output pulse slowly increases in width resulting in a slow amplitude increase of the output signal voltage until the feedback loop takes over. Diode CR7 isolates U5 pin 9 and the loop stabilizing network R24 and C7 from the

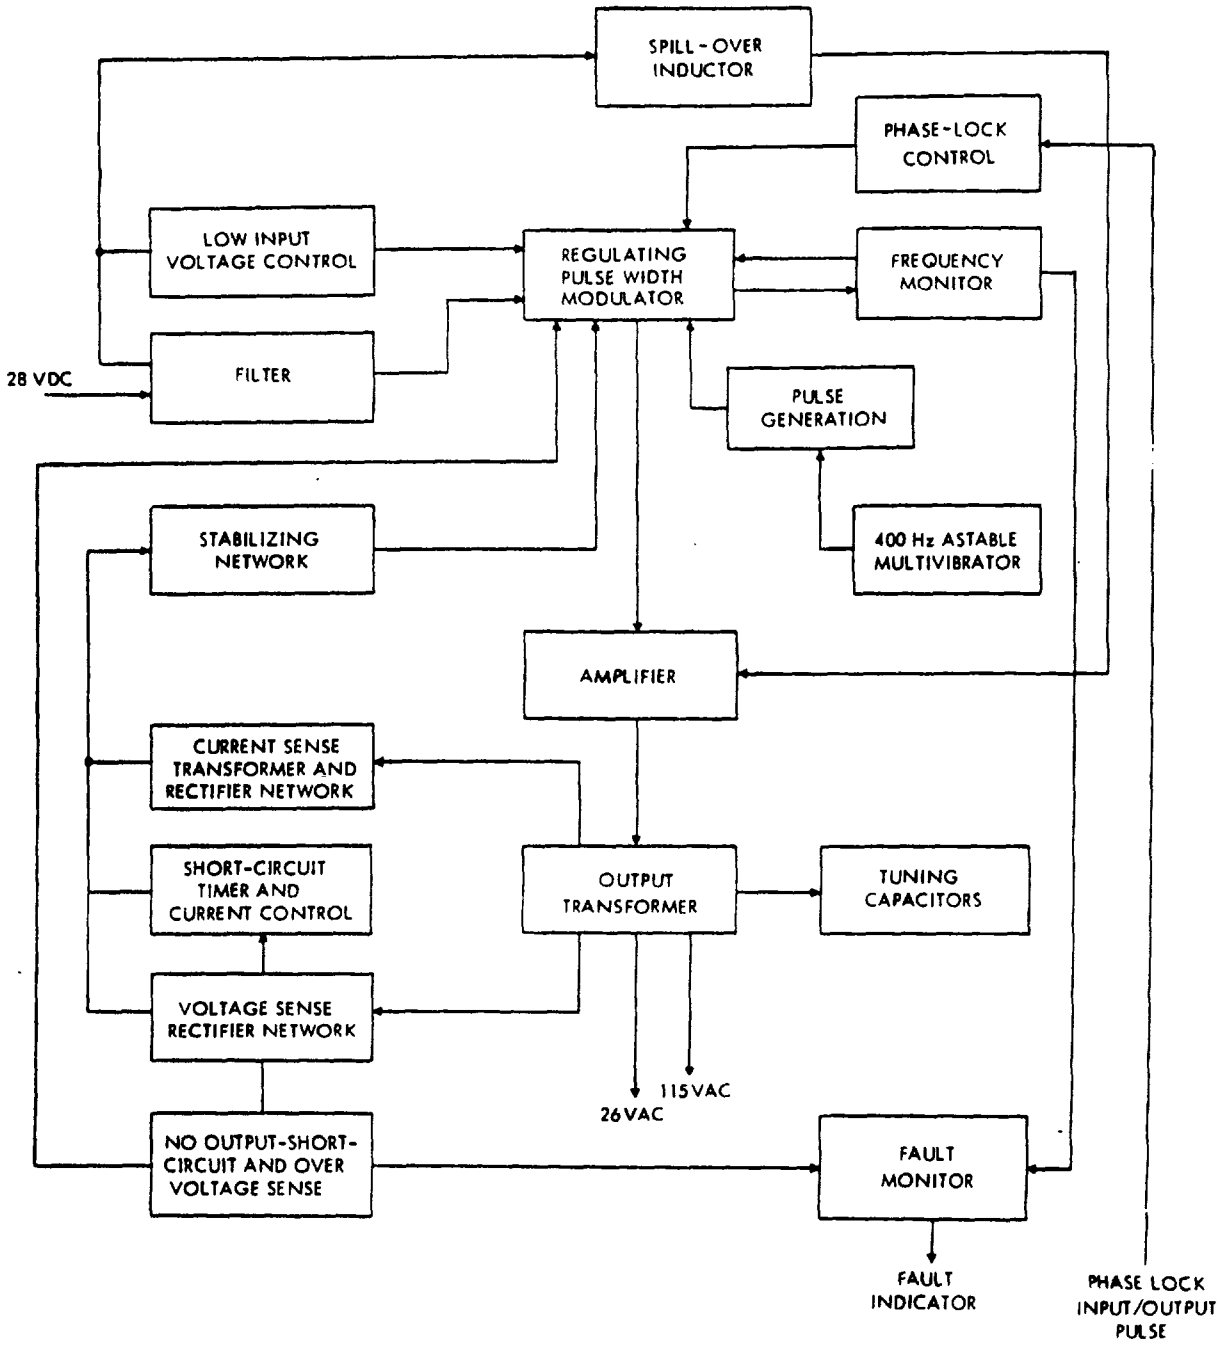
* The "in phase" or locked condition is shown in full lines. If an out of phase condition existed, the pulses would be displaced as shown by the dotted lines. The out of phase condition cannot exist in single unit operation and should not be present for more than 2.5 ms when two inverters are connected in parallel.

Phase Lock Operation Timing Diagram
Figure 7

Fault Warning Light Installation
Figure 8

soft start capacitor C9 whenever capacitor C9 is charged up. Quick discharge of C9 is insured through transistor Q6.

Q. Remote ON/OFF (PC-250-1C) (See Figure 201.) With J1 pin A open, voltage at U3B pin 5 is high, thus U3B pin 4 and U3A pin 3 are high, Q6 is conducting, and U5 pin 9 is in a low state, keeping the inverter turned "off". Grounding J1 pin A puts U3B pin 5 and U3A pin 3 in the low state. Q6 stops conducting, allowing C9 to charge through R28 and the inverter goes through the soft start mode.



2.1 Operation (See Figure 8A) PC-250 Series, Mod Level A

The operation of the PC-250's incorporating modification level A differs only very slightly from that of the PC-250's. The following paragraphs expand only on those functions whose operation deviates from that described in paragraph 2.0.

Mod Level A
PC-250's identified with "MOD LEVEL A" incorporate a revised printed circuit board assembly including short circuit current fold back feature, a fault monitoring function for frequency drift, overvoltage, no AC or output short circuit condition and no DC power to the inverter.

A. Same as paragraph 2.0A.

B. Same as paragraph 2.0B.

PC-250 Series, Mod Level A Functional Block Diagram
Figure 8A

C. Input DC Filtering. (See Figure 201A.) Same as paragraph 2.0C.

D. 400 Hz Frequency and Pulse Generation. (See Figure 201A.) Same as paragraph 2.0D.

E. Pulse Width Modulation. (See Figure 201A.) Same as paragraph 2.0E.

F. Power Amplification. (See Figure 201A.) Same as paragraph 2.0F.

G. Output Filtering. (See Figure 201A.) Same as paragraph 2.0G.

H. Voltage Sensing and Regulation. (See Figure 201A.) Same as paragraph 2.0H.

I. Current Sensing. (See Figure 201A.) Same as paragraph 2.0I.

J. Short Circuit Current and Fold-Back Control. (See Figure 201A.) The center tap of the current sense transformer (T2) is returned to the negative output of the bridge rectifier (U6) connected to the voltage sensing winding of output transformer (T3). Under normal operating conditions, the negative DC output of the bridge rectifier sets a back-bias on diodes CR15 and CR16, and reduces the output voltage of the current sensing circuit such that it does not affect the voltage regulation circuit. Under short circuit conditions, the back-bias is removed and the current sensing circuit output voltage is increased substantially and fed to pin 1 of integrated circuit (U5). The high voltage at pin 1 of U5 takes control of the error amplifier circuit, which, in turn, reduces the output pulse width to maintain the power dissipation and the output short circuit current to a predetermined value. R46 is adjusted to obtain a short circuit current of 200% of the rated load current.

In addition, under a short circuit condition, the voltage at the junction of R74, R66 and C30 drops to zero, forcing through CR37, the reset input (pin 12) of U10 counter, to a potential below the disable level. The counter then starts dividing the output signal of the integrated oscillator. The oscillator frequency is set at approximately 100 Hz by the C37, R75 time constant.

Five seconds after the start of the counting, pin 15 of U10 goes from a low to a high state. CR35 is then back biased, causing a rise in the voltage at the junction of R49 and R51, and U5 pin 1, thus reducing the pulse width at U5, subsequently decreasing the inverter's short circuit current to a safe level. U10 pin 15 going high, causes pin 10 to go high through CR36, blocking the oscillator, thus forcing the counter to maintain its present state until reset.

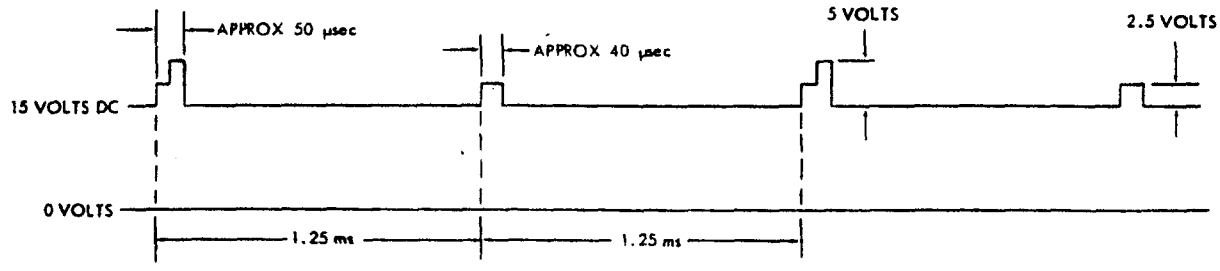
The duration of high short circuit current may be changed from 5 seconds to 30 seconds or one minute by connecting the junction of CR35 and CR36 to a higher division output at pins 1 or 3 of the counter; however, the short circuit current must then be decreased to 175% of rated load current.

Removal of the short circuit resets the counter and the inverter automatically returns to normal operation.

K. Overvoltage Control. (See Figure 201A.) The output of rectifier bridge U6 is fed to a resistive divider, R66 and R67. The voltage at the junction of R66 and R67 is compared to a reference voltage into comparator U4D at pins 10 and 9, respectively. In the event of over-voltage from 125 to 138 RMS, the voltage at U4D, pin 10 becomes higher than the reference voltage at U4D pin 9. Voltage at U4D pin 8, and input 5 of OR gate U3C goes high. The U3C (4) and successively U3A (10), go high making transistor Q6 conduct to saturation. U5 (9) is grounded and the inverter is turned "off". The high output of comparator U4D at pin 8 is fed back through CR26 and R64 to the positive input at pin 10 and latches the U4D comparator to a high output position, keeping the inverter "off" even when the output voltage has dropped to zero. The inverter may be restarted by setting the remote on/off switch to OFF, then ON. Capacitor C30 provides a delay to prevent nuisance activation of the overvoltage circuit when a short overvoltage surge occurs, as during sudden unloading of the inverter.

L. *Low Voltage Shutoff.* (See Figure 201A.) The DC power input is fed to U4C pin 6 through a voltage divider R62 and R63. Whenever voltage at U4C pin 6 is lower than the reference voltage applied to U4C pin 5, the output of U4C pin 7 is high. OR gate outputs U3B (11) and U3A (10) are high, keeping transistor Q6 conducting to saturation, driving U5 pin 9 to ground, and the inverter to the "off" state. Whenever the DC input reaches approximately 15 volts, the output of U4C goes low, gates outputs U3B (11) and U3A (10) go low, Q6 is turned off and the voltage at U5 pin 9 goes high through R28, letting the inverter go through the soft start mode.

M. Frequency Monitor (See Figure 201A.) The frequency control circuit monitors the inverter frequency whether it is driven from its own internal oscillator or from an outside source. The master pulse at the collector of Q3 drives pulse width modulator U5 and is also routed through resistor R35 to an active filter composed of operational amplifier U4A, resistors R37, R36, and capacitors C10 and C11. Metal film resistors and mica capacitors are used for their excellent stability over a wide range of temperatures. The filter is tuned at 800 Hz and has a Q of approximately 12. When the pulse repetition rate is between 770 and 830 Hz, the output U4A pin 14 is of high enough amplitude



that after rectification through CR9, it will maintain pin 2 of U4B at a higher level than the reference voltage applied at pin 3 of U4B. When U4B pin 2 is high, U4B pin 1 is low and the outputs of OR gates U3C pin 4 and U3A pin 10 are low. Q6 is then turned "off" and the inverter operates. When the pulse repetition rate is outside of the frequency limit of 740 and 860 Hz, the output at U4A pin 14 is low, the output at U4B pin 1 is high driving U3C pin 4 and U3A pin 10 to the high state. Q6 becomes conductive, maintaining U5 pin 9 to ground potential and the inverter in the "off" mode. When U4B pin 1 is high, Q19 base is high and transistor Q19 is turned "off" isolating the faulty inverter phase-lock output line. Calibration of the frequency monitor bandwidth limits is achieved by adjustment of R30.

N. Phase Lock Control (See Figure 201A.) The PC-250 may be phase-locked to one or more additional PC-250's for parallel operation, or to an external means of a multi-level signal fed to the inverter at J1 pin F.

(1) Parallel operation. For a parallel mode of operation, the system will automatically lock onto the highest pulse repetition rate present on the lock line. The lock signal appears on the lock line as shown in Figure 5. To insure proper load distribution, the output voltage of all inverters to be paralleled must be within a .20 volt of each other. (Consult factory.)

(2) Polyphase operation. For a polyphase mode of operation, the inverter is phase-locked to a signal generated from an external source such as the three phase adapter PC-3Ø, providing the required waveform and sequencing. A typical signal fed to the lock line of one inverter of a polyphase system is shown in Figure 8B.

For polyphase operation resistor R71 (10 ohm) must be removed and Q19 emitter to collector junction must be shorted together on the PC board of each inverter. Soldering pads are provided on the PC board.

NOTE: 1. R71 removed from P.C. board.
2. Q19 emitter to collector junction must be shorted.

Phase Lock Control Polyphase Operation (Mod Level A)
Figure 8B

(3) Phase lock operation. The principle of operation of phase-locking is similar in both parallel and polyphase operation, with the exception that in a polyphase operation, the internal multivibrator of each inverter is inhibited by the 15 volts DC present in the lock signal. As R71 has been removed, the DC signal is then divided into R4 and R5 and fed to pin 13 of "NOR" gate U1C where it inhibits the multivibrator action of U1C and U1D, whereas, in the parallel mode, the multivibrator is not inhibited, but synchronizes to the highest repetition rate present on the lock line.

The lock signal entering J1 pin F goes through DC blocking capacitor C1 to a first comparator U2A pin 7. The reference level at pin 6 of U2A is 1.6 volts DC delivered from the voltage divider R22, R23, R25, and R27. All the pulses present on the lock line will appear at pin 1 of U2A, then inverted at pin 10 of "NOR" gate U1D, inverted again at pin 2 of U2D, differentiated through C8 and R30 and on through the normal path to pin 3 of U5. These pulses provide the desired repetition rate for synchronization, but do not carry phase information.

The lock signal at the negative end of C1 also goes to a second comparator U2B pin 8. The reference level at pin 9 of U2B is 3.4 volts DC. Therefore, only the pulses with 5 volts amplitude will appear inverted at pin 14 of the comparator U2B. These pulses are fed to pin 2 of "NOT" gate U1A. The 400 Hz signal drive at pin 12 of U5 is fed to pin 1 of "NOR" gate U1A. Whenever the signals at pins 1 and 2 of U1A are such that there are no simultaneous zero levels, the output at pin 3 stays at ground level. If, however, simultaneous zeros appear at pins 1 and 2 of U1A, a pulse will appear at U1A pin 3, then at U1B pin 4, and, finally, at U5 pin 3. This pulse, additional to the regular clock pulse, will generate a phase reversal in the pulse width modulator U5 and no more pulse will appear at U1A pin 3.

For parallel operation, the lock signal is generated in the inverter as follows: the clock signal at 800 Hz is differentiated through C8 and R30, then fed to comparator U2C pin 11. At the comparator output, the pulse is limited to approximately 3 volts amplitude and routed to J1 through emitter follower amplifier Q1 and capacitor C1. Also, the 400 Hz drive signal at pin 13 of U5 is differentiated through C2, R14, R13, and CR4, amplified to a 5 volt level through Q2 and "ANDED" with the pulse from Q1 to form a complete lock signal, then routed to J1 through C1. It should be noted that when lock is achieved, the pulses coming to J1 pin F from the external source and the pulses going out from J1 pin F are coincidental; therefore, one set of pulses only can be seen on an oscilloscope. A timing diagram of the phase lock operation is shown in Figure 7.

O. Fault Monitor (See Figure 201A.) Under normal operating conditions, transistor Q6 collector is a 5 volts DC. Gate U3D pin 3 is high, causing transistor Q12 to conduct to saturation. 27 volts DC at 100 ma is then available at the collector of Q13 to power an annunciator device. If the frequency of the inverter shifts beyond the preset limits of 370 and 430 Hz, the outputs of gates U3C and U3A go high, driving Q6 to saturation and the output of gate U3D goes low, turning transistors Q12 and Q13 "off". The only power then available to the annunciator is through R78.

During an overvoltage condition, pin 8 of comparator U4D goes high driving U3C output pin 4 high and, as in above paragraph, turning transistors Q12 and Q13 "off". No power is then available to the annunciator. In the event of no output or short-circuit conditions, the junction of CR24, CR23 is at ground potential, holding pin 1 and 2 of U3D to ground through CR33, keeping transistors Q12, Q13 off, thus turning off power to the annunciator except that available through R78.

Resistor R78 (4.7K) provides a constant current of 5 to 6 ma to the fault monitor output jack to insure back biasing of CR28 and subsequent turn on of transistors Q12 and Q13 when the fault monitor output is not shorted to ground. Should accidental ground short be applied at J2, CR28 conducts, turning off Q12 and Q13 thus preventing destruction of the transistors.

If the warning device used in a particular installation is of a high impedance type, it may be necessary to provide additional parallel loadings at the fault monitor output to obtain the desired voltage swing to operate the device.

A typical fault warning light installation is shown in Figure 8.

P. Soft Start Control (See Figure 201A.) Same as paragraph 2.0P.

Q. Remote ON/OFF (PC-250-1C) (See Figure 201A.) With J1 pin A open, voltage at U3B pin 2 if high, thus, U3B pin 11 and U3A pin 10 are high, Q6 is conducting, and U5 pin 9 is in a low state, keeping the inverter turned "off". Grounding J1 pin A puts U3B pin 12 and U3A pin 10 in the low state. Q6 stops conducting, allowing C9 to charge through R28 and the inverter goes through the soft start mode.

3. Installation

A. General. This paragraph provides general guidelines for the installation of the Model PC-250 static inverter. It is not intended to apply to any particular airplane. The Model PC-250 is a single-phase, 115 VRMS, 400-Hz inverter ready to be installed when delivered from the factory. It will deliver 250 VA of power to a load having a power factor between 0.9 leading and 0.8 lagging. It will operate into loads which are more reactive; however, an external power factor correction will be required to maintain regulation and distortion characteristics.

CAUTION: THE SHORT CIRCUIT CURRENT ON THE 26-VOLT OUTPUT WILL INCREASE TO 14 AMPERES. APPLICABLE PRECAUTIONS NEED TO BE TAKEN IN INSTALLATION TO AVOID DAMAGE TO THE INTERCONNECTING CABLE IN CASE OF SHORT CIRCUIT.

To maintain reliability, care must also be taken not to exceed the specified VA delivered by the equipment. The Model PC-250 is suitable for parallel or polyphase operation.

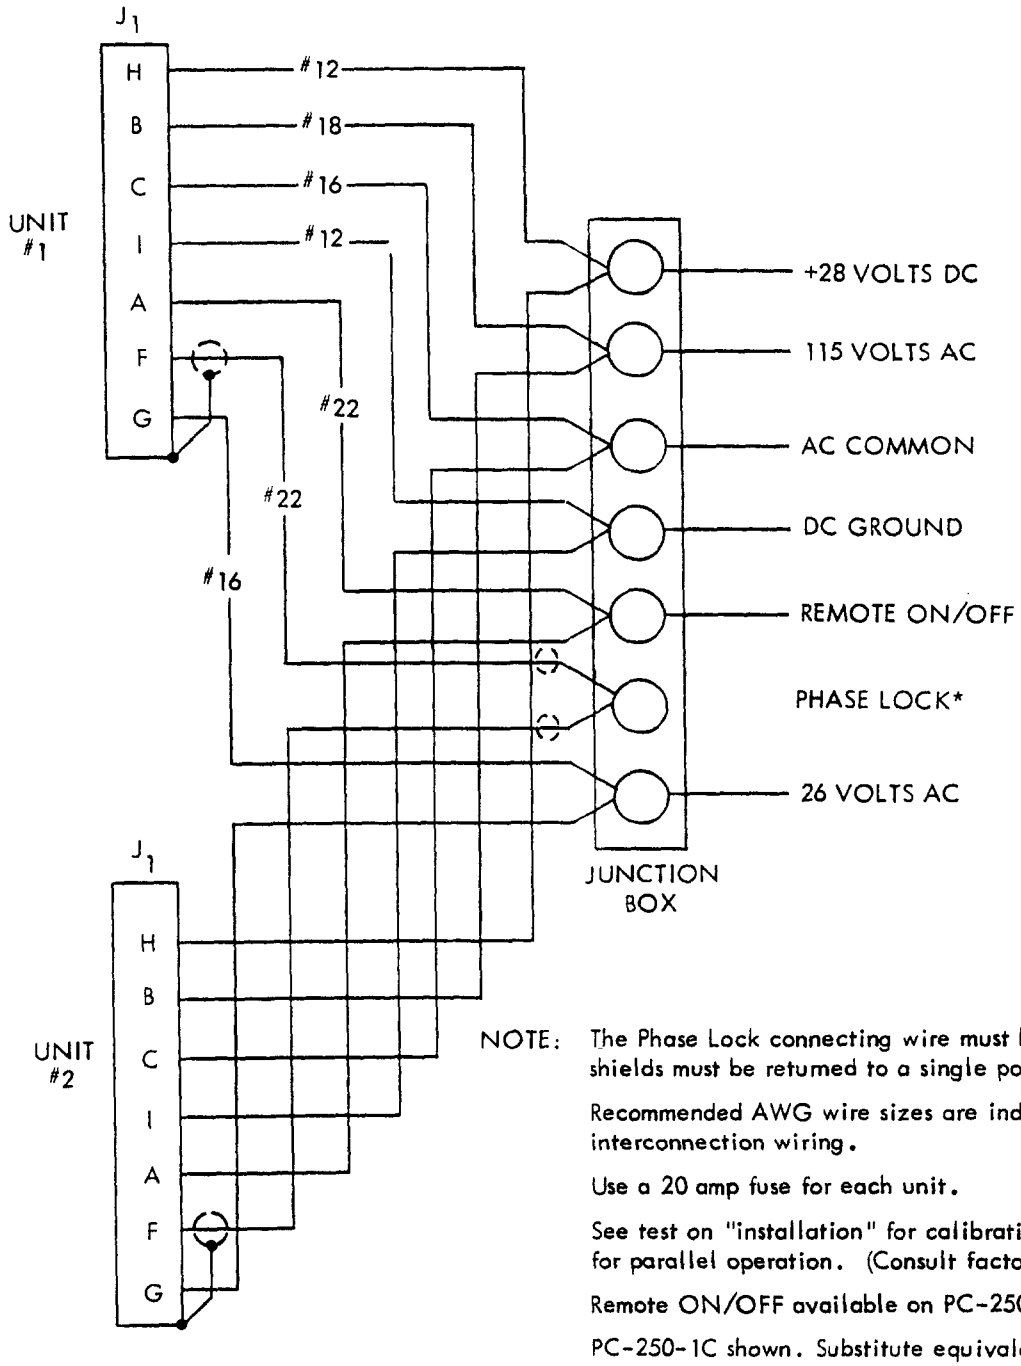
For installations where more than 250 VA of 26-volt and 115-volt, single-phase, 400 Hz power is a continuous requirement, two or more PC-250's may be installed and connected in parallel. All units must be turned on simultaneously at all times. To insure proper load distribution, all units to be paralleled must be calibrated such that their output voltage is within .20 volt of each other. See Figure 9 for typical installation diagram. (Consult factory.)

When two or more PC-250's must operate in phase synchronization, but the AC output is connected to separate busses, each inverter may be controlled by a separate remote ON/OFF control. (See Figure 10 for a typical installation diagram.)

CAUTION: IN A NEW INSTALLATION, IT IS RECOMMENDED THAT THE INVERTER'S PHASE LOCK CONTROL AND OUTPUT VOLTAGE BE CHECKED FOR PROPER OPERATION BEFORE CONNECTING THE INVERTERS IN PARALLEL.

For installations where 2-phase or 3-phase power is required, two or more PC-250's may be installed, along with a Flite-Tronics PC-3Ø External Phase Adapter, or suitable equivalent.

The PC-250 inverter is wired with the case connected to DC ground. In installations where it is desirable to keep the case floating, the jumper connecting DC ground to case may be removed. Consult factory for additional information.



B. Installation Procedure: The Model PC-250 static inverter is designed to mount on an equipment rack or any suitable structure on the aircraft. Consideration must be given to accessibility for inspection and maintenance, as well as protection from environmental stresses, primarily, vibration and temperature.

To preserve the effectiveness of the convection cooling, the PC-250 must be installed in a location allowing free air flow around the inverter.

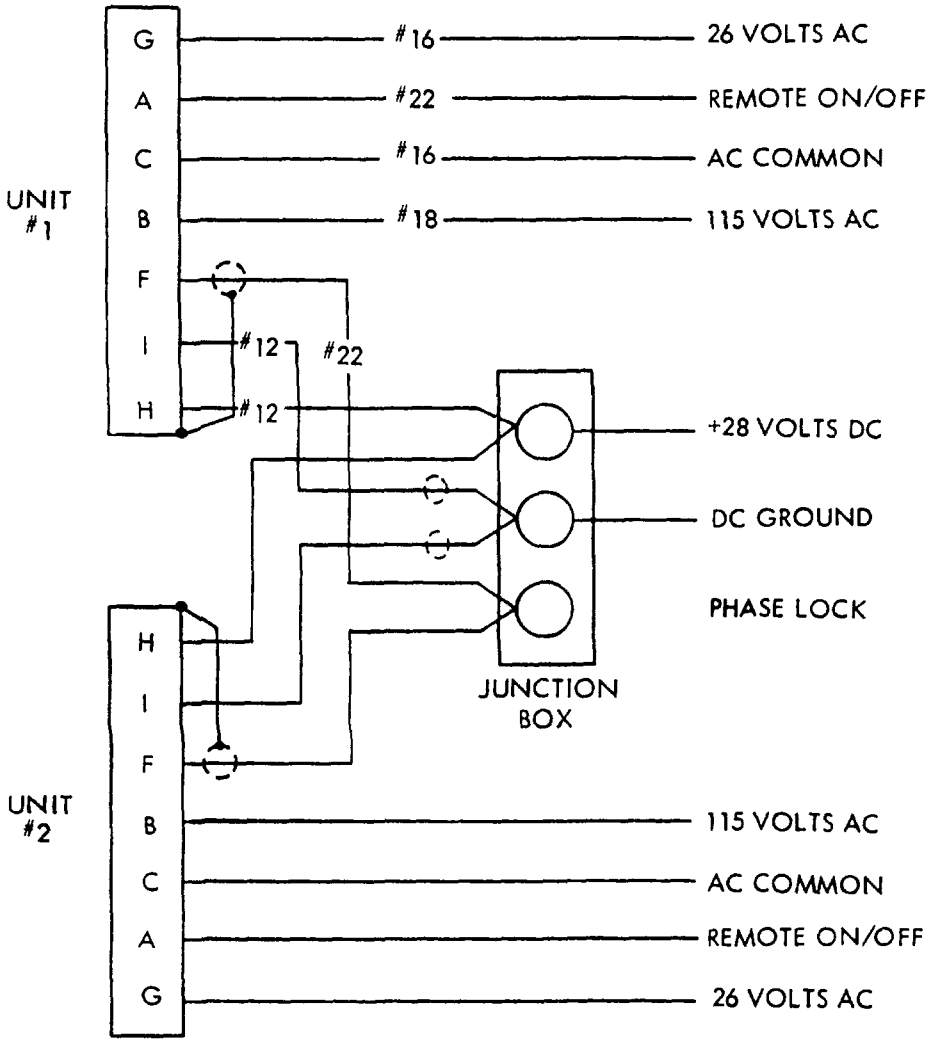
The Model PC-250 static inverter may be installed in any position; however, to insure optimum reliability, it must be attached directly to a thick metal plate or structure providing heat sinking and conduction cooling.

CAUTION: THE MODEL PC-250 STATIC INVERTER MUST NOT BE INSTALLED IN AN AREA WHERE AMBIENT AIR TEMPERATURE OR MOUNTING SURFACE TEMPERATURE MAY EXCEED 71°C (162°F) AT SEA LEVEL. AT NO TIME SHALL THE OPERATING REQUIREMENTS EXCEED THAT OF CURVE A FOR CLASS 2 EQUIPMENT OF MIL-E-5400.

Forced air cooling must be provided whenever the convection and conduction cooling requirements are not met.

NOTE: The Phase Lock connecting wire must be shielded. The shields must be returned to a single point ground.

Recommended AWG wire sizes are indicated on the interconnection wiring.



Use a 20 amp fuse for each unit.

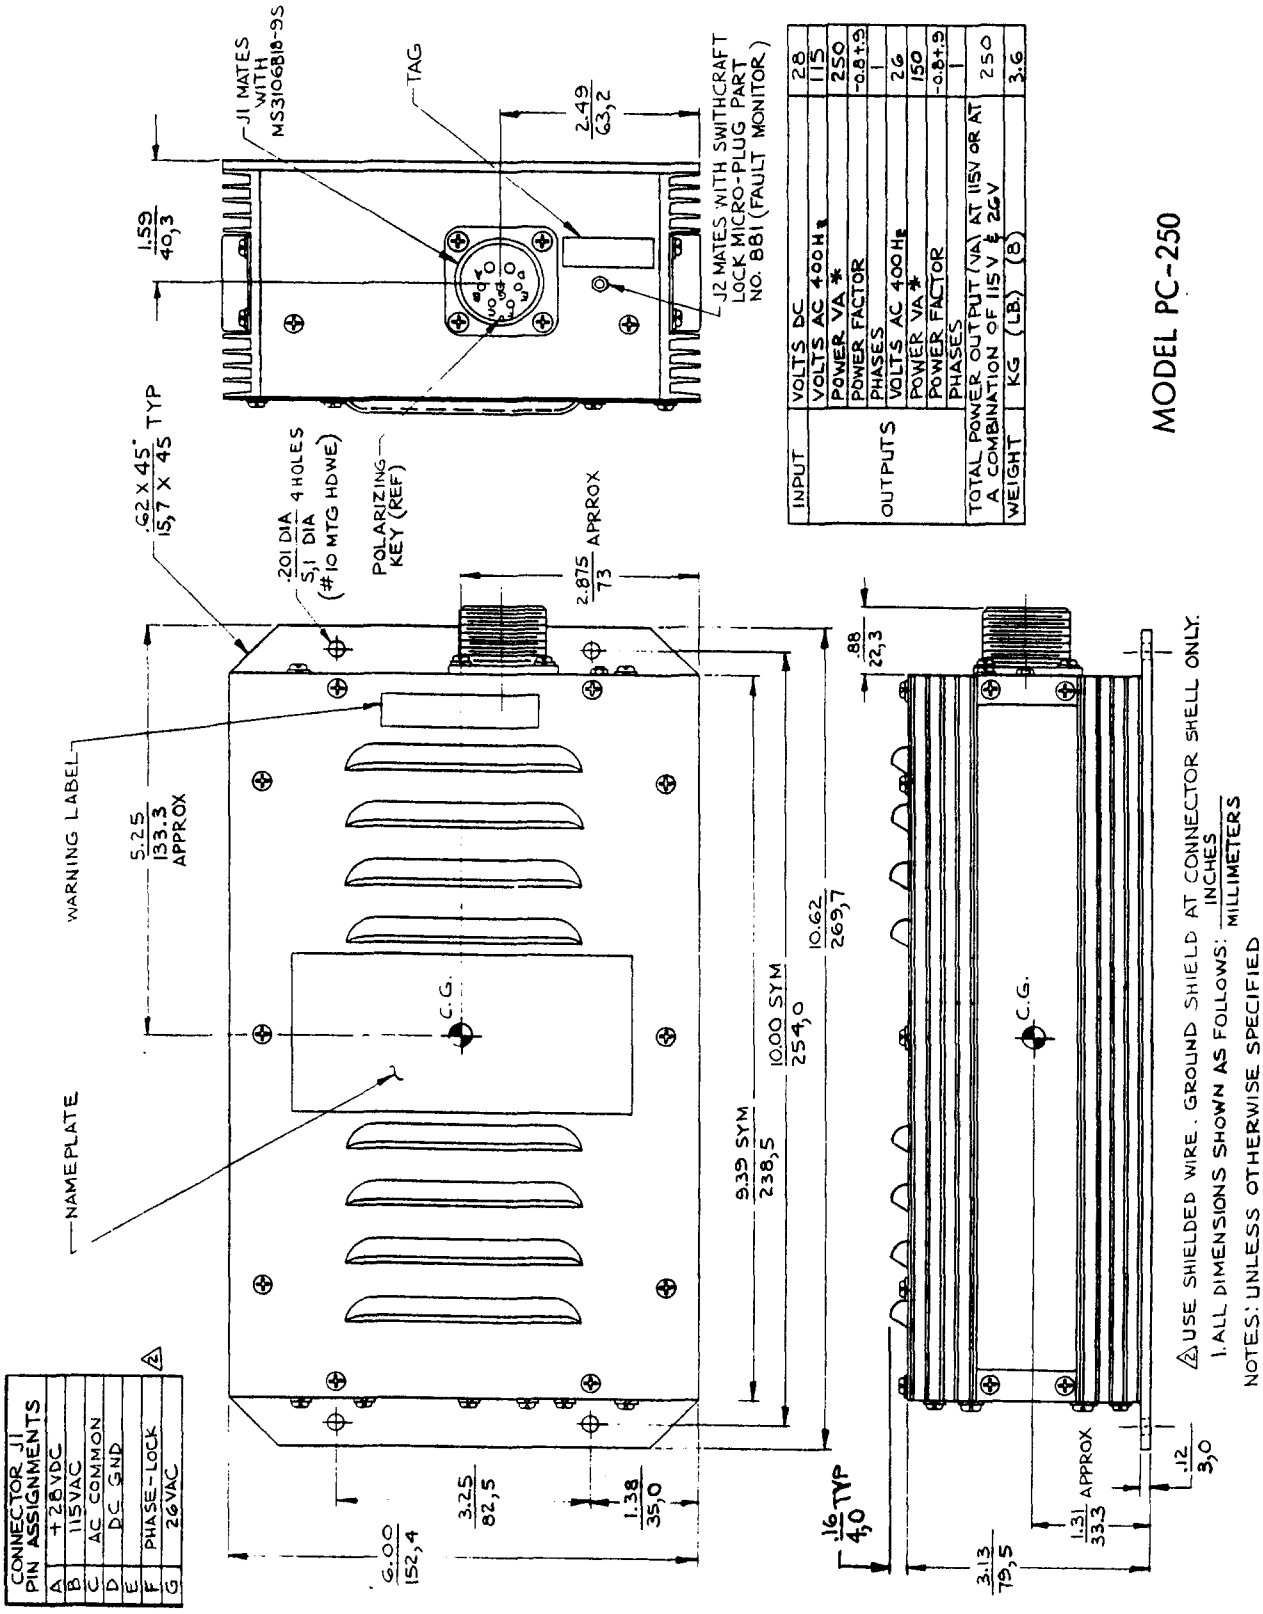
See test on "installation" for calibration requirements for parallel operation. (Consult factory)

Remote ON/OFF available on PC-250-1C only.

PC-250-1C shown. Substitute equivalent pins for other models.

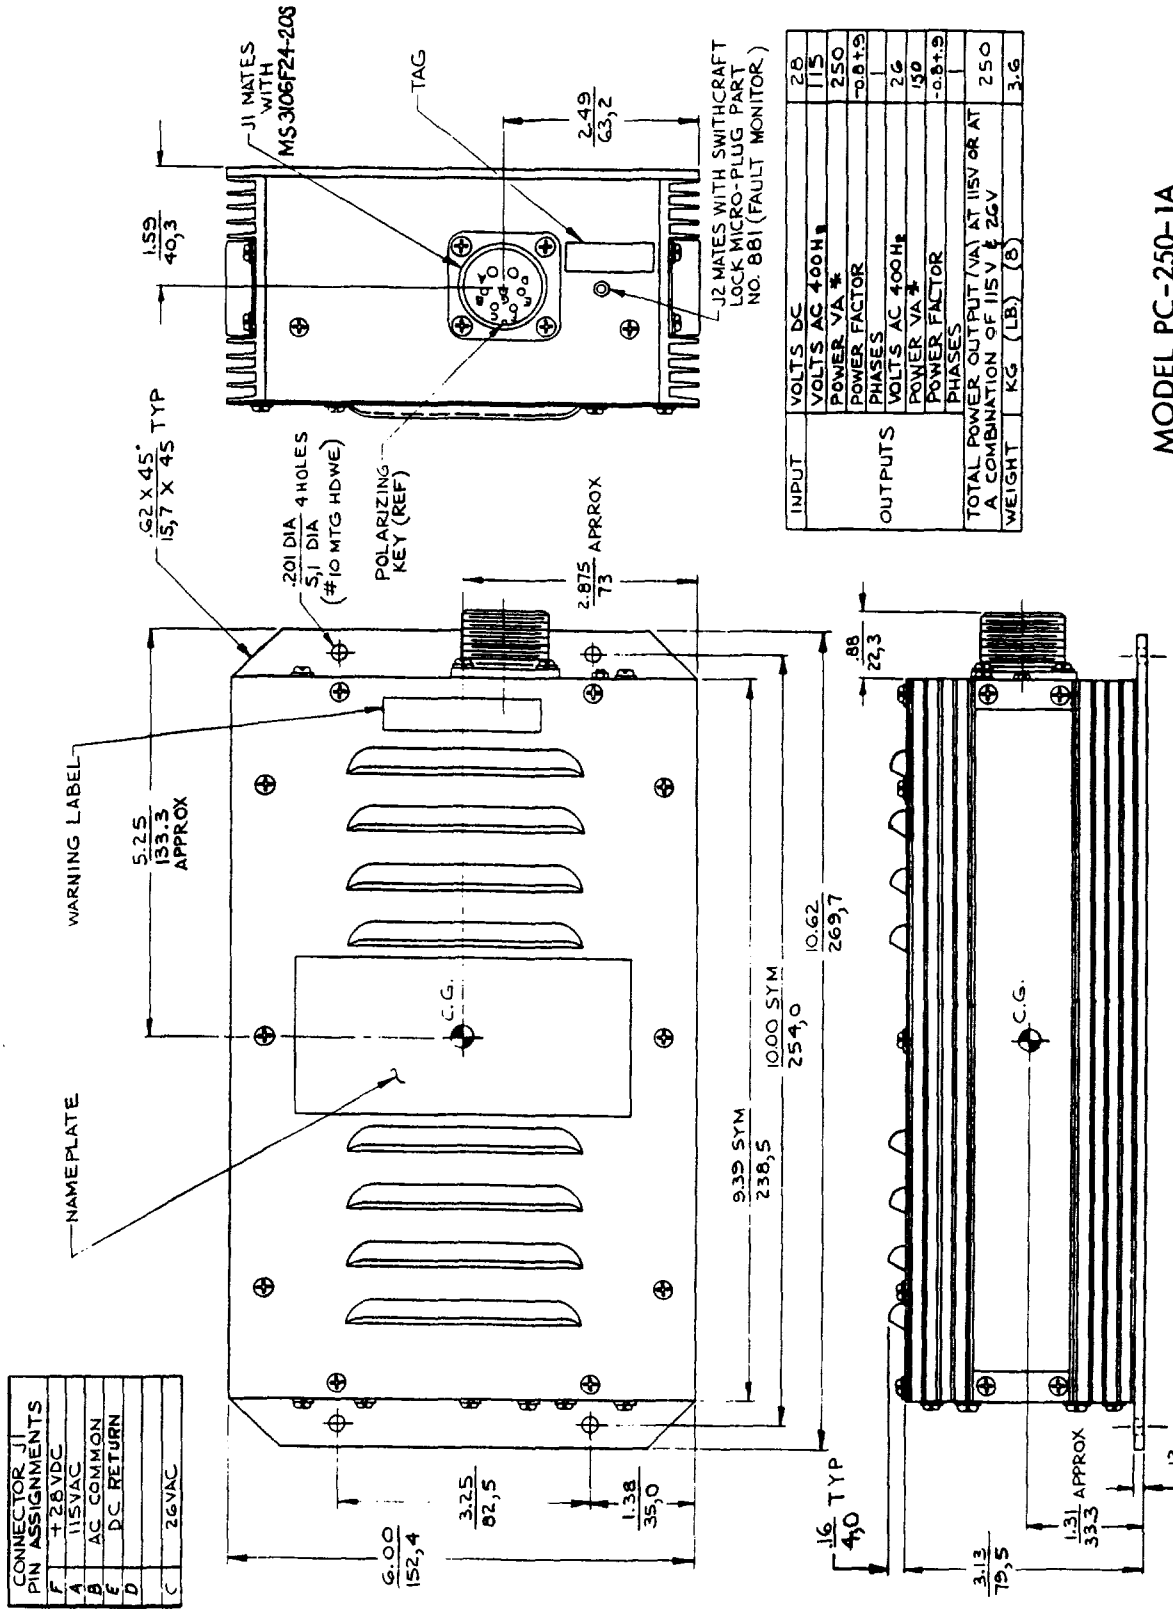
Typical Interconnection for Parallel Operation
Figure 9

NOTE: The Phase-lock connecting wire must be shielded. The shields must be returned to a single point ground.



Recommended AWG wire size indicated on the interconnections.

Use a 20 amp fuse for each unit.



Remote ON/OFF available on PC-250-1C only.

PC-250-1C shown. Substitute equivalent pins for other models.

TESTING

1. General

The test procedures outlined in this section should be performed on a static inverter prior to maintenance in order to determine the extent of maintenance required. The tests should be repeated after maintenance to verify the correct results of the maintenance.

2. Test Equipment

Refer to Table 101 for a list of test equipment required.

TABLE 101
TEST EQUIPMENT

DESCRIPTION	PART/MODEL NO.	SOURCE
Power Supply, 0-37 volts, 20 amperes, adjustable current limiting	Commercial	Local Purchase
Oscilloscope	5440	Tektronix
Amplifier	5A48	Tektronix
Time-base Plug-ins	5B40	Tektronix
Current Probe Amplifier	Type 134	Tektronix
Current Probe	P6021	Tektronix
AC, DC Voltmeter	8040A	Fluke
Current Shunt	80J-10	Fluke
Frequency Counter	5381A	Hewlett-Packard
Distortion Analyzer	334A	Hewlett-Packard
Function Generator	3310A	Hewlett-Packard
DC Ammeter	931-2902001	Weston
AC Ammeter	433-2906005	Weston

TABLE 101
TEST EQUIPMENT

DESCRIPTION	PART/MODEL NO.	SOURCE
Capacitance Decade Box (Suitable for 115 VAC 400 Hz operation)		
0.01 to 1.1 uf	CDB3	Cornell Dubilier
1 to 10 uf	CDC3	Cornell Dubilier
Resistance Decade Box		
0 ohm to 1.11 megohms	Microray Model 7	The Microray Co. 1059 Fernview Drive St. Louis, Mo 63141

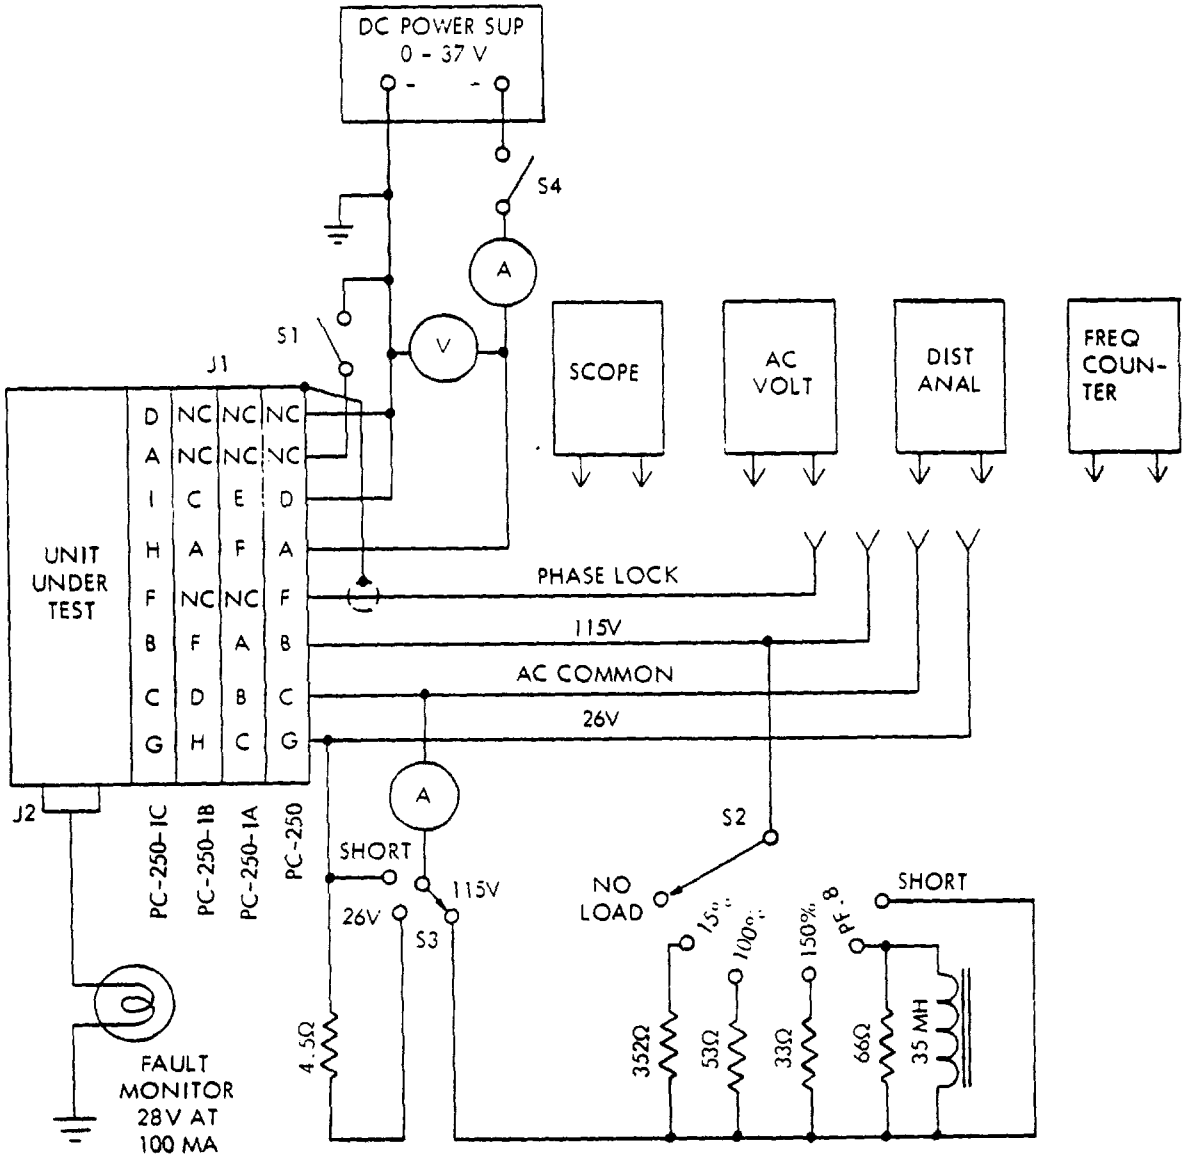
NOTE: Equivalent substitutes may be used.

3. Output Voltage Test

A. Install static inverter in test setup shown in Figure 101.

B. Set switch S2 to 100% load position.

C. Set the DC input voltage to 28 volts. Output voltage (pins B and C)* shall be 115 ±2.5 volts RMS, output signal distortion shall be less than 3.25 percent, and DC input current shall be less than 12.0 amperes.



D. Set the DC input voltage to 24 volts. Output voltage (pins B and C) shall be 115 ±3.0 volts RMS, output signal distortion shall be less than 5.0 percent, and DC input current shall be less than 14.0 amperes.

E. Set the DC input voltage to 20 volts. Output voltage (pins B and C) shall be greater than 111 volts RMS output signal distortion shall be less than 8.0 percent, and DC input current shall be less than 16.5 amperes.

F. Set the DC input voltage to 17 volts. Output voltage (pins B and C) shall be at least 100 volts RMS and output signal distortion shall be less than 10 percent.

G. Set the DC voltage to 32 volts. The output voltage (pins B and C) shall be 115 ±3.0 volts, output signal distortion shall be less than 5.0 percent, and DC input current shall be less than 10.7 amperes.

NOTE: *J1 Pin identification is given for the basic PC-250
Substitute equivalent pin identification for other models.

NOTES:

A. USE NO. 12 AWG WIRE OR SMALLER NUMBER FOR CONNECTIONS TO J1, PINS A & D.

B. USE NO. 16 AWG WIRE FOR PINS B, C, & G.

C. USE NO. 22 OR NO. 24 AWG WIRE FOR CONNECTION TO J1, PIN E.

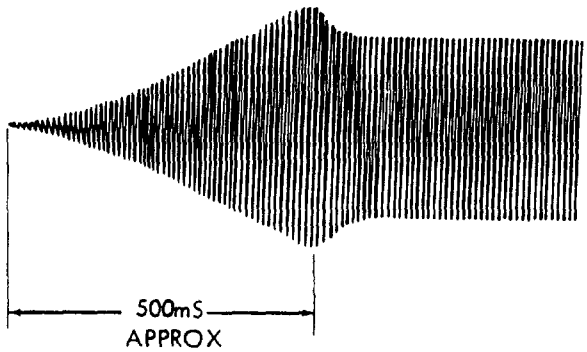
D. USE SHIELDED WIRE #20 OR 22 FOR PHASE-LOCK LINE.

E. NC DENOTES NO CONNECTION.

Test Setup
Figure 101

H. Set the DC input voltage to 37 volts. The output voltage (pins B and C) shall be 115 ±3.5 volts.

I. Vary the DC input voltage from 18 to 36 volts. The output (pins B and C) frequency shall stay within 398.0 and 402.0 Hz.



J. Set switch S2 to PF.8 (power factor 0.8) position.

K. Vary the input DC voltage from 22 to 35 volts. The output voltage (pins 3 and 6) shall stay within 112 to 118 volts and the output signal distortion shall be less than 8.0 percent.

L. Set switch S4 to OFF position. Wait until the input voltage is less than 0.25 volts.

M. Set switch S4 to ON position and observe the oscilloscope. The output voltage rise shall be similar to that shown in Figure 102 (soft start).

NOTE: The voltage measurements must be made at the PC-250 connector input.

Soft Start Voltage Rise
Figure 102

N. Set switch S3 to the 26 volts position. Connect the AC voltmeter to the 26 volts output (pins C and F).

O. Set the input DC voltage to 28 volts. The output voltage (pins G and C) shall be 26 ±1 volts RMS.

4. Overvoltage Test

NOTE: Test of the overvoltage function cannot be performed without removing the dust cover. If required, it may be performed as follows:

A. Set switch S2 to 100% load position.

B. Set DC input to 28V.

C. Slowly decrease the resistance value of R53 until the inverter goes to overvoltage mode. The fault monitor light should go off.

D. At the tripping point, the output voltage should be 125 to 138 volts RMS.

E. Reset R53 to maximum resistance value (full CCW). The inverter should stay in the over voltage mode.

F. Restart the PC-250 by setting switch S1 to OFF, then to ON.

G. Set potentiometer R53 to obtain 115 ±0.5 volts at the output.

H. Remove static inverter from test setup and install dust cover.

CAUTION: WHEN PERFORMING THE OVERVOLTAGE TEST, DUE PRECAUTION MUST BE TAKEN THAT NO EQUIPMENT WHICH MAY BE DAMAGED BY THE OVERVOLTAGE CONDITION IS CONNECTED TO THE INVERTER.

5.0 Frequency Control Test (PC-250 Series)

A. Set switch S2 to 15% load position.

B. Apply lock pulse as defined in Figure 103 to J1 pin F.

C. Vary pulse repetition rate from 800 pps to 860 pps, then to 740 pps.

D. The inverter output should drop to zero for frequencies higher than 860 pps or lower than 740 pps and the fault light should go off.

E. Remove the lock pulse from J1 pin F. The inverter should operate normally.

5.1 Frequency Control Test (PC-250 Series, Mod Level A)

A. Set switch S2 to 15% load position.

B. Rotate potentiometer R21 to change the pulse repetition rate at J1(F) from 800 pps to 860 pps, then to 740 pps.

C. The inverter output and the pulses appearing at J1(F) should drop to zero at or before reaching the pulse repetition rate of 860 pps or 740 pps.

NOTE: Due to components and manufacturing tolerances, the pulse repetition rates may not be reached at both the high and the low limits.

5.2 Alternate Method

A. Temporarily remove R71 from the PC board and temporarily short Q19 emitter and collector together (solder pads are provided on the board).

B. Set switch S2 to 15% load position.

C. Apply lock pulse as defined in Figure 103 for J1 pin F.

D. Vary pulse repetition rate from 800 pps to 860 pps, then to 740 pps.

E. The inverter output should drop to zero at or before the pulse rate reaches 860 pps or 740 pps.

F. Remove lock pulse from J1 pin F. The inverter should operate normally.

G. Replace R71 and remove short from Q19 emitter to collector functions.

6.0 Phase Lock Test (PC-250 Series)

A. Apply lock pulse as defined in Figure 103 to J1 pin F.

B. Verify that the output of the inverter is locked in phase with the output of the function generator.

6.1 Phase Lock Test (PC-250 Series, Mod Level A)

A. Proceed as described in paragraphs 5.1.A, 5.1.B, and 5.1.C of the alternate method.

B. Verify that the output of the inverter is locked in phase with the output of the function generator.

C. Remove the lock pulse connection.

D. Replace R71 and remove the shorting jumper from Q19 emitter to collector functions.

7. Output Transistors Load Sharing Test

Under normal operating conditions, the collector current of the output transistors Q8, Q9, Q10, Q11 should be within 30% of each other.

The transistor collector current must be measured using an oscilloscope current probe and amplifier. It is important to insure that the current probe is not driven to saturation or improper measurements will result. A typical collector current waveform is shown in 13 figure 202.

When a transistor needs to be replaced, a part bearing the same code letter must be selected.

8.0 Overload and Short Circuit Test (PC-250 Series)

A. Set switch S2 to 150% load position.

B. Adjust resistor R46 to obtain an output voltage 2 volts lower than that obtained at step 3.C.

C. Place switch S2 to SHORT position.

D. Adjust resistor R46 to obtain a short-circuit AC current of 3.25 to 3.75 amperes.

NOTE: The short-circuit test should be performed in 15 seconds. In no case should the short-circuit test be on for more than one minute.

E. Set switch S2 to the 100% load position.

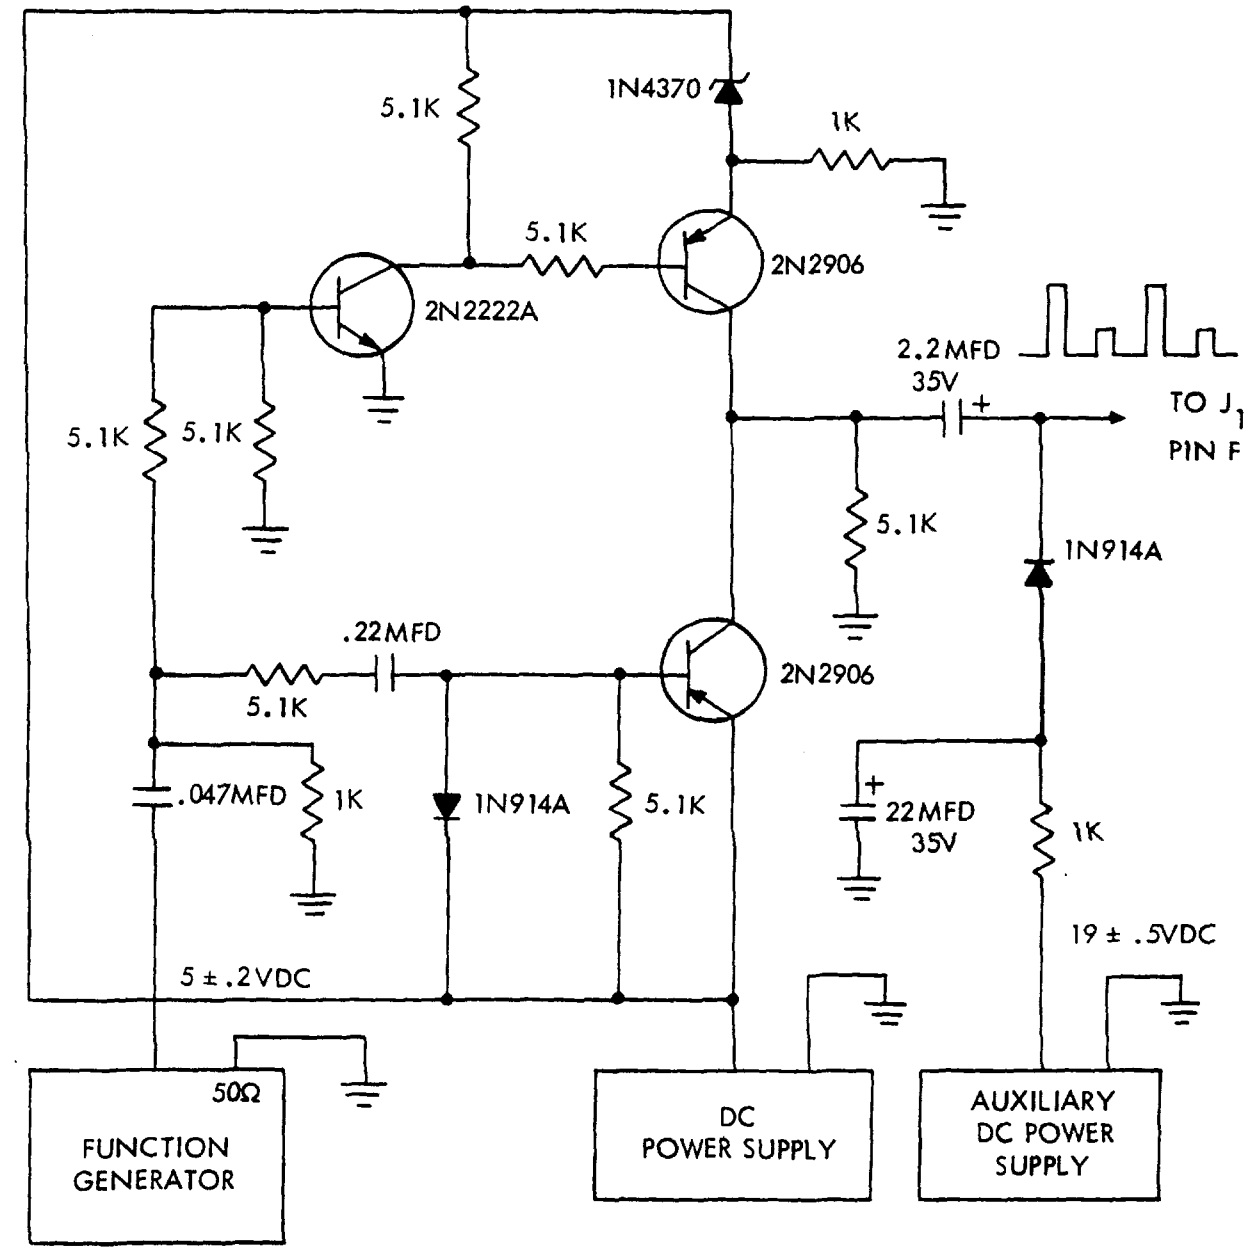
F. Verify that the output voltage is not more than 0.5 volt lower than that obtained at step 3.C.

8.1 Overload and Short Circuit Test (PC-250 Series, Mod Level A)

A. Set switch S2 to 150% load position.

B. Adjust resistor R46 to obtain an output voltage 2 volts lower than that obtained at step 3.C.

C. Place switch S2 to SHORT position.



D. Adjust resistor R46 to obtain a short-circuit AC current of 3.75 to 4.0 amperes.

E. Verify that after a short-circuit duration of 5 to 7 seconds the AC current output folds back to not more than 2.0 amperes.

F. Verify that during short-circuit condition the fault lamp is off.

G. Set switch S2 to 100% load position.

H. Verify that the output voltage is not more than 0.5 volt lower than that obtained at step 3.C.

TROUBLE SHOOTING

1. General

   A. This section provides guidance for locating malfunction within the PC-250 static inverter. In association with this test, refer to the schematic diagram, Figure 201.

   B. Whenever there is a doubt about the proper operation of the static inverter, it is recommended to start and operate the unit at low DC input (approximately 16 volts) to avoid damaging components. The DC input voltage may be gradually increased to 20 volts where the waveforms are essentially the same as those obtained at nominal input voltage. Note that at low input voltage, the voltage sensing and regulating circuit will not function. When the operation of the inverter at low voltage is satisfactory, the input voltage may be gradually increased to the nominal 28 volts DC.

   C. The DC input to the static inverter must be current-limited or adequately fused to prevent damage to components in case of malfunction.

2. Trouble Shooting Instructions

   Refer to Table 201 for trouble shooting instructions. Refer to Figure 202 for referenced waveforms. J1 pin identification is given for the basic PC-250. Substitute to the equivalent pin identification for other models.

TABLE 201 (Sheet 1 of 6)
TROUBLE SHOOTING

MALFUNCTION	POSSIBLE CAUSE	REMEDY
Short circuit between J1, pins A and D	Input capacitor C14, C15, C16 or C17 shorted to ground	Replace shorted capacitor.
	Diode CR12 shorted to ground	Replace diode.
	Input filter inductor L2 shorted to ground	Replace input filter inductor.
Low voltage and heavy DC current at pin A of J1	Input capacitor C14, C15, C16, C17, C18 or C19 shorted	Replace shorted capacitor.
	CR11 shorted	Replace CR11.
	CR12 shorted	Replace CR12.
	Q8, Q9, Q10 or Q11 damaged	Replace Q8, Q9, Q10 or Q11.

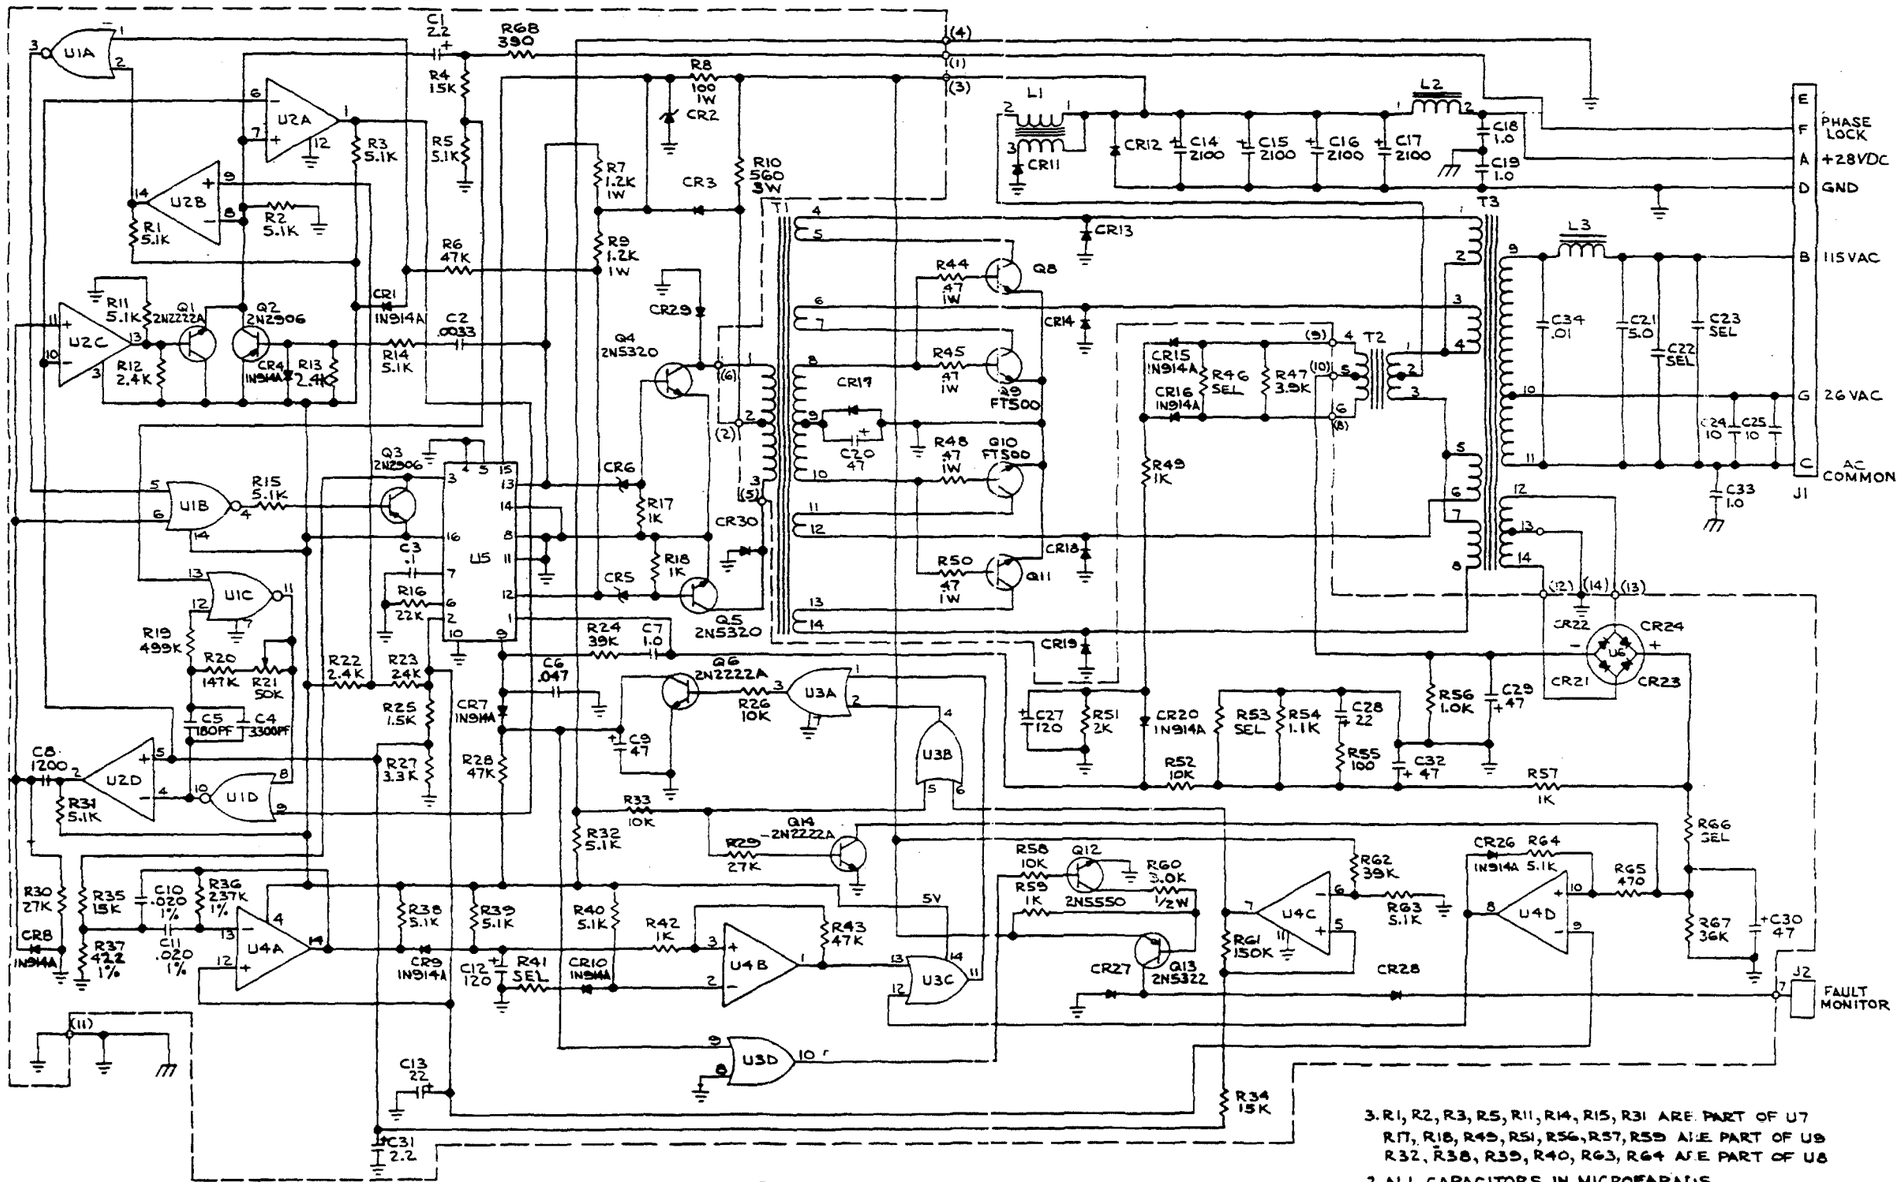
TABLE 201 (Sheet 2 of 6)
TROUBLE SHOOTING

MALFUNCTION	POSSIBLE CAUSE	REMEDY
	Inductors L1, L2 or connecting wires shorted to ground	Replace shorted inductors or connecting wires.
No DC at cathode of CR2	Connecting lead open	Repair open lead.
	R8 open	Repair R8.
Frequency of VAC output at pins B and C of J1 is not within 398 and 402 Hz	Defective or miscalibrated precision astable multivibrator components, U1, C4, C5, R20 or R21	Replace defective parts.
	Coupling capacitor C8 open	Replace C8.
	Defective components Q3, U1, or U2	Replace defective parts.
No output at pins B and C of J1	a. Transistor Q6 is not saturated	
	(1) Defective integrated Circuit U5	Replace integrated circuit U5.
	(2) Defective driver transistors Q4 and Q5	Replace driver transistors Q4 and Q5
	(3) Open connections to T1, T2, Q8, Q9 Q10 or Q11.	Repair open connections.
	(4) Choke L3 open	Replace choke L3.
	b. Transistor Q6 is saturated	
	(1) Defective over-voltage or under-voltage circuits; U4D, U4C, U3B, or U3A	Replace defective components.
	(2) Defective frequency control circuit; U4A, U4B, U3C, or U3A	Replace defective components.
	(3) Defective multivibrator circuit; U1C, U1D, U2D, U1B or Q3	Replace defective components.

TABLE 201 (Sheet 3 of 6)
TROUBLE SHOOTING

MALFUNCTION	POSSIBLE CAUSE	REMEDY
	Defective remote on/off circuit; open connections to J1(E), U3B, or U3A	Repair open connections.
	Defective phase lock circuit; U2C, Q1, Q2, U2B, or U2A	Replace defective components.
Output voltage at pins B and C of J1 out of tolerance	Defective integrated circuit U5	Replace defective integrated circuit.
	Defective resistor network (wrong value of reference voltage at pin 2 of U5 - voltage at pin 16 of U5 is correct)	Replace defective resistor network.
	Miscalibration of voltage control	Reselect resistor R53.
	Miscalibration of current limiting circuit	Reselect resistor R46
	Defective output transformer T3	Replace defective output transformer.
	Defective current transformer T2	Replace defective current transformer.
	Defective spillover inductor L1	Replace defective spillover inductor.
	Defective rectifier bridge U6	Replace defective rectifier bridge.
	Open connections to PC board	Repair open connections.
	Defective tuning capacitors C21, C22, and C23	Replace defective capacitors.

TABLE 201 (Sheet 4 of 6)
TROUBLE SHOOTING

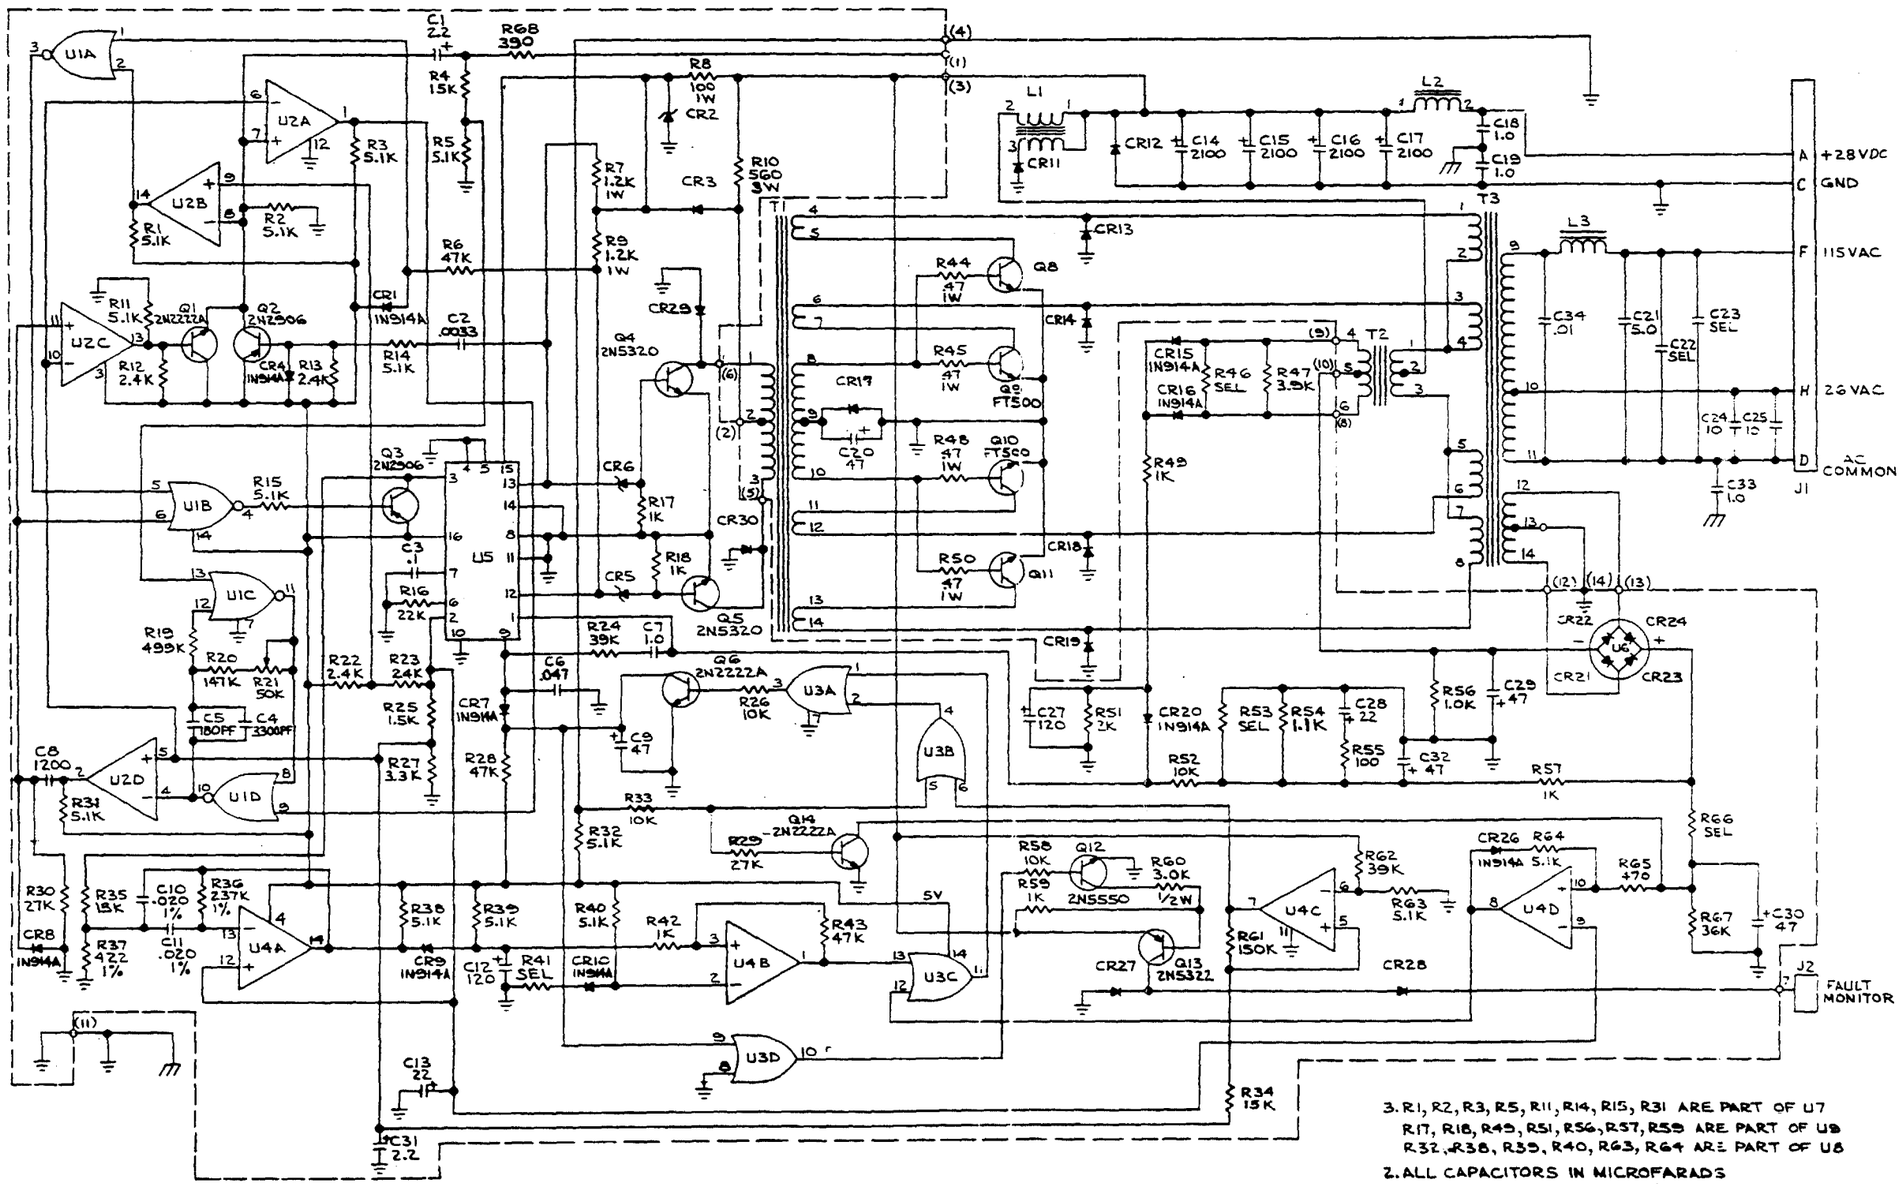


MALFUNCTION	POSSIBLE CAUSE	REMEDY
	Defective transistors Q8, Q9, Q10 and/or Q11	Replace defective transistors.
Transistors Q8, Q9, Q10 and Q11 fail at nominal DC input (See waveforms 4 and 5)	Defective connection to one or more transistors	Repair defective connections.
Current limiting circuit inoperative	Defective current transformer T2	Replace defective current transformer.
	Open connections to PC board	Repair open connections.
	Defective diodes CR15 and CR16	Replace defective diodes.
Output signal distortion at pins B and C of J1 out of tolerance	Defective tuning capacitors C21, C22, and C23	Replace defective capacitors.
	Defective spillover inductor L1	Replace defective spillover inductor.
Output signal at pins G and C of J1 is not 25 to 27 volts	Defective output transformer T3	Replace defective output transformer.
Remote ON/OFF control is inoperative	Defective integrated circuit U3B or U3A	Replace defective components.
	Defective integrated circuit U5	Replace defective component.
	Defective transistor Q6	Replace defective component.
Output at pins B and C of connector J1 is in excess of 118 VAC when input at pins A and D of connector is in excess of 32 VDC	Defective integrated circuit U5	Replace integrated circuit.

TABLE 201 (Sheet 5 of 6)
TROUBLE SHOOTING

MALFUNCTION	POSSIBLE CAUSE	REMEDY
Soft-start is inoperative causing immediate voltage rise at turn-on	Open diode CR7	Replace diode.
	Open capacitor C9	Replace capacitor.
	Defective transistor Q6	Replace transistor.
Inverter locks on overvoltage mode	Defective divider R66 and R67	Replace R66 and/or R67.
	Defective integrated circuit U4	Replace integrated circuit U4.
	Defective transistor Q14	Replace transistor Q14.
	Defective capacitor C30	Replace capacitor C30.
Inverter will not start	Defective low voltage control U4, R62, and R63.	Replace defective components.
	Defective start circuit U3A, U3B, and Q6	Replace defective components.
	Defective multivibrator and coupling circuit U1D, U1C, U2D, C8 and CR8.	Replace defective components.
	Defective frequency control circuit U4A, U4B, U3C, and U3A	Replace defective component.
	Defective pulse drive circuit U1B or Q3	Replace defective components.

TABLE 201 (Sheet 6 of 6)
TROUBLE SHOOTING



MALFUNCTION	POSSIBLE CAUSE	REMEDY
Inverter will not phase-lock	Defective phase-lock circuit U1A, U1D, U2D, U2A, U2B, U2C, Q1, and Q2	Replace defective components.
Fault monitor (J2) inoperative	Defective gate U3D, transistors Q12, Q13, diode CR28	Replace defective components.
	Improper connection at J2 or defective jack	Replace defective components.
	PC-250 Series (Mod Level A)	
Short circuit current foldback timers delay inaccurate	Defective counter U10	Replace defective component.
	Defective capacitor C37 or resistor R75	Replace defective components.
Short circuit current foldback inoperative	Defective counter U10	Replace defective component.
	Defective diode CR35	Replace defective component.
	Defective diode CR37	Replace defective component.

DISASSEMBLY

1. General Disassembly Instructions

This section contains complete disassembly instructions for the static inverter. However, disassembly should be initially limited to removal of the dust cover (3, Illustrated Parts List, Fig. 1) and the transistor covers (6). Removal of these parts allows visual inspection of all assemblies and parts of the static inverter. Further disassembly should be limited to removal of only those items required for repair or replacement of worn or defective parts of the unit. Disassembly instructions for removal of assemblies or parts not involved should be disregarded.

2. Specific Disassembly Instructions

Disassemble the static inverter in the sequence of item numbers assigned to IPL Figure 1, observing the following:

A. Do not remove nameplate (2) or warning label (23) from dust cover (3) unless required for replacement.

B. Remove screws (4) and lock washers (5), and separate dust cover (3) from static inverter.

C. Remove screws (7) and lock washers (8), and separate transistor cover (6) from left heat sink assembly (10).

D. Remove screws (11), and nuts (13) and separate left heat sink assembly from base plate assembly (22). Tag and unsolder wire leads from left heat sink assembly (10).

NOTE: Refer to REPAIR for disassembly of left heat sink assembly.

E. Remove screws (7) and lock washers (8), and separate transistor cover (6) from right heat sink assembly (9).

F. Remove screws (11), and nuts (13) and separate right heat sink assembly from base plate assembly (22). Tag and unsolder wire leads from right heat sink assembly (9).

NOTE: Refer to REPAIR for disassembly of right heat sink assembly.

G. Tag and unsolder wire leads from circuit board assembly (14). Remove screws (15), lock washers (16), and flat washers (17) and separate circuit board assembly from front plate assembly (18) and base plate assembly (22).

NOTE: Refer to REPAIR for disassembly of circuit board assembly.

H. Remove screws (19) and separate front plate assembly from base plate assembly (22). Tag and unsolder wire leads from front plate assembly (18).

NOTE: Refer to REPAIR for disassembly of front plate assembly.

I. Remove screws (21) and separate rear plate assembly from base plate assembly (22). Tag and unsolder wire leads from rear plate assembly (20).

NOTE: Refer to REPAIR for disassembly of rear plate assembly.

CLEANING

1. General Cleaning Instructions

Care must be taken during all cleaning operations to avoid damaging parts and electrical wiring. Avoid entrapment of cleaning fluids and, after cleaning, dry all parts in warm air at 38° to 52°C (100° to 125°F). When cleaning diffcult areas, use a soft bristle brush.

2. Specific Cleaning Instructions

A. Clean base plate, end plates, heat sinks, and dust cover as follows:

(1) Clean all surfaces with isopropyl alcohol or a mild detergent (Ref. Table 401) using a soft bristle brush in slots and corners.

(2) Dry parts in warm, clean air.

B. Clean printed circuit board as follows:

(1) Wash printed circuit board with soap and distilled water in areas where a large portion of fungus-proof material has been removed.

(2) Clean components using freon TF (Ref. Table 401) applied with a soft bristle brush. Ensure that all contaminants are removed from electrical wiring.

(3) Dry parts in warm, clean air.

C. Clean electrical connector as follows:

(1) Remove surplus solder from wells of pin inserts in connector using a 25 watt soldering iron and a solder removing tool.

(2) Clean all parts of connector with freon TF (Ref. Table 401) ensuring that all contamination such as flux residue and old solder is removed from contact pin inserts.

(3) Dry connector in warm, clean air.

TABLE 401
CONSUMABLE MATERIALS FOR CLEANING

DESCRIPTION	DESIGNATION	SOURCE
Detergent	Dreft	Proctor and Gamble Co., 5201 Spring Grove Cincinnati, Ohio 45217 Proctor and Gamble Co., of Canada Ltd. Toronto, Ontario
Freon TF (MS180)	MIL-C-81302	Dupont E.I. de Nemours and Co., Inc. Freon Products Division 10th and Orange Sts. Wilmington, Del. 19898 Miller-Stephenson Chemical Co., Inc. P.O. Box 628 16 Sugar Hollow Rd. Danbury, Conn. 06810
Isopropyl Alcohol 99% grade	TT-I-735	Local Purchase

CHECK

1. General

Ensure that all contaminants are removed to provide clean surfaces for adequate inspection and, immediately following cleaning, carry out a thorough visual inspection of all components. Special attention must be given to all signs of corrosion. Reject all parts which fail to meet check requirements except where local repair is permitted (Ref. REPAIR).

2. Plates, Covers, and Heat Sink

Visually check all surfaces for corrosion, cracks, scratches, nicks, scores, gouges, dents and damage caused by impact. Check irridated surfaces for damaged or worn areas exposing bare metal. Check tapped holes for condition of threads. If cracks are suspected after careful visual check, perform fluorescent penetrant check of suspected parts in accordance with latest revision and amendments to Military Specification MIL-I-6866. Cracks are not permitted. Check electrical connector on front plate for damaged threads, cracked or distorted shell and bent or burned pins. Damage beyond the scope of instructions given in REPAIR is cause for rejection of parts.

3. Electrical Wiring

A. Check all interconnecting wires for cuts, breaks, proper lacing, or damaged insulation. Replace wires as required (Ref. REPAIR).

B. Check for security and condition of soldered connections. These shall be bright with no flux, and free of broken or loose strands and corrosion.

C. Check ends of wires, previously unsoldered to remove assemblies or parts, for length and for frayed or missing insulation. These wires shall be replaced if necessary, and cut, stripped, and tinned as described in REPAIR.

4. Electronic Components

Check electronic components for obvious damage, loose or broken terminals or leads, evidence of overheating and for security of mounting. Check circuit board for copper track damage, proper soldering, proper conformal coating, and corroded terminals.

REPAIR

1. General Repair Instructions

A. Repair of the static inverter is normally limited to repair of minor damage to structural parts and to repair and replacement of interconnecting wires and replacement of electronic components.

B. Smooth out nicks, scratches and similar damage sufficiently to remove all sharp edges and raised metal using abrasive cloth (Ref. Table 601), and/or a fine stone. After blending, protect repaired areas by treating with chemical film in accordance with Military Specification MIL-C-5541 (Ref. Table 601).

TABLE 601
CONSUMABLE MATERIALS FOR REPAIR

DESCRIPTION	PART/MODEL NO.	SOURCE
Cloth, Abrasive, No. 400 grit	P-C-451	Local Purchase
Chemical Film	MIL-C-5541	Local Purchase
Flux, Rosin	No. 1545	Kester Solder Co. Chicago, Il 60607
Solder, Tin/Lead	No. 44	Kester Solder Co. Chicago, Il 60607
Isopropyl Alcohol, 99% grade	TT-I-735	Local Purchase
Staking Compound	Loctite Grade H	Loctite Corp. Newington, CT 06111
Silicone Adhesive Clear*	GF2562-01DP	Local Purchase
Silicone Adhesive Gray**	DC-3145	Dow Corning Corp. Midland, MI 48640
Tie Wrap	MS18034	Local Purchase
Sleeving, Nylon, 20 ga	Commercial	Local Purchase
Buss Wire, 20 ga	Commercial	Local Purchase

NOTE: Equivalent substitutes may be used for above items.
* Do not use in circuit areas.
** Use in circuit areas.

C. Clean up surface corrosion by careful polishing with abrasive cloth (Ref. Table 601), removing as little base material as possible. Protect cleaned up areas against further corrosion by treating with Chemical Film in accordance with Military Specification MIL-C-5541.

D. Clean up minor damage to threads by blending out burrs and nicks with a fine stone or file. If necessary, chase threads with appropriate tap or die.

2. Specific Repair Instructions

A. Repair wires, previously unsoldered to allow removal of assemblies or parts as follows:

(1) Remove all existing solder from ends of all wires. If wire requires trimming, remove as little as possible to maintain sufficient length for connection. Replace if necessary.

(2) On all unattached ends of insulated wire, trim insulation back and on 20 gauge bus wire, install nylon sleeving (Ref. Table 601) to expose 0.19 inch of bare wire. Clean exposed ends with isopropyl alcohol (Ref. Table 601) and tin bare wire using 25 watt soldering iron with resin flux and solder (Ref. Table 601). Repeat CLEANING to remove all residue flux.

(3) Solder wires to terminals as tagged at removal with 25-watt soldering iron and solder (Ref. Table 601).

NOTE: Refer to Figure 601, Wiring Diagram.

B. Repair right heat sink assembly as follows (See IPL Figure 2):

(1) Tag and unsolder wire leads and component leads as required.

(2) Remove unserviceable parts and install new parts.

(3) Install new insulators (9 and 10) when installing new transistors (7).

(4) When installing new rectifier (6), use attaching parts supplied with rectifier.

(5) Solder wire leads and component leads to terminals as tagged at removal in accordance with paragraph 2.A.

C. Repair left heat sink assembly as follows (See IPL Figure 3):

(1) Tag and unsolder wire leads and component leads as required.

(2) Remove unserviceable parts and install new parts.

(3) Install new insulators (11 and 12) when installing new transistors (9).

(4) Solder wire leads and component leads to terminals as tagged at removal in accordance with paragraph 2.A.

D. Repair circuit board assembly as follows (See IPL Figure 4):

CAUTION: WHEN REPLACING TRANSISTORS, CARE MUST BE TAKEN TO CONDUCT EXCESSIVE HEAT AWAY FROM SEALS, OTHERWISE HEAT OF SOLDERING IRON MAY CRACK SEALS AND DAMAGE TRANSISTORS.

(1) Heat soldered joints and remove unserviceable part by pulling free with needle nose pliers.

(2) Remove all existing solder from vacated holes in circuit board using a solder removing tool.

(3) Clean area with isopropyl alcohol (Ref. Table 601) applied with a soft brush.

(4) Position new part at same location as removed item and insert contact wires into holes in circuit board.

CAUTION: WHEN INSTALLING DIODES, CARE MUST BE TAKEN TO OBSERVE POLARITY. BLACK BANDS IDENTIFY CATHODE ENDS OF DIODES.

(5) Secure parts to circuit board using a 25 watt soldering iron with rosin flux and solder (Ref. Table 601).

(6) Clean area of soldered points with isopropyl alcohol (Ref. Table 601) and a soft brush to remove all traces of residue flux.

E. Repair front plate assembly as follows (See IPL Figure 5):

(1) Tag and unsolder wire leads and component leads as required.

(2) Remove unserviceable parts and install new parts.

(3) When installing new tie-mounts (7), apply staking compound (Ref. Table 601) to threads of screws (8).

(4) Install capacitors (5 and 6) in tie mounts (7) with tie wraps (Ref. Table 601).

(5) Secure capacitors (5 and 6) to front plate with Silicone adhesive (Ref. Table 601).

(6) Solder wire leads and component leads to terminals as tagged at removal in accordance with paragraph 2.A.

F. Repair rear plate assembly as follows (See IPL Figure 6):

(1) Tag and unsolder wire leads and component leads as required.

(2) Remove unserviceable parts and install new parts.

(3) When installing new tie mounts (8), apply staking compound (Ref. Table 601) to threads of screws (9).

(4) Install capacitors (2, 3, 4, 5, and 6) and choke (7) in tie mounts (8) with tie wraps (Ref. Table 601).

(5) Secure capacitors (2, 3, 4, 5, and 6) and choke (7) to rear end plate with Silicone adhesive (Ref. Table 601).

(6) Solder wire leads and component leads to terminals as tagged at removal in accordance with paragraph 2.A.

G. Repair base plate assembly as follows (See IPL Figure 7):

(1) Tag and unsolder wire leads and component leads as required.

(2) Remove unserviceable parts and install new parts.

(3) When installing mounting posts (14), apply staking compound (Ref. Table 601) to threads of screws (15).

(4) When installing standoff terminals (16), apply staking compound (Ref. Table 601) to threads of screws (17).

(5) Solder wire leads and component leads to terminals as tagged at removal in accordance with paragraph 2.A.

H. Repair bracket assembly as follows (See IPL Figure 8):

(1) Tag and unsolder wire leads and component leads as required.

(2) Remove unserviceable parts and install new parts.

(3) When installing standoff terminals (5) into standoff terminals (4), apply staking compound (Ref. Table 601) to threaded portion of standoff terminals (5).

(4) Install capacitors (2) on mounting bracket (7) with tie wraps (3) and with positive end of all capacitors together.

(5) Secure capacitors (2) to bracket with Silicone adhesive.

(6) Solder wire leads and component leads to terminals as tagged at removal in accordance with paragraph 2.A.

ASSEMBLY

1. General Assembly Instructions

Assembly of the static inverter is essentially the reverse of disassembly. All soldered connections made during assembly must be accomplished with a 25-watt soldering iron using rosin flux and solder (Ref. Table 701) and must be bright and free of flux.

TABLE 701
CONSUMABLE MATERIALS FOR ASSEMBLY

DESCRIPTION	DESIGNATION	SOURCE
Flux, Rosin	No. 1545	Kester Solder Co. Chicago, IL 60607
Solder, Tin/Lead	No. 44	Kester Solder Co. Chicago, IL 60607
Staking Compound	Loctite Grade H	Loctite Corp. Newington, CT 06111
Barrier Material	MIL-B-121	Local Purchase
Plastic Bag	PPP-B-260	Local Purchase

NOTE: Equivalent substitutes may be used for above items.

2. Specific Assembly Instructions

Assemble the static inverter in the reverse sequence of item numbers assigned to IPL Figure 1, observing the following:

A. Apply staking compound (Ref. Table 701) to threads of screws (21). Install rear plate assembly (20) to base plate assembly (22) with screws (21).

B. Apply staking compound (Ref. Table 701) to threads of screws (19). Install front plate assembly (18) to base plate assembly (22) with screws (19).

C. Solder wire leads as tagged during DISASSEMBLY between front plate assembly (18), back plate assembly (20), and base plate assembly (22).

NOTE: Refer to Figure 701, Wiring Diagram.

D. Install right heat sink assembly (9) on base plate assembly (22) with screws (11), and nuts (13). Apply staking compound to screws (11).

E. Install left heat sink assembly (10) on base plate (22) with screws (11), and nuts (13). Apply staking compound to screws (11).

F. Holding circuit board assembly (14) in place above inverter, solder all remaining wire leads as tagged during DISASSEMBLY.

NOTE: Refer to Figure 701, Wiring Diagram.

G. Install circuit board assembly (14) on front plate assembly (18) and base plate assembly (22) with screws (15), lock washers (16), and flat washers (17).

H. After successful completion of paragraph 3, Calibration, and TESTING, install dust cover (3), with screws (4), and lock washers (5), and transistor covers (6) with screws (7) and lock washers (8).

I. If removed, install nameplate (2) and warning label (23) on dust cover (3).

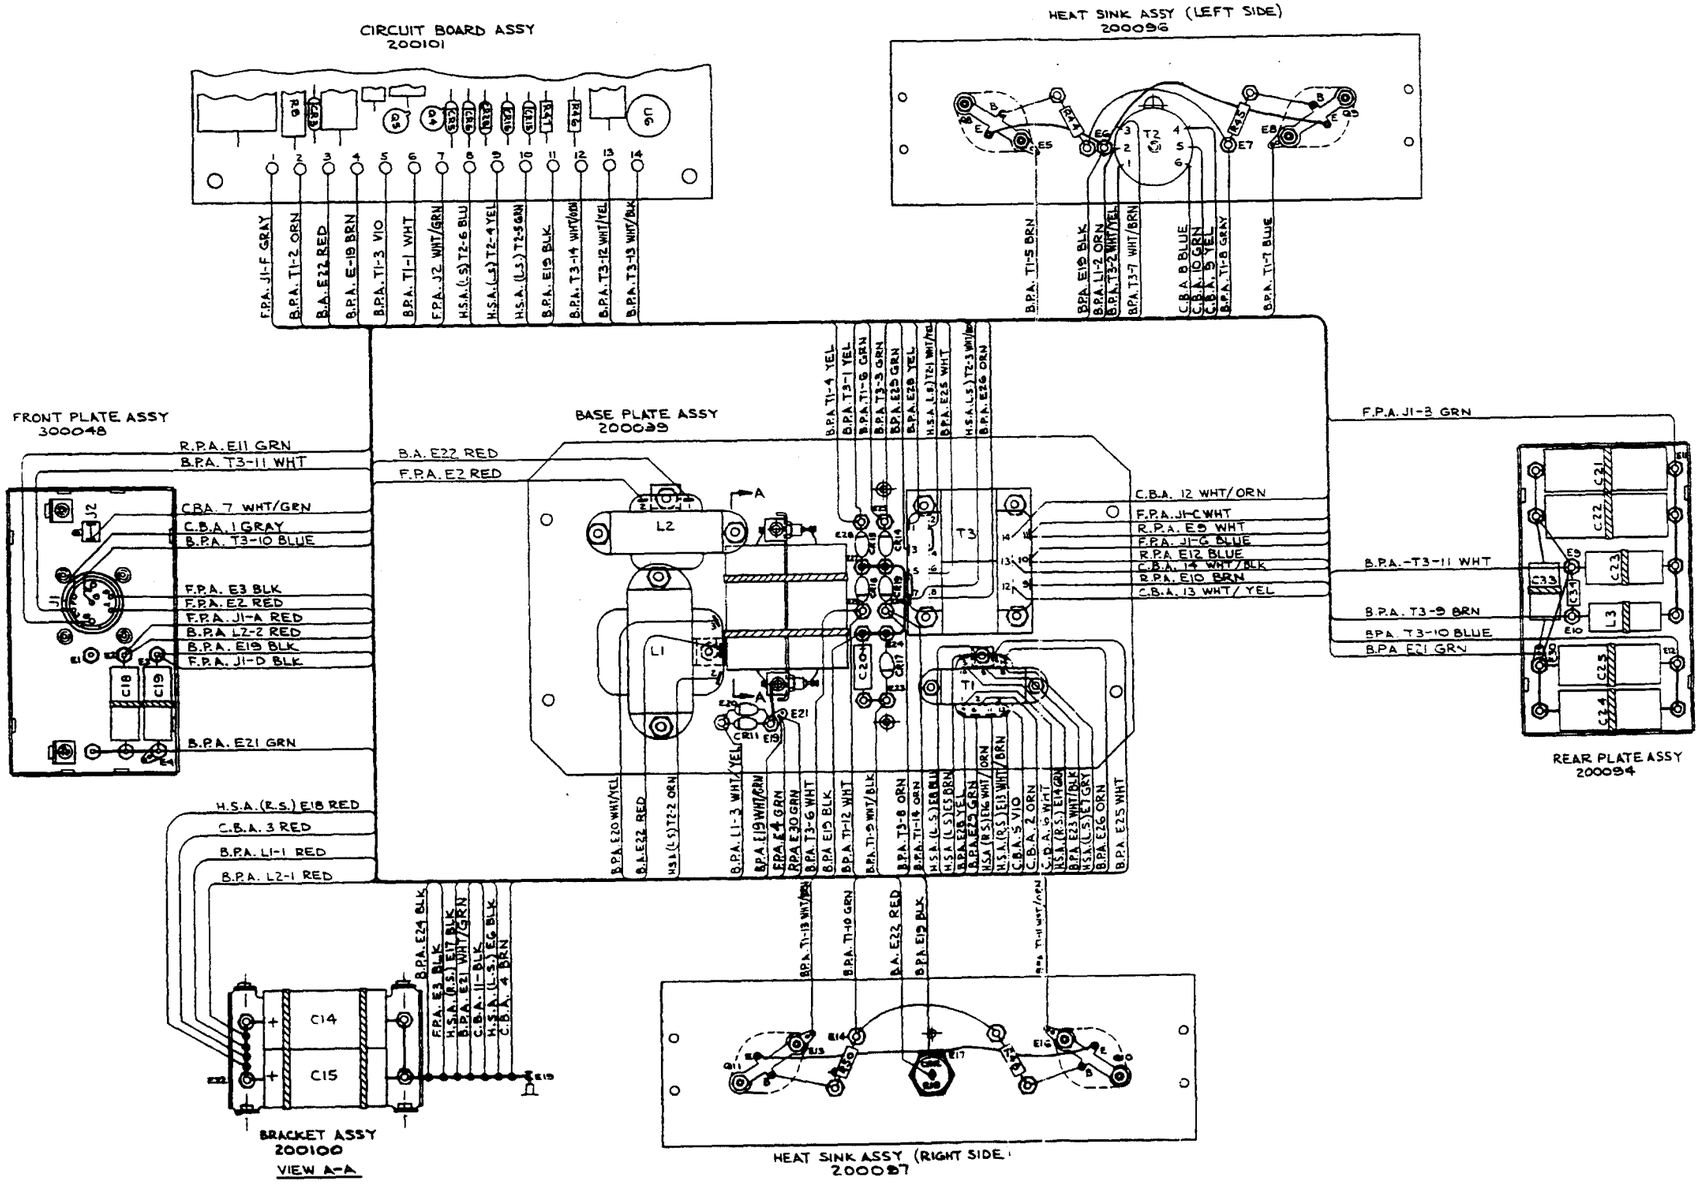
3. Calibration

If major components of the static inverter have been replaced with new components, it may be necessary to install resistors R46 and R53 on the printed circuit board and capacitors C22 and C23 on the rear plate assembly that have been selected for value by test in order to insure correct operation of the static inverter. Proceed as follows:

A. Install the static inverter in test setup shown in Figure 201, using test equipment listed in Table 201.

B. Frequency Calibration

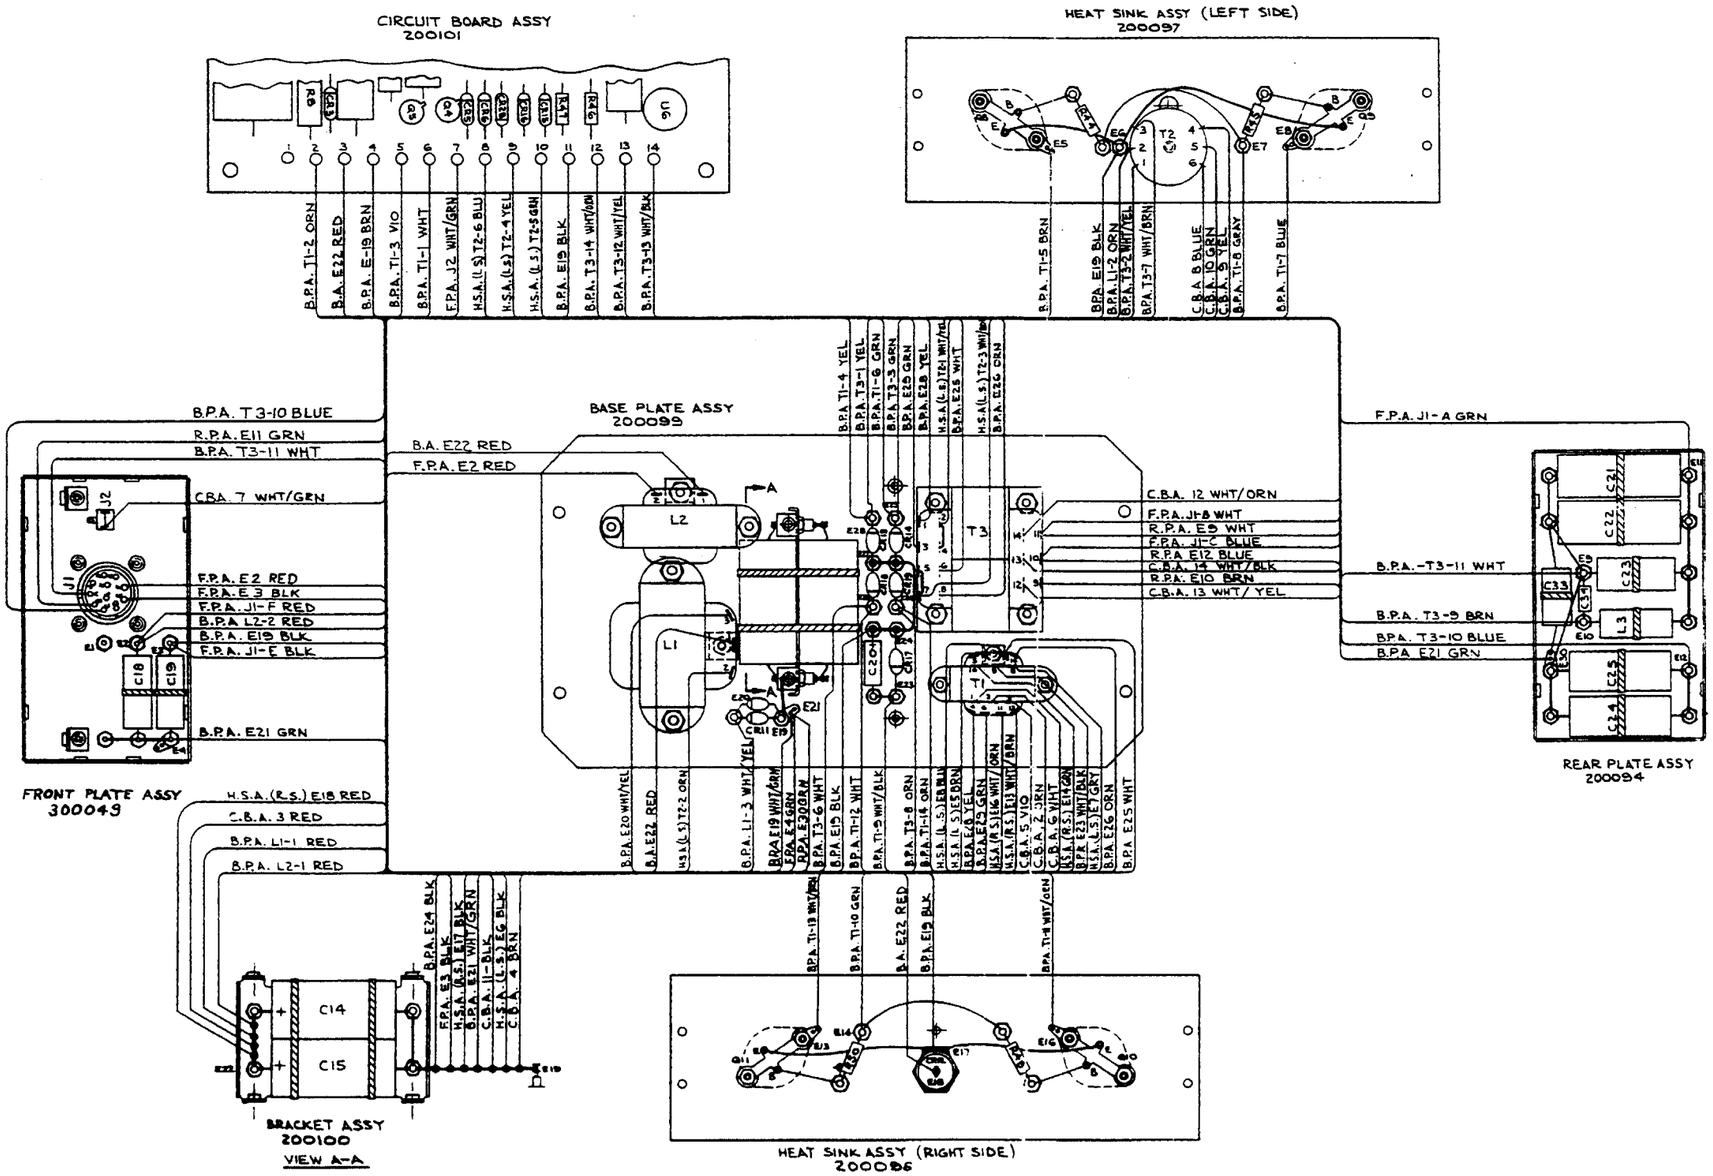
(1) Set the frequency counter gate time at 1 second. Adjust variable resistor R21 to obtain a reading of 400 $\pm$2 Hz.



(2) Set the frequency counter gate time at 10 seconds. Adjust variable resistor R21 to obtain a reading of 400 $\pm$1 Hz.

C. Output Transformer Tuning

(1) Disconnect all output loads from inverter.



(2) Connect the capacitor decade box across the 115 volts output.

(3) Connect the current probe to the tuning capacitor lead.

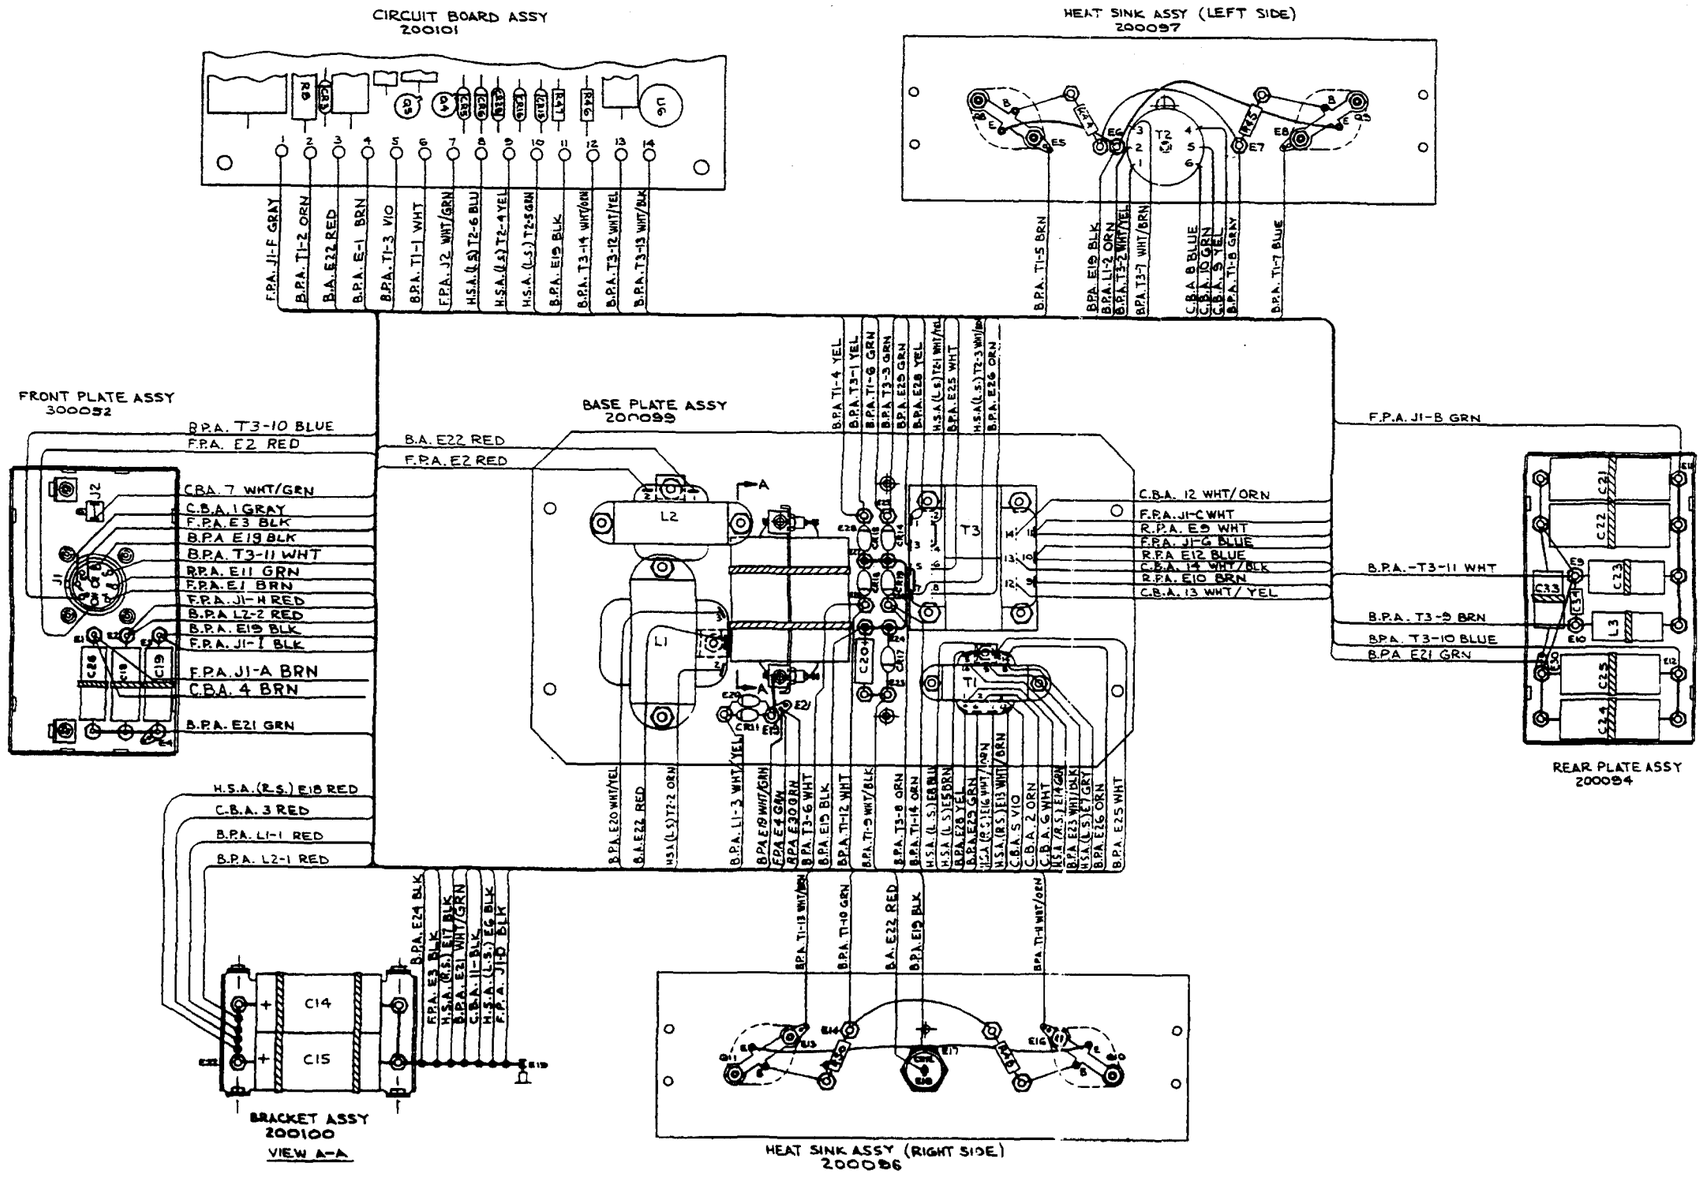
Figure 701 (Sheet 1 of 4)

MODEL PC-250



Wiring Diagram
Figure 701 (Sheet 2 of 4)

MODEL PC-250-1A

Wiring Diagram
Figure 701 (Sheet 3 of 4)

MODEL PC-250-1B

Wiring Diagram
Figure 701 (Sheet 4 of 4)

MODEL PC-250-1C

(4) Set switch S3 to 115V position and switch S2 to NO LOAD position.

(5) Adjust capacitor decade box to obtain a sinewave with notches at the zero crossover points. Read capacitance value on decade box.

(6) Install at positions C22 and C23 on rear plate assembly, one or two capacitors totaling the value or the closest higher value of that read on the decade box in step (5).

D. Output Voltage and Overvoltage Adjustment

(1) Install shorting jumper across resistor R46 position.

(2) Set switch S2 to NO LOAD.

(3) Set potentiometer R53 to highest resistance value (full CCW).

(4) Slowly decrease the resistance of R53 to obtain 130 volts RMS at the output.

(5) Select R66 such that the inverter just goes to overvoltage mode. Install R66.

(6) Reset potentiometer R53 to highest value.

(7) Restart inverter by setting switch S1 to "OFF", then to "ON".

(8) Verify overvoltage tripping point to be from 125 to 138 VRMS.

(9) Set potentiometer R53 to obtain 115 ±0.5 volts at the output. Note the resistance value indicated on the decade box.

(10) Remove shorting jumper across R46.

E.0 Current Limiting Adjustment (PC-250 Series)

(1) Connect resistor decade box across R46 position.

(2) Set switch S2 to 150% load position.

(3) Select resistor value on the decade box to obtain an output voltage 1 volt lower than that obtained at step 3.D.(10).

(4) Set switch S2 to SHORT position.

(5) Select resistor value on the decade box to obtain an AC output current between 3.25 and 3.75 amperes RMS.

(6) Remove to the decade box connections and install selected resistor closest to the indication on the decade box.

CAUTION: THE SHORT CIRCUIT TEST SHOULD BE PERFORMED IN LESS THAN 20 SECONDS. THE SHORT CIRCUIT MUST NOT BE LEFT ON FOR MORE THAN 1 MINUTE.

(7) Verify the AC short circuit current to be between 3.25 and 3.75 amperes RMS.

(8) Set switch S2 to 150% load position.

(9) Verify that the output voltage is not more than 2 volts lower than that noted at step 3.D.(10).

E.1 Current Limiting Adjustment (PC-250 Series, Mod Level A)

(1) Set switch S2 to 15% load position.

(2) Adjust potentiometer R46 to obtain an output voltage 1 volt lower than that obtained at step 3.D.(9).

(3) Set switch S2 to SHORT position.

(4) Adjust potentiometer R46 to obtain an AC output current of 3.75 to 4.0 amperes RMS.

(5) Verify that the output voltage is not more than 2 volts lower than that noted at step 3.D.(9).

(6) Verify that after a short-circuit duration of 5 to 7 seconds the AC current output folds back to not more than 2.0 amperes.

F. Inductive Load Check

(1) Set switch S2 to PF .8 (power factor 0.8) position.

(2) Verify that the output voltage is between 112.0 and 117 volts.

(3) Verify that the distortion is less than 9% with a DC input voltage of 24 to 32 VDC.

4. Preparation for Storage or Shipment

A. Place static inverter in a plastic bag (Ref. Table 701) and staple bag closed.

B. Wrap static inverter in barrier material (Ref. Table 701) and place in a suitable corrugated cardboard carton.

Store inverter indoors under normal environmental conditions.

SPECIAL TOOLS, FIXTURES, AND EQUIPMENT

1. Special Tools

No special tools are required.

2. Fixtures

No fixtures are required.

3. Equipment

Refer to Table 901 for equipment required.

TABLE 901
EQUIPMENT

DESCRIPTION	PART/MODEL NO.	SOURCE
Power Supply, 0-37 volts, 15 amperes, adjustable current limiting	Commercial	Local Purchase
Oscilloscope	5440	Tektronix
Amplifier	5A48	Tektronix

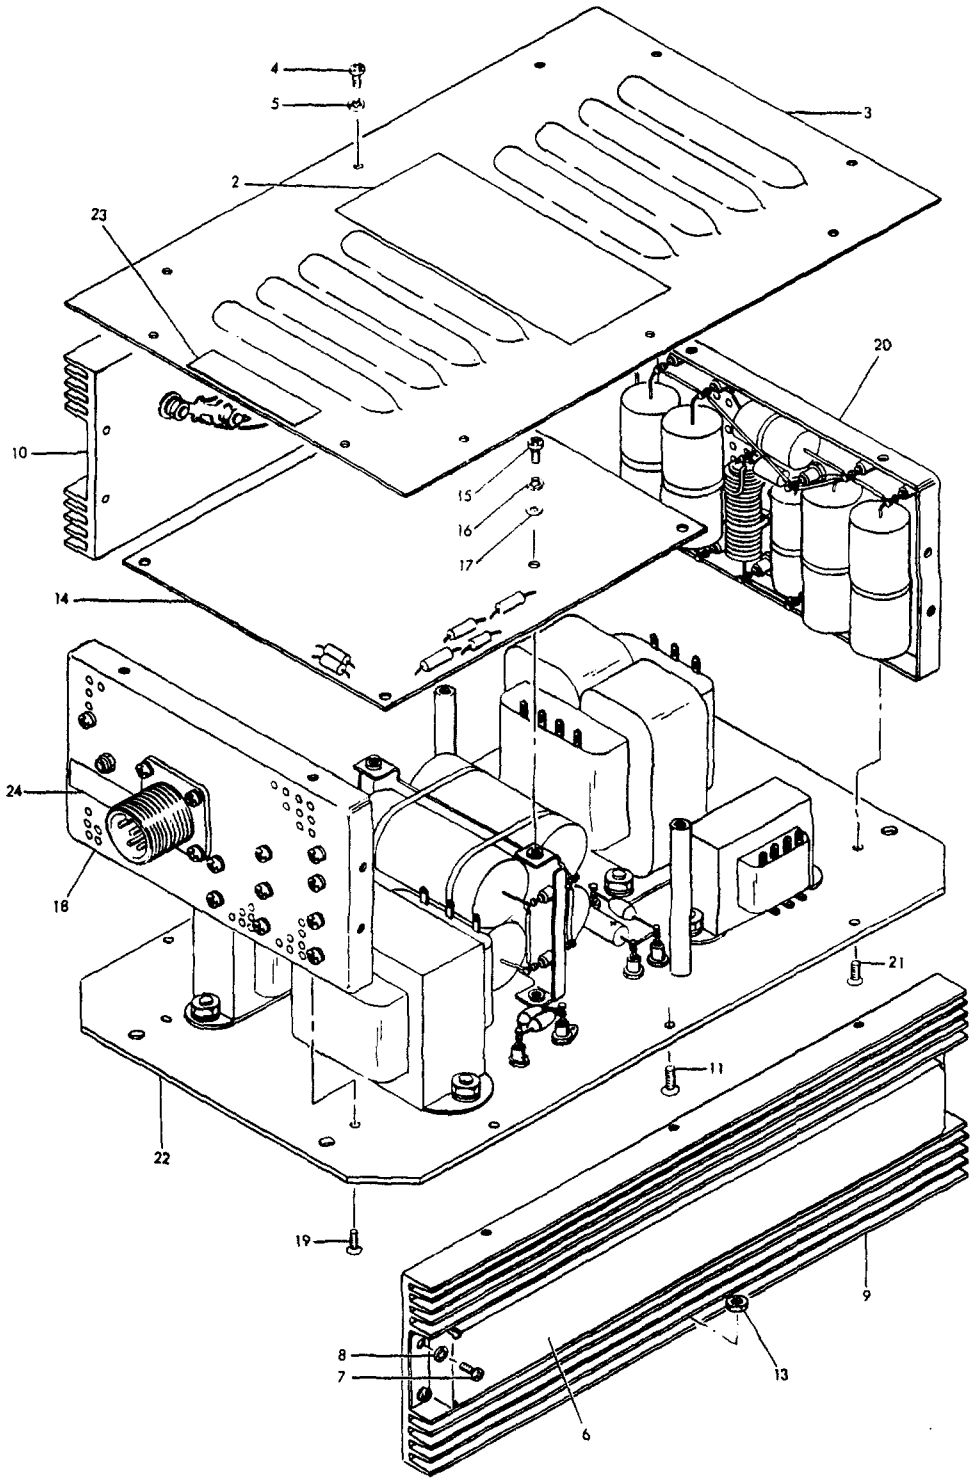
NOTE: Equivalent substitutes may be used.

ILLUSTRATED PARTS LIST

1. The illustrated parts list contains a complete breakdown of replaceable parts for the 250 VA Static Inverters, listed in order of disassembly. Entries in the Nomenclature column are indented to assist in identification of the parts of each assembly or subassembly.



2. Item numbers assigned to each part in the parts list correspond to the item numbers identifying the parts in the respective exploded view illustrations, Figures 1 through 8. Item numbers for parts listed but not illustrated are preceded by a dash.

3. Parts supplied by vendors are identified by the five-digit manufacturers' code, preceded by the letter "V", and listed in parenthesis following the nomenclature of the part. Applicable vendor codes and vendors are listed below.

CODE	VENDOR	CODE	VENDOR
V06383	Panduit Corp. 17301 Ridgeland Tinley Park, IL 60477	V79963	Zierick Mfg. Corp. Radio Circle Mt. Kisco, NY 10549
V08289	The Delbert Blinn Co., Inc. 1678 E. Mission Blvd. P.O. Box 2007 Pomona, CA 91766	V88245	Litton Precision Products, Inc. USECO Div. Litton Industries 13536 Saticoy St. Van Nuys, CA 91409
V71468	ITT Cannon Electric 666 E. Dyer Rd Santa Ana, CA 92702	V95987	Weckesser Co., Inc. 4444 W. Irving Park Rd. Chicago, IL 60641

4. The letters in the EFFECT CODE column indicate usage of parts in specific PC-250 models. Absence of a code indicates the part is used in all models.

   A Denotes use on basic PC-250 (Effective through S/N 1115)
   B Denotes use on basic PC-250-1A, Mod Level A (Effective original production)
   C Denotes use on basic PC-250-1B (Effective through S/N 102)
   D Denotes use on basic PC-250-1C (Effective through S/N 122)
   E Denotes use on basic PC-250, Mod Level A (Effective S/N 1116 and subsequent)
   F Denotes use on basic PC-250-1B, Mod Level A (Effective S/N 103 and subsequent)
   G Denotes use on basic PC-250-1C, Mod Level A (Effective S/N 123 and subsequent)

1. INTRODUCTION

A. GENERAL

This publication provides operation and maintenance instructions for the Static Inverter, Part Number 607742-1-1 manufactured by Garrett Manufacturing Limited (a subsidiary of the Garrett Corporation), Rexdale, Ontario, Canada.

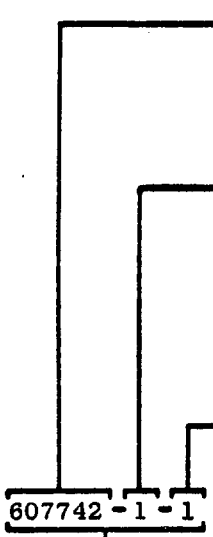
B. IDENTIFICATION

The nameplate of each unit reflects the manufacturer's identification (see figure 1).

2. DESCRIPTION AND OPERATION

A. DESCRIPTION

The Static Inverter has been designed for installation in the Twin Otter aircraft to provide 115 volts 400 cps, square wave, single phase ac power supply. It is a compact solid-state/magnetic device and operates from the aircraft 28 volt dc power supply.



B. OPERATION (See figure 5)

(1) General

The inverter consists of a magnetic multivibrator utilizing two power transistors (Q1 and Q2), two transformers (T1 and T2), and associated components. Short circuit protection is provided by transistors Q3, Q4, and associated components.

(2) Timing and Output Circuit

The dc input is applied between connector pins A(-) and B(+); either transistor Q1 or Q2 will conduct. The supply voltage is applied across one half of the primary of the output transformer T1, and as T1 and T2 primary windings are parallel connected, the same voltage will appear across T2 primary. The applied voltage across the primaries induces voltage into the transformer secondaries, with the polarity as indicated by the dots adjacent to the transformer windings on the schematic, and magnitude proportional to the turns ratio. When one of the transistors is biased on with a negative base voltage, the other transistor will be biased off with a positive base voltage. Timing transformer T2 has a smaller volt/second characteristic than output transformer T1; therefore it will commence to saturate earlier in the cycle, thus reducing the induced secondary voltage and consequently reducing the base drive to the conducting

Indicates a basic design series.

The first dash number denotes a specific configuration within the basic design series, and indicates that all units (within the same basic design series) bearing the same first dash number are interchangeable. Units bearing a different first dash number are not interchangeable. First dash numbers are assigned in numerical order, the first specific configuration being identified with the number "1".

The second dash number classifies the unit with respect to minor differences which do not affect interchangeability of the unit but which do involve a change in spare parts and/or technical data. Second dash numbers are assigned in numerical order (starting with "1") against each specific configuration of unit.

This is the Complete Part Number. It is stamped on the nameplate in the "Part No." slot.

Provision may be made on the nameplate or on a separate modification plate for the identification of retrofitted minor changes. These changes do not affect interchangeability of the unit but may affect spare parts and/or technical data. These changes may be made out of sequence and are therefore separately identified. Accordingly, the notation "2" stamped in the slot would indicate the incorporation of "Change 2" but would not indicate the incorporation of "Change 1" unless the notation "1" also appeared.

This is the Complete Serial Number. It is stamped on the nameplate in the "Serial No." Slot.

Actual serial number, allocated in numerical sequence. The first unit is serialized -101. The dash number quoted in the example would therefore represent the sixteenth unit off the production line.

Scheduled for production during the ninth month of the first year, i.e., September, 1961. The letter code is used to identify the applicable Manufacturing Division within The Garrett Corporation:
No letter — AiResearch, Los Angeles.
P — AiResearch, Phoenix.
C — Garrett Manufacturing Limited.

Manufacturer's Identification
Figure 1

transistor. As one transistor turns off, the induced voltage is reversed, thus causing the other transistor to conduct, this cycle continuing at the frequency determined by the components in the timing circuit and the input voltage. Voltage stabilization to the frequency determining circuit is provided by the rectifier bridge, CR14 through CR17 and Zener diode VR2. The output voltage is determined by the input voltage times the turns ratio of the output transformer T1.

(3) Short-Circuit Protection Circuit

Transistor Q3 operates as an on-off gate controlling the base drive to the power transistors Q1 and Q2. During normal operation of the inverter, Q3 is conducting, but in the event of a short-circuit being detected across the output, Q3 is cut off, removing the drive from Q1 and Q2 thus rendering the inverter inoperative. When the inverter is switched on, the input voltage is applied to the base of transistor Q4 via high resistance R8. Transistor Q4 starts to turn on and applies drive to Q3 which in turn conducts. Now Q3 collector voltage is applied to the base of Q4 via low impedance, R3, C3, driving both transistors Q4 and Q3 full on. This drive however has only a short duration, as when C3 is fully charged it blocks the input voltage from appearing at the base of Q4. If there is no other source of base drive, the transistors Q4 and Q3 cease conducting. With the input voltage still applied to the inverter, the foregoing starting cycle will be repetitive, giving an on-off pulsing condition when the output of the inverter is shorted or for some other reason there is no output voltage. Circuit constants are such that the on time is short compared to the off time thus ensuring that in the event of a short-circuit the transistors and components in the inverter are protected. During normal inverter operation, the output voltage (sensed at the 26 volt tap (connector pin F) on the output transformer) is rectified by CR2 and fed to the base of Q4, via R2, R13 - providing continuous self-drive to maintain inverter output.

Diodes CR5, CR6, in conjunction with R10, R11, form a bias network ensuring safe start and stop at all load and temperature conditions.

(4) Other Protection Devices

Diodes CR8, CR9 are included in the circuit to prevent damaging reverse current flowing to the bases of transistors Q1 and Q2. With a highly inductive load a path must be provided for the lagging currents to bypass Q1 and Q2 when they are switched off. Feedback diodes CR3, CR4 are used for this purpose.

Transient spikes in the input to the inverter, which could be damaging to Q1, Q2, are clipped by Zener diode VR1, capacitor C1 being used as a filter component.

C. LEADING PARTICULARS

The leading particulars of the unit are shown in table I.

TABLE I. LEADING PARTICULARS

Input Voltage	18.5 to 29.5 vdc
Input Voltage Ripple	MIL-STD-704
Input Source	Battery and generator
Output Voltage	115 v nominal between connector pins C & D 26 v nominal between connector pins F & D
Efficiency	70% approx at full load, P.F. = 1.0
Number of Phases	One
Output Frequency	400 cps ±10%
Output Power (normal rating)	65 VA
Power Factor Rating	0.4 lag to unity
Short-circuit Capability	The inverter is self-protected
RFI Suppression	MIL-STD-6181D
Ambient Operating Temperature Range	-62° to 159.8°F (-55° to 71°C)
Electrical Connections:	
Connector J1	MS3112E10-6P
Pin A	dc return
Pin B	28 vdc positive input
Pin C	115 v, 400 cps output
Pin D	ac common ground
Pin E	Not used
Pin F	26 v, 400 cps output
*Mating Connector P1	MS3116E10-6S
Overall Dimensions	5.75 x 4.03 x 3.34 in. (max)
Weight	3.0 lb (approx)

*This information given for test purposes only and is not necessarily connector used on aircraft installation.

3. PERIODIC INSPECTION

A. GENERAL

The inspection schedule detailed herein is a recommendation only. Service experience will dictate actual requirements.

B. PRE-FLIGHT INSPECTION

None.

C. 100 HOUR INSPECTION

Check electrical connections and security of mounting.

D. REPAIR/OVERHAUL

There is no prescribed repair/overhaul period. No adjustment or repair to the inverter can be carried out in the aircraft, but if a malfunction is suspected, the unit should be removed and subjected to the functional test detailed in paragraph 6.

4. LUBRICATION

Not applicable.

5. BENCH SERVICING

A. GENERAL

Repair of the static inverter is limited to replacement of components as detailed in the parts list (paragraph 10) and/or replacement of wiring (see figure 9). If a malfunction is suspected, subject the unit to the functional test detailed in paragraph 6. before disassembly. The unit may not be malfunctioning and may not require servicing.

B. CLEANING

In normal service the internal parts of the static inverter will not require cleaning. If necessary, use a soft brush moistened with solvent (refer to table II).

TABLE II. CLEANING MATERIALS AND COMPOUNDS

Solvent (Inhibited Trichloroethane Solvent M-50, John B. Moore Corp., Nutley, New Jersey, or equivalent)
WARNING: USE SOLVENT IN A WELL-VENTILATED AREA. AVOID BREATHING FUMES OR SKIN CONTACT. DO NOT IMMERSE ELECTRONIC PARTS IN SOLVENT.

C. INSPECTION

(1) Check all components for physical damage.

(2) Check wire insulation and sleeving for deterioration.

(3) Check resistors for discoloration due to overheating.

(4) Check printed wiring board for damage. Examine carefully for hair line cracks in printed wiring.

(5) Examine adjacent components on printed wiring board for shorting due to small metallic particles.

D. REPLACEMENT OF COMPONENTS

(1) Components on Printed Wiring Board (See figure 7)

If a component on the printed wiring board is found to be defective it must be replaced without causing damage to the board. Where the component has wire ends (e.g. a resistor) it is recommended that one wire termination is cut, as close to the body of the component as possible, the component then raised from the board to allow it to be held by pliers, while the remaining wire termination is heated (on the opposite side of the board to the component), allowing removal. If the wire terminations are bent on the underside of the board it may be more convenient to cut both ends and apply the soldering iron to remove the wire ends.

An alternative method is to leave the wire ends in the board and use these as anchor points for the replacement components. With this method there is less possibility of damage to the board but its use depends on available space and length of wires.

When replacing transistor Q3, removal of the heat sink is facilitated by inserting a screwdriver blade into the gap and applying slight pressure to expand the heat sink from the body of the transistor. Do not lever the heat sink with the screwdriver blade between the heat sink and board. Coat the body of the replacement transistor with thermal joint compound before replacing the heat sink. When removing transistors Q3 or Q4, heat must be applied to the electrode connections quickly to allow withdrawal of the transistor from the board. A suitable pencil bit soldering iron with a rating of 25 to 65 watts is recommended. Great care must be taken to ensure that the printed wiring board is not damaged. When the defective components have been removed, the board and particularly the holes must have any excess solder removed. If a soldering iron with a suction attachment is not available, a piece of braiding of the type used on screened connecting wire is useful for removing excess solder. The end of the braiding is dipped in resin flux (acid fluxes should not be used) and applied to the board on the solder to be removed. Applying the soldering iron to the braiding will result in the excess solder being drawn into the braiding. For further application of the

braiding, trim off the end and re-coat with flux. When the holes in the board are cleaned, the serviceable transistor can be installed and soldered. Do not leave the tip of the soldering iron on the transistor connection any longer than necessary to ensure a good soldered joint.

When replacing diodes and capacitors, observe the polarity as marked on the body of the component and the printed wiring board layout (see figure 7).

(2) Power Transistors Q1 and Q2

If it is necessary to replace a power transistor, the following points should be observed:

(a) Use thermal joint compound on the surface of the case (collector) mating with the heat sink. Assemble the transistor to the heat sink using the mica insulator, Teflon insulators, solder tag, washers, screws and nuts as shown in figure 6.

(b) Tighten the two screws evenly to prevent distortion, ensuring that the transistor is seated correctly on the heat sink to give maximum heat transferance.

(c) After soldering the connections but before applying power to the inverter, check the resistance of collector to ground. This should be between 0.3 and 0.5 ohms (with all other components in circuit).

(3) Diode Rectifier, CR1

When replacing this diode, coat with thermal joint compound and fit insulator supplied with replacement diode.

(4) Zener Diode, VR1

When replacing this diode, coat with thermal joint compound but do not fit insulator. Discard the insulator supplied with replacement.

(5) Zener Diode, VR2

When replacing this diode, coat with thermal compound and fit insulator supplied with replacement diode.

NOTE: When reassembling printed wiring board to inverter, secure the four fixing screws with Loctite, Grade E.

TABLE III. REPAIR MATERIALS AND COMPOUNDS
Solder (Federal Specification QQ-S-571, Type Sn63-W-AR-P2).
Thermal Joint Compound (Type 120 Model 128, Wakefield Engineering, Inc., Wakefield, Massachusetts, or equivalent).
Thread-locking Sealant (Loctite Composition E, American Sealants Co., Hartford, Connecticut, or equivalent).

6. FUNCTIONAL TEST

A. POWER SUPPLY

Refer to paragraph 9A.

B. SPECIAL TOOLS AND TEST EQUIPMENT

Refer to paragraph 9B and C.

C. TEST PROCEDURE

The following instructions provide a means of testing the inverter using the test setup shown in figure 2. To facilitate testing, a typical test data recording sheet is shown in figure 3. This figure has been printed on one side only of translucent material to permit reproduction by contact printing or direct copying, such as Xerography.

(1) Short-Circuit Test

(a) Connect test setup as shown in figure 2 but leave load decades and variable transformer disconnected to give a no-load condition.

(b) Set input voltage (M2) to 27.5 vdc and apply a short-circuit across the output. Input current shall not exceed 1.5 amps (M1).

(c) Remove short-circuit. The inverter shall restart into normal operation.

(d) Connect load decades across the output as shown in figure 2. Short-circuit inductance decade and set resistance decade to 33 ohms.

(e) Adjust input to 27.5 vdc (M2) and adjust variable transformer to give full load conditions, 65 watts (M4).

(f) Short-circuit the output of inverter. Input current (M1) shall not exceed 1.5 amps.

(g) Remove short-circuit from output, inverter shall restart into normal operation.

(h) Record on test data sheet that inverter is acceptable or rejected.

(2) Input, Reverse Polarity Test

(a) With the power supply switched off check diode CR1 (see figure 5) with ohmmeter. In the forward direction a reading of approximately 1K shall be obtained and infinity in the reverse direction. If a short-circuit is indicated in either direction do not apply input power until CR1 has been replaced (see paragraph 5.D.(3)).

(b) Apply input power to inverter. Inverter shall operate.

(c) Reverse polarity of power supply to inverter. Inverter shall not operate.

(d) Restore correct polarity and check that inverter operates.

(3) Test No. 1

(a) Disconnect resistance and inductance load decades, and variable transformer to give a no-load condition.

(b) Adjust input voltage to 27.5 volts.

(c) Observe input current (M1) and record on test data sheet (I_{DC}).

(d) Observe output voltage (M3) and record (V_{AC}). This shall be 122 ±5 volts.

(e) Observe frequency (M5) and record (F cps). This shall be 396 ±15 cps. Reconnect load components.

(4) Test No. 2

(a) Set load at 65VA, P.F. = 1, setting resistance decade to 33 ohms and short-circuiting inductance decade. Adjust variable transformer to give a reading of 65 watts (M4).

(b) Observe input current (M1) and record (I_{DC}).

(c) Calculate input power (V_{DC} x I_{DC}) and record (W_{IN}).

(d) Observe output voltage (M3) and record (V_{AC}). This shall be 113 ±5 volts.

(e) Observe frequency (M5) and record (F, cps). This shall be 401 ±15 cps.

(f) Calculate efficiency = $\frac{W_O}{W_I} \times 100$

The efficiency shall not be less than 72%.

(5) Test No. 3

(a) Set load at 65VA, P.F. = 0.4 lag, by setting resistance decade to 33 ohms, removing short-circuit from the inductance decade and setting it to 30 mh. Adjust variable transformer to give a reading of 26 watts (M4).

(b) Observe input current (M1) and record (I_{DC}).

(c) Calculate input power ($V_{DC} \times I_{DC}$) and record (W_{IN}).

(d) Observe output voltage (M3) and record (V_{AC}). This shall be 122 ±4 volts.

(e) Observe frequency (M5) and record (F cps). This shall be 408 ±15 cps.

(f) Calculate efficiency = $\frac{W_O}{W_I} \times 100$

The efficiency shall not be less than 44%.

(6) Test No. 4

(a) Disconnect resistance and inductance load decades, and variable transformer to give a no-load condition. Adjust input voltage to 29.5 volts.

(b) Observe input current (M1) and record (I_{DC}).

(c) Observe output voltage (M3) and record (V_{AC}). This shall be 131 ±5 volts.

(d) Observe frequency (M5) and record (F cps). This shall be 400 ±5 cps.

(e) Reconnect load components.

(7) Test No. 5

(a) Set load at 65 VA, P.F. = 1, by setting resistance decade to 33 ohms and short-circuiting inductance decade. Adjust variable transformer to give a reading of 65 watts (M4).

(b) Observe input current (M1) and record (I_{DC}).

(c) Calculate input power (V_{DC} x I_{DC}) and record (W_{IN}).

(d) Observe output voltage (M3) and record (V_{AC}). This shall be 122 ±5 volts.

(e) Observe frequency (M5) and record (F cps). This shall be 404 ±15 cps.

(f) Calculate efficiency = $\frac{W_O}{W_I}$ x 100

The efficiency shall not be less than 70%.

(8) Test No. 6

(a) Set load at 65 VA, P.F. = 0.4 lag, by setting resistance decade to 33 ohms, removing short circuit from the inductance decade and setting it to 30 mh. Adjust variable transformer to give a reading of 26 watts (M4).

(b) Observe input current (M1) and record (I_{DC}).

(c) Calculate input power (V_{DC} x I_{DC}) and record (W_{IN}).

(d) Observe output voltage (M3) and record (V_{AC}). This shall be 131 ±5 volts.

(e) Observe frequency (M5) and record (F cps). This shall be 410 ±15 cps.

(f) Calculate efficiency = $\frac{W_O}{W_I}$ x 100

The efficiency shall not be less than 42%.

(9) Test No. 7

(a) Adjust input voltage to 18.5 volts. Disconnect resistance and inductance decades, and variable transformer to give a no-load condition.

(b) Observe input current (M1) and record (I_{DC}).

(c) Observe output voltage (M3) and record (V_{AC}). This shall be 79 ±5 volts.

(d) Observe frequency (M5) and record (F cps). This shall be 386 ±15 cps.

(10) Test No. 8

(a) Set load at 65 VA, P.F. = 1, by setting resistance decade to 33 ohms and short-circuiting inductance decade. Adjust variable transformer to give a reading of 65 watts (M4).

(b) Observe input current (M1) and record (I_{DC}).

(c) Calculate input power (V_{DC} x I_{DC}) and record (W_{IN}).

(d) Observe output voltage (M3) and record (V_{AC}). This shall be 61 ±5 volts.

(e) Observe frequency (M5) and record (F cps). This shall be 391 ±15 cps.

(f) Calculate efficiency = $\frac{W_O}{W_I} \times 100$

The efficiency shall not be less than 69%.

(11) Test No. 9

(a) Set load at 65 VA, P.F. = 0.4 lag, by setting resistance decade to 33 ohms, removing short circuit from the inductance decade and setting it to 30 mh. Adjust variable transformer to give a reading of 26 watts (M4).

(b) Observe input current (M1) and record (I_{DC}).

(c) Calculate input power (V_{DC} x I_{DC}) and record (W_{IN}).

(d) Observe output voltage (M3) and record (V_{AC}) this shall be 83 ±5 volts.

(e) Observe frequency (M5) and record (F cps). This shall be 396 ±15 cps.

(f) Calculate efficiency = $\frac{W_O}{W_I} \times 100$

The efficiency shall not be less than 52%.

(12) Test No. 10

(a) Disconnect output load from connector pin C and connect to pin F (26V output tap).

(b) Disconnect resistance and inductance load decades, and variable transformer to give a no-load condition.

(c) Set input voltage to 27.5 volts.

(d) Observe input current (M1) and record (I_{DC}).

(e) Observe output voltage (M3) and record (V_{AC}). This shall be 27 ±3 volts.

(f) Observe frequency (M5) and record (F cps). This shall be 396 ±15 cps.

(g) Reconnect load components.

(13) Test No. 11

(a) Set load at 30 VA, P.F. = 1, by setting resistance decade to 6 ohms and short circuit inductance decade. Adjust variable transformer to give a reading of 30 watts (M4).

(b) Observe output voltage (M3) and record (V_{AC}). This shall be 26 ±3 volts.

(c) Observe frequency (M5) and record (F cps). This shall be 401 ±15 cps.

(14) Test No. 12

(a) Set load at 30 VA, P.F. = 0.4 lag, by setting resistance decade to 6 ohms and inductance decade to 5 mh. Adjust variable transformer to give a reading of 12 watts (M4).

(b) Observe output voltage (M3) and record (V_{AC}). This shall be 27 ±3 volts.

(c) Observe frequency (M5) and record (F cps). This shall be 404 ±15 cps.

(d) Disconnect test setup.

7. TROUBLE SHOOTING

A. GENERAL

In the event of a malfunction, the inverter should be connected to the test setup (see figure 2).

To determine the nature of the malfunction a full-load test should be carried out (see paragraph 6.C.(4) Test No. 2). This will usually show a fault condition which can be placed in one of the following categories:

No output

Low voltage

Incorrect frequency.

B. NO OUTPUT

When power (27.5 v) is applied to the input of the inverter and no output is obtained, providing the input current is not excessive, i.e., power supply tripped or fuses blown, troubleshooting can proceed with power applied, after first removing the cover, secured by three screws.

The first step is to ascertain that the inverter is oscillating. A 400 cps audible signal usually emanates from the output transformer T1 but a visual check can be obtained by connecting an oscilloscope to the collectors of transistors Q1 and Q2 to ground, in turn. The trace obtained, if the transistors are oscillating will be similar to the trace shown in figure 4.

If it is found that the inverter is oscillating, make oscilloscope checks in the secondary circuit of the output transformer (T1) to find the point where the 400 cps signal is lost due to an open circuit condition.

In the majority of "no output" faults, the device will not be oscillating and in this condition proceed by checking the dc input voltage through the reverse polarity protection diode CR1, L1 to the emitters of transistors Q1 and Q2.

Check the base voltage of Q1 and Q2 (Table IV), checking R4, R5, CR8, CR9 and the secondary winding of T2 if no potential exists. If the voltage checks are satisfactory connect a jumper wire from terminal 1 on the printed wiring board to the collector of Q3. If the inverter commences to oscillate, the fault is in the protection circuit (Q3, Q4 or associated components). Remove the jumper wire from terminal 1 to Q3 collector and connect it between the collector and emitter of Q4. This effectively bypasses Q4 and its associated components, if no other fault exists, Q3 will be switched on and the inverter will operate. Remove

the jumper and proceed to locate the fault in the Q4 stage by checking each component. If connecting the jumper wire across Q4 does not produce oscillation, check the components including the transistor in the Q3 stage.

NOTE: A typical waveform of the short-circuit protection pulses is shown in figure 4. This waveform will be produced only under short-circuit conditions.

TABLE IV. VOLTAGE MEASUREMENTS

ELECTRODE	Q1	Q2	Q3	Q4
EMITTER	27.3 V	27.3 V	28.0 V	0.65 V
BASE	27.0 V	27.0 V	27.0 V	1.4 V
COLLECTOR	0.1 V	0.1 V	27.5 V	0.75 V

The above voltages are typical using a Avometer Model 8 connected between the appropriate transistor electrode connection and ground. Input voltage 27.5 V - no load condition.

If the diode CR1 goes open circuit, loss of output will result, requiring the replacement of CR1.

C. LOW OUTPUT

If the output voltage is low, check the transistor voltages as shown in table IV. If any incorrect readings are obtained check the components associated with the particular transistor(s).

Low gain of either Q1 or Q2 will cause low output (see figure 4) as will insufficient drive to the base of Q3. The latter can be confirmed by placing a jumper wire from collector to emitter of Q4.

D. INCORRECT FREQUENCY

If the inverter is producing a low or high frequency output, the following steps should be taken to correct the fault.

(1) Check the voltage stabilization circuit VR2, CR14 through CR17 and ensure that the Zener diode is controlling at 24 volts ±5%.

(2) If VR2 is inoperative, necessitating replacement, it might be found that due to variation in Zener diode characteristics that the frequency is still out of tolerance.

(3) If a supply of Zener diodes is not available to enable selection of a suitable one, the taps on the primary winding of timing transformer T2 can be altered but it is suggested that this method be used only as a last resort to correct the frequency. The black and brown taps on the transformer are fine adjustments and coarse adjustment is given by the blue, green and violet taps.

8. STORAGE INSTRUCTIONS

Pack the unit in a sealed, padded carton for storage or shipment; a dessicant must be included. (Refer to table V.)

The unit may be stored for an indefinite period. Before putting the unit into service, it should be subjected to the functional test as detailed in paragraph 6.

TABLE V. STORAGE MATERIALS AND COMPOUNDS

Desiccant (Military Specification MIL-D-3464)

9. POWER SUPPLY, SPECIAL TOOLS AND TEST EQUIPMENT

A. POWER SUPPLY

The power supply, used during functional test and trouble shooting of the static inverter, must provide 0 to 30 volts dc at 4 amperes (minimum). It is strongly recommended that the power supply be provided with built-in current limiting facilities to protect the inverter during trouble shooting. The power supply unit listed in table VI meets this requirement.

B. SPECIAL TOOLS

Not applicable.

C. TEST EQUIPMENT

Test equipment required for functional testing and trouble shooting is listed in table VI.

TABLE VI. TEST EQUIPMENT

Nomenclature	Part, Model or Type Number	Application
Test Setup	See figure 2.	Functional test.
Oscilloscope	Model 502A, Tektronic Inc., Beaverton, Oregon, or equivalent.	Trouble shooting.
Multimeter	Avometer Model 8, Avnet Instrument Corp., Plainsview, New York, or equivalent.	Trouble shooting.
Power Supply: 0 to 36 volts, 0 to 5 amperes	Model 808A, Harrison Laboratories Inc., Berkeley Heights, New Jersey, or equivalent.	Functional test and trouble shooting.

10. ELECTRONIC PARTS LIST

All electronic components are listed in table VIII, arranged in alpha-numerical sequence by reference designation. Applicable vendor codes are listed in table VII.

TABLE VII. VENDOR CODES

Code	Vendor Name and Address
V07217	Garrett Manufacturing Limited, Rexdale, Ontario, Canada.
V35005	Dale Electronics Canada Ltd., Toronto, Ontario, Canada.
V56289	Sprague Electric Co., North Adams, Massachusetts.
V89869	Delco Radio Division of General Motors Corp., Detroit, Michigan.

TABLE VIII. ELECTRONIC PARTS LIST

REFERENCE DESIGNATION	DESCRIPTION	PART NUMBER	VENDOR CODE	TYPE OR VALUE
CR1	Diode	1N3209	-	-
CR2 thru CR6	Diode	1N645	-	-
CR8 thru CR10	Diode	1N645	-	-
CR14 thru CR17	Diode	1N645	-	-
C1	Capacitor, Tantalum	CS13BF476M	-	47 µF ±20%, 35 vdcw

D-C REVERSE-CURRENT AIR-CIRCUIT BREAKER

TYPE XRP12A

LOW VOLTAGE SWITCHGEAR DEPARTMENT

GENERAL ELECTRIC

PHILADELPHIA, PA.

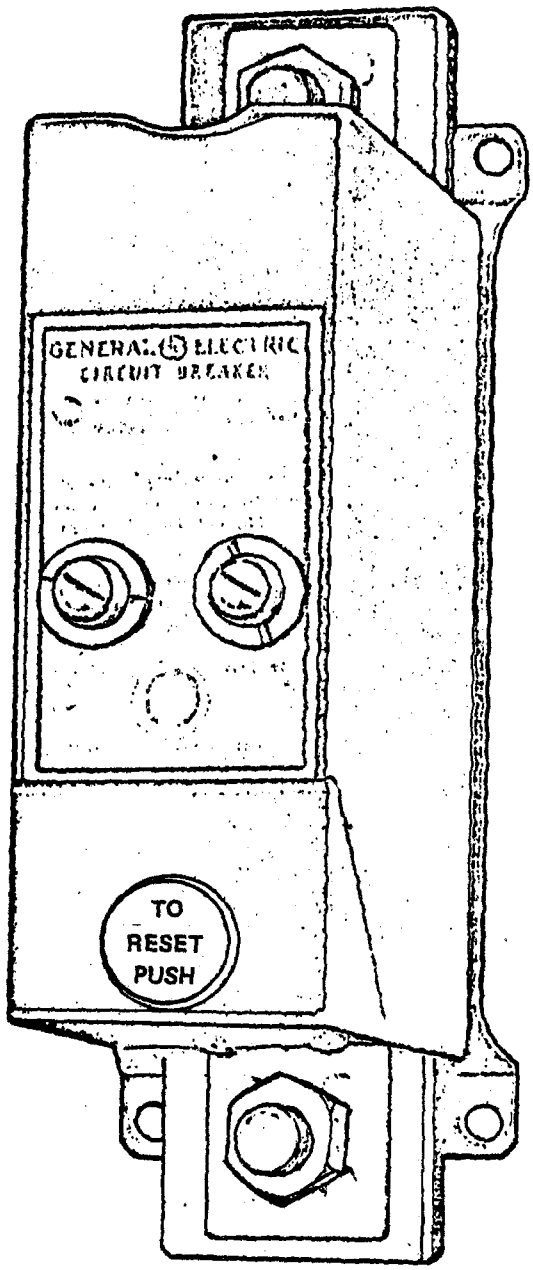

Fig. 1 (8001198) G-E Reverse-Current Circuit Breaker Type XRP12A

D-C REVERSE - CURRENT AIR - CIRCUIT BREAKER TYPE XRP12A

GENERAL INFORMATION

The Type XRP air circuit breaker is a circuit-protective device designed especially for aircraft use. It is connected in the generator circuit between the generator relay and the positive bus. In case of an electrical fault occurring in the generator, the generator relay, or their connecting cables, the Type XRP breaker will trip on the reversed flow of current from the bus. This will interrupt the current, and at the same time, an auxiliary switch on the Type XRP breaker opens the shunt-field circuit of the faulted generator. Interruption of the field "kills" the generator excitation so that it cannot continue to feed current into the fault.

OPERATING CHARACTERISTICS

The standard Type XRP breaker Model 12XRP12A1 shown in Fig. 1 is suitable for use with standard 28.5 volt aircraft generators of either 300 or 400 ampere rating.

The breaker is electrically tripped on reverse current only, and is manually reset after removal of the fault.

Reverse currents occur in normal operation. Large values exceeding the generator rating are experienced during recovery from system faults, by interruption of the field circuit, etc. Small values occur when, for example, the generator speed is reduced to a point at which its generated voltage is lower than the bus voltage. In this case, the generator relay operates to disconnect the generator from the bus. The Type XRP12A does not trip for these normal reverse currents because the reverse current-time characteristic shown in Fig. 2 gives adequate time delay. However, all new system designs should be tested under service conditions to assure that the characteristic of Fig. 2 is satisfactory for that system.

When a fault occurs in the generator circuit, however, the reverse current may rise quickly to values far in excess of the interrupting ability of the generator relay. In such a case, the Type XRP12A device rapidly trips and clears the fault.

A typical external connection diagram, Fig. 3, shows the application of the Type XRP breaker.

RATINGS

The breaker has a continuous rating of 30 volts and 300 amps, a current-interrupting capacity of 15,000 amperes and has a minimum reverse-current trip setting of 300 amperes. The band of operation is given in Fig. 2.

The continuous current rating of the breaker may be increased to 400 amperes on applications where two cables of size 1/0 or larger are used at each terminal of the breaker. The minimum reverse-current trip setting will remain at 300 amperes for this increased rating.

UNPACKING

The breaker should be unpacked and inspected for possible damage in shipment. If injury or rough handling is evident, a damage claim should be filed at once with the transportation company and the nearest General Electric Sales Office should be notified.

INSTALLATION

Outline internal connections and mounting dimensions are shown in Fig. 4. Four holes in the base are provided for mounting the breaker. The mounting can be made in any position on any flat surface.

After mounting, external connection should be made as shown in Fig. 3. Particular attention should be given to insure that the polarities are as indicated, i.e., the generator cable should be connected to the terminal marked "generator" (see Fig. 4) and the positive bus should be connected to the terminal marked " + bus".

OPERATION AND MAINTENANCE

As the breaker only functions to remove a fault in the generator circuit, its operations will be limited in number. In the event of such an operation, the generator circuit should be completely checked and the insulation failure corrected. The operation is indicated by an orange signal appearing through the hole in the nameplate of the breaker. With the insulation failure corrected, the Type XRP breaker should be given a millivolt drop test as outlined below to check the

These instructions do not purport to cover all details or variations in equipment nor to provide for every possible contingency to be met in connection with installation, operation or maintenance. Should further information be desired or should particular problems arise which are not covered sufficiently for the purchaser's purposes, the matter should be referred to the General Electric Company.

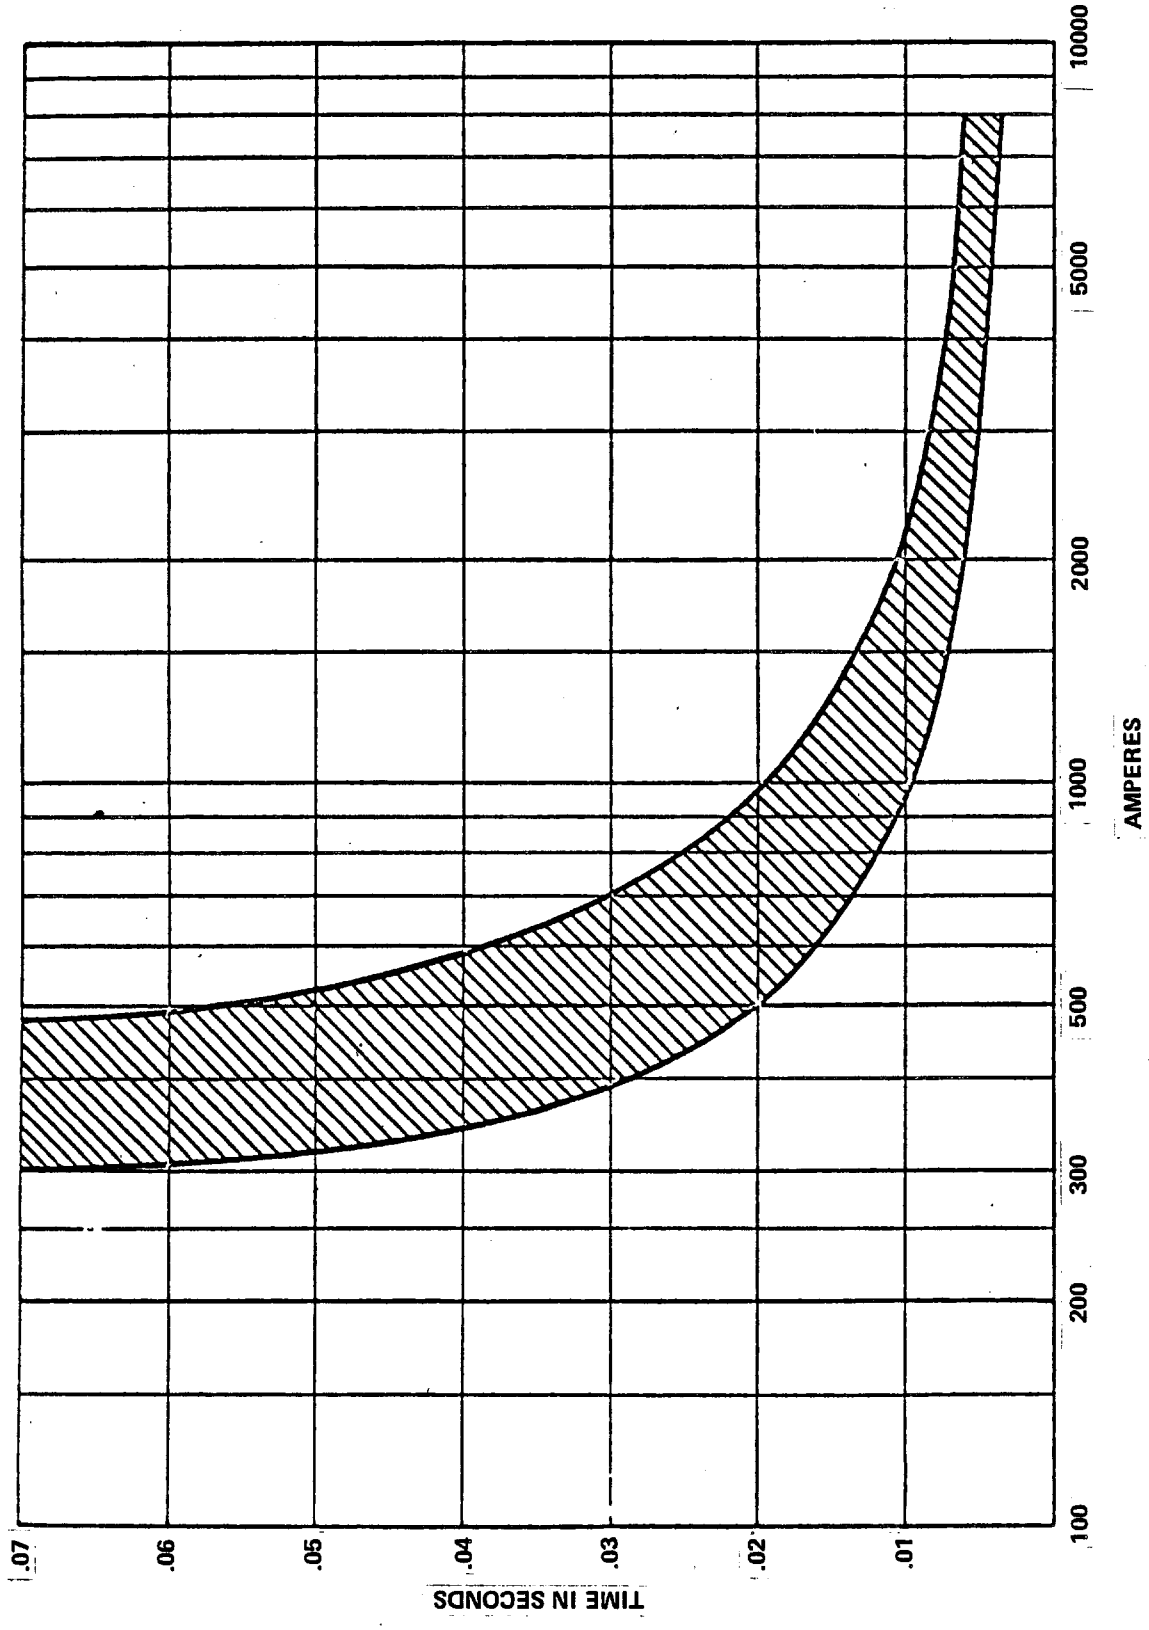

Fig. 2 (K-6400176) Time-Current Characteristic For Type XRP12A Application Showing Time To Release Trip Armature (Time To Interruption Add Approximately .006 Second.)

condition of the main contacts. The millivolt drop after a tripping operation should not exceed 100 millivolts. The breaker can be manually reclosed by pushing on the bell crank (Fig. 6) through the flexible reset cover as indicated in Fig. 5, making the generator available to the system through the generator relay.

The breaker may also serve to remove the generator in such case where the generator relay fails to disconnect the circuit provided that there is sufficient connected system capacity to supply the load and to produce reverse currents to the generator of tripping magnitude.

Should the breaker be damaged or fail to function correctly, it should be replaced. For the safety of equipment and plan, the system should be deenergized when working on the Type XRP breaker.

INSPECTION AND TEST

Being a protective device and not subject to control operation, this breaker should require no more that a general inspection and calibration test after 1000 hours or at the time the plane receives a complete overhaul. A millivolt drop test should be made after each operation of a breaker, to indicate the condition of the contacts.

To test the breaker, a d-c source capable of supplying approximately 400 amperes in increments of 10 amperes or less is required. The positive bus should be connected to the terminal marked " + bus" to produce a reverse current through the breaker. The trip should be within the limits indicated by Fig. 2. The nominal setting is 375 amps.

A millivolt drop test on the breaker gives an electrical check of the main contacts. Applying 400 amps with the positive bus connected to the "generator" terminal the drop through the breaker should not exceed 100 millivolts. (NOTE: If a breaker has been standing for a considerable time with contacts open, its millivolt drop may exceed 100 mv.) This measurement should be made on the contact bar and not through any terminal stud or lugs. In general, it is necessary to switch the positive bus to the generator terminal to prevent its tripping with the 400 amps. The condition of the main contacts will vary the millivolts reading and if the value exceeds the above limits, the breaker is not satisfactory for further use without repair.

The protective case as one of its functions is intended to maintain the armature gap free from foreign materials and should not be removed at any time before or while the breaker is in service. As most repairs will require special tools, it is recommended that the breaker be returned to the factory without removing the protective case.

In Fig. 6, the protective case has been removed to show the internal construction and some of the parts have been marked for identification purposes. Under special conditions where a disassembly is needed and where the techniques used in manufacturing can be applied a partial disassembly showing the main and arcing contacts can be made by removing the four screws from the magnet supports and the four screws from the frame supports. As the mechanism is removed from the base, the latch will be released and the bell crank will operate to the tripped position. An arc shield is located between the frame support post and the base and is assembled with a post to stop the latch armature.

RENEWAL PARTS

The replacement requirements for the Type XRP breaker should be very small and it is recommended that spare breakers be carried in stock rather than several parts requiring special assembly tools for utilization. Orders should be addressed to the nearest sales office of the General Electric Company with quantity required, name or description of part, and complete nameplate data.

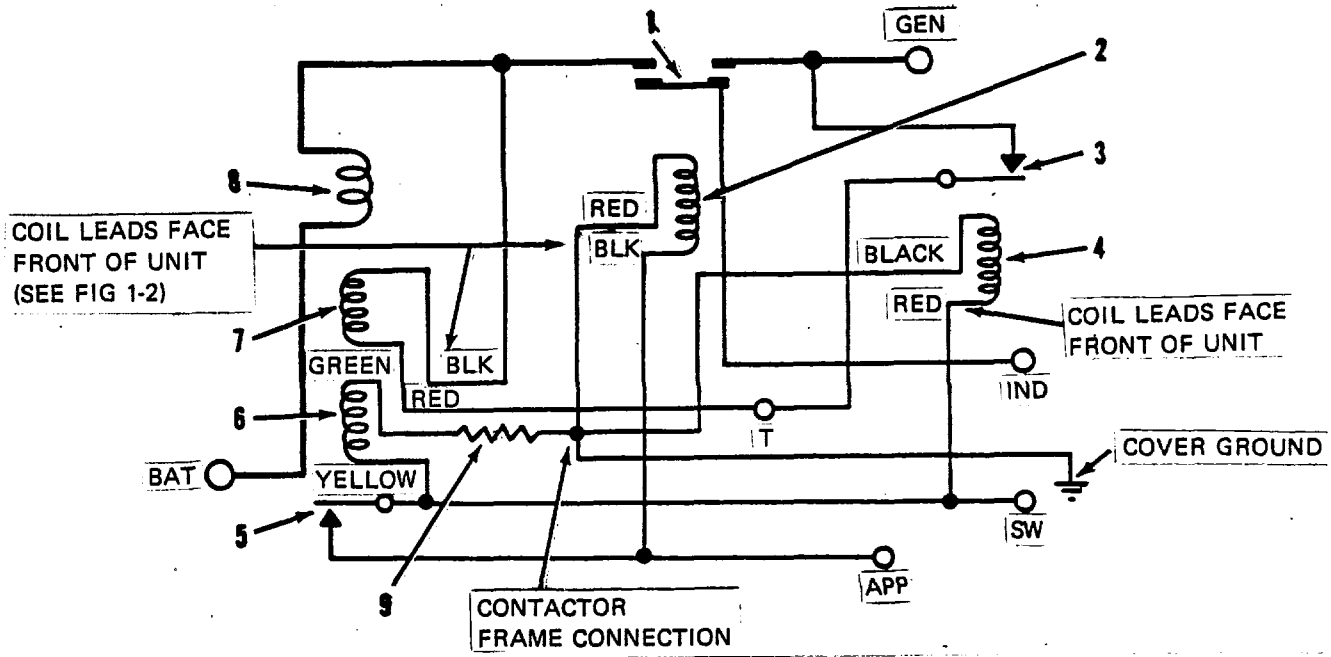
SECTION I

INTRODUCTION

1-1. IDENTIFICATION.

1-2. This handbook provides overhaul instructions and test procedures for the Cutout Relay AN 3025-300, USAF Stock No. 3380-218800-2855: The unit is manufactured by The Hartman Electrical Manufacturing Company, Mansfield, Ohio under their Part Number A-700AP. (See figures 1-1 and 1-2 for identifying views of the basic equipment unit.)

1-3. Sections I, II and III contain a description of the equipment, overhaul instructions and test procedure for the A-700AP Cutout Relay. Overhaul and test instructions for additional models are listed in Section IV by use of Difference Data Sheets. The additional models are listed in the Section IV index.



1-4. Overhaul and test procedures for the models included in Section IV are the same as the procedures given in Sections II and III, except for the specified differences noted by the applicable Difference Data Sheets.

1-5. PURPOSE OF EQUIPMENT.

1-6. The purpose of the cutout relay is to connect the generator, supplying the electrical power for the airplane, to the main bus system when the generator voltage builds up sufficiently to exceed the bus voltage. This equipment unit also serves to automatically disconnect the generator from the power bus whenever the generator voltage drops below the bus or system voltage.

1-7. Figure 1-3 is a schematic wiring diagram of the unit and shows the internal connections with the contacts in their normal positions. The sequence of operation is explained by referring to this diagram. The voltage relay coil (4) senses the generator voltage. When the generator voltage reaches between 21 to 24 volts and is of the correct polarity, the voltage relay contacts (3) will close. This energizes the differential voltage coil (7) which is connected across the main contactor contacts (1). At this time, these main contactor contacts are in the open position. The voltage on the differential voltage coil (7) is now the difference between the voltage of the generator and that of the bus or battery. When the generator voltage exceeds the bus voltage by a value between 0.35 and 0.65 volts, the differential relay contacts (5) will close. This applies voltage to the main contactor coil (2) which immediately closes the main contactor contacts (1), thereby connecting the generator to the bus system.

1-8. The generator is disconnected from the bus in a

1	MAIN CONTACTS	4	VOLTAGE RELAY COIL	7	DIFFERENTIAL VOLTAGE COIL
2	MAIN CONTACTOR COIL	5	DIFFERENTIAL RELAY CONTACTS	8	REVERSE CURRENT COIL
3	VOLTAGE RELAY CONTACTS	6	BIASING COIL	9	RESISTOR

Revised Figure 1-3. Schematic Wiring Diagram

similar manner. Whenever the generator voltage decreases below the bus voltage, a reverse current flows from the bus to the generator and through the reverse current coil (8). When the reverse current reaches a value between 16 and 25 amperes, the differential relay contacts (5) open. Voltage is then removed from the main contactor coil (2) which, in turn releases the main contactor contacts (1), disconnecting the generator from the bus.

1-9. The reverse current cutout may be opened by removal of power to the SW terminal as well as by the flow of reverse current. A biasing coil is included for the purpose of causing the differential relay contacts to open if the main contactor coil is de-energized by removal of power to the SW terminal. The differential relay contacts are, therefore, in their proper open position permitting the reverse current cutout to perform its differential voltage sensing function on the next cycle of operation.

1-10. LEADING PARTICULARS.

1-11. The leading particulars for the Cutout Relay A-700AP are listed in Table I.

TABLE I. LEADING PARTICULARS

CHARACTERISTICS	VALUE
Regulated System Voltage (d-c volts)	28
Continuous Duty Load (amperes)	300
Operating Range--Temperature (degrees)	
Minimum	-55°C (-67°F)
Maximum	71°C (158°F)
Performance:	
Operates; Voltage relay closes (volts)	21-24
Differential relay closes (volts)	0.35-0.65
Contactor pickup maximum (volts)	18
Disconnects; Voltage relay opens (volts)	18-20
Differential relay opens--reverse current (amperes)	9-25
Contactor dropout maximum (volts)	5
Terminal Connections:	
Main Terminals; Number	2
Size and thread	3/8-24
Control Terminals; Number	3
Size and thread	10-32
Weight--Approximate net (pounds)	2.7
Dimensions--Overall (inches)	
Length	4
Width	4
Height	4
Mounting Details:	
Number of Holes--0.196-inch diameter	4
Mounting Centers--(inches)	3 x 3

SECTION II

OVERHAUL INSTRUCTIONS

2-1. SPECIAL TOOLS.

2-2. A remagnetizing fixture shown in Table II is the only special tool required for the overhaul of this equipment.

TABLE II. SPECIAL TOOLS

PART NO.	NOMENCLATURE	PROCURING SERVICE STOCK NO.
8175	Remagnetizing Fixture	

2-3. DISASSEMBLY.

2-4. GENERAL. This unit of equipment consists of a number of assemblies, subassemblies, parts and attaching hardware. These are illustrated by means of a series of exploded view illustrations which show the appearance of each assembly, parts and attaching parts. During the disassembly and reassembly operations, frequent reference should be made to these illustrations. Identify all parts with respect to their positions in disassembly to ensure reassembly in the same relative positions if still usable.

NOTE

Figure 1-2 is a three-quarter view (with the cover removed) of the cutout relay. Throughout the handbook, all references to left-hand or right-hand, front or rear, top or bottom parts will be when viewing equipment as shown in this illustration.

2-5. DISASSEMBLY OF CUTOUT RELAY. (See figure 2-1.)

CAUTION

Before overhauling any unit of equipment, a visual inspection and complete bench test should be performed in order to determine what parts are defective and in need of replacement. Needless complete teardowns will be avoided if this procedure of inspecting and bench testing the equipment is followed.

a. Remove name plate (1) by removing two screws (2). Take out four screws (4) and lift off the cover base insulating plate (3). Peel off the base sealing tape (5). Remove two nuts (6), washers (7 and 8), three nuts (9) and washers (10 and 11).

b. Slide the cover (12) out after removing four screws (13). Unsnap the two relay cover assemblies and remove them from their respective positions. Disassemble the relay cover clamp (14) from the relay cover (15) if replacement is necessary.

NOTE

Using a suitable tool, remove the sealing compound covering the screws (13) to accomplish removal of the cover.

c. Unhook and remove the voltage relay spring (16) located at the top right-hand side. Take out the four screws (18) and carefully lift off the pivot bridge assemblies (17) and magnet assemblies (19).

CAUTION

Exercise care when removing the pivot bridge assembly to prevent damage to the small copper lead attached to the magnet assembly.

d. Unsolder the lead wires at the terminal points of the resistor (20). Remove the resistor by removing nut (21), washer (22) and screw (23); take off the two mica washers (24).

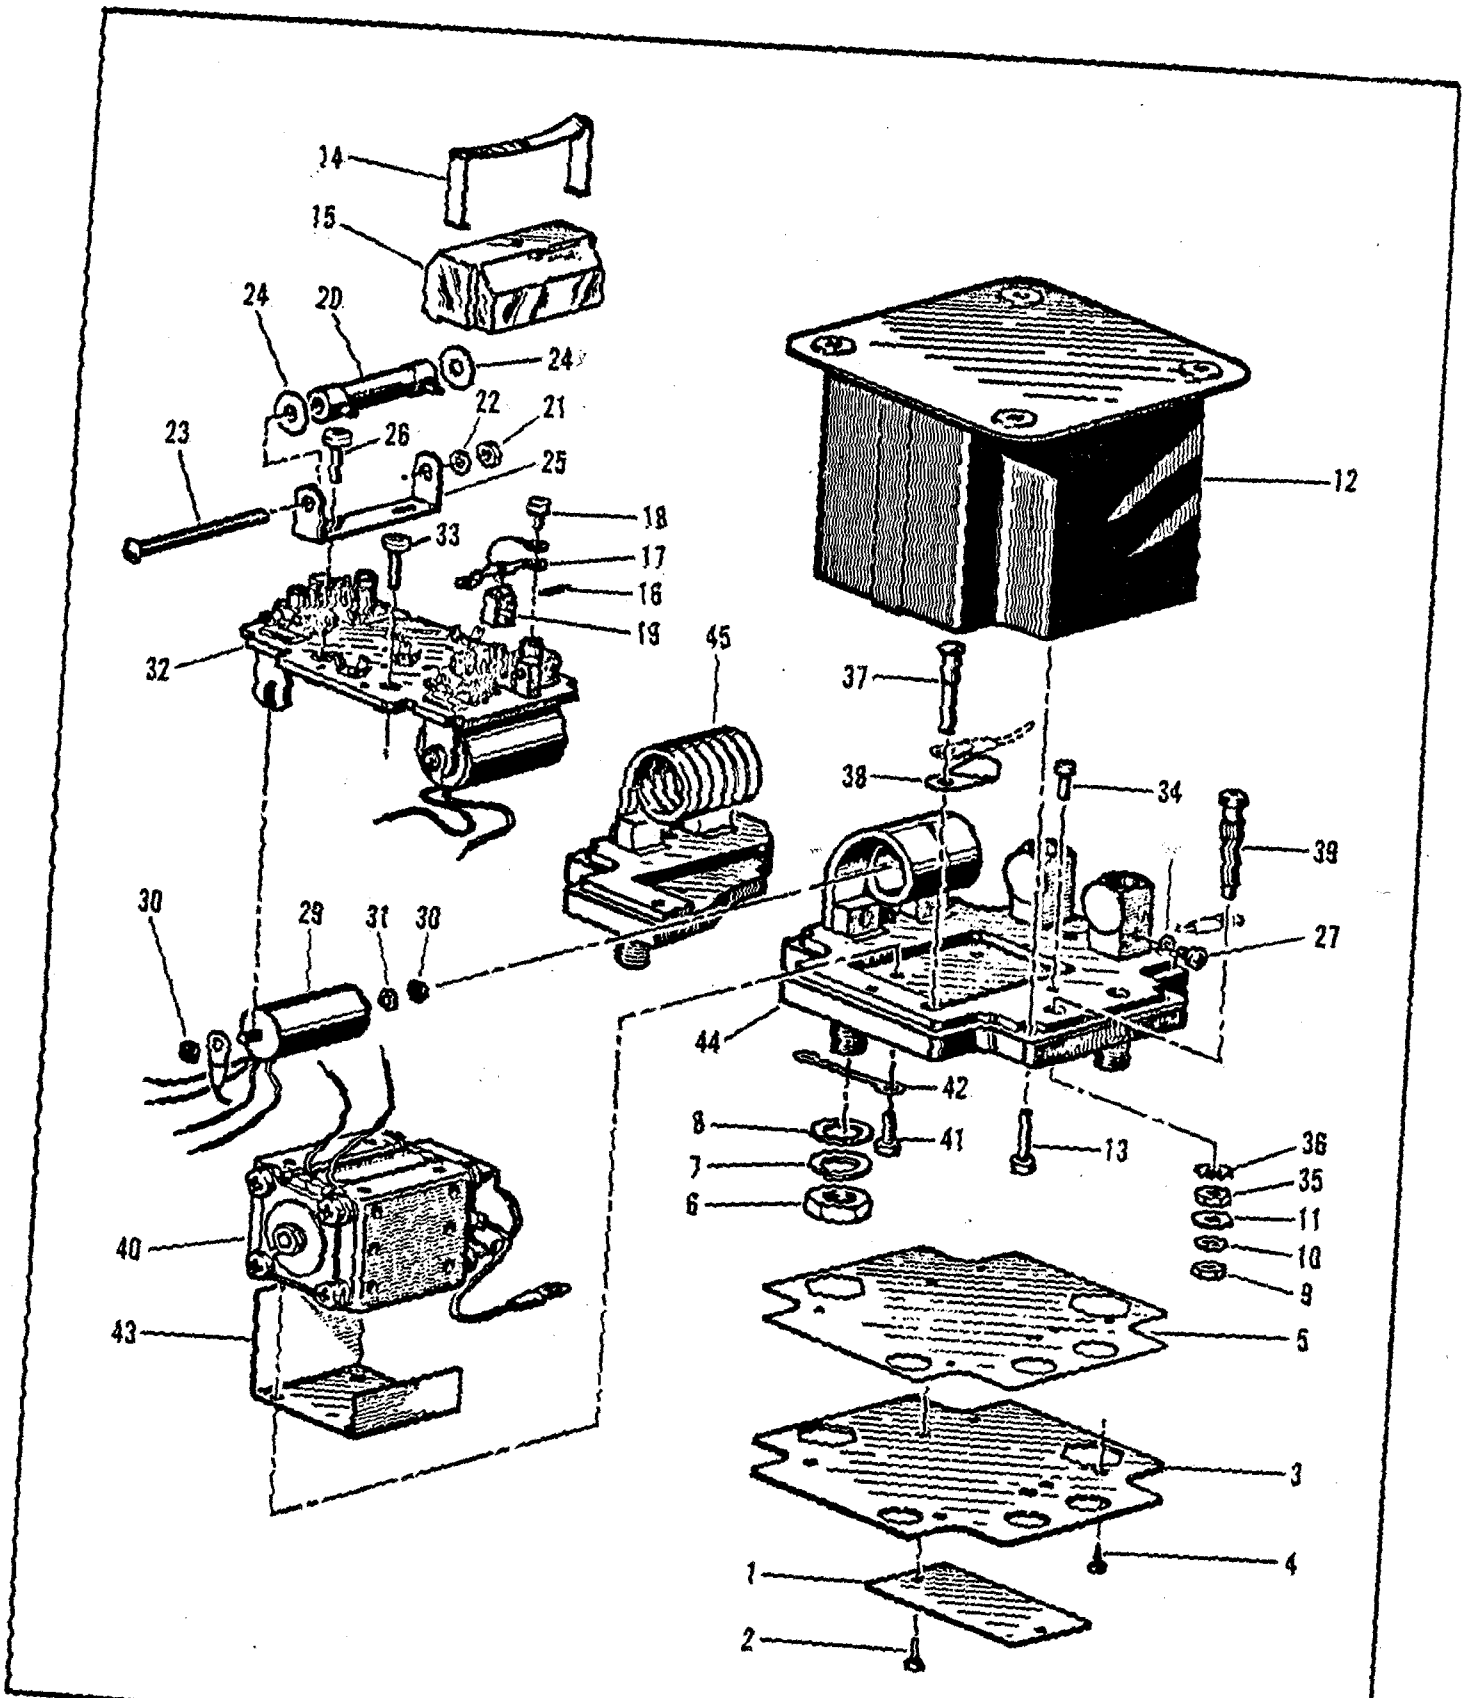

Figure 2-1. *Exploded View* of Cutout Relay Part Number A-700AP and A-718AP

NOTE

During disassembly, unsolder the lead wires of the accessible part at their respective terminal ends at time of removal. Identify the parts and lead wires with respect to their positions to ensure reassembly in the same relative positions.

e. Take out two screws (26) releasing the resistor mounting bracket (25). Remove the two screws (27) and washers (28) attaching the wire lead from the differential coil assembly (29) and voltage coil assembly (1, figure 2-2) to the contact assemblies located in the rear of the cutout relay.

f. Remove two nuts (30, figure 2-1) and one washer (31) securing the differential coil assembly (29) in place. Lift up the voltage and differential relay assembly (32) after removing two screws (33). Slide out the differential coil assembly. Removal of items (29 and 32) is accomplished after unsoldering the proper lead wires.

g. Unscrew and remove screw (34), three nuts (35) and washers (36). Using a suitable arbor, press out two long terminal screws (37) releasing the SW terminal shield (38); also press the vented terminal (39) from the main base assembly (44).

h. Remove the contactor assembly (40) from the main base assembly by removing four screws (41). Take off the two negative base connector links (42) and contactor insulating plate (43).

2-6. DISASSEMBLY OF VOLTAGE AND DIFFERENTIAL RELAY ASSEMBLY. (See figure 2-2.)

a. Take off two nuts (2) and one washer (3) to separate the voltage coil assembly (1) from its attached position, freeing the relay coil head washers (4).

b. Remove two nuts (5) and the relay spring adjusting screw (6). Loosen nuts (8) and remove the magnet adjusting screws (7). Also loosen nuts (10) and remove tipped screw contacts (9).

c. Detach the long round bridge post (11) by removing screw (12). Remove the short round bridge post (13) after taking out screw (14) thus releasing the relay spring bracket (15). Take out the two rectangular bridge posts (16) after removing screws (17). Lift out the four relay frames (18), and push out the relay mounting bushings (19) from the relay mounting plate assembly (20).

2-7. DISASSEMBLY OF CONTACTOR ASSEMBLY. (See figure 2-3.)

a. Insert nail or small drill through notch in movable contactor core (3) and hole of bottom frame tie plate (17), and remove core nut (1) and washer (2). Remove movable contactor core (3) and shims (4).

NOTE

Record the amount of shims removed; this will facilitate the amount needed in reassembly.

b. Withdraw the contact and rod assembly and remove core nut (5), washer (6), contact insulating nut (7), main movable contact assembly (8), indicator terminal lead assembly (9) and main contact loading spring (10) from the core rod and bushing assembly (11).

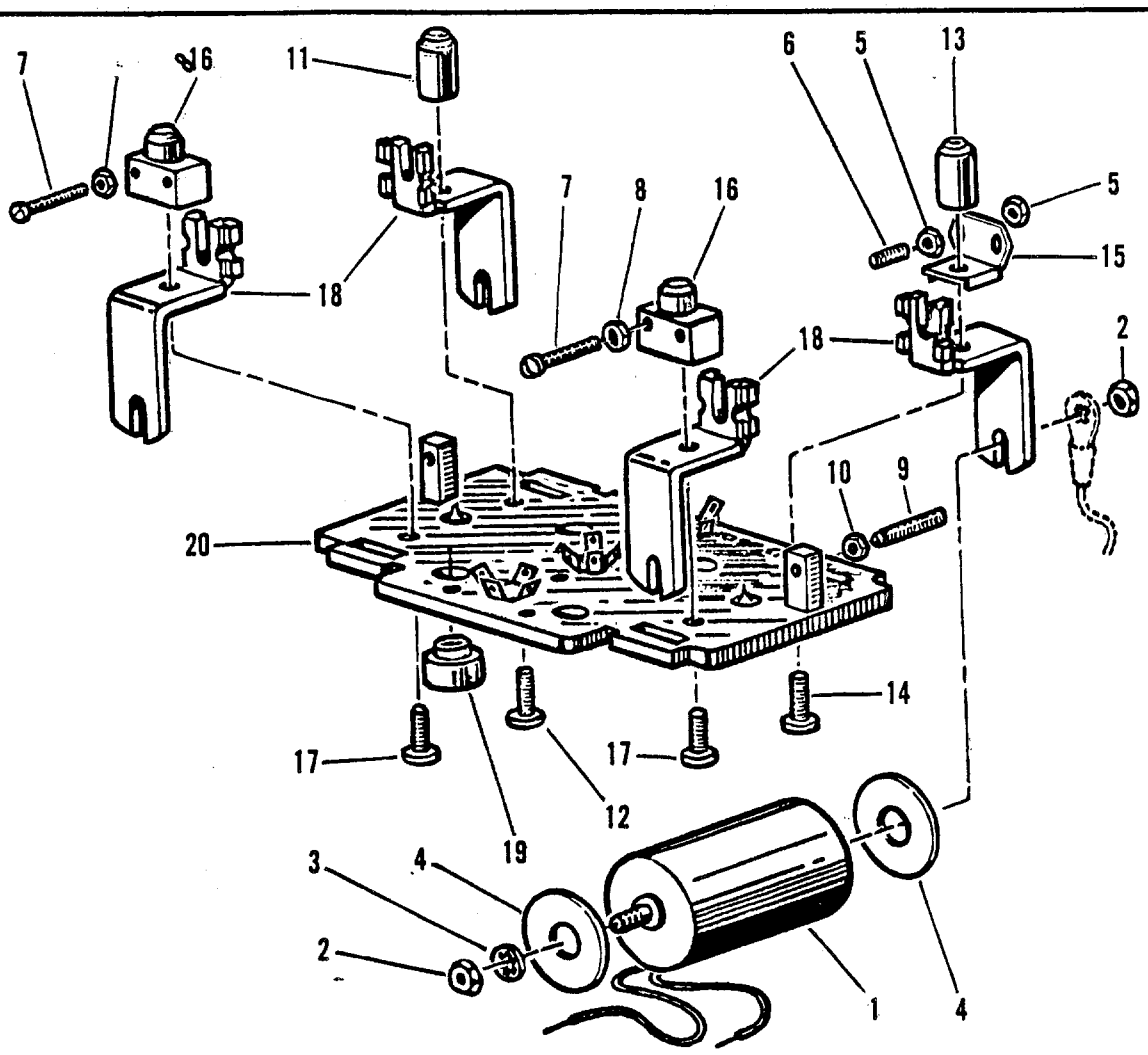
c. Remove the contactor core spring (12), stationary core locking nut (13) which locks the stationary core assembly (22) to the top frame tie plate (14). Take off the top frame tie plate by removing four screws (15) and two washers (16). Also remove the bottom frame tie plate (17) after removing four screws (18).

d. Disassemble the two contactor frames (19), coil insulating plate (20), coil spring washer (21) and stationary core assembly (22) from the contactor coil assembly (23).

2-8. DISASSEMBLY OF MAIN BASE ASSEMBLY. (See figure 2-4.)

a. Take out the main short stationary contact assembly (1) after removing the special screw (2) and the wide bearing lock washer (3). Remove terminal post locking nut (5) and lift out the main long stationary contact assembly (4).

b. Withdraw the series coil assembly (6) after taking out special screw (8), wide bearing lock washer (9) and terminal post locking nut (10). If necessary to replace the guide base (11), remove it by removing two rivets (12).



c. Lift out the contact post link (13), two base spacer washers (14) and four large base spacer washers (15). Remove the base gasket (16) and base stud seat washers (17) from the main base (18).

2-9. CLEANING.

2-10. GENERAL. Before reassembling the magnets into the relays which have been torn down, the magnets shall be demagnetized, cleaned of all chips, and remagnetized. All parts, including the relay while magnets are out should be blown clean with compressed air. Hold the air hose about one foot away. The magnets can be remagnetized by means of the remagnetizing fixture Part No. 8175, used with a suitable magnet charger. Care should be taken to remagnetize in the same direction (North and South) as originally magnetized. The contacts may be cleaned by rubbing on paper, or by running paper between the contacts after magnets are assembled in the relay. No cleaning of the large contacts is necessary. Clean the cover with a dry cloth.

CAUTION

Do not permit any two magnets to touch after magnetization.

1 Voltage Coil Assembly	8 Nut	15 Relay Spring Bracket

6 Relay Spring Adjusting Screw	13 Short Round Bridge Post	20 Relay Mounting Plate Assy
7 Magnet Adjusting Screw	14 Screw	

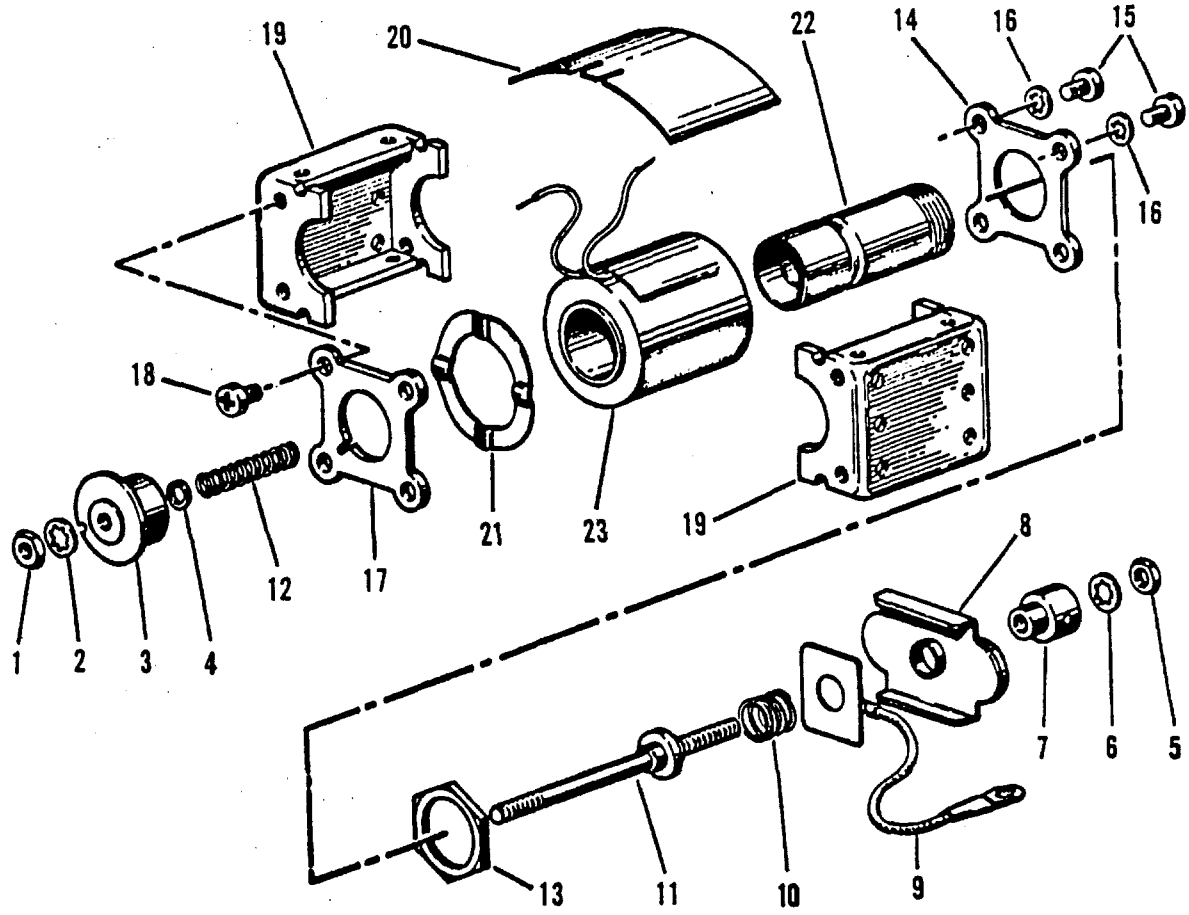
Figure 2-2. Exploded View of Voltage and Differential Relay Assembly

2-11. INSPECTION.

2-12. GENERAL. Inspect the voltage relay spring for discoloration from heat. Examine coil leads and wire leads for broken wires or insulation. Check and replace any part which appears to be worn, burned, broken or distorted.

NOTE

Continuity check can be made with an ohmmeter to determine if lead wires or part is intact.



2-13. TESTING.

2-14. GENERAL. Check the resistance of the parts shown in Table III at a temperature of 25°C (77°F). Replace any part which is not within its specified value.

2-15. REPAIR OR REPLACEMENT.

2-16. GENERAL. Any part found to be worn, burned, broken, or distorted should be replaced.

a. Replace all lead wiring having damaged insulation

1. Core Nut
2. Washer
3. Movable Contactor Core
4. Shim
5. Core Nut
6. Washer

17. Base Stud Seat Washer
18. Main Base

Figure 2-4. Exploded View of Main Base Assembly

2-17. LUBRICATION.

2-18. No lubrication of the equipment is required.

2-19. REASSEMBLY.

2-20. GENERAL. Refer to the exploded view illustrations and the Schematic wiring diagram (figure 1-3) when reassembling the equipment. Reassembly is essentially the reverse of disassembly and in accordance with the exploded views except for the following instructions.

CAUTION

The rewiring and soldering of the various parts are best accomplished at time of reassembly of the component part or parts. All wires that are not insulated should have a piece of tubing between the connecting points. Excessive flux and solder should be avoided at all connection points.

2-21. REASSEMBLY OF MAIN BASE ASSEMBLY. (See figure 2-4.)

a. Position the two base stud seat washers (17) in the recessed holes provided for in the main base (18). Place the base gasket (16), large base spacer washers (15), base spacer washers (14) and the contact post link (13) into their respective positions on the main base.

b. If the guide base (11) was removed, replace it and secure with two rivets (12). Fasten the series coil assembly (6) to the main base with terminal post locking nut (10), wide bearing lock washer (9) and special screw (8).

c. Insert the main long stationary contact assembly (4) into place and secure with terminal post locking nut (5). Attach the main short stationary contact assembly (1) in position with wide bearing lock washer (3) and special screw (2).

2-22. REASSEMBLY OF CONTACTOR ASSEMBLY. (See figure 2-3.)

a. Thread the stationary core assembly (22) through the top frame tie plate (14). Loosely thread the stationary core locking nut (13) onto the stationary core assembly. Place the contactor coil assembly (23) over the stationary core assembly, position the coil spring washer (21) and coil insulating plate (20) on the contactor coil assembly (23).

b. Position the two contactor frames (19) around the contactor coil assembly with the leads up and through the notches in the coil insulating plate. Loosely fasten the top frame tie plate (14) to the contactor frames with washers (16) and screws (15). Attach the bottom frame tie plate (17) to the contactor frames with the notch pointing to the left and towards the bottom. Pressing frames toward each other, secure bottom frame tie plate with four screws (18). Tighten screws (15).

c. Adjust stationary core assembly (22) by means of the slot at the end until it just touches the movable contactor core (3) held tightly in place with the fingers. Lock with stationary core locking nut (13) and stake to top frame tie plate (14) and on thread of stationary core assembly in this position.

NOTE

A slotted wrench holding a section of hacksaw blade cut to fit the stationary core slot assembly will be helpful in making this adjustment.

d. Place the main contact loading spring (10), indicator terminal lead assembly (9) and main movable contact assembly (8) over the core rod and bushing assembly (11). Then screw the contact insulating nut (7) until the rod extends beyond the contact insulating nut approximately 1/8-inch. Install the washer (6) and core nut (5), tightening the nut while holding the insulating nut with a 3/32-inch rod or drill inserted in the hole of the insulating nut.

e. Insert core rod and bushing assembly (11) through the cavity in the stationary core assembly (22) and position contactor core spring (12) over the core rod and bushing assembly; replace shims (4) which were removed during disassembly. Screw movable contactor core (3) on the core rod and bushing assembly until there is a 0.093-inch gap between shoulder of movable contactor core and bottom frame tie plate (17).

f. The notch in shoulder of the movable contactor core should be aligned with notch in the bottom frame tie plate. Install washer (2) and core nut (1), tighten core nut while holding movable contactor core with nail or small drill inserted through notch in its rim and notch in the bottom frame tie plate.

2-23. REASSEMBLY OF VOLTAGE AND DIFFERENTIAL RELAY ASSEMBLY. (See figure 2-2.)

2-24. Reassembly is in the reverse of disassembly and in accordance with the exploded view figure 2-2, except as follows:

2-25. Do not run in relay spring adjusting screw (6), magnet adjusting screw (7) and tipped screw contact (9) all the way in or tighten the nut until adjusting the relay as described in a later paragraph.

NOTE

The manufacturer recommends that radio service cement, part number 30G, manufactured by the General Cement Mfg. Co., Rockford, Illinois, or equivalent be used to seal the heads of screws (12, 14 and 17) after assembling screws into position.

2-26. REASSEMBLY OF CUTOUT RELAY. (See figure 2-1.)

2-27. Reassembly is in the reverse of disassembly and in accordance with the exploded view figure 2-1, except as follows:

a. Solder lead wires to their respective components as shown in figure 1-3.

NOTE

Use rosin-flux core solder, Composition Sn60, Federal Specification QQ-S-5716.

CAUTION

Exercise care when replacing the pivot bridge so that damage is not caused to the small copper lead of the magnet assembly.

b. Do not assemble the cover (12, figure 2-1) or relay covers (15) until preliminary adjustment procedure has been accomplished as described in paragraph 2-29.

c. Apply radio service cement to adjusting screws and nuts after preliminary adjustments have been completed. Application to be made with a toothpick.

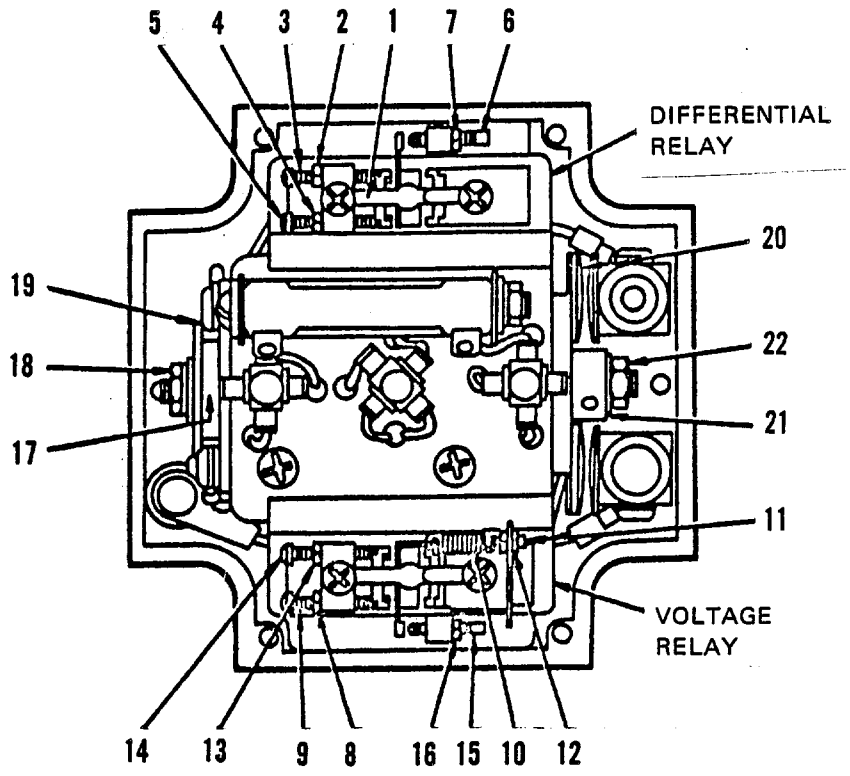
d. The manufacturer of this equipment recommends that the two cover screws (13), which do not have ground links under them and the two rivet heads attaching the cover base (3) to the main base assembly (45) be covered with microstone green gypsum material, or equivalent manufactured by the Whip-Mix Corporation, Louisville, Kentucky.

2-28. IDENTIFICATION. At the completion of the overhaul or repair of an equipment unit, a stamp bearing the name of the overhaul activity and the date of overhaul or repair should be applied to the unit.

2-29. ADJUSTMENT PROCEDURE.

2-30. GENERAL. Adjustments are made after the unit is assembled complete except for unit cover and relay covers. See figures 2-5 and 2-6 for adjustment points and test procedures, respectively.

CAUTION



Extreme care must be taken to prevent metal chips from collecting on the armature magnets during adjustments. Any which do collect should be carefully removed with the aid of a sharply pointed pick or scribe.

2-31. DIFFERENTIAL RELAY ADJUSTMENT.

a. Adjust the end play of the magnet assembly to approximately 0.005-inch by loosening the locking nut on the pivot bridge assembly (1, figure 2-5) turning the pivot screw in or out as required. Lock nut on pivot screw.

NOTE

On units which do not have the threaded pivot, adjust the end play of the magnet assembly to approximately 0.005-inch by carefully bending the pivot bridge assembly (1) as required.

20. Movable Contact
21. Insulating Nut
22. Nut

Figure 2-5. Adjustment Procedure Diagram

b. Connect the unit into the test circuit shown in figure 2-6, placing all switches in the open position.

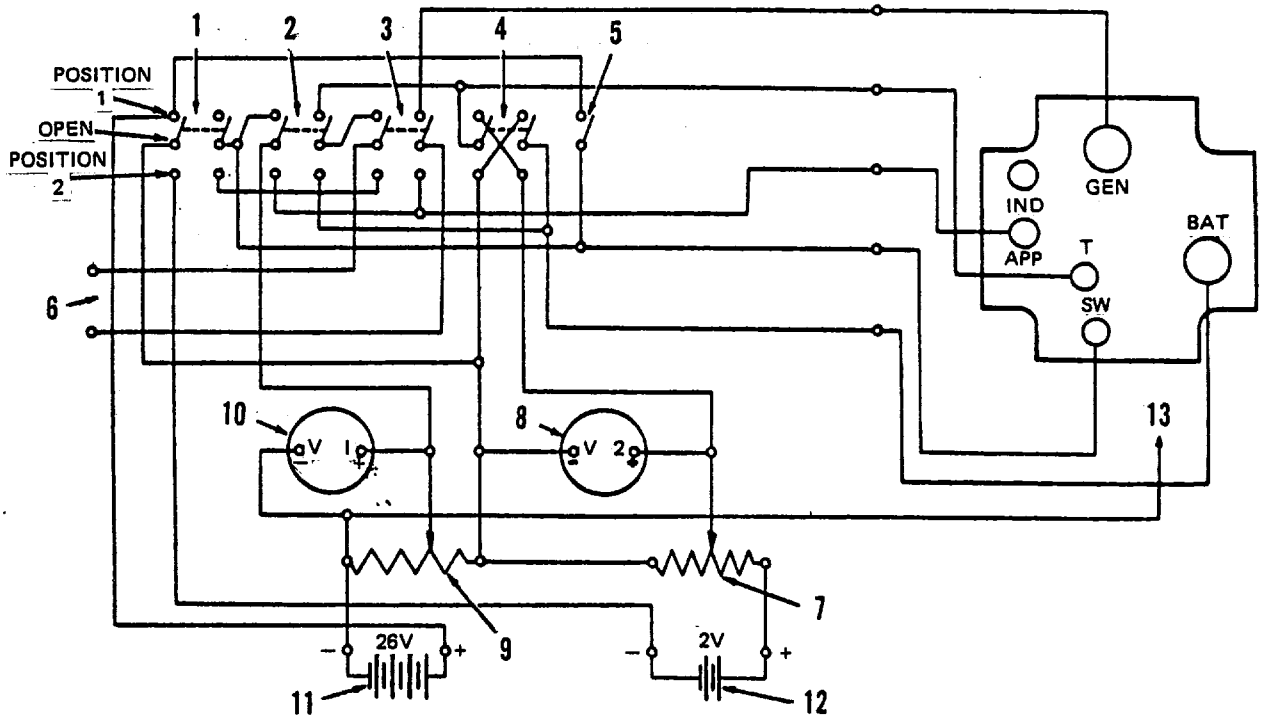
c. Place switch (1) in position 2, switch (4) in position 1, and close switch (5). Vary voltage by means of potentiometer (7) and read on voltmeter (8).

NOTE

The voltage relay may close, if its adjustment is approximately correct. Place a piece of paper, or other insulation, between the voltage relay contacts, because the contacts should not touch during this adjustment.

d. Loosen lock nut (2, figure 2-5) and adjust screw (3) until relay closes at a voltage between 0.45 and 0.55 volt. Tighten nut (2).

NOTE



When the differential relay contacts close, the main contactor will close also. After each adjustment is made, the adjusting screw should be held firmly while the lock nut is tightened.

e. Place switch (4, figure 2-6) in position 2, reversing the polarity of the voltage applied to the differential coil.

f. Loosen lock nut (4, figure 2-5) and adjust screw (5) until the relay opens at a voltage between 0.31 and 0.37 volt, and with contact screw (6) set so that when the relay is closed, the contacts would remain engaged for at least one-half turn if screw (6) is backed out. Tighten nut (7) on screw (6).

g. Open switch (5, figure 2-6), place switch (4) in position 1, and remove the insulation from the voltage relay contacts. Vary potentiometer (7) to reclose the differential relay, disregarding the closing voltage reading.

h. Decrease the voltage by means of potentiometer (7) until the relay opens. The relay must open at a voltage above 0.04 volts.

1. DPDT Switch
2. DPDT Switch
3. DPDT Switch
4. DPDT Switch
5. SPST Switch
6. Ohmmeter Connections
7. 0.25 Ampere, 100 Ohms Potentiometer
8. 0-2 Volts DC Voltmeter
9. 1.5 Ampere, 50 Ohms Potentiometer
10. 0-30 Volts DC Voltmeter
11. 26 Volt DC Battery
12. 2 Volt DC Battery
13. Negative Connection to Frame of Contactor Assy

Figure 2-6. Test Circuit Used for Adjustments

NOTE

The above adjustments will result in the differential relay opening when there is a flow of reverse current as well as when the "SW" terminal is de-energized.

i. Open all switches before proceeding with the next adjustment.

2-32. VOLTAGE RELAY ADJUSTMENT.

a. Adjust the end play of the magnet assembly to approximately 0.005-inch by loosening the locking nut on the pivot bridge assembly (1, figure 2-5) turning the pivot screw in or out as required. Lock nut on pivot screw.

NOTE

On units which do not have the threaded pivot, adjust the end play of the magnet assembly to approximately 0.005-inch by carefully bending the pivot bridge assembly (1) as required.

b. Adjust screw (9) until relay armature gaps are approximately equal. Lock screw (9) with nut (8).

c. Place switches (1 and 2, figure 2-6) in position 1 and vary the voltage by means of potentiometer (9).

d. Adjust tension of spring (10, figure 2-5) by means of spring screw (11) and nuts (12) until relay closes at approximately 22 volts. Increasing tension of spring (10) will increase both the closing and opening voltages, while decreasing tension will lower both voltages.

NOTE

Adjust tension of spring (10) by first loosening one nut (12) and then tightening other nut (12). Make adjustments in small steps, each time tightening the nut.

e. Loosen lock nut (13) and adjust screw (14) until relay opens at 19 volts and with contact screw (15) set so that when the relay is closed, the contacts would remain closed for at least one-half turn if screw (15) were backed out. Lock screw (14) with nut (13) and screw (15) with nut (16).

2-33. CONTACTOR ADJUSTMENT.

a. Adjust the gap (17) between the core rim and the contactor frame to 0.093-inch. This gap represents the total movable core travel. To adjust, loosen nut

(18) and screw movable core (19) in or out. The core can be held while tightening nut (18) by inserting a 3/32-inch rod or drill through the notch in the movable core into the hole in the frame.

b. The contact overtravel, which is the distance the core travels after the contacts (20) touch, should be adjusted to approximately 0.020-inch. To make this adjustment, insert a 3/32-inch rod or drill in the hole in insulating nut (21), and hold nut to loosen lock nut (22). Still holding nut (21), rotate entire core and rod assembly. Lock nut (22).

c. Place switch (1, figure 2-6) in position 1 and switch (2) in position 2, and vary the voltage by means of potentiometer (9) to close and open the contactor. It should close between 14 and 15 volts, and open below 5 volts.

NOTE

This test should be conducted before the coil has become heated, and with the contactor in a horizontal position. The position will have some affect on the operating voltage, even though the cutout may be mounted in any position in the aircraft.

d. If the contactor closes below or above the limits, remove the movable core (19, figure 2-5) and add or remove shims, respectively, as required. In no case shall there be more than three shims used. Replace the movable core, readjust, and repeat the test, outlined in paragraph 2-33c, until the contactor closes within the limits.

e. If the contactor picks up, but does not complete its full stroke within the specified voltage limits, reduce the main contact overtravel slightly.

SECTION III

TEST PROCEDURE

3-1. TESTING WITH TEST STAND.

3-2. EQUIPMENT REQUIRED. (See figure 3-1.)

a. Direct Current Generator, 0-28 volts 300 amperes.

b. Voltage Regulator.

c. SPDT Switch.

d. Generator Field Rheostat.

e. SPDT Switch.

f. SPDT Switch.

g. 0-30 Volt DC Voltmeter.

h. SPST Switch.

i. SPDT Switch.

j. 0-5 Volt DC Voltmeter.

k. 300-0-30 Ampere DC Ammeter.

l. 300 Ampere at 28 Volts Load Bank.

m. 0-100 Millivolts DC Millivoltmeter.

n. 26 Volt DC Battery.

3-3. DIFFERENTIAL VOLTAGE AND REVERSE CURRENT OPERATION.

a. Connect the relay as shown in figure 3-1.

b. Place all switches on the "OFF" position.

c. Operate the generator (1) at a speed between 3000 and 4500 revolutions per minute.

d. With the switch (3) in position 1, adjust the generator voltage by means of the rheostat (4) so that the voltage is approximately one volt less than battery voltage.

NOTE

The voltages of the battery (14) and generator (1) can be read and readily compared by means of placing the switch (6) alternately in positions 1 and 2 and noting the reading on voltmeter (7).

e. With the switch (5) in position 1 and switch (8) closed, place switch (9) in position 1 and slowly increase the generator voltage by means of the rheostat (4). When the cutout operates, the voltage indicated on voltmeter (10) will go to zero. The differential voltage is the reading just before the voltmeter reading goes to zero and should be between 0.35 and 0.65 volts.

CAUTION

Switch (9) must be opened before the next test.

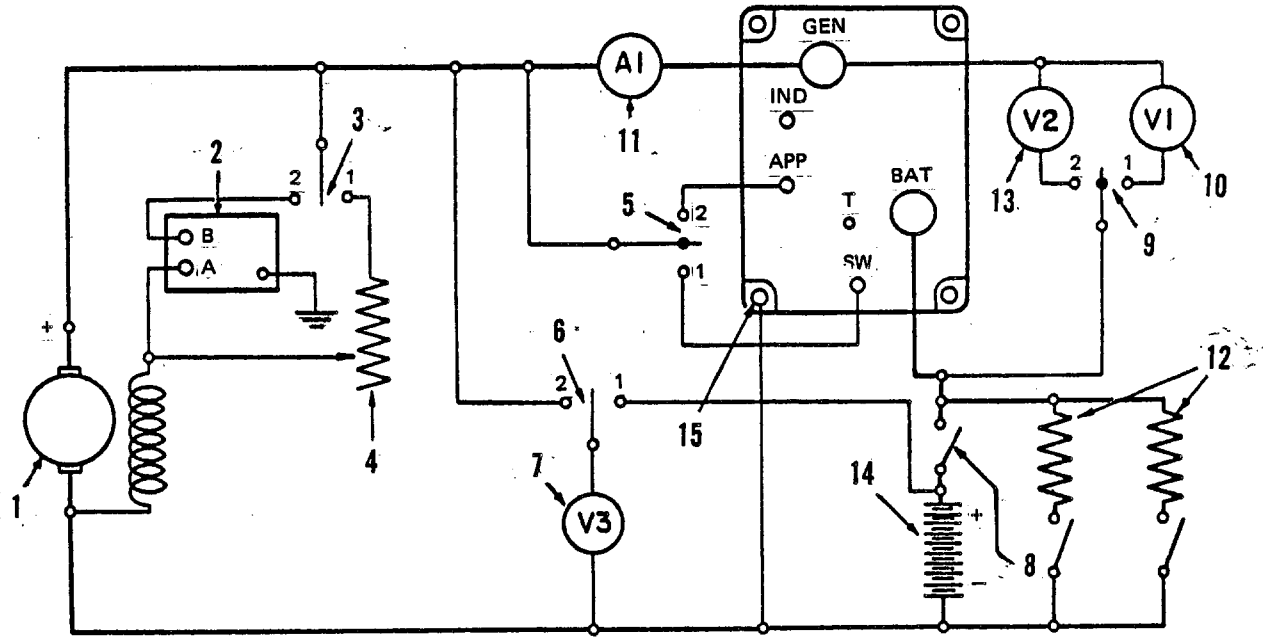
f. Measure the reverse current opening by slowly decreasing the generator voltage by means of the rheostat (4) until the cutout opens. The reverse current is read on ammeter (11) just before the reading goes to zero. The reverse current opening should be between 9 and 25 amperes when the generator voltage is at 26 volts. If the generator voltage read on voltmeter (7) with switch (6) in position 2 is not 26 volts, use Table IV to obtain the corresponding reverse current opening for various voltages.

TABLE IV. REVERSE CURRENT OPENING

GENERATOR VOLTAGE (volts)	REVERSE CURRENT (amperes)	
	Min	Max
28	11	27
26	9	25
24	7	23
22	5	21

g. Test for opening of the differential relay due to removal of power to the "SW" terminal, first repeat the procedure steps, paragraphs 3-3c through 3-3e.

h. Decrease the generator voltage by means of rheostat (4) until the current reading on ammeter (11) has decreased to approximately zero, then open switch (18).



i. Again decrease the generator voltage, dropping out the contactor, then continue to decrease the voltage to the lowest value possible.

j. Open switch (5). The differential contacts now should have opened. To check for open contacts, place an ohmmeter across terminals "SW" and "APP", and note the resistance reading. The ohmmeter should read approximately 200 ohms. If the contacts remained closed, the ohmmeter will read zero resistance.

k. If the cutout does not operate within the specified limits, refer to Table V.

3-4. TESTING VOLTAGE RELAY.

a. Set all switches in the "OFF" position.

1. 28 Volt DC 300 Ampere Generator
2. Voltage Regulator
3. SPDT Switch
4. Generator Field Rheostat
5. SPDT Switch
6. SPDT Switch
7. 0-30 Volts DC Voltmeter
8. SPST Switch
9. SPDT Switch
10. 0-5 Volt DC Voltmeter
11. 300-0-30 Ampere DC Ammeter
12. 300 Amp at 28 Volts Load Bank
13. 0-100 Millivolts DC Millivoltmeter
14. 26 Volt DC Battery
15. Negative Cover Connection

Figure 3-1. Test Circuit with Test Stand

b. Operate the generator at a speed between 3000 and 4500 RPM.

c. Place switches (3 and 5) in position 1, and switch (6) in position 2. Slowly vary the voltage by means of rheostat (4). The closing voltage should be between 20 and 24 volts and is read on voltmeter (7) when the relay operates. The opening voltage should be above 18 volts.

d. Connect an ohmmeter from the "GEN" terminal to the "T" test terminal to indicate when the voltage relay contacts have closed. Remove the name plate and make a connection to terminal "T" by means of a 6-32 screw, 1/2-inch or longer, screwed into the tapped hole. This hole is located approximately midway between terminals "APP" and "SW". File a point on the screw so that you may be sure of a positive connection. After testing, remove the screw and replace the name plate.

3-5. TESTING CONTACTOR.

a. Set all switches in the "OFF" position.

NOTE

This test should be made before the contactor coil has become heated, and with the relay placed such that the four mounting holes are flat on the table. The position of the relay will have some effect on this operating voltage, even though the relay may be mounted in any position in the aircraft.

b. Operate the generator at a speed between 3000 and 4500 rpm.

c. Place switch (3) in position 1, switches (5 and 6) in position 2, then vary the voltage by means of rheostat (4) to close and open the contactor. The closing voltage, read on voltmeter (7), should be between 14 and 15.5 volts. The opening voltage should be 5 volts or below.

3-6. MILLIVOLT DROP TEST.

a. Set all switches in the "OFF" position.

b. Operate the generator at a speed between 4500 and 6000 rpm.

c. Place switch (3) in position 2, and adjust regulator to 28.5 volts.

d. Place switch (5) in position 2, then close load bank switches until a current of 300 amperes is read on ammeter (11).

e. Place switch (9) in position 2 and read the millivolt drop on millivoltmeter (13). The drop should not exceed 100 millivolts.

CAUTION

Place switch (9) in the open position before permitting the relay to open.

f. If the millivolt drop exceeds the allowable limit, refer to Table V, "Trouble Shooting".

3-7. DIELECTRIC TEST.

a. Remove the two screws (13, figure 2-1) which connect the cover (12) and negative base connector links (42) to the main base assembly (44).

b. Using a suitable dielectric tester, apply a voltage of 1250 volts rms, commercial frequency, for a period of one second between the following points: each terminal to cover: "BAT" terminal to terminals "IND", "APP" and "SW"; "GEN" terminal to terminals "IND", "APP" and "SW". No breakdown shall occur as a result of this test.

c. Apply 500 volt rms, commercial frequency, for a period of one second between terminals "GEN" and "BAT". No breakdown shall occur.

3-8. TROUBLE SHOOTING.

3-9. A list of the most common troubles, their probable cause and suggested remedy is shown in Table V.

TABLE V. TROUBLE SHOOTING

TROUBLE	PROBABLE CAUSE	REMEDY
VOLTAGE RELAY WILL NOT CLOSE	Improperly connected or faulty generator.	Check connection, generator voltage and polarity.
	Relay coil open or leads broken.	Replace coil.
	Relay improperly adjusted.	Readjust relay.
	Chips on permanent magnet.	Remove chips.
VOLTAGE RELAY WILL NOT OPEN	Broken or damaged spring.	Replace spring.
	Relay improperly adjusted.	Readjust relay.
	Chips on permanent magnet.	Remove chips.
DIFFERENTIAL RELAY WILL NOT CLOSE BUT VOLTAGE RELAY IS CLOSED	Relay coil open or leads broken.	Replace coil.
	Voltage relay contacts not touching.	Clean contacts and readjust voltage relay.
	Chips on permanent magnet.	Remove chips.
	Relay improperly adjusted.	Readjust relay.
DIFFERENTIAL RELAY WILL NOT OPEN	Chips on permanent magnet.	Remove chips.
	Relay improperly adjusted.	Readjust relay.
REVERSE CURRENT OPENING TOO LOW	Differential relay improperly adjusted.	Readjust relay.
	Bias winding of differential relay open.	Replace differential coil.
	Resistor open.	Replace resistor.

TABLE V. TROUBLE SHOOTING (Cont)

TROUBLE	PROBABLE CAUSE	REMEDY
CONTACTOR WILL NOT CLOSE BUT VOLTAGE RELAY AND DIFFERENTIAL RELAY ARE CLOSED	Differential relay contacts do not touch.	Clean contacts and readjust differential relay.
	Contactor coil open or leads broken.	Replace coil.
	Excessive friction on movable core.	Replace stationary core.
	Core rod bent.	Replace core rod.
CONTACTOR WILL NOT OPEN BUT DIFFERENTIAL RELAY IS OPEN	External short circuit between "SW" and "APP" terminals.	Correct short circuit.
	Core rod bent.	Replace core rod.
	Contactor contacts out of adjustment.	Readjust contacts.
CONTACT MILLIVOLT DROP ABOVE MAXIMUM LIMIT	Insufficient contact overtravel.	Readjust contacts.
	Insufficient contact spring pressure.	Stretch contact spring slightly.
	Contactor contacts dirty.	Clean contacts.

SECTION IV

DIFFERENCE DATA SHEETS

NOTE

Overhaul and test procedures for the items included in this section are the same as procedures for the cutout relay Part Number A-700AP except for the difference noted by the applicable Difference Data Sheets. Section I through III contain complete overhaul and test information for the cutout relay Part Number A-700AP.

INDEX OF PART NUMBERS

Part Number	Page
A-718AP	19

CUTOUT RELAY — PART NO. A-718AP

THE INSTRUCTIONS CONTAINED IN PRECEDING SECTIONS OF THIS HANDBOOK APPLY EXCEPT FOR THE DIFFERENCES GIVEN IN THIS DATA SHEET.

TABLE VI. LEADING PARTICULARS

CHARACTERISTICS	VALUE
Continuous Duty Load - - (amperes)	100
Disconnects - - Differential relay opens - - reverse current (amperes)	4-10

SPECIAL TOOLS. Same as Part No. A-700AP.

DISASSEMBLY. Same as Part No. A-700AP except as follows:

a. Remove main base assembly (45, figure 2-1) instead of (44). Remove 6T series coil assembly (7, figure 2-4) instead of series coil assembly (6).

CLEANING. Same as Part No. A-700AP.

INSPECTION. Same as Part No. A-700AP.

TESTING (during overhaul). Same as Part No. A-700AP.

LUBRICATION. Same as Part No. A-700AP.

REASSEMBLY. Same as Part No. A-700AP except as follows:

a. Reassembly is the same except as noted in the disassembly portion of this data sheet and as described here.

b. Instead of the adjustment as stated in paragraph 2-31f, it should read as follows: Loosen lock nut (4, figure 2-5) and adjust screw (5) until relay opens at a voltage between 0.37 and 0.43, and with contact screw (6) set so that when the relay is closed the contacts would remain engaged for at least one-half turn if screw (6) is backed out.

TEST PROCEDURE (after overhaul). Same as Part No. A-700AP except as follows:

a. Paragraph 3-3f should read: measure the reverse current opening by slowly decreasing the generator voltage by means of rheostat (4, figure 3-1) until the cutout opens. The reverse current is read on ammeter (11) just before the reading goes to zero. The reverse current opening should be between 4 to 10 amperes when the generator voltage is at 26 volts. If the generator voltage reading on voltmeter (7) with switch (6) in position 2 is not 26 volts use Table VII to obtain the corresponding reverse current opening for various voltages.

b. The following table of reverse current opening values should be used instead of Table IV.

TABLE VII. REVERSE CURRENT OPENING

GENERATOR VOLTAGE (volts)	REVERSE CURRENT (amperes)	
	Min	Max
28	4.75	10.75
26	4	10
24	3.25	9.25
22	2.50	8.50

c. Paragraph 3-6d should read: place switch (5) in position 2, then adjust the current to 100 amperes. The millivolt drop should not exceed 100 millivolts with a current of 100 amperes.

SECTION I

INTRODUCTION

1-1. GENERAL.

1-2. This Illustrated Parts Breakdown provides complete information necessary to identify and requisition the parts, subassemblies and assemblies for the type AN3025-300 and AN3025-100 Cutout Relays. The Cutout Relays are manufactured by The Hartman Electrical Manufacturing Company, Mansfield, Ohio, under their P/N A-700AP, USAF S/N 3380-218800-2855 and A-718AP, USAF S/N 3380-218800-2755 (See figure 1 for an assembled view of representative equipment.)

1-3. The Table of Contents shows the method of grouping the assemblies and the sequence of the groups and indicates that the handbook is divided into three sections.

1-4. The first column lists the figure and index numbers for all items illustrated in each exploded view. The Part Number and description of the assembly or part are given in the next two columns with the quantity required shown in the fourth column. The last column provides for model variations as applicable. In the Group Assembly Parts List section, all of the assemblies and parts are arranged in the order of disassembly with the exception of the attaching parts which follow immediately after the item to be attached. Subassemblies are indented to indicate their relationship to the complete assembly. Associated with each list is an exploded view illustration. These drawings serve to show the relative positions of the various components and to fully identify all assemblies and parts. Where a subassembly requires an additional illustration to show the breakdown of detail parts, a cross reference is provided in the group assembly listing to locate the details of the subassemblies.

1-5. In this handbook the Hartman part numbers assigned to cover the complete units of equipment are prefixed with the letter "A". Each Hartman number used to identify parts is either a four or five digit number. In some instances, a dash suffix has been assigned as an aid in requisitioning parts so that correct parts can be obtained for maintenance purposes. Air Force and Navy standard parts are prefixed with the letters AN. Commercial parts are identified by the use of the symbol COMM.

1-6. The quantities listed in the "UNITS PER ASSY" column of the Group Assembly Parts List are in the case of assemblies, the total quantity used per unit of equipment at the location indicated, while the component parts indented under the assemblies only show the quantity used per assembly. Therefore, the quantities specified are not necessarily the total used per unit of equipment. Refer to the Numerical Index (Section III) for the total quantities of all items required.

1-7. Overhaul instructions for the Cutout Relay, covered in this Illustrated Parts Breakdown, are contained in T.O. 8R1-3-2-93.

1-8. When the stock number of a listed part does not appear in this Illustrated Parts Breakdown, refer to the Master Numerical Index S-00-1.

1-9. In the Numerical Index (Section III), all parts in the Group Assembly Parts List section are rearranged in alpha-numerical order. The numerical part number filing system is described as follows:

(1) The arrangement sequence of each numbered part begins at the extreme left-hand position and continues left-to-right, one column at a time, until part number numerical arrangement is determined.

(2) The order of precedence in part number numerical arrangement is as follows:

(1) In the first position, letters A through Z, then numerals 0 through 9.

(2) In the second position and in all succeeding positions the order of precedence is as follows:

(1) Space (blank column)
(2) Diagonal (slant) /
(3) Point (period)
(4) Dash (-)
(5) Letters A through Z
(6) Numerals 0 through 9

NOTE

Alphabetic O's shall be considered as numerical zeros. Spaces, diagonals, points and dashes shall not appear in the extreme left-hand position of the part number. However, they may be used in the second and succeeding positions of the part number and shall take precedence over letters and numerals as indicated above.

1-10. The figure and index number is listed for the first appearance only of AN and Hartman standard parts. The total quantities of all parts required for a complete unit are also indicated.

1-11. USABLE ON CODE. Part variations between models are indicated by letter symbols placed in the "USABLE ON CODE" column of the Group Assembly Parts List. Where the same parts are used on both models, the coding column is left blank. The coding used in this parts breakdown is as follows:

PART NUMBER	USABLE ON CODE
A-700AP	A
A-718AP	B

1-12. SOURCE CODING. Source coding as applied to the Numerical Index has been assigned by Department representatives.

1-13. SOURCE CODE DEFINITIONS.

1-14. CODE "P" - PARTS UNDER INVENTORY STOCK CONTROL

(1) Code "P" is applied to parts which are procured in view of relatively high usage. Code "P" parts may be requisitioned and installed

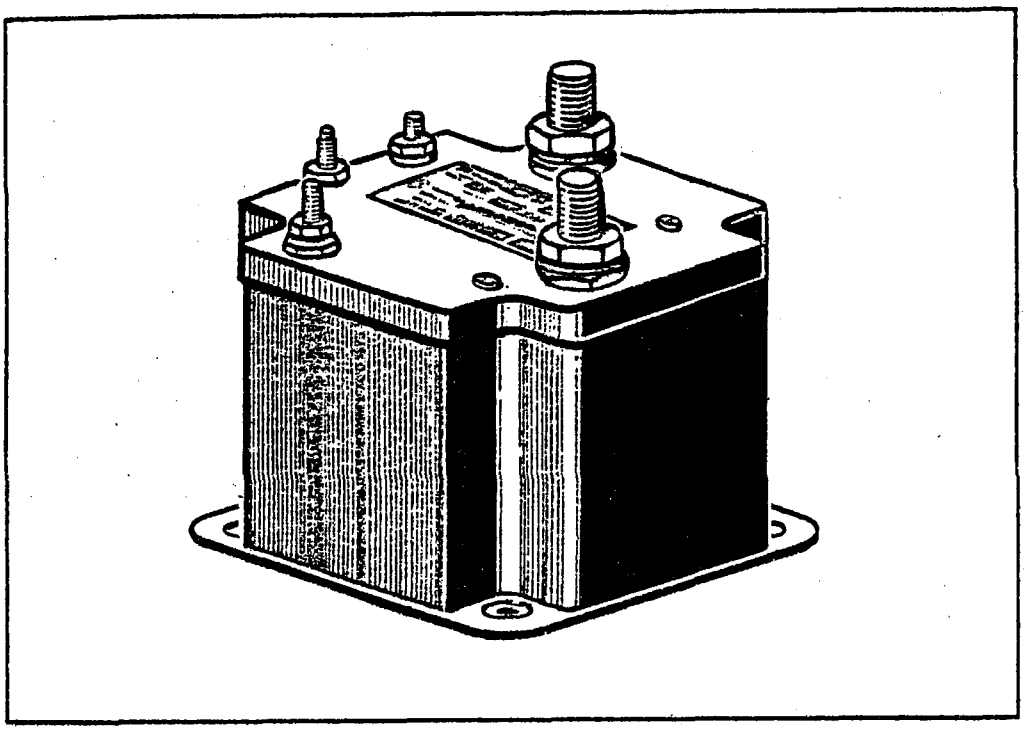

Figure 1. Assembled View of Representative Equipment

by any maintenance level, unless followed by the letter - "O", which restricts requisition and replacement to Depot (O&R) level only. Restricted service manufacture is considered practicable but only after an attempt has been made to procure from Supply Sources. In lieu of Procurement of "P" Coded parts, the Department may designate a Depot (O&R) level activity to manufacture supply requirements for the Program.

(2) CODE "P1" is applied to parts which are very difficult or uneconomical to manufacture. Service manufacture is considered impracticable. Code "P1" parts may be requisitioned and installed by any maintenance level unless followed by the letter "O" which restricts requisition and replacement to Depot (O&R) level only.

1-15. CODE "M" - MANUFACTURE; PARTS NOT PROCURED

(1) CODE "M" is applied to parts which are within the facilities of any activity to manufacture. Procurement and stocking are not justified in view of the relatively low usage, or storage and installation factors, of these parts. Needs are to be met by local manufacture as required.

(2) CODE "M1" is applied to parts which can be manufactured only by utilizing the facilities of the Depot (O&R) activity. Procurement and stocking of these parts are not justified in view of their relatively low usage and installation factors. The needs of all activities are to be met through salvage, or by Depot (O&R) level manufacture.

1-16. CODE "A" - ASSEMBLE; ASSEMBLY NOT PROCURED

(1) CODE "A" is applied to assemblies made up of two or more units each of which carry individual part numbers and description and which may be assembled by any Maintenance level.

(2) CODE "A1" is applied to assemblies made up or two or more parts each of which carry individual part numbers and description which may be assembled only by activities having Depot (O&R) facilities.

1-17. CODE "X" - PARTS CONSIDERED IMPRACTICABLE FOR MANUFACTURE OR PROCUREMENT

(1) CODE "X" is applied to Main Structural Members or similar parts which, if required, would suggest extensive aircraft or equipment reconditioning. The need of a part, or parts, coded "X" (wing spar caps, center section structure) should normally result in a recommendation to retire the aircraft or equipment from Service.

(2) CODE "X1" is applied to parts for which procurement of the next higher assembly is justified; e.g., an integral detail part, such as welded segments, inseparable from its assembly; a part machined in a matched set; or a part of an assembly which, if required, would suggest extensive reconditioning of each assembly.

(3) CODE "X2" as applied to parts which are neither procured nor stocked. Activities requiring such parts shall attempt to obtain from salvage; if not obtainable from salvage, such parts shall be requisitioned through normal supply channels with supporting justification.

1-18. CODE * - PARTS NOT PROCURED, MANUFACTURED OR STOCKED

(1) CODE "*" applies to installation drawings, diagrams, instructions or field service drawings, basic drawing numbers which cannot be procured or manufactured and obsolete parts.

1-19. HOW TO USE THIS ILLUSTRATED PARTS BREAKDOWN

1-20. HOW TO FIND THE PART NUMBER AND DESCRIPTION WHEN THE PART NUMBER IS NOT KNOWN.

(1) When the part number is not known and it is desired to locate the part number and correct description, turn to the Table of Contents to determine to which assembly the part number is applicable.

(2) Locate the illustration from the Table of Contents, then identify the part in question on the exploded view.

(3) Using the index number assigned to the part in the exploded view, locate this number in the "FIG. & INDEX NO." column in the Group Assembly Parts List (Section II). The correct part number, description and quantity required will be found following the index number.

1-21. HOW TO FIND THE ILLUSTRATION AND DESCRIPTION FOR A PART IF THE PART NUMBER IS KNOWN.

(1) Refer to Section III, Numerical Index, and find the part number, and the figure and index number for the part.

(2) Turn to Section II, Group Assembly Parts List, and find the figure and index number indicated in Section III for that part.

(3) Opposite the figure and index number in the Group Assembly Parts List, find the complete description for that part.

(4) On the corresponding illustration, find the index number determined in paragraph 1-20 (2).

REVERSE CURRENT CUTOUT RELAY

PART NUMBER

A-701D

THE HARTMAN ELECTRICAL MANUFACTURING CO.
MANSFIELD, OHIO

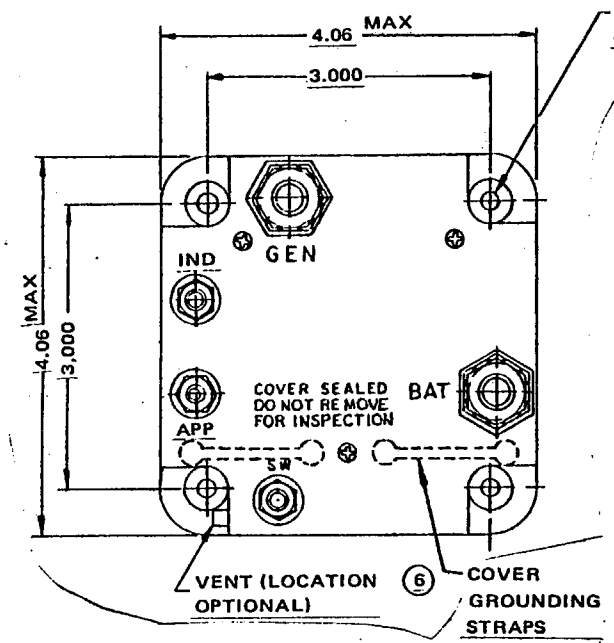
A-701D

The A-701D is an A-700AP or A-700ZC-7 style cutout with 400 amp contacts incorporating the A-703 battery starting main contactor operation from the APP terminal.

The purpose of the A-700AP or A-700ZC-7 reverse current cutout operation is to provide a connection between the generator and the battery or bus and to provide reverse current protection in the event of generator failure or a loss of generator voltage.

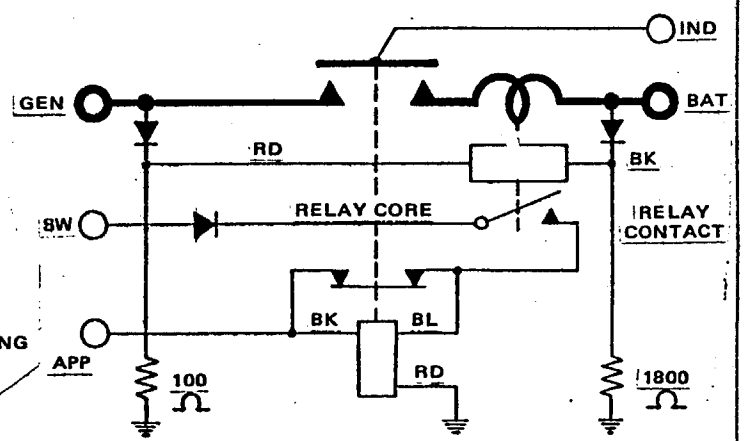
In the case of the A-701D, the values of reverse current and contactor rating differ from A-700ZC-7. The operation is as follows:

In the normal installation the terminals marked GEN and SW are connected to a generator positive, the terminal BAT is connected to battery positive or the positive bus to which a battery is normally connected, and the unit cover provides the ground return circuit. To complete the circuit, of course, the generator negative terminal and the battery negative are tied to common ground.



As the generator voltage increases the polarized differential relay senses when the generator is approximately 1/2 volt or more above the battery or bus and closes, applying power to the main contactor coil which closes the main contacts. The generator is now connected to the battery or bus. In the event of an unexcited bus, the differential relay closes the main contactor before the generator exceeds 24 volts.

It will be noted that after the main contacts close differential voltage no longer exists. The differential relay, however, is latching and therefore remains closed.



Should there be a loss of generator voltage for any reason, that is whether the generator has failed or whether the system is merely being shut down, the battery or bus will force reverse current to flow back to the generator, through the reverse current coil. When this current reaches a value of 25 to 50 amperes, the differential relay will open, opening the circuit for the main contactor coil, dropping out the main contactors.

Should the generator be shut down without reverse current, from an unexcited bus or by opening the SW, the differential relay will remain closed. Now if the bus is energized by another generator or by battery voltage the reverse differential voltage from battery or bus to the generator will open the differential relay contacts, returning the unit to the original condition. If the generator is restarted without the bus having been excited the main contactor will close when there is sufficient voltage, approximately 18 volts. In this latter case a diode in series with the main contactor coil prevents main contact closure if the generator polarity is reversed.

RELAY NO. A-701D

FINAL COPY

The LEECE-NEVILLE Company

INSTALLATION INSTRUCTIONS

NEW HIGHER OUTPUT A.C.-D.C. GENERATING SYSTEM

BASE ASSEMBLY TYPE 24554

AAF. Part Number	40-D-8445-2
Leece-Neville Part Number	24554
Length	6-1/2 Inch
Width	4 Inch
Height	1-15/16 Inch
Weight	0.64 Lb.

INSTALLATION OF VOLTAGE REGULATOR ON TYPE 24554 BASE

STEP 1

Insert the two small ears on the regulator sub-base into the slotted brackets riveted to the bakelite base. These ears must fit the brackets snugly, but without forcing. Make certain that the slotted brackets are not bent away from the side of the base assembly.
(Fig. 1)

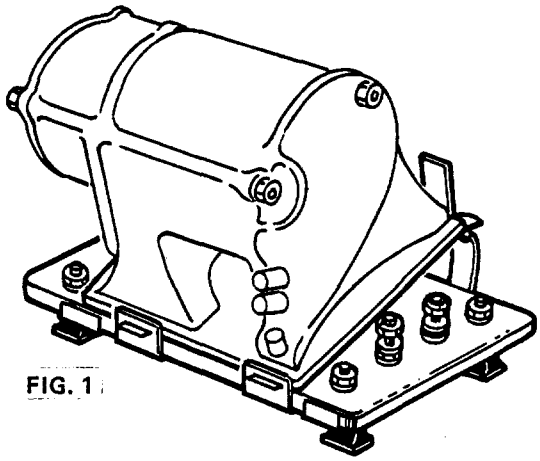

FIG. 1

STEP 2

Press the voltage regulator directly downward into the base. This will force the spring hold-down clips out far enough to admit the long vertical tabs on the voltage regulator. Do not bend these spring clips outward with pliers or a screw driver, as they must exert a pressure both downward on the tabs and across the base toward the slotted brackets.
(Fig. 2)

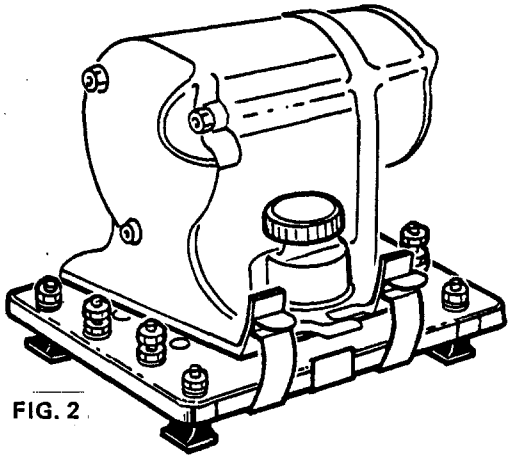

FIG. 2

STEP 3

Holding the voltage regulator tightly against the regulator base, snap the spring clips into position by pressing them against the regulator tabs as illustrated. (Fig. 3) If the spring clips do not pass over the regulator tabs, remove the regulator and examine both regulator and base for foreign objects causing interference.

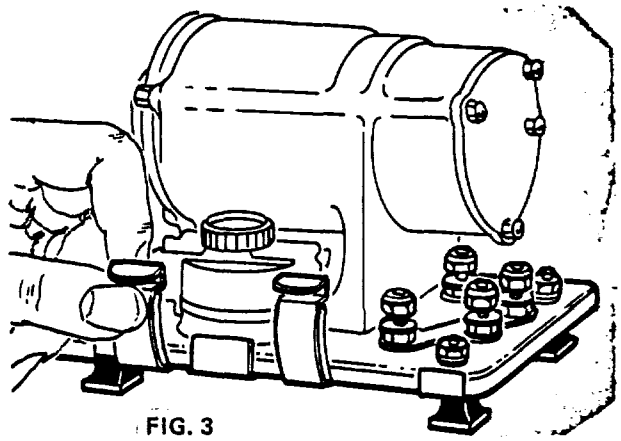

FIG. 3

INSTALLATION OF TYPE 24554 BASE ASSEMBLY

If the vibration mounts are not removed when the regulator base is installed, the following method is used:

Insert the mounting studs of the regulator base in the holes provided for them on the airplane mounting panel, and assemble the guard washers, lockwashers and hexagon nuts.

KEEP WRENCH TIGHT AGAINST MOUNTING PANEL

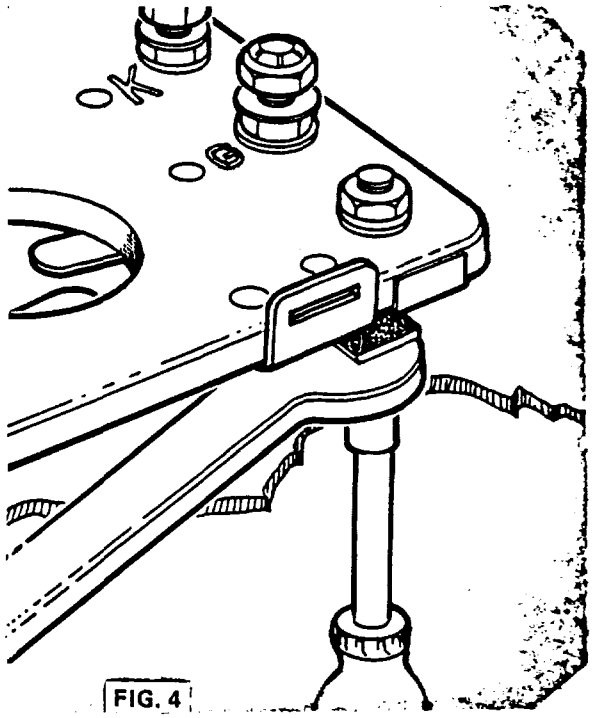

FIG. 4

To tighten, grip the bottom of the vibration mount lightly with an open end wrench, pressing the wrench tightly against the mounting surface. This is necessary in order to make sure that the wrench does not grip the rubber above the square steel insert and cause tearing of the rubber.

If it is necessary to remove the vibration mounts from the base for installation in the airplane, use the following method:

Remove the vibration mounts from the Voltage Regulator Base. Fasten the mounts to the mounting panel of the airplane, using either an open end wrench as in figure 4, or a 1/2 inch square box wrench.

Do not let the wrench slip up onto the rubber while tightening the lower nut. The sides of the rubber mounts must be parallel with the base when it is in position, as shown in fig. 5.

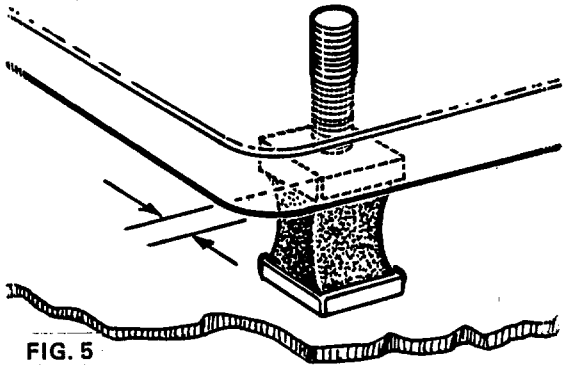

FIG. 5

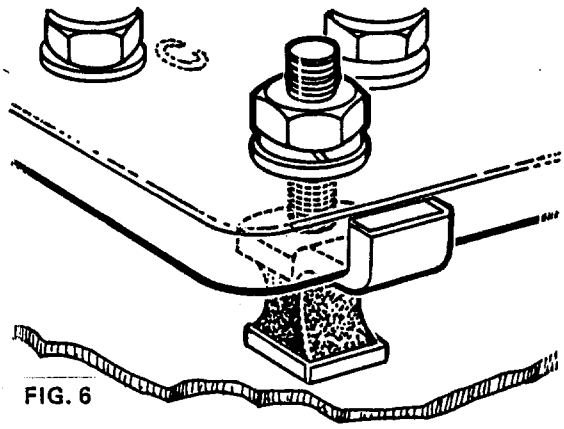

FIG. 6

Place the locking clip over the vibration mount as shown in fig. 6. The long tab must fit up over the long sides of the base.

The locking clips will hold the mount in correct position while the top hexagon nuts are tightened. The elastic stop nuts have been replaced by hexagon nuts, lockwashers and guard washers.

In any case, the mount must not be installed with any amount of twist in the rubber, as shown in fig. 7.

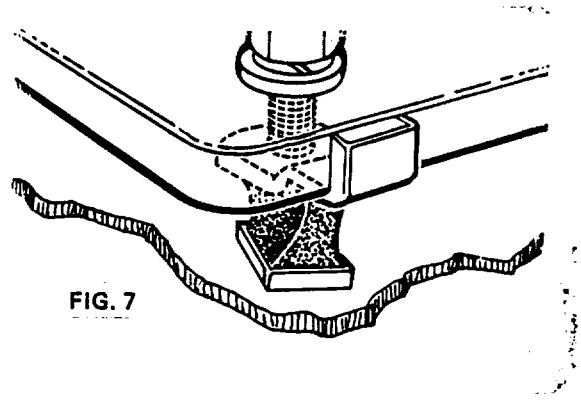

FIG. 7

SERVICE INSPECTION

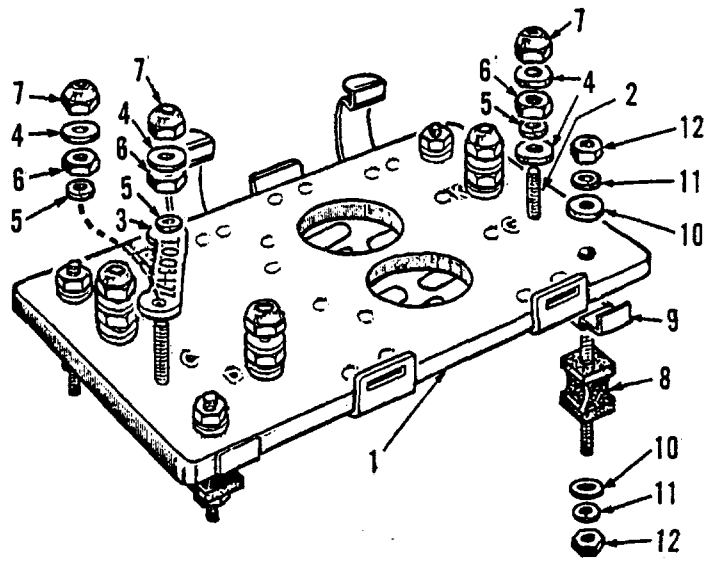
The voltage regulator base should be inspected each time before a new voltage regulator is installed. The inspection procedure outlined below should be followed.

Inspect the contact blades for cracks, broken blades, corrosion, rust, or loss of tension.

Inspect the vibration absorption mounts for torn rubber or broken and damaged studs.

Inspect the spring clips for cracks or loss of tension.

Inspect the six terminal posts for tightness and damage to threads.



MAINTENANCE

The spring contact blades should be cleaned before the installation of a new voltage regulator. This may be accomplished by the use of crocus cloth to polish the areas at the tip of the blades which make contact with the voltage regulator pins. After cleaning, wipe the blades with a clean cloth moistened with carbon tetrachloride.

CAUTION: Do not use emery cloth or sandpaper on the contact blades. Do not scrape the blades with a sharp object, or the silver plating will be removed.

SERVICE TROUBLES AND REMEDIES

TROUBLE	PROBLEM CAUSE	REMEDY
Poor Contact With Voltage Regulator	Spring contact blades dirty.	Clean as instructed.
	Contact blades have lost tension.	Replace regulator base assembly.
	Loose or dirty connections in the wiring to the base.	Clean and tighten all connections.
No Contact Between Regulator And Base	Contact blades broken.	Replace base assembly.
	Contact blades deformed–not making contact.	Replace base assembly.
Regulator Base Loose In Airplane	Vibration mounts torn or broken.	Replace rubber vibration mounts.
	Nuts fastening base have come loose.	Tighten all mounting nuts.

INTRODUCTION

This manual has been prepared to acquaint you with the fundamental operating characteristics of MARATHON sintered-plate, nickel-cadmium batteries and to assist you in obtaining maximum performance with minimum maintenance and servicing.

Over a period of years, literally thousands of battery units have been operating in aircraft, missiles, satellites, ground vehicles, communication equipment, marine installations, ground power standby equipment and hundreds of other applications where rechargeability, flexible voltage and reliable power are essential.

Your Marathon battery is manufactured to the highest precision standards. Care has been taken in every step of the manufacture to assure a product of the very highest quality. Your battery has been carefully tested at factory laboratories before being shipped. Proper care and maintenance, as outlined in this manual, will aid you in keeping your battery at peak performance and prolong its useful life.

PART I-PRINCIPLES OF OPERATION

1.0 Electro-Chemical Principles of the Marathon Battery

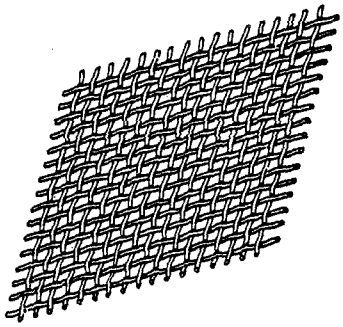
1.1 DURING CHARGE

The active material of the negative plate is cadmium-oxide. When the charging current is applied. this material gradually loses its oxygen and becomes metallic cadmium. The active material of the positive plate is nickel-oxide. This is brought to a higher state of oxidation by the charging current. As long as this current continues, changes take place until both materials are completely converted.

Toward the end of this charging process, and during overcharge, Marathon cells will gas. This is a result of electrolysis of the water component of the electrolyte. The gas created at the negative plates is hydrogen and that at the positive plates is oxygen. The amount of gas created is dependent upon the temperature and the amount of charging current.

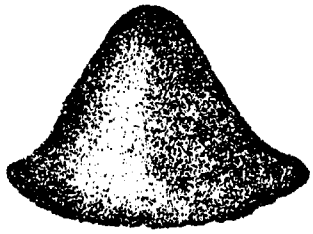
The cells will accept charge at temperatures ranging from −65° to +165° F. However, at extreme temperatures, the length of charge time must be limited. The electrolyte does not enter into any chemical reaction with either the negative or positive plates, but acts merely as a conductor of current between them. There is no significant change in the specific gravity, since the electrolyte acts only as a conductor.

1.2 DURING DISCHARGE



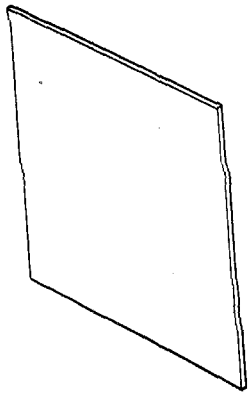
A chemical action in reverse of that which occurs during charge is immediately initiated when electrical energy is withdrawn from the cell. The negative plate gradually gains back oxygen and the positive plate gradually loses oxygen. There is no gassing on normal discharge due to this interchange of oxygen.

This process results in the conversion of the chemical energy of the plates into electrical energy. The rate of which this conversion takes place is primarily determined by the external resistance imposed by the electrical circuit to which the cell is connected. Due to the type of cell construction, there is extremely low internal resistance within the cell. The chemical nature of the electrolyte and its specific gravity remain unchanged during discharge. The relative constancy of the cell voltage during discharge is due mainly to these factors.

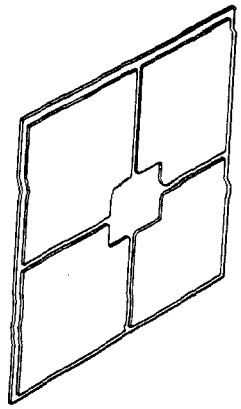


2.0 Construction of the Marathon Battery

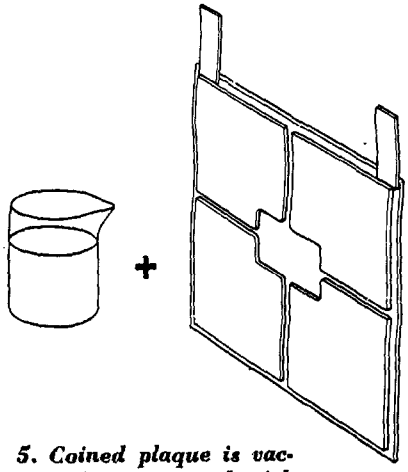
2.1 PLAQUES AND PLATES



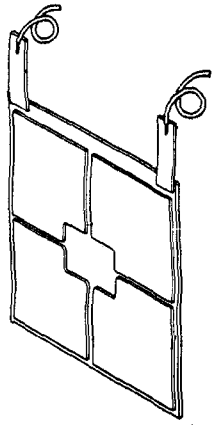
The basic feature of the Marathon battery is its sintered plate, as shown in the series of diagrams below.



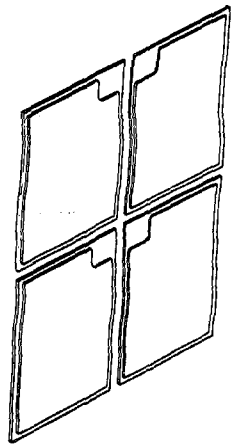
1. Here's how a Marathon battery is made. We start with a nickel screen.



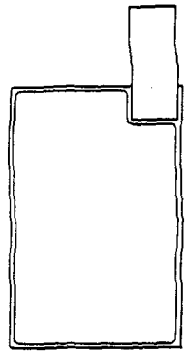
2. Then nickel powder is sintered about screen.



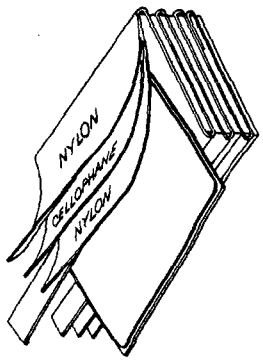
3. This forms a plaque approximately 80% porous at this stage.



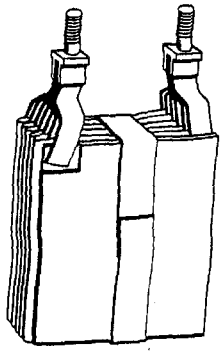
4. Plaque is coined with a plate die.



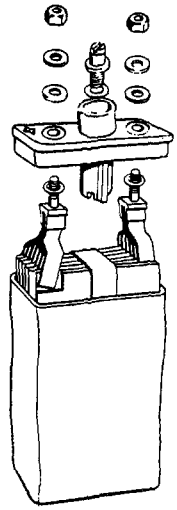
5. Coined plaque is vacuum impregnated with nickel or cadmium salts, electrochemically deposited within pores.



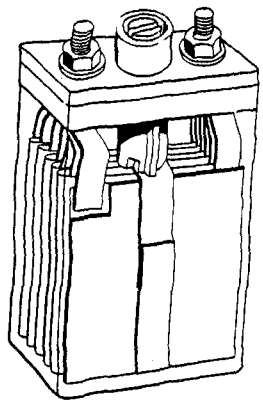
6. Current is passed through plaque in presence of electrolyte, to convert nickel or cadmium salts to final form.



7. After washing and drying, finished plaque is cut into plates.



8. A nickel tab is spot welded to plate.



9. "Stackup" is prepared by folding separator material between alternate positive and negative plates.

10. Nickel terminals are welded to completed "stackup," which with its cellophane binder forms the complete assembly of the core.

11. Cover and vent assemblies are attached and sealed to "stackup."

12. Entire unit is inserted in cell case and sealed.

2.2 SINTERED-PLATE CONSTRUCTION METHODS

Sintering is that process by which micro-fine powder is fused together at high temperatures to form a porous plaque structure. The porous structure of the Marathon plaque is obtained by sintering nickel powder to a fine-mesh wire screen. The active material which distinguishes between the negative and positive plates is then electrochemically deposited within the pores of the plaque. Positive plaques are made by depositing nickel-hydroxide, negative plaques by depositing cadmium-hydroxide.

The plaques are then formed, washed, dried and cut into the desired plate size. Nickel connecting tabs are welded to one corner of each plate. Positive and negative plates are then grouped into a core assembly. The connecting tabs of all plates project upward toward the proper terminals, to which they are welded.

The sintered plates are positioned very closely together and are kept from actual physical contact by a thin multi-layer laminate, known as a separator.

While the surface of a sintered plate appears to be relatively smooth, it is actually a maze of tiny hills and valleys *(see Figure 1)*. This physical property multiplies the apparent surface area several hundred times and permits the utilization of a tremendous area of active material. The porosity of the plate permits the absorption of electrolyte. This further increases the volume of active material in direct contact with the electrolyte.

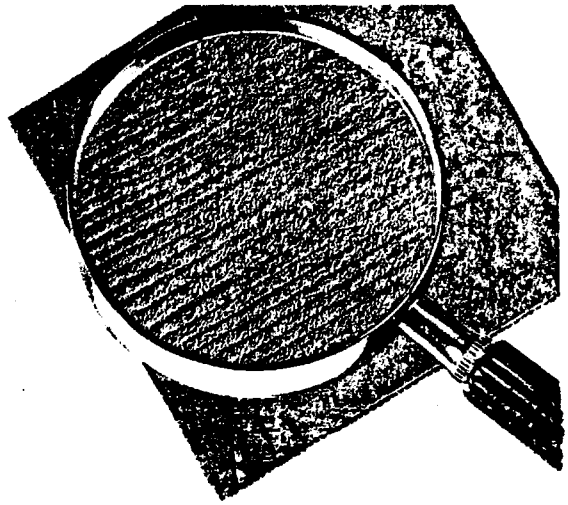


FIGURE 1

The porosity of Marathon plates is created by a partial sintering of the nickel powder. This powder has been carefully selected for particle size and shape. After sintering, the total active surface area of one Marathon nickel-cadmium plate is equal to that of several hundred solid plates of the same size.

2.3 SEPARATORS

A continuous strip of highly specialized fabric and pliable plastic composes the separator. This continuous separator is interposed between the plates as each successive plate is added to the "stackup" in preparing the core assembly. Thus the plates within the core are separated by a porous insulating barrier. This design provides the needed physical strength with minimum bulk and excellent electrical insulation, as well as efficient electrolytic conduction when immersed in the electrolyte. To insure complete insulation, the separator is slightly wider than the dimensions of the plate.

2.4 CELLS

The core assembly in a Marathon battery is firmly affixed to a plastic or metal cover. This integral unit is then fitted snugly within a transparent plastic or metal case and the cover is cemented or welded in position. The cell thus becomes a compact, enclosed unit. The plates extend to the bottom of the cell, since no active material will flake or shed from them. This contributes to the solidity of the cell and gives it the ability to withstand extreme conditions of shock and vibration.

2.5 VENTS

Each cell is provided with a vent plug. This plug consists of a metal or plastic core and an outer collar of rubber. It can be removed for the addition of distilled water or adjustment of the electrolyte. When in place, the rubber expansion collar permits the gas created on charge to escape. Since there is no gassing on discharge, the vent automatically seals the cell, preventing leakage of electrolyte and also preventing entrance of foreign substances into the cell.

2.6 BATTERY ASSEMBLIES

To provide the voltage for a given application, cells are assembled into batteries and are housed in a steel battery case. An individual cell may be replaced in the event of damage, thus eliminating loss of the entire battery.

2.7 ELECTROLYTE

A 30%-by-weight solution of potassium hydroxide (KOH) in distilled or demineralized water is used as the electrolyte in the Marathon battery.

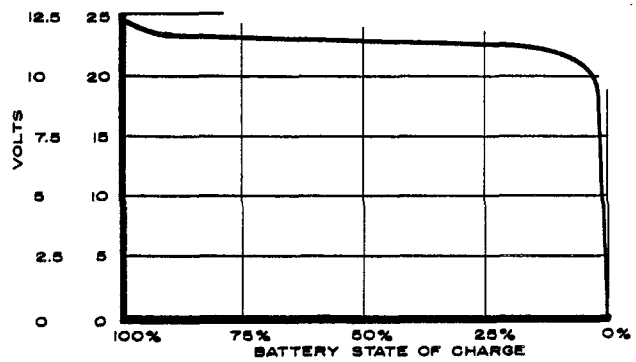
No overall chemical change occurs in the electrolyte during charge or discharge. As a result, no appreciable changes in the specific gravity are observed. The specific gravity of the electrolyte at room temperature remains between 1.24 and 1.30. The electrolyte level, observed through the windows in the side walls of the battery case or by looking into the vent wells, should be at the top of the plate portion of the core assembly. Marathon batteries are normally shipped wet from the factory, since shelf life is not affected.

3.0 Discharge Characteristics of Three Basic Marathon Battery Types

3.1 PLATE THICKNESSES

Marathon batteries of the sintered-plate, nickel-cadmium type are divided into three classes, in accordance with the following discharge requirements:

a. *H-TYPE BATTERIES*—Contain thin plates and are intended for very high current service such as required in turbine engine starting applications, particularly during cold temperature operation.



b. *M-TYPE BATTERIES*—Contain medium thick plates and are intended for medium rate current requirements, such as reciprocating engine starting applications. They will perform satisfactorily at all temperature ranges—from sub-zero Antarctic conditions to the blistering tropics.

c. *L-TYPE BATTERIES*—Contain thick plates and are intended for low current drains where great capacity at a low rate is required, such as transistorized power supplies. They will perform satisfactorily at low temperatures at very low current drains.

3.2 TYPICAL DISCHARGE CHARACTERISTICS

All Marathon batteries offer a constant voltage throughout their discharge. Figure 2 illustrates a typical discharge voltage curve under moderate load.

FIGURE 2

TYPICAL DISCHARGE VOLTAGE CURVE UNDER MODERATE LOAD

PART II-INSTALLATION

4.0 Unpacking and Inspection of New Batteries and Cells

4.1 INSPECTION PRIOR TO INSTALLATION

When the battery is unpacked, a thorough inspection should be made to insure that no damage occurred during shipment. Inspect the shipping container, as well as the battery, to make certain that the cells have not been damaged. Before putting your battery in service, follow these points carefully:

4.2 CHECK LIST

a. *CHECK FOR DAMAGE*—See if any liquid has spilled into the shipping container. This may be a sign of a damaged cell.

b. *CHECK ELECTRICAL CONNECTION*—Check all electrical connections for tightness. Test all screws and nuts on all terminals to insure tightness. Poor electrical contact may result in damage to your battery.

c. *CHECK LIQUID LEVEL*—CAUTION: Marathon batteries are shipped with the proper amount of liquid. Do not add liquid until you have first attempted to charge your battery. When a battery has been discharged or allowed to stand unused for a long period of time, the electrolyte becomes absorbed into the plates. Your battery has been shipped discharged, which is the chief reason why the liquid level is low. Charging the battery will cause the liquid level to rise to a point just above the tops of the plates.

d. *CHECK VENTS*—Your battery is equipped with special type vents which permit the gases to escape from the cells. Do not obstruct these vents in any manner which will interfere with their operation. Some batteries are shipped with solid vent plugs which are used as shipping plugs. If these have been used on your battery, the battery will be marked with a tag, "Remove Shipping Plugs." The vent plugs are then inside a small cloth bag tied to the battery. Replace shipping plugs with the vent plugs before charging the battery.

e. *INDIVIDUAL CELLS*—When individual cells have been ordered, care must be exercised in charging. Do not charge individual cells unless the plastic cell case is supported externally in some manner. Gas pressure during charge on unprotected cells may crack the cell case. If no clamping device is available, remove the filler caps or vent screws to prevent a buildup of gas pressure inside the cell during charge *(consult Operation and Maintenance, 5.0)*.

4.3 INSTALLATION OF THE BATTERY

4.3.1 CLEANING COMPARTMENTS

Prior to installation, compartments or battery boxes which have previously housed lead-acid batteries must be washed out, neutralized with ammonia or washing soda solution, allowed to dry thoroughly and then painted with alkaline-resistant paint.

4.3.2 CHARGING NEW BATTERY

Your battery has been discharged prior to shipment. It will therefore need charging before installation *(see Table I)*. If by special order your battery is shipped in a charged state, it is advisable to give it a freshening charge *(consult Charging Methods, 5.3)*.

4.3.3 SECURING BATTERY IN POSITION

When installing the battery in its permanent location, care should be taken to see that all post nuts are drawn down tight and that all electrical connections are made secure. Leads to the battery should be of sufficient size to carry the maximum current encountered without excessive voltage drop. If the battery is in mobile service, such as on an aircraft or other vehicle, it must be secured by holddowns. It is desirable to arrange the compartment so that the battery is either accessible or can be readily removed for servicing.

4.3.4 PROPER AIR CIRCULATION

Stationary batteries consisting of several tray groups should be installed with trays separated from each other to permit some circulation of air. This air space around the trays also serves to break up possible current leakage paths. Tray-to-tray connectors are of proper length to allow a minimum of ⅛" between trays.

4.3.5 VENTING OF GASES

Where the batteries are installed in a confined location, it must be realized that some hydrogen and oxygen gases are evolved during the charging cycle. It is therefore necessary to provide some means of ventilation to remove these gases from this confined area, avoiding accidental ignition of the hydrogen.

There are two types of venting systems to be considered. The first is a battery case containing vent nozzles and the second the battery case containing viewports or cover containing louvers. If the battery case contains vent nozzles, these must be used to vent gases either overboard or into a compartment that will meet the air flow requirements outlined below. If the battery case contains viewports or cover has louvers, the air flow must be of sufficient volume to keep the mixture of air and hydrogen below 5%. In both cases mentioned above, the air flow should be a minimum of 5 cubic feet per minute.

4.3.6 CHECKING POLARITY

Check the polarity of each cell or group of cells to be sure that they are connected in proper series. The polarity of each cell is indicated by a plus sign molded into the cell cover adjacent to the appropriate cell post.

4.3.7 INSULATING BATTERY

Marathon has recently developed a new epoxy coating for its line of aircraft batteries. This epoxy coating is designed to improve the insulation between the cells and the battery container. It will eliminate the small discharge current formerly produced when spillage or spewage of electrolyte was encountered. This is a standard item on certain batteries produced at this time and will be a standard item on most units produced in the future.

Batteries in the field that are not now epoxy coated may have this done by returning the battery to Customer Return Department, Marathon Battery Company, Cold Spring, N.Y. 10516. The cost is determined by the battery type. Where batteries are mounted in groups, it may be necessary to provide insulation from each other and from the trays in which they are mounted *(consult Trouble Shooting, 7.0).*

4.3.8 VOLTAGE REGULATION

Where the battery is being used in a mobile application, such as aircraft or ground vehicles, it will be necessary to make certain that the voltage regulating device is set to the proper limits, *as indicated in Table I.* This is an extremely important phase of your installation, as an improper voltage regulator setting can destroy a Marathon sintered-plate, nickel-cadmium battery in a relatively short period of operation.

4.3.9 QUICK DISCONNECT DEVICES

Should the battery be installed using a multipin quick-disconnect type of plug, it is important to be certain that the connecting half of the plug, which is normally attached to the vehicle or aircraft, is wired correctly with respect to the terminal pins on the battery. A battery installed in an electrical circuit with the polarity reversed will not perform and may become seriously damaged.

4.3.10 SAFETY WIRING

In installations where safety wiring is to be used, be extremely cautious about the use of this wire near or on battery and cell terminals. It is in some instances, possible to completely isolate the metal battery case from the electrical system into which it has been installed and then establish a direct short to ground through the improper use of safety wire.

When installation is completed, be sure that no loose objects, such as screws or tools, have been accidentally left in the battery compartment or inside the battery.

PART III-
OPERATION, MAINTENANCE AND TROUBLE SHOOTING

5.0 Operation and Maintenance

5.1 GENERAL CARE

To obtain continued peak performance, a Marathon battery should be kept in a clean, dry state. Batteries that are subjected to deposits of metallic dust on the cells, such as those in locomotive or steel plant stations, should be covered. The buildup of metallic dust or any other conductive substance will self-discharge the cells more rapidly by providing a conductive path.

Keep open flame and metal objects, such as tools, etc., away from the exposed parts of the battery. If objects are accidentally dropped across the terminals, these might cause a short circuit that could damage a cell or cells.

Should the batteries accumulate dust or a white deposit which sometimes forms around the tops of the cells, it is advisable to flush the tops of the batteries with ordinary tap water.

CAUTION: Do not attempt to clean the battery tops with solvents, acids or any chemical solution. Marathon batteries are primarily constructed with plastic or nylon cells. The plastic may be injured by introducing solvents, etc. While flushing the batteries with tap water—if necessary—it is permissible to use a bristle brush to clean any stubborn dirt particles.

CAUTION: Do not use wire brushes. After cleaning, any excess liquid should be drained and the batteries should be permitted to dry. Where possible, this drying may be accelerated by the use of compressed air.

5.2 CHARGING CHARACTERISTICS

A Marathon nickel-cadmium battery will accept a charge at a much faster rate than a lead acid battery and may be charged at temperatures below −20°F. Charging is more efficient at battery temperatures between +40° and +80°F.

5.3 CHARGING METHODS

As mentioned earlier in the section entitled *Installation*, it will be necessary to charge your battery prior to putting it into service. While in service in many installations, the battery will be charged by the equipment in which it is installed. During particular maintenance and inspection removals, however, it may be necessary to charge the battery in the shop. *IMPORTANT— BATTERIES MUST BE CHARGED IN AN UPRIGHT POSITION.* The construction of the Marathon sintered-plate cell is such that it is readily adaptable to standard charging systems. These include constant voltage, constant current, stepped constant current charge or float charging. Most efficient performance from a constant current will result when the charging rate is such that 140% of the rated capacity of the cell is returned at the rates *indicated in Table I.*

The following material is devoted to various charging methods:

5.3.1 CONSTANT CURRENT CHARGING

The length of time required to charge a battery by the constant current method depends on the size or capacity of the battery, the state of charge of the battery and the magnitude of the charge current. In order to maintain a constant current, it should be noted that the voltage of the system will run from 1.4 volts per cell at the beginning of charge to a maximum of 1.75 volts per cell at the end of charge. In *Table I*, we recommend a constant current rate which is arrived at in the following manner: Take the current output at the 5-hour rate and charge at that current for 7 hours. *Example—the recommended constant current charge for a 40-ampere-hour battery would be computed as follows: 40 ampere hours divided by 5 hours equals 8 amperes.* You would therefore charge this battery at 8 amperes for 7 hours. A typical constant current charging curve *is shown in Figure 3.*

Constant current charging can be accomplished manually by monitoring the charging apparatus and adjusting the voltage periodically to maintain a constant charge rate. Chargers of the self-regulating rectifier type are available to provide constant current without the attention of an operator. Marathon manufactures a Battery Charger/Analyzer designed

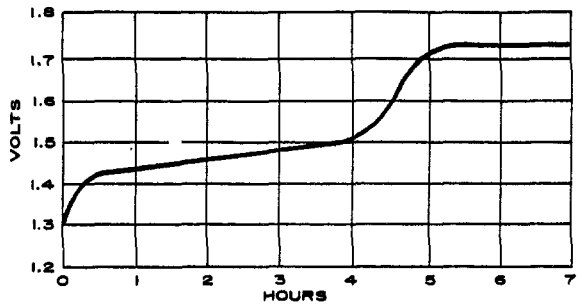


FIGURE 3
TYPICAL VOLTAGE VARIATION DURING CONSTANT CURRENT CHARGE

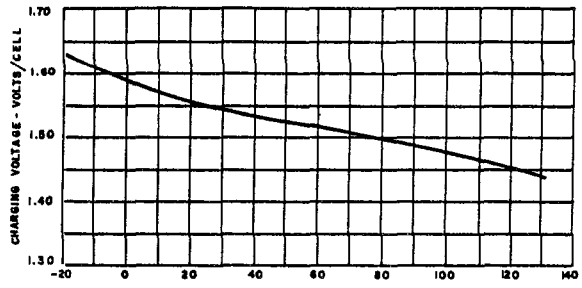

FIGURE 3A
RECOMMENED CONSTANT POTENTIAL CHARGE VOLTAGE AT VARIOUS TEMPERATURES

for this purpose. A complete brochure may be obtained from the Field Service Manager, Marathon Battery Company, Cold Spring, N.Y. 10516. *Request Data Sheet BA-226.*

If a battery is partially discharged, the charge rate *shown in Table I* will still apply. It may not be necessary, however, to charge the battery for the full length of time indicated. To determine whether the battery has reached the full charge state, monitor the battery and note the time that the voltage takes the sharp rise *indicated in Figure 3.* After the sharp voltage rise, it is then necessary to permit the battery to charge for an additional 2 hours at the rate *shown in Table I.* During this 2-hour portion of charge, it is possible to check the cell voltages and determine whether all cells are rising evenly. Should some cells indicate a voltage lower than 1.55 volts, it is advisable to leave the battery on charge until these cells come up to a minimum of 1.55 volts.

Note: During the greater portion of charge, the cell voltages will remain between 1.4 and 1.45 volts. On a conditioned battery, when it has been charged for approximately 70% of the time necessary to charge it fully, the voltage will take the sharp rise mentioned above. Should the individual cell voltage fail to rise to 1.55 volts or more, it may be necessary to replace these cells *(consult Trouble Shooting, 7.0).*

5.3.2 STEPPED CONSTANT CURRENT CHARGING

If it is necessary to obtain a rapid charge, the principles of the previous paragraph still apply—the battery may be permitted to charge at a current equal to its capacity. *Example—a 40-ampere-hour battery at a charging rate of 40 amperes.* At this high rate, the battery should be monitored and when the total battery voltage averages 1.50 volts per cell, the rate should then be reduced to the rate shown on Table I. At the time of reduction, a conditioned battery will have completed approximately 70% of the charge cycle if it was completely discharged to begin with. This method of charging must be monitored, as the high rate will eventually use all the water in the battery if permitted to continue past the gassing point. This loss of water will cause higher concentration of the electrolyte and possible overheating which will damage the cell.

5.3.3 FLOAT CHARGING

Fully charged batteries may be floated across a line voltage of approximately 1.42 volts per cell. Example—a 24-volt aircraft battery which contains 19 cells may be trickle charged at 27.0 volts. A battery floated in this manner will draw about .003 amperes per ampere hour of capacity. *Example—a 40-ampere-hour battery will float at approximately .120 amperes.* This voltage setting will vary slightly with ambient temperature of operation.

5.3.4 CONSTANT VOLTAGE CHARGING

In most applications where Marathon sintered-plate, nickel-cadmium batteries are used, the constant voltage charging method is employed. Aircraft, automobiles, boats, factory equipment and all mobile applications use the voltage-regulated genera-

NOTE: Additional constant current charging instructions when using Marathon Battery BB-449/U at low temperatures—current of 2.8 amperes should be used for a period of 7 hours. Although this method may be used at temperatures below −20°F, it is usually not recommended.

tor charging circuit. The graph *shown in Figure 4 (Page 22)* indicates what happens essentially during this type of charge.

A voltage produced by the generator permits current to flow to the battery. In a discharged battery, the maximum surge of current will be approximately 10 times the rated capacity. The high surge currents are due to the low internal resistance of the battery. Make certain that the charging source is protected against overload in the event of a marginal power supply. As the battery approaches a charged state, the current falls off rapidly and the voltage rises. The recommended voltage setting for the regulator, *shown in Table I*, is computed by multiplying the number of cells in the battery by a factor of 1.5 to 1.55. *Example—a 12-volt automotive battery which contains 10 cells should have the regulator set to cut out between 15.0 and 15.5 volts.*

It should be noted that this type of charging, particularly in applications where the battery is excessively discharged, may produce an unbalance in cell capacity *(consult Trouble Shooting—Apparent Loss of Capacity, 7.1)*. If the battery requires equalization and a constant current charging source is not available, it may be equalized by the method *shown in Reconditioning Service Procedures, 9.3.*

5.4 TEMPERATURE EFFECTS ON GASSING POTENTIAL

If charging is required at high ambient temperatures, adjustments must be made in the charging voltage to be assured that a thermal runaway condition will not exist. In the graph below (see Figure 3A), you will find recommended constant potential charging voltages at various temperatures. Multiply the recommended voltage per cell by the number of cells to obtain the correct voltage setting for charging from a constant potential source.

Nickel-cadmium batteries are capable of sustaining very high current drains and performing well at temperature extremes. However, the effective capacity of a battery will decrease when subjected to high current demands and extreme temperatures. The optimum operating temperature for nickel-cadmium cells ranges from 60° to 90°. An increase or decrease in the above temperatures causes a corresponding reduction in capacity.

At lower temperatures the battery will accept the charge if proper adjustments are made to the regulating source. If the voltage is not corrected, the battery will not deliver its rated capacity. When operating at elevated battery temperatures, the battery is subjected to the danger of thermal runaway due to overcharge. This condition is characterized by continuously increasing current and rising battery temperature during the constant potential charge. (Note: If the battery temperature exceeds 120°F, no charging should be attempted.)

The continual charging above the gassing potential results in excess water loss due to decomposition and heat generation. At high ambient temperatures the heat loss of the battery through radiation and conduction is lower than the heat generating rate. This results in a net increase in the battery's temperature. The increase causes a higher charge current during the constant potential charge. This higher charge current further increases the temperature which continues to drive off water through decomposition. If allowed to continue, the proceeding mode of operation will completely destroy a battery. The cellophane separator will begin to disintegrate resulting in a break down of the gas barrier. If this condition is not detected, it will eventually lead to cells shorting.

For the reason stated above, it is extremely important that the battery be monitored more frequently when operating in high ambient temperatures or when the battery has been subjected to high duty cycles, such as, in aircraft starting.

5.5 DISCHARGING THE BATTERY

You will note, in the section entitled *Replacement of Damaged Cells, 6.1*, that you are instructed to discharge the battery. The following information is designed to help you in this operation.

5.5.1 USING EQUIPMENT AS A LOAD

A battery may be discharged by merely permitting it to operate the equipment in which it is installed without permitting the generator or other charging source to replenish it.

When the battery fails to operate the equipment, it is in a state of partial discharge. It should then be removed from the equipment and discharged through a resistance high enough to permit the current to flow at approximately the 2-hour rate. *Example—a 40-ampere hour battery may be permitted to discharge at 20 amperes or less.* When the voltage has dropped to a sufficiently low point that the current has apparently ceased to flow, the battery can then be considered discharged. Where cells are to be individually shorted *(see Figure 5)*, it is important that the shorting wires or bars be placed in position on the cells while the resistance is still connected to the battery.

Should the battery be permitted to stand after the resistance has been removed, it will recover sufficiently so that the application of the shorting devices will create severe arcing and intense heat. To determine when a battery has been sufficiently discharged and ready for short circuit, the terminal voltage of the entire battery must be less than 10% of the rated voltage. It is then safe to short circuit. *Example—a 12-volt battery having been discharged at a rate equal to or lower than the 2-hour rate may be short circuited when the terminal voltage of the entire battery is 1.2 volts or less.* Where possible, the shorting of individual cells is suggested.

5.5.2 USING A RESISTANCE LOAD BANK

A battery being discharged in the shop may be discharged through a resistance which will permit the current to flow at a rate no higher than its 1-hour rate. Example—a 40-ampere hour battery may be discharged at a rate of 40 amperes. When the battery appears to be discharged and current is no longer flowing, it is then advisable to continue to discharge through a slightly higher resistance, permitting the current to flow at the 2-hour rate or lower. *Example*

(Continued on Page 12)

—a 40-ampere-hour battery may be permitted to discharge at 20 amperes.

IMPORTANT—Do not attempt to discharge a Marathon sintered-plate, nickel-cadmium battery at an excessively high rate and then attempt to short circuit each cell at the end of this discharge. Batteries which have been discharged at high rates are not fully discharged. Application of shorting devices to the individual cells at the end of such a high discharge will produce severe arcing and intense heat. To determine when a battery has been sufficiently discharged and ready for short circuit, the terminal voltage of the entire battery must be less than 10% of the rated voltage. It is then safe to short circuit. *Example—a 12-volt battery having been discharged at a rate equal to or lower than the 2-hour rate may be short circuited when the terminal voltage of the entire battery is 1.2 volts or less (consult Description of Reconditioning Service, 9.4).*

5.6 LIQUID LEVEL ADJUSTMENT

During the normal operation of the Marathon sintered-plate, nickel-cadmium battery, it is necessary occasionally to add liquid. The amount of water used is relatively small when compared to the amount used in a lead acid battery. Usage rate will depend upon the application, charging voltage, ambient temperature and several other factors. For this reason, it is advisable to maintain accurate records on particular applications so a realistic water replacement schedule can be established. Use only distilled or demineralized water. Storage batteries are easily contaminated through the use of tap water which contains minerals, chlorines, softening agents and other foreign materials. Water additions to adjust the liquid level should be made immediately after charging or after the battery has been permitted to remain in a state of rest for a minimum of three hours. Never adjust the electrolyte level after discharge unless abnormal high voltage readings (greater than 1.5 volts) are encountered immediately after placing a discharged battery on charge.

WARNING: Do not use acid. Injury may result and equipment damage can occur. Never use tools which have any acid deposit on them.

FIGURE 5

5.6.1 PROPER LIQUID LEVEL

The proper liquid level of all Marathon sintered-plate, nickel-cadmium batteries is just above the tops of the plates or plastic insert (¼" immediately after charge or ⅛" after 3-hour stand). In some Marathon batteries, it is possible to see the liquid level through the ports in the side of the battery can. In Marathon batteries where these ports are not provided, such as certain aircraft types, it is necessary to determine this liquid level by looking down into the vent well after the filler cap has been removed.

If it is not possible to determine the liquid level in this manner, we recommend the use of a polystyrene tube, open on both ends and having approximately ⅛-inch inside diameter about six inches long *(see Figure 6).*

This tube is inserted into the filler opening deep enough to touch the top of the plates or plastic insert. Grasping the tube between the thumb and the middle finger of the right hand, place the index finger over the top open end of the tube and remove the tube from the filler well. If the level in the lower

NOTE: Additional instructions on the liquid level adjustment when using Marathon Battery BB-449/U—the proper electrolyte level is ⅝" above the tops of the plates measured from 3 to 6 hours after charge. An open end glass or preferably a transparent plastic tube ⅛" to ¼" in diameter should be used for this, as described above.

end of the tube is as stated above, the liquid level is adjusted properly. If no liquid is withdrawn, add distilled or demineralized water until the proper level is reached in the polystyrene tube, using the method described above. Adjustments in liquid level may be made by a syringe of the type *pictured in Figure 7.*

5.7 ELECTROLYTE SPECIFIC GRAVITY

The electrolyte is a solution consisting of 70% distilled water and 30% potassium hydroxide, resulting in a specific gravity of 1.3. Cells which have lost electrolyte by accidental overfilling may have a lower specific gravity. Specific gravities after use may range between 1.240 and 1.320 without any appreciable effect on battery operation at normal ambient temperatures. We *do not* recommend that the user attempt to readjust this specific gravity unless it is extremely impractical to remove this battery from service long enough to have it properly adjusted at the factory. Should you find it necessary to make this adjustment, a supply of electrolyte may be purchased from your local Marathon aircraft battery distributor or the Field Service Manager, Marathon Battery Company, Cold Spring, N.Y. 10516.

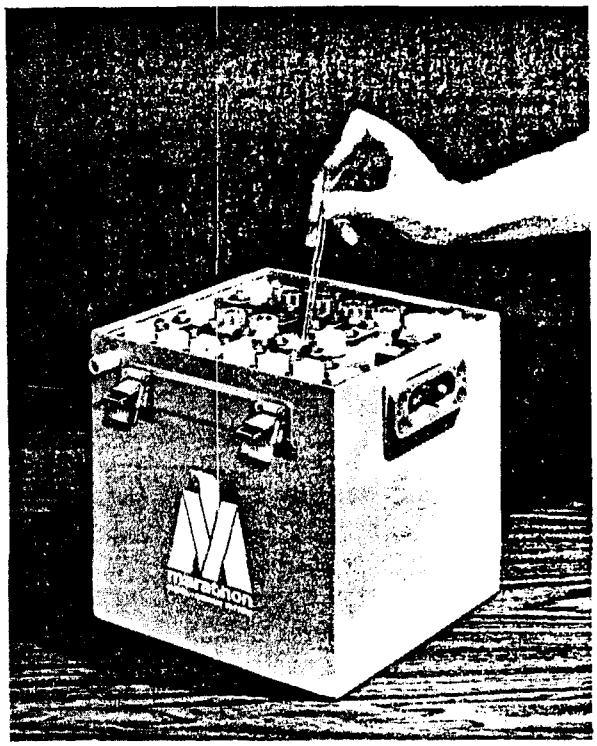

FIGURE 6

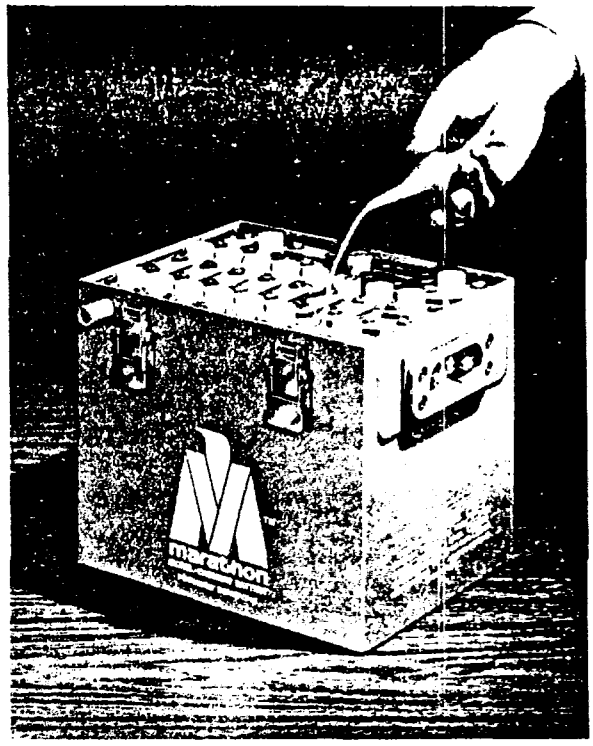

FIGURE 7

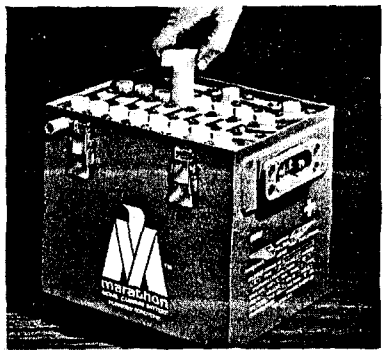
NOTE: Additional instructions on the electrolyte specific gravity when using Marathon Battery BB-449/U—for low temperature operation at −40°F, the specific gravity should be 1.280 to 1.320.

6.0 Repair and Replacement



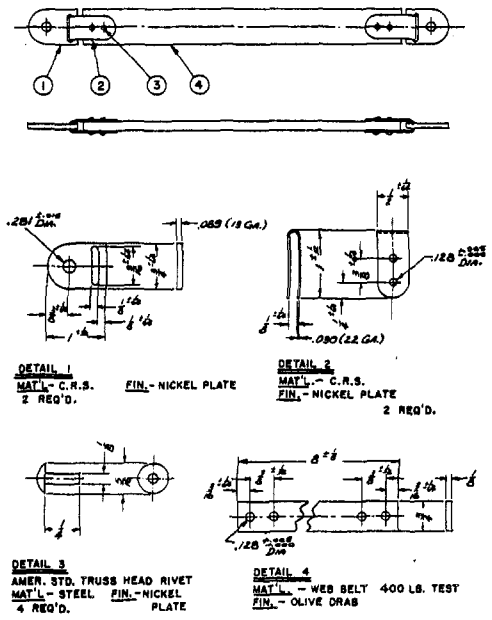


FIGURE 8

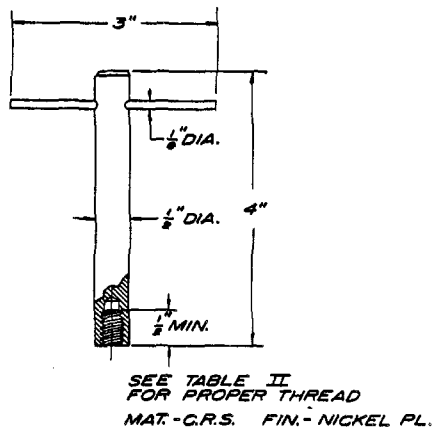
6.1 REPLACEMENT OF DAMAGED CELLS



If a cell becomes contaminated or physically damaged and the cell must be replaced, the procedure is as follows:

a. Clean battery *(consult General Care, 5.1).*
b. Remove end terminal connections. Save all the hardware.
c. Remove all vent plugs, using vent wrench *shown in Figure 8.*
d. Remove enough cell connections to permit the cell to be withdrawn from the battery case.
e. Do not withdraw cell from battery unless replacement cell is available immediately.
f. Withdraw cell, using one of the tools *shown in Figure 9. Also see Figure 10.*
g. Replace with new cell, making certain to insert the cell with the polarity symbols in the right direction. Cells are connected plus to minus. If the cell is difficult to insert, apply a light coat of petroleum jelly or silicone grease to the sides of the cell case before reassembly.
h. Replace connectors, assembling hardware finger tight. CAUTION: Do not use "homemade" hardware, as many of these parts are specifically designed to produce an adequate electrical connection. Spare or replacement hardware may be obtained from your local Marathon Aircraft Battery Distributor or Field Service Manager, Marathon Battery Company, Cold Spring, N.Y. 10516.
i. Torque terminal connections to the values *indicated in Table II,* using calibrated torque

The tools shown in Figure 9 are not available from Marathon. They are of simple construction and can be made in any machine shop.

CELL PULLER - CAP SCREW TYPE

CELL PULLER - HEX NUT TYPE

FIGURE 9

wrench. A typical torque wrench *is shown in Figure 11.*

j. Discharge entire battery *(consult Discharging a Battery, 5.4)*. Monitor each cell to determine that all cells are completely discharged. Should some cells reverse and others retain a portion of their charge, it will be necessary to short the cells individually until each cell is completely at zero *(see Figure 5)*.

k. Charge battery by constant current method *(consult Charging Methods, 5.3)*.

l. Adjust liquid level *(consult Liquid Level Adjustment, 5.5)*. The battery is then ready to be put into service.

m. Return damaged cells for analysis and possible repair to Customer Return Department, Marathon Battery Company, Cold Spring, N.Y. 10516.

6.2 REPLACEMENT OF DAMAGED END CONNECTORS

In some battery types, primarily those used in aircraft, the battery is provided with a special quick disconnect receptacle such as a type manufactured by Elcon or Cannon or any of a number of MS type receptacles. Should one of these connectors become damaged, it will be necessary to replace it with a replacement part obtained from your local Marathon aircraft battery distributor or the Field Service Manager, Marathon Battery Company, Cold Spring, N.Y. 10516. Care should be taken in the removal of this connector to preserve all the hardware and gasketing, if possible, so that the new part may be installed properly.

To remove the connector, first remove those connections which go to the end cells in the battery, thus reducing the possibility of a short circuit when the connector body is removed from the battery case *(see Figure 12)*. All Marathon batteries have the same hardware arrangement, attaching the end connector to the battery, as is used on the intercell connectors. When installing the replacement part, it is necessary to *consult Table II* for torque values.

CAUTION: Do not substitute "home-made" hardware. Care must be taken that the polarity of the end connector is carefully observed so that, when the battery is installed in the equipment, the system will function properly.

6.3 MAINTENANCE RECORD KEEPING

In order to provide an accurate source of information on each battery in service, it is advisable to keep

(Continued on Page 17)

a maintenance log on each. Should a battery malfunction, you will then be able to give the complete history of this specific unit to the Field Service Manager, Marathon Battery Company, Cold Spring, N.Y. 10516, and assist us in the determination of the problem. *A typical battery log is illustrated in Figure 13, inside back cover.*

Following is a list of typical malfunctions encountered in the maintenance and operation of sintered-plate, nickel-cadmium batteries. This list will serve as an index to the preceding information.

7.0 Trouble Shooting

7.1 APPARENT LOSS OF CAPACITY

A characteristic observed in nickel-cadmium batteries is apparent loss or temporary loss of capacity. When this temporary loss occurs, the battery capacity will be lower than the rated capacity. This effect is more common when recharging across a constant potential bus, such as in aircraft, than when recharging by the constant current method. The loss of capacity is normally an indication of imbalance between cells because of differences in temperature, charge efficiency, self discharge rate, etc., in the cells. In applications where lead acid batteries have been used, the serviceman is likely to treat this loss of capacity as a natural aging quality of the battery. Nickel-cadmium battery capacity does not decrease appreciably with age. A loss of capacity is a warning and should not be treated lightly. Periodic deep cycling will be an invaluable aid in alleviating this condition *(consult Reconditioning Service Procedures, 9.3).*

7.2 COMPLETE FAILURE TO OPERATE

Where a battery fails to operate at all, the trouble can usually be traced to an electrical connection. In some instances, the defective connection will be in the circuitry of the equipment in which the battery is installed. This would show up as a broken lead, a relay which fails to operate, improper plug or receptacle installation or similar difficulties. Failure in the battery itself can be caused by an end terminal connector becoming loose or disengaged or perhaps because the charge cycle failed to operate. Should the failure be due to poor intercell connection within the battery, clean and retighten hardware using the proper torque values *(consult Table II).*

7.3 EXCESSIVE SPEWAGE

A battery which has spewed excessively will usually display large crystalline deposits on the tops of the cells. In some cases, a considerable amount of liquid will collect in the bottom of the battery container. A battery in this condition has been subjected to high charge voltages or high ambient temperatures during charging or a combination of the two. The liquid level may also have been improperly adjusted. To correct this condition, clean the battery *(consult General Care, 5.1).* Then charge the battery as required and adjust the electrolyte level *(consult Liquid Level Adjustment, 5.5).* Place battery back into service.

7.4 DISTORTION OF CELL CASES

When a battery has one or more cells with distorted plastic cases, the battery may have been overcharged as described in *Excessive Spewage, 7.3.* This battery must be removed from service and either returned to the factory or sent into the maintenance shop for cell replacement *(consult Replacement of Damaged Cells, 6.1).*

7.5 FAILURE OF ONE OR MORE CELLS TO BALANCE WITH OTHERS

During the charging procedure *(consult Constant Voltage Charging, 5.3.4),* it is sometimes noted that one or more cells fail to rise to the required 1.50 to 1.55 volts at the end of charge. The battery should be treated *as described in Constant Current Charging, 5.3.1.* If these cells still fail to rise to the required voltage they should be removed and replaced according to the procedure *outlined in Replacement of Damaged Cells, 6.1.*

7.6 FOREIGN MATERIAL WITHIN THE CELL CASES

Cells which have been removed because of failure to respond to the normal charging procedures *see preceding paragraph,* may display some evidence of foreign substances within them. This material may be gray, black or brown in color. Such foreign substances are most commonly introduced into the cell through the addition of impure water or water contaminated with acid. Other causes for this dissolution

can be heat generated by extremely high rate charging, charging without sufficient electrolyte in the cell, too high a concentration of electrolyte or a combination of two or more of these conditions.

For instance, a battery has been serviced and electrolyte (potassium hydroxide) has been added to raise the specific gravity. The battery is then permitted to charge at a sufficiently high rate and drive off water. This produces a high concentration of electrolyte, which in turn generates some heat. This set of circumstances will damage the materials in the cell plates and will be indicated by the appearance of black or gray particles in the cell. These cells will usually show up as unbalanced *(consult Apparent Loss of Capacity, 7.1)* and must be removed from service.

7.7 FREQUENT ADDITION OF WATER

If one or more cells require more water than the others, they may be out of balance *(consult Apparent Loss of Capacity, 7.1)*. Discharged cells will always appear low in liquid *(consult Liquid Level Adjustment, 5.5)*.

7.8 CORROSION OF TOP HARDWARE

Excessive rust appearing on the top hardware of a battery may be caused by the presence of acid fumes in the area. This condition will be prevalent where batteries are installed in chemical plants or other places where they are subjected to corrosive fumes, spray or chemical moisture. The battery should be kept clean *(consult General Care, 5.1)* and installed in a compartment which has been cleaned *as per the instructions in Installation of Battery, 4.3.*

7.9 APPEARANCE OF BURN MARKS ON CONNECTORS

When an intercell connector or an end connector shows indication of burning, this usually denotes that the connectors involved have not been properly tightened. For proper torque values, *see Table II.* Burned outer connecting plugs is an indication of plug failure. The battery plug or the mating half should be replaced if necessary *(consult Replacement of Damaged End Connectors, 6.2)*.

7.10 OVERHEATING OF INTERCELL CONNECTORS

If intercell connectors become hot or show signs of overheating, disassemble, clean and reassemble. Torque the connections properly *as specified in Table II.*

7.11 BATTERY CASE LEAKAGE TO GROUND

When a battery has been in an aircraft for a considerable period of time, a voltage can sometimes be detected between either terminal pin or the metal battery case. This voltage is most usually caused by a collection of electrolyte around the cells, usually as a result of spewing from the cell vent caps. The electrolyte is conductive. It is for this reason that voltage can be read. Voltage is merely potential and of itself can do no harm.

The measure of whether or not this potential is affecting battery performance is the amount of current that this leakage path will support. If, for instance, the leakage path will support .050 amperes, this would be the equivalent of a battery self-discharging completely in 500 hours (CA-20 or CA-4). Usually, we consider .050 amperes or less a safe leakage path. Beyond that value, it is advisable to flush the battery vigorously with tap water and permit it to dry in the sun, if possible, or by applying forced warm air. When the battery is completely dried out, this leakage path should no longer be apparent.

The leakage may also be caused by a damaged case-to-cover seal on an individual cell. To determine which cell is damaged, the following method should be applied.

a. Place one probe of the voltmeter on either the positive or negative terminal post and the other against the battery case.
b. Observe the voltage.
c. Leaving the probe on the metal battery case, move the other probe from cell terminal to cell terminal.
d. The indicated voltage should decrease and finally go negative. At this changeover point, you will find the leaking cell.
e. This cell should be removed from service and returned for repair to the Customer Return Department, Marathon Battery Company, Cold Spring, N.Y. 10516.
f. Inspect surrounding cells and hardware for damage.
g. A new cell should be added *in accordance with Repair and Replacement, 6.0.*

7.12 HEATED BATTERIES

In some special applications, Marathon has provided a specially designed battery which incorporates the use of an internal heater blanket and the

accompanying thermostats and input plug necessary to energize the heater. Batteries of this nature are composed of the same type of cells previously discussed in the various sections of this manual and, therefore, these difficulties encountered in cell performance can be handled exactly as though the battery were not equipped with a heater. The heater itself is usually an insulating blanket containing a wire filament. Failure of the blanket to operate can be caused by a break in this filament and is easily detected through the use of a continuity meter. Another cause of heater failure is sometimes centered in the operation of the thermostat. Thermostats can be checked by submitting them to sizeable temperature differences and checking their operation with a continuity meter.

Heater blankets and thermostats cannot be repaired in the field and, should a breakdown be experienced, the material must be returned for replacement to the Customer Return Department, Marathon Battery Company, Cold Spring, N.Y. 10516. Because of the large number of possible variations in heated battery design, it is not possible in this manual to become any more specific on this subject. In applications where heated batteries are used, if other troubles are encountered, contact Field Service Manager, Marathon Battery Company, Cold Spring, N.Y. 10516.

8.0 Storage

8.1 CHARGE RETENTION

Marathon sintered-plate, nickel-cadmium batteries may be stored for long periods of time in any state of charge. The charge retention will depend largely on the ambient temperature of the storage area. A battery stored at 80°F will retain approximately 60% of its rated capacity over a period of one year. A battery stored in an ambient temperature of 0°F will retain approximately 90% of its capacity for a period of one year.

8.2 STORAGE MAINTENANCE

The active materials of the plates are insoluble in the electrolyte and therefore cannot react in any way with the electrolyte when the battery is stored on open circuit. Before placing a battery in storage, the battery should be cleaned *(consult General Care, 5.1)*. If long periods of storage are expected, it is advisable to coat the intercell connectors with a light coat of silicon grease to prevent any corrosion from forming. A battery being placed into service after storage should be given a freshening charge prior to installing it into the equipment *(consult Charging Methods, 5.3)*.

PART IV-SHOP PROCEDURE

9.0 Recommended Shop Procedure to Determine Condition of Aircraft Battery

The information in this part is a condensation of some of the procedures outlined in this manual, plus special information on aircraft batteries.

9.1 SEPARATION OF NICKEL-CADMIUM AND LEAD ACID BATTERY FACILITIES

Nickel-cadmium batteries use potassium hydroxide and distilled water as an electrolyte. Chemically, this electrolyte is an exact opposite of an acid electrolyte.

Anything associated with the lead acid battery (acid fumes included) should never come in contact with the nickel-cadmium battery or its electrolyte. Even traces of sulphuric acid from a lead acid battery entering the electrolyte of a nickel-cadmium battery will result in damage. Also, acid fumes can damage the hardware of the nickel-cadmium battery.

Separate shops are recommended for the two types of batteries. If separate shops are not possible, separate bench facilities shall be provided at opposite ends of the service area. Indicate each area clearly and keep all tools and materials separate and clearly marked.

9.2 VISUAL INSPECTION

A visual inspection of the battery in the aircraft should be made at least once every 50 flight hours on non-epoxy coated batteries and once every 100 hours on epoxy batteries. The battery connector, receptacle and vent lines should be checked for contact failure or damage and the allenhead screws or nuts should be torqued, *as per Table II.*

The cover should be removed to inspect for excess spewage and discoloration or deterioration of intercell hardware. Some slight deposits of potassium carbonates (white in color) may be encountered. If it is excessive, the battery should be removed and cleaned *(see below)*. The electrolyte level in each cell should be checked. If it is below the minimum requirement (consult Liquid Level Adjustment, 5.5), the battery should be removed from service. If this is impractical, the level should be adjusted while in the aircraft. Further inspection and replacement of parts is described in this manual.

9.3 RECONDITIONING SERVICE PROCEDURES

Flight hours are the main factor determining the frequency of reconditioning service procedure, depending on these four variables:

a. Type of starting service.
b. Duty cycle for battery.
c. Ambient operating temperatures.
d. Generator voltage regulator setting.

Therefore, we can only suggest an average time between reconditioning cycles *(Table III)* because of the widely varied flight profiles seen by individual aircraft. The user will eventually apply his experiences and the information gained during the reconditioning service in determining the maximum time. At no time should a battery be allowed to deteriorate to a point where the operation of the battery affects the mission or operation of the aircraft.

TABLE III

Aircraft Type	Approximate Flight Hours Between Reconditioning Cycles
Lear Jet Model 23	100
Jet Commander	100
Grumman Gulfstream I	500
Grumman Gulfstream II	200
Fairchild F-27	200
Fairchild F-227	200
Fan Jet Falcon	100
Boeing 727	400
Boeing 737	400
Grand Commander	500
Beech King Air	100
Beech 99	100

TABLE III (continued)

Aircraft Type	Approximate Flight Hours Between Reconditioning Cycles
North American Sabreliner	200
Lockheed JetStar	150
Turbo Commander	100
MU-2	100
DH-125	150
Hansa Jet	100
Twin Otter	100
Merlin, I & IIB	100

NOTE: In aircraft flying commuter service routes, the battery water level must be checked every 50 hours.

The use of a service log for each battery and aircraft is especially helpful to the user in determining the optimum period between reconditioning. A sample log and check list will be found on the inside back cover of this manual *(Figure 13)*.

9.4 DESCRIPTION OF RECONDITIONING SERVICE

The procedure for removing a battery for a reconditioning cycle should start with a visual inspection in the aircraft *(consult Visual Inspection, 9.2)*. If the battery needs cleaning, it can be performed in the maintenance area. If the spewage is minor, it can be removed with a nylon bristle brush and the battery flushed with water as follows:

9.4.1 FLUSHING OF BATTERY

a. Prior to flushing the battery with water, check the tightness of the vent plugs.
b. Tip battery on side away from battery receptacle.
c. The top of the cells should then be flushed with tap water.
d. Air hose away excess water.

NOTE: If any of the rubber insulation has deteriorated or pulled away from the can, the battery should be disassembled and the rubber recemented.

Use rubber-to-metal cement type 35-2 by G. C. Electronics or equivalent. Replacement can also be made by using neoprene rubber of a 40-60 dryrometer by Minor Rubber Company or equivalent. The rubber thickness is 1/16" to 1/32", depending upon the type of battery.

9.4.2 CHECKING CURRENT FLOW

After flushing and air hose drying, check the current flow between the positive terminal and the case, then the negative terminal and case.

a. First select a meter, such as Simpson 261 or 263, which contains an amperage scale of a minimum of 500 milliamperes. Select the highest current setting on the meter.

b. Take the positive lead of the meter and place on the positive terminal of the battery receptacle and the negative lead on the battery can.
c. Decrease the current setting until a scale is reached where, if any current flow exists, it is readable. Record the current.
d. Move the selector switch on the meter to the highest current setting. Place the negative lead of the meter on the negative terminal of the battery receptacle and the positive lead on the battery can. Proceed as outlined above.
e. If the current flow is more than 100 milliamperes, the unit should be disassembled and cleaned.

NOTE: Do not use the voltage reading between the terminals and the battery can as a criteria for rejection, since current flow is the determining factor.

9.4.3 EPOXY-COATED BATTERIES

Most Marathon nickel-cadmium batteries are now supplied with the battery container and cover epoxy-coated. In this instance, the current flow may be measured by reading from the battery terminals of the receptacle to the snaps that restrain the cover. This is mainly a safety precaution, since in epoxy-coated cans the cells should be completely insulated from the battery case.

9.4.4 CHARGING

The battery should then be charged on a charger/analyzer *(Marathon Model PCA-131—see later reference)* on a constant current source at a 5-hour charge rate or on a constant potential source at 28.5 volts for a 24-volt battery. *(For aircraft batteries of other voltages, use 1.5 volts by the number of cells = constant potential charge volts.)* If the constant current charge is used, continue until the total battery voltage reaches a minimum of 30 volts *(average 1.58 volts/cell).*

9.4.5 USING CONSTANT POTENTIAL

If a constant potential charge is used, continue charge only until the current tapers off and stabilizes.

This simulates the battery's full charge condition as it would appear in the aircraft, making the discharge time recorded an accurate indication of the battery's capacity. It will also allow the adjustment of the electrolyte level to be performed which will prevent the discharge and recharge of a dry battery.

9.4.6 ADJUSTING ELECTROLYTE

At this time the electrolyte level may be adjusted to ¼" above the top of the plates or visible insert. *If the battery is allowed to stand 2 to 4 hours after charge, then the level should be adjusted to ⅛" above the plates or visible insert.*

NOTE: Make adjustments with distilled, deionized or demineralized water. We do not recommend *the addition of potassium hydroxide, as water only* is normally lost due to electrolysis. Potassium hydroxide should be added only on specific instructions from the Field Service Manager, Marathon Battery Company, Cold Spring, N.Y. 10516.

9.4.7 DETERMINING STATE OF CHARGE

Unlike a lead acid battery, the electrolyte in a nickel-cadmium battery acts only as a conductor. Therefore, it is impossible to determine the state of charge from the specific gravity or from open circuit voltage readings. The only way to tell the state of charge is by measured discharge.

9.4.8 DISCHARGE

At this time, the battery is ready for discharge. Select a discharge rate of either the 1 or 2-hour rate *(see Table IV).*

a. The total battery voltage should be monitored until an average of 1.0 volt/cell is reached.
b. At this point, the time should be recorded.
c. A supplemental discharge should be performed on any battery failing the capacity test. If the discharge time is less than 70% of that specified *(see Table IV)*, then a supplemental discharge (deep cycle) must be performed.

TABLE IV

Battery Type	*Rate 1-Hour*	*2-Hour*	*Battery Type*	*Rate 1-Hour*	*2-Hour*
CA-4	20	11	CA-40	38	20
CA-5	34	17	CA-44	38	20
CA-6	20	11	CA-51	5.0	2.5
CA-7	10	5.5	CA-52	5.0	2.5
CA-9	20	11	CA-53	5.0	2.5

CA-24	20	11	CA-121	10	5.5
CA-27	20	11	CA-125	5.0	1.5
CA-31	3.0	1.5	CA-727	20	11

Cutoff voltage of 1.0 volt/cell.

9.4.9 DEEP CYCLING

The deep cycle consists of continuing the discharge listed above.

a. As each individual cell reaches 0.6 volt or less,

a metal shorting strap should be placed across the terminals while the load is still applied. It will be impossible to short out all cells within a battery since, during constant resistance discharge, the current decreases as the voltage decreases. Therefore, when approximately 75% of the cells are shorted with metal straps, a 1.0 ohm resistor of 1 or 2 watts should be placed across each of the remaining cells.

b. The battery should remain shorted as above for a period of 3 or more hours.

c. If the discharge time is 70% or greater than that specified *(see Table 11)*, the supplemental discharge (deep cycle) can be eliminated if time is a factor.

TABLE V

Battery Type	*Time*	*Current*	*Battery Type*	*Time*	*Current*
CA-4	7-hour	5-amp	CA-40	7-hour	8-amp
CA-5	"	8-amp	CA-44	"	8-amp

			CA-737	"	5-amp

9.4.10 FINAL CHARGE

The battery is now ready for charge. Charge battery by the constant current method only.

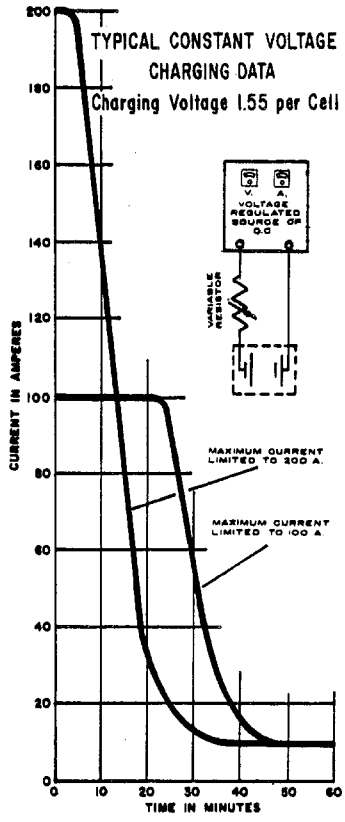
a. Place the battery on charge at the 5-hour rate for 7 hours *(Table V)*. Care should be taken to see that the total ampere-hour charge equals that outlined in Table V. If the charge current decreases during charge, manually adjust current to maintain the proper value.

b. During the final 5 minutes of charge (for automatic chargers that have terminated, reset the charge for 10 additional minutes), the voltage of each individual cell should be read.

c. The minimum voltage should be 1.55 volts/cell and the maximum 1.80 volts/cell at room temperature (70-80°F). If any cell fails to rise to at least 1.55 volts, the constant current charge should be continued for an additional hour. At this time, monitor the cell voltage again.

d. Any cell that fails to rise above 1.55 volts or exceeds 1.75 volts should be removed from service and may be returned for rebuilding or overhaul to Customer Return Department, Marathon Battery Company, Cold Spring, N.Y. 10516.

NOTE: Any battery having a discharge time less than 70% of that specified in Table IV SHOULD be given another discharge and recharge *(per Discharge, 9.4.8, and Deep Cycling, 9.4.9)*.



CAUTION: Any battery having a discharge time less than 50% of that specified in Table IV MUST be given another discharge and recharge *(per Discharge, 9.4.8, and Deep Cycling, 9.4.9)*.

9.4.11 COMPLETION OF CHARGE

Following completion of the charge, the electrolyte level should again be checked, using the levels outlined earlier *(consult Adjusting Electrolyte, 9.4.6)*. Torque the nuts or allenhead screws, attached to the intercell connectors *(see Table II for correct torque values)*.

9.4.12 CHECKING CURRENT PATH

The final step now is to recheck the current path between the cell and battery case, using the maximum current outlined previously *(consult Checking Current Flow, 9.4.2)*.

10.0 Marathon Battery Charger/Analyzer PCA-131 Series

10.1 IMPORTANCE OF RECONDITIONING

The data obtained in performing the reconditioning cycle is invaluable for determining the maximum flight hours between reconditioning service. More frequent reconditioning is recommended whenever possible, however.

In aircraft where more than one battery is used, either in series or parallel starting, care should be taken that the batteries are not allowed to become unbalanced. Perform the reconditioning service on both batteries during the same inspection period.

The Marathon Model PCA-131 Series Charger/Analyzer is designed to provide maximum service from nickel-cadmium aircraft batteries. It features a "Go, No-Go" indication of battery condition.

The correct charge and discharge current is preselected with the setting of the switch position. The battery can be left unattended during charge and automatically adjusts for changes in line voltage. It will automatically terminate the discharge if the average battery voltage falls below a preselected end voltage. You can then determine the actual discharge time from the running timer. The discharge percentages discussed previously also apply to the Marathon Charger/Analyzer.

10.2 PCA-131 CHARGER/ANALYZER NICKEL-CADMIUM BATTERY DEEP CYCLING PROCEDURE

a. Clean battery if necessary. Use water only.

b. Check the current flow between positive terminal and case, then negative terminal and case. If the reading is more than 50 milliamps, the battery should be disassembled and cleaned.

c. Connect battery to PCA-131 *before turning on power* and set selector to proper battery type.

d. Turn power on PCA-131 and rotate clock to TOPPING CHARGE.

e. Top charge until battery voltage reaches 30 volts minimum.

f. Check the water level. If it is less than ¼" above the plates, adjust to ¼" immediately after charge. If battery stands 2-4 hours, adjust level ⅛" above plates.

g. Rotate clock to START OF DISCHARGE.

h. (1) If the battery gives the proper capacity, then it will automatically go into the main and over charge modes.

(2) If the capacity is less than the 120 minutes required, the battery LOW LIGHT will light. If this occurs, proceed as follows: Throw the automatic-manual switch to MANUAL DISCHARGE and continue discharge. As cell voltage reaches 0.6 volts, place a short across them. Continue discharge until approximately 75% of the cells are shorted. If possible, short remaining cells prior to disconnecting battery or place a 1 Ohm- 1 Watt resistor across each cell. Disconnect the battery from PCA-131. Leave shorts on for three to 24 hours. Remove shorts, connect battery to PCA-131, throw the automatic-manual switch to AUTOMATIC position, turn unit "on," rotate clock to MAIN CHARGE MODE. The unit will not operate until the voltage builds up to 19 volts. This is accomplished automatically.

i. In reference to h2, the charge is to continue until completion, which includes main and topping charge.

j. During the final five minutes of topping charge (in the event the unit has turned off, reset to TOPPING for five minutes) the voltage of each cell should be checked. Minimum voltage 1.55 volts; maximum voltage at room temperature 1.80 volts. If the voltage is under 1.55 volts, reset the TOPPING CHARGE for one (1) hour and recheck voltage. If it does not rise to 1.55 volts or it decreases below 1.55 volts, the cell or cells should be removed for rebuilding. If the voltage is over 1.80 volts, the cell or cells should also be removed for rebuilding.

k. Check the water level (consult step f).

l. Recheck current flow between terminal and case (consult step b).

m. Where time allows, all batteries failing capacity test should be recycled. Any battery with a discharge time of 50% or less of that specified must be recycled.

Complete information on Marathon's solid state Charger/Analyzer, the Model PCA-131—such as operation instructions and charger/analyzer specifications—may be obtained from the Field Service Manager, Marathon Battery Company, Cold Spring, N.Y. 10516. (request Data Sheet BA-226).

CROSS REFERENCE AND REPLACEMENT DATA ON MARATHON NICKEL-CADMIUM AIRCRAFT BATTERIES

These listings indicate the Marathon battery types used as original equipment, retrofitted and recommended replacement types for corporate, business, private, commercial and helicopter aircraft. To use, simply locate the aircraft and model you are now flying. The Marathon battery or recommended replacement then appears in the extreme right hand column.

PHOENIX AEROSPACE INC. STANDARD WARRANTY

1. Sellers Standard Warranty

(a) Phoenix Aerospace, Inc. herein called Seller, warrants that each unit delivered shall, at the time of delivery thereof to Buyer or Buyer's customers, be free from defects in material and workmanship and from defects or faults in design in view of the state of the art at the time of design thereof. Any defect must have become apparent and Buyer must have notified Seller thereof within twenty-four (24) months after installation in aircraft, not to exceed thirty (30) months after date of manufacture on unit nameplate. The extent of Seller's liability is limited to the repair, replacement, overhaul, or modification of any defective unit.

(b) Seller's obligation hereunder is conditioned upon the return as soon as practicable of the defective unit with all transportation charges prepaid to Seller in Phoenix, Arizona. Returned units must be accompanied by properly authorized Purchase Order, specifying the nature of the defect, if known, and containing reasonable proof to Seller that the defect is due to a matter embraced within Seller's warranty. An allowance will be made for inbound transportation charges in the Continental United States, but inbound transportation charges are the responsibility of Buyer outside the limits of the Continental United States. Overhauled or repaired units will be returned via air, transportation charges prepaid to destination anywhere in the world. Removal of the unit from any aircraft and reinstallation shall be at Buyer's expense.

(c) The warranty hereunder shall not apply to any unit installed in any Aircraft if such Aircraft shall not have been operated in accordance with the Federal Aviation Regulations issued by the Federal Aviation Administration, or if such unit shall not have been operated or maintained in accordance with Seller's instructions applicable to such unit, or if such unit shall have been repaired, altered or modified without Seller's approval, or operated with an accessory or part not authorized for use therewith, or if such unit shall have been operated subsequent to its involvement in an accident, or if the unit shall have been subject in any way to improper operation, maintenance, repair, alteration or modification.

(d) THE WARRANTY AND THE OBLIGATIONS AND LIABILITIES OF SELLER HEREUNDER ARE EXCLUSIVE AND IN SUBSTITUTION FOR AND BUYER HEREBY WAIVES ALL OTHER WARRANTIES, EXPRESS OR IMPLIED, ARISING BY LAW OR OTHERWISE (INCLUDING, WITHOUT LIMITATION, THE IMPLIED WARRANTY OR MERCHANTABILITY, ANY IMPLIED WARRANTY ARISING FROM COURSE OF PERFORMANCE, COURSE OF DEALING OR USAGE OF TRADE, ANY IMPLIED WARRANTY OF FITNESS, AND ANY OBLIGATION OF SELLER WITH RESPECT TO INCIDENTAL OR CONSEQUENTIAL DAMAGES), AND SHALL NOT BE EXTENDED, ALTERED OR VARIED EXCEPT BY A WRITTEN INSTRUMENT SIGNED BY SELLER AND BUYER.

2. General Instructions

(a) Overhaul, modification or repair of all Phoenix Aerospace units is authorized only at Seller's facility. Any overhaul, repair, alteration or modification without Seller's approval will negate or void the terms of Seller's Standard Warranty stated herein. Units in need of repair should be shipped directly to:

Phoenix Aerospace Inc.
1022 South 23rd Street
P. O. Box 20804
Phoenix, Arizona 85036

Units in warranty are repaired at the factory under the terms and conditions of Seller's Standard Warranty at no charge. There will be a charge imposed for Units returned within the warranty period which are found not to be defective or for a defect found not to be included within Seller's Standard Warranty or which have been removed or returned as a result of any program of preventive maintenance.

(b) Units out of warranty are repaired at the factory at Seller's standard charge in effect at the time of receipt of unit. Inbound and outbound transportation charges are the responsibility of the Buyer.

PHOENIX AEROSPACE INC.

VR-1010-24-1A/P.N. 095001

INTRODUCTION

In conformance with A.T.A. Specification No. 100 for Manufacturers' Technical Data, two manuals have been prepared concerning the Model VR-1010-24-1A DC Voltage Regulator. These manuals, if used as intended, will facilitate the effective, continued operation of the equipment. Technical data is grouped according to usage in the manual as described.

MAINTENANCE MANUAL

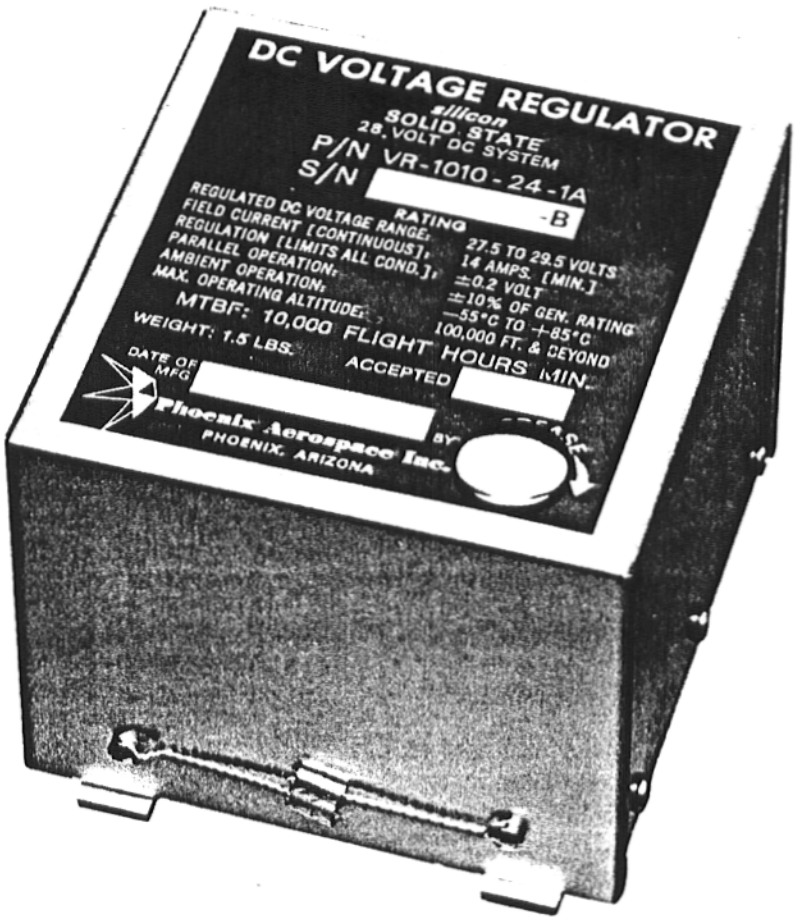
This manual is intended for use by flight line and hangar maintenance personnel. A detailed description and operation procedures, including a table of leading particulars are presented for reference. Mounting information and cabling information are presented as an aid to installation. Trouble-shooting information is limited to procedures required to trace a trouble to the overall unit for replacement.

OVERHAUL MANUAL WITH ILLUSTRATED PARTS CATALOG

The Overhaul Manual contains all the information required for shop testing, replacement of defective parts, alignment and adjustment, mechanical disassembly, inspection, and reassembly. Detailed circuit theory is given with emphasis on theory that will be especially helpful for effective trouble-shooting. Performance tests as well as functional (go/no-go) checks, which may be used to determine condition of equipment and for retesting after repairs.

The Illustrated Parts Catalog provides a means to determine the manufacturer's part number and the physical location on the equipment of a part if the reference designation is known, or to determine the reference designation and the manufacturer's part number when the physical location of the part is known but no other information is available.

DESCRIPTION AND OPERATION



1. GENERAL.

A. Purpose of Manual.

This manual contains maintenance and installation procedures for the Model VR-1010-24-1A, DC Voltage Regulator, Silicon Solid-State, illustrated in Fig. 1.

B. Purpose of Equipment.

The Model VR-1010-24-1A, DC Voltage Regulator is used to control all 28 volt direct current generators and starter generators conforming to FAA TSO-C56 and/or Military Specification MIL-G-6162. The regulator performs the function of maintaining constant output voltage under varying speed and load conditions in single generator or multiple generator systems.

Model VR-1010-24-1A, DC Voltage Regulator
Figure 1

2. DESCRIPTION.

A. The Model VR-1010-24-1A, DC Voltage Regulator is a compact self-contained unit utilizing state-of-the-art solid-state techniques. The regulated voltage is adjustable through access hole in top cover, by removing chrome plug button, and resetting mechanically locked potentiometer. Operating power for the regulator is obtained from the regulated generator. The regulator automatically adjusts field current to produce a constant voltage at the generator output under varying speeds and loads. The unit mounts in several military and commercial type mounts for ease in installation and retrofit operations.

B. The primary characteristics, capabilities, overall weight, and dimensions are listed in Table of Leading Particulars, Table 1.

GENERAL:

Duty: Continuous, unattended.

Temperature Rise: 15° C (maximum).

Cooling: Self-cooled by natural convection, conduction, and radiation.

Ambient Temperature Range: −85° to +85° C.

Maximum Operating Altitude: 100,000 feet and beyond.

Reliability: 10,000 hours MTBF (minimum).

ELECTRICAL:

Regulated DC Voltage Range: 27.5 to 29.5 VDC, no load to full load, over rated generator speed and temp/alt. operating range.

Field Current (Continuous): 14 Amperes (minimum).

Regulation: ±0.2 Volts, no load to full load, over rated generator speed and temp/alt. operating range.

Voltage Adjustment Limits: 26 VDC to 31 VDC, continuously variable.

Equalizer Circuit: ±2.5 Volts, minimum change, no load to full load, at minimum rated speed for regulation, when 0.25 volts is applied to equalizer bus terminals.

Parallel Operation: ±10 per cent equal division of load, two or more generators operated in parallel, no load to full load, over rated generator speed range.

Table of Leading Particulars
Table 1

ELECTRICAL (cont):

Regulator Equivalent Resistance: High Value—More than 100 ohms.
Low Value—Less than 0.5 ohms.

Current Regulation: Regulation for balancing current between parallel generators in multiple generator systems.

Recovery Time: 0.05 Seconds, full load switched ON-OFF-ON, controlled voltage recovers to and remains within 10 per cent of steady state condition.

Overload Current: 14 Amperes (minimum) for one hour.

Induced Ripple: Less than 1.5 volts peak to peak.

Transient Protection: ±80 volts for 40 milliseconds,
±600 volts for 10 microseconds.

MECHANICAL:

Weight: 1.6 pounds (729.6 grams).

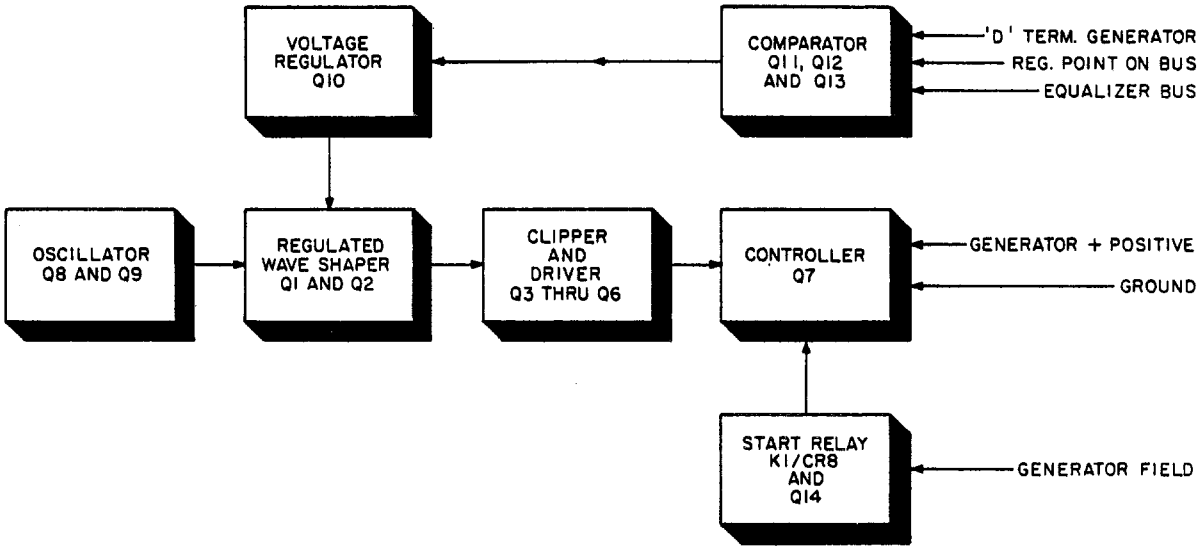
Overall Dimensions: 3-1/2 in. wide (8.89 cm) by
3-3/4 in. long (9.425 cm) by
3 in. high (7.62 cm).

Electrical Connections: Connections made through contactors of associated mounting base, positive spring loaded in base.

Mounting: Unit plugs into MS Bases: AC40D-8445-2, AF49C-7573 and AN3204, Commercial Bases: Bendix Types 1700, 19E04, and 32E04. New applications permit use of Bendix Type 1B38-1 when desired.

Cooling: Self-cooled by natural convection, conduction, and radiation.

Installation: Mounts in any position, without degradation of regulation, heating, operating life, or other operating characteristics.



Adjustment: Voltage set potentiometer, INCREASE, adjusts voltage and paralleling in a single operation, located under removable plug button at top of unit.

3. OPERATION.

The subsequent paragraphs cover the theory of operation for the Model VR-1010-24-1A, DC Voltage Regulator. The Block Diagram Theory will aid in conveying the overall circuit operation to non-technical oriented personnel, while the Detailed Circuit Theory will enable the technician to understand in detail the operation of equipment.

A. Block Diagram Theory.

The subsequent paragraphs together with the block diagram of Fig. 2, cover in concise form the signal flow and circuit operation for the Model VR-1010-24-1A, DC Voltage Regulator.

Model VR-1010-24-1A, DC Voltage Regulator
Block Diagram
Figure 2

(1) Generator Start Relay. Relay K1 in the de-energized condition, contacts closed, completes the generator field circuit, until operating speed and voltage output are attained. Relay K1 energizes at a voltage of approximately 20 volts, when Zener diode ZR3 conducts and biases transistor Q14 to turn-on. Relay K1 contacts open, and the generator field circuit is completed through the controller circuit of the regulator, transistor Q7. Operating power for the regulator circuit is obtained from the generator output.

(2) Stabilized Oscillator. Transistors Q8 and Q9 generate a sine wave signal at a frequency of approximately 400 Hertz. The sine wave signal is coupled through auxiliary windings of oscillator transformer T1 to the input of the regulated wave shaper circuits.

(3) Regulated Wave Shaper. Transistors Q1 and Q2 in a push-pull circuit receive the sine wave signal from the stabilized oscillator. Voltage applied from the voltage regulator circuit determines the shaping operation to control duty cycle and regulator operation. The shaped output is coupled to the input of the clipper circuit.

(4) Clipper and Driver. Transistors Q3, Q4, Q5, and Q6 in cascaded push-pull stages provide additional shaping and amplification of the 400 Hertz signal. The amplified signal is applied to the controller circuits.

(5) Controller. Transistor Q7 and diodes CR2 and CR3 comprise the controller circuitry. Transistor Q7 switches the generator field current at a rate of approximately 800 pulses per second, derived by rectification of the 400 Hertz signal by diodes CR2 and CR3. Variation in the width, duty cycle, determines the amount of field current. Clamp diode CR4 maintains continuous field current.

(6) Voltage Regulator. Transistor Q10 delivers the regulating bias to control pulse width of the regulated wave shaper circuit. Reference and control signals are derived from the voltage comparator circuit.

(7) Voltage Comparator. Transistors Q12 and Q13 are operating as a voltage comparator circuit with temperature stabilized reference voltages and an adjustable set point. Transistor Q11 is a current comparator circuit for paralleling operation.

B. Detailed Circuit Theory.

The following sub-paragraphs cover the individual circuits and their operation. Occasional reference to the overall schematic diagram of the equipment, Fig. 3, will be necessary to determine circuit configuration.

(1) Generator Start Relay. The generator start relay K1 with normally closed contacts in the de-energized condition allows maximum field current to flow during start-up of generator. When the generator voltage reaches approximately 20 volts, Zener diode ZR3 conducts and biases transistor Q14 to 'turn-on' and permits relay K1 to energize, opening the field current by-passing contacts. The generator field current path is now passing through the controller circuit through transistor Q7. Operating power is supplied from the generator (+), to the control circuits. Diode CR8 across the coil of relay K1 functions as a suppressor diode. Resistors R39 and R40 determine the maximum base current flow of transistor Q14.

(2) Stabilized Oscillator. The stabilized oscillator utilizes transistors Q8 and Q9 in a Hartley oscillator circuit. Toroidal transformer T1 with multiple windings provides the tuned circuit, feedback, and output windings for the oscillator. The tuned circuit is tuned by capacitor C3 to approximately 400 Hertz. Capacitor C8 provides parasitic suppression in the oscillator tank circuit. The feedback winding provides sustained oscillation to the base-collector circuit. Resistors R21 and R22 provide the bias to the base circuits of the transistors to insure starting and sustained oscillation. Resistor R15 provides degeneration for improved stability of the oscillator circuit. Output to the regulated wave shaper circuit is through remaining winding on transformer T1.

(3) Regulated Wave Shaper. The regulated wave shaper receives the 400 Hertz sinusoidal signal from transformer T1. The input signal applied to the bases of transistors Q1 and Q2 is through resistors R1 and R2 to limit the amount of base current. Transistors Q1 and Q2 conduct alternately on positive half-cycles of the input signal. The point of conduction and duration, resultant increase or decrease in duty cycle is determined by the bias supplied to the emitter circuits from transistor Q10, voltage regulator. Diode CR1 serves as a clamp diode to set bias level of transistors Q1 and Q2. The output across the collectors is a quasi-square wave signal and is applied to the input of the clipper circuit.

(4) Clipper and Driver. The clipper and driver circuit provide additional shaping of the signal and amplification for application to the controller circuit. The clipper circuit consists of transistors Q3 and Q4 in a push-pull circuit. The quasi-square wave signal is coupled to the base circuits of

transistors Q3 and Q4 through limiting resistors R3 and R5, respectively. The output of the clipper circuit is a quasi-square wave with improved rise time. The output is coupled to the base circuits of the driver transistors Q5 and Q6 through resistors R7 and R8, respectively. Resistors R9 and R10 provide a low impedance return for leakage currents. Output in the collector circuit is developed across toroidal transformer T2 and coupled to the controller circuit. Zener diode ZR1 and resistor R14 provide voltage regulation to the clipper and driver circuits.

(5) Controller. The controller circuit comprised of transistor Q7 and diodes CR2 and CR3 control the generator field current to regulate the output voltage of the generator. The quasi-square wave output across transformer T2 is converted to a uni-directional positive voltage by rectification circuit comprised of diodes CR2 and CR3. The positive pulses with a nominal pulse rate of 800 per second are applied to the base of transistor Q7 to control turn on and turn off. Variation of the pulse width, varies in step with the voltage adjustment setting of variable resistor R35, effectively controlling duty cycle. The results of this variation in duty cycle determines the on-off time of transistor Q7 and subsequent variations in generator field current to achieve voltage regulation at the generator output. The regulator operating at a nominal rate of 800 pulses per second in the controller section is adequate to provide proper smoothing of the current to the generator field. The predominate AC component on the DC output of the generator is due primarily to commutator ripple and not from the contribution of the field excitation. RF filter L1 in the collector circuit of transistor Q7 and in series with pin C of the regulator, provides additional filtering of the 800 pulse per second controller output and harmonics of the fundamental frequency. Since the generator field is highly inductive, continuous field current is achieved by the action of clamp diode CR4. The voltage waveform at pin A of the regulator, emitter of transistor Q7, is a positive pulse with an excursion from ground to a positive value approximating generator voltage, typically 27.5 to 29.5 volts. The current flowing in the generator field is constant due to the action of clamp diode CR4. Capacitor C2 and resistor R13 provide a series path for high speed transients which might appear across the collector to emitter circuit of transistor Q7.

(6) Voltage Regulator. The voltage regulator consists of transistor Q10, and associated biasing and time constant circuitry. Resistors R18 and R19 comprise a voltage divider and bias network for the emitter while resistor R17 and capacitor C4 establish the time constant of regulation. Control is applied to the base circuit from the voltage comparator. Output at the collector is applied to the emitter and base circuit of transistors Q1 and Q2, across clamp diode CR1.

(7) Voltage Comparator. The voltage comparator circuit comprised of transistors Q12 and Q13 samples the voltage on the generator bus, pin B of the regulator. The circuit operates as a differential comparator. The base of transistor Q13 receives the voltage from regulation point on generator bus, as adjusted by setting of voltage adjustment increase-EADJ, variable resistor R35, while the base of transistor Q12 is referenced to the temperature compensated Zener voltage at the collector of transistor Q11. Any change in voltage at the regulation point on bus of the generator develops a voltage across resistor R23 in the base of transistor Q10 to apply a change in bias to the voltage regulator. Parallel generator operation is achieved by sampling the voltage between the equalizer bus, pin K of the regulator, and the equalizer sense point, terminal D on generator, pin D of the regulator. The change in voltage appears across resistor R27 and causes a change in the voltage drop across resistor R28 in the collector circuit, and adds in series with the reference voltage derived from temperature compensating diode CR5, CR6, and CR7 in series with Zener diode ZR2. Diode CR9 and resistor R26 establish a reference voltage at the base of transistor Q11. Unequal generator currents cause a change in generator voltage output in a direction to equalize generator currents.

TROUBLE SHOOTING

1. GENERAL.

The following paragraphs define procedures suitable for determining that a fault exists in the DC Voltage Regulator. These procedures do not cover trouble shooting within the regulator or associated generator. For equipment trouble shooting procedures refer to the overhaul manual and perform only in an overhaul shop.

2. PRELIMINARY SYSTEM CHECK.

Refer to the airframe wiring diagram and the cabling information given in Fig. 205 or 206 as applicable, and check wiring between generator/s and regulator/s for continuity and proper connection.

3. OPERATIONAL CHECK.

After preliminary checks have been completed an operational check may be made to determine the malfunctioning component of the system. All checks are made with the generator operating at or above minimum rated speed. When performing checks in a parallel system, check one generator and its associated equipment at a time. The remaining generator/s in the system should be off the line.

NOTE: Observe the engine manufacturers' instructions carefully to prevent overheating when operating the engine on the ground. As soon as checks are completed the engine should be throttled down.

Proceed with checks as outlined in Table 101 to determine malfunction.

CAUTION: UNDER NO CIRCUMSTANCES SHOULD THE REGULATOR BE DISASSEMBLED IN THE FIELD FOR REPAIRS. ANY REGULATOR FOUND TO BE DEFECTIVE MUST BE RETURNED TO AN OVERHAUL REPAIR SHOP FOR REPAIR AND RECONDITIONING.

Trouble Shooting Chart
Table 101 (Sheet 1 of 4)

SYMPTOM	PROBABLE CAUSE	CHECK	REMEDY
Generator ammeter reads zero.	Mounting base contact springs making poor contact with pins in regulator base.	Remove regulator from mount, check tension of contact springs and condition of pins and springs.	Clean and polish contact springs on mount and pins on regulator. Reinstall regulator.
	DC Voltage Regulator not adjusted properly or malfunctioning.		Remove regulator and install tested and properly adjusted regulator. Return malfunctioning unit to overhaul repair shop.
	Defective or damaged generator.	Check and inspect in accordance with generator manufacturer's instructions.	Remove defective generator and install operative unit. Return defective unit to overhaul repair shop.
	Damaged wiring between generator and regulator.	Inspect wiring for shorts and continuity using airframe manufacturer's installation drawings.	Replace defective wiring, check, and secure all connections.
	Defective ammeter.	Check operation and calibration in accordance with manufacturer's instructions.	Replace defective ammeter. Return defective parts to overhaul repair shop.
	Generator main power switch open, fusible link or battery relay open.	Check circuit for continuity and malfunctions.	Replace defective or malfunctioning unit. Return defective unit to overhaul repair shop.
Generator voltage zero.	DC Voltage Regulator malfunctioning.		Remove regulator and install tested and properly adjusted regulator. Return malfunctioning unit to overhaul repair shop.

Trouble Shooting Chart
Table 101 (Sheet 2 of 4)

SYMPTOM	PROBABLE CAUSE	CHECK	REMEDY
Generator voltage zero (cont).	Damaged wiring between generator and regulator.	Inspect wiring for shorts and continuity using airframe manufacturer's installation drawings.	Replace defective wiring, check, and secure all connections.
	Defective or damaged generator.	Check and inspect in accordance with generator manufacturer's instructions.	Remove defective generator and install operative unit. Return defective unit to overhaul repair shop.
Output voltage too high.	DC Voltage Regulator not adjusted properly or malfunctioning.		Remove regulator and install tested and properly adjusted regulator. Return malfunctioning unit to overhaul repair shop.
	Mounting base contact springs making poor contact with pins in regulator base.	Remove regulator from mount, check tension of contact springs and condition of pins and springs.	Clean and polish contact springs on mount and pins on regulator. Reinstall regulator.
	Damaged wiring between generator and regulator.	Inspect wiring for shorts and continuity using airframe manufacturer's installation drawings.	Replace defective wiring check, and secure all connections.
Output voltage too low.	DC Voltage Regulator not adjusted properly or malfunctioning.		Remove regulator and install tested and properly adjusted regulator. Return malfunctioning unit to overhaul repair shop.
	Mounting base contact springs making poor contact with pins in regulator base.	Remove regulator from mount, check tension of contact springs and condition of pins and springs.	Clean and polish contact springs on mount and pins on regulator. Reinstall regulator.
	Damaged wiring between generator and regulator.	Inspect wiring for shorts and continuity using airframe manufacturer's installation drawings.	Replace defective wiring, check, and secure all connections.

Trouble Shooting Chart
Table 101 (Sheet 3 of 4)

SYMPTOM	PROBABLE CAUSE	CHECK	REMEDY
Voltmeter or ammeter fluctuates rapidly under steady load conditions.	Malfunctioning DC Voltage Regulator.		Remove regulator and install tested and properly adjusted regulator. Return malfunctioning unit to overhaul repair shop.
Output voltage varies with application or removal of load.	Malfunctioning DC Voltage Regulator.		Remove regulator and install tested and properly adjusted regulator. Return malfunctioning unit to overhaul repair shop.
Load division in a parallel system out of limits.	Defective ammeter.	Check operation and calibration in accordance with manufacturer's instructions.	Replace defective ammeter. Return defective parts to overhaul repair shop.
	DC voltage regulator not adjusted properly or malfunctioning.		Remove regulator and install tested and properly adjusted regulator. Return malfunctioning unit to overhaul repair shop.
	Damaged wiring between generator and regulator.	Inspect wiring for shorts and continuity using airframe manufacturer's installation drawings.	Replace defective wiring, check, and secure all connections.
	Generator grounding straps not secured.	Check grounding of generator per airframe and generator manufacturer's instructions, and value of resistance specified.	Secure and ground strap generator properly.
	Equalizer switch/relay open-circuited or grounded.	Check switch/relay in accordance with manufacturer's instructions.	Replace defective switch/relay.
	Equalizer switch/relay wiring shorted or open.	Check wiring in accordance with manufacturer's instructions.	Replace defective wiring and secure all connections.

SYMPTOM	PROBABLE CAUSE	CHECK	REMEDY
System voltage drops when a generator in the parallel system is removed from line.	Equalizer switch/relay shorted.	Check switch/relay in accordance with manufacturer's instructions.	Replace defective switch/ relay.
	Equalizer switch/relay wiring shorted.	Check wiring in accordance with airframe manufacturer's drawings.	Replace defective wiring and secure all connections.

Trouble Shooting Chart
Table 101 (Sheet 4 of 4)

MAINTENANCE PRACTICES

1. GENERAL.

The following paragraphs cover in detail operations associated with maintenance, installation/removal, etc. of the Model VR-1010-24-1A DC Voltage Regulator.

2. SERVICING.

Periodic servicing or maintenance of the (solid-state) DC Voltage Regulator is not required or recommended. The equipment should not be removed from the airframe unless required by maintenance practices observed by the using agency. The use of solid state devices in a completely transistorized circuit eliminates the major causes of failures and periodic maintenance procedures. In the event a failure occurs refer to the Installation/Removal procedures and remove unit for repair by the overhaul shop or for return to vendor.

3. INSTALLATION/REMOVAL.

The following sub-paragraphs outline the installation and removal procedures for the DC Voltage Regulator.

A. Installation.

(1) Refer to Fig. 201, Fig. 202 and Fig. 203 to determine clearance requirements for DC Voltage Regulator and the selected mounting base. In the event types other than shown in Fig. 202 and Fig. 203 are used, care must be taken to insure clearance. Modification of installation instructions to accommodate other types will be obvious.

CAUTION: USE CARE IN DRILLING OPERATION OF SUBSEQUENT PARAGRAPH, TO PREVENT DAMAGE TO AIRFRAME STRUCTURE, WIRING, OR CONTROLS.

(2) Refer to Fig. 202 or Fig. 203, mark and drill mounting holes for the selected mounting base. Typical drilling information is given on Fig. 202 and Fig. 203.

(3) Install selected regulator mounting base and secure to airframe in conformance with manufacturer's instructions supplied with the mounting base. All hardware shall meet or exceed applicable MS or AN specification. Length of screws must be determined at time of installation and screw must have at least one and one-half threads showing after installed and securely tightened.

(4) Refer to Fig. 204 and connect wiring to mounting base in accordance with information given on wiring diagram. For single generator system connection refer to Fig. 205. For parallel generator system connection refer to Fig. 206. During wiring operations, reference to the airframe manufacturer's installation and wiring diagrams will aid in checking and completing the wiring operation.

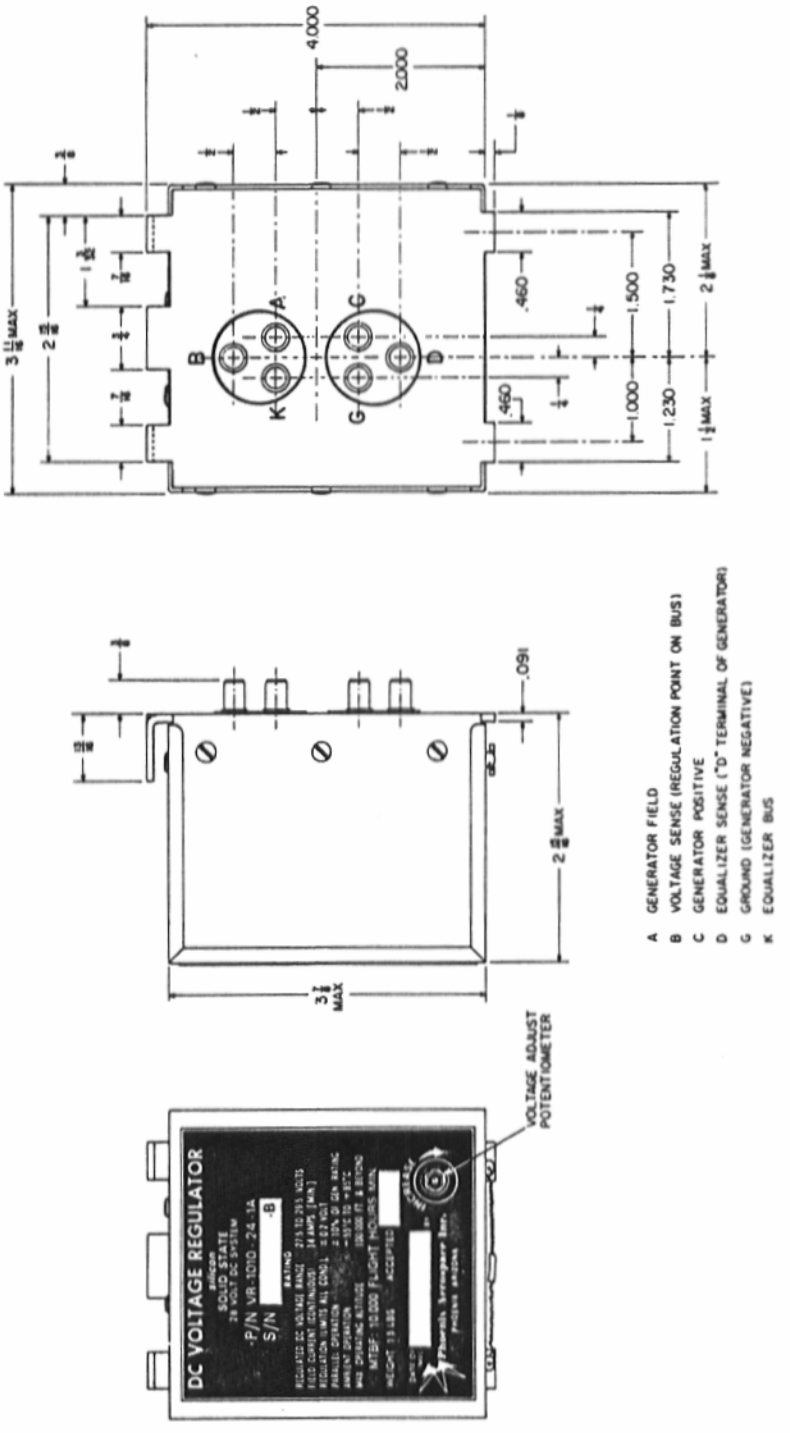
NOTE: In most cases the mounting base will be installed and wired properly for the system with which regulator is to be used.

(5) Install regulator in mounting base and secure as follows:

(a) Insert the two small tabs on the DC Voltage Regulator into the slotted brackets on the mounting base. The tabs should fit snug, but without forcing. Check to see the brackets are not bent out from the mounting base, which would permit the tabs to slip up and out.

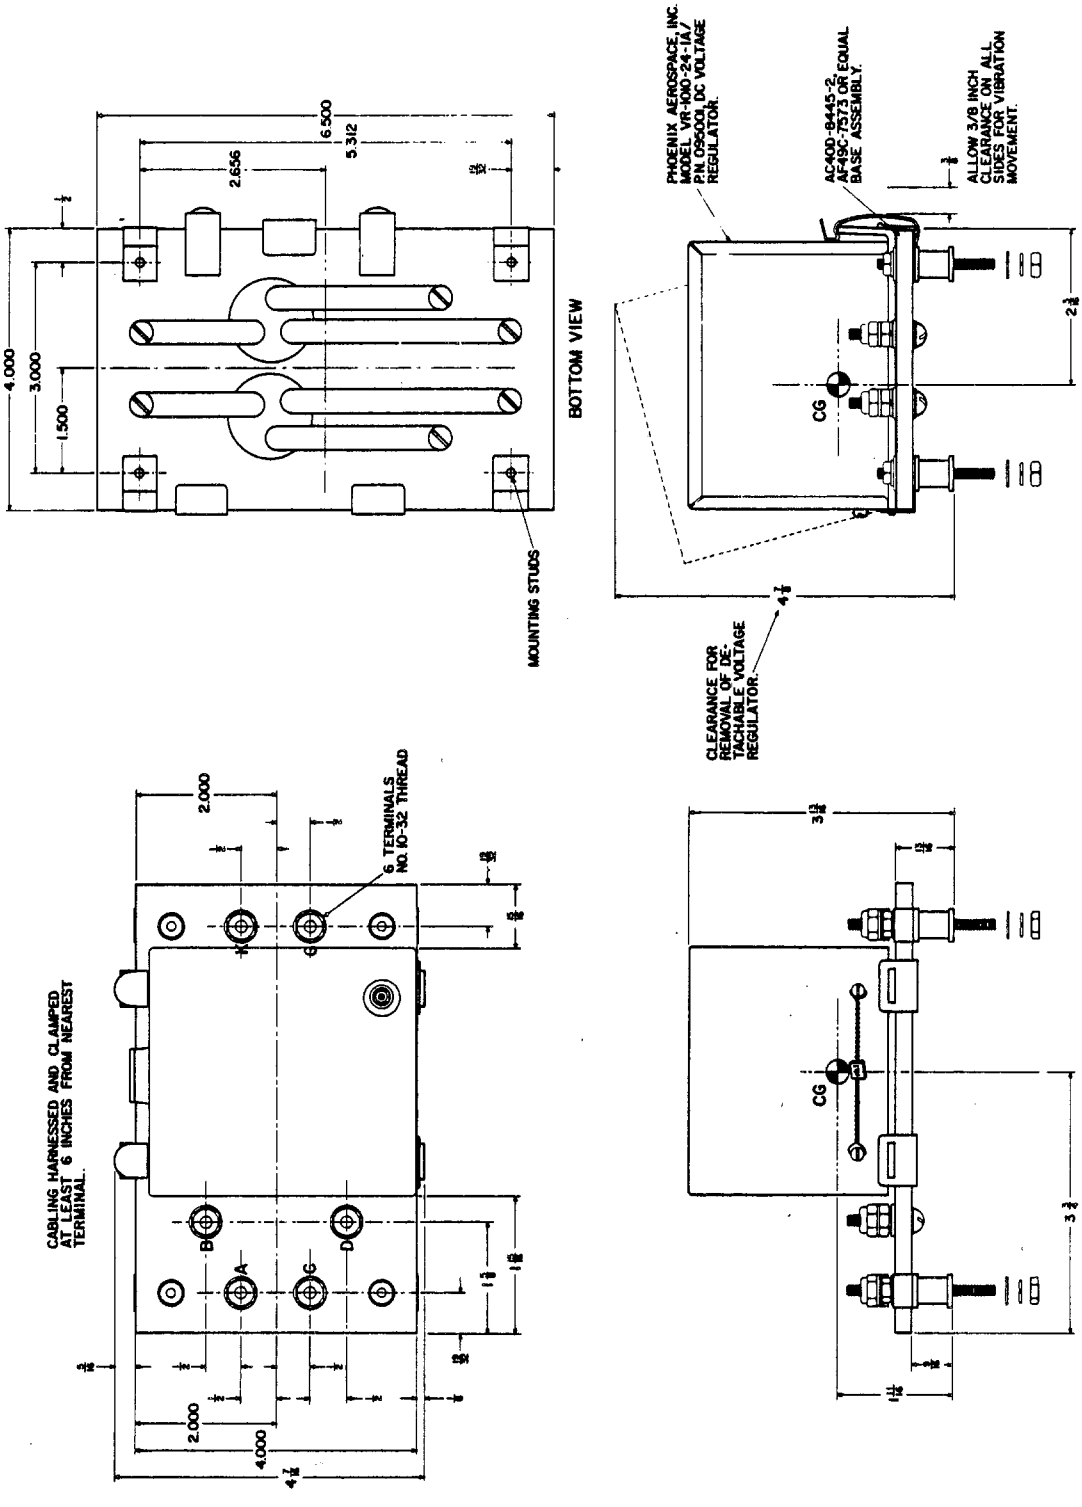
(b) Press the voltage regulator downward to the base, forcing the spring hold-down clips out far enough to admit the two vertical tabs on the voltage regulator. DO NOT bend these spring clips outward with pliers or a screwdriver, as they must exert pressure both downward and across the base toward the slotted brackets.

(c) Holding the voltage regulator firmly against the regulator base, snap the spring clips into position by pressing them against the vertical tabs on the regulator. In the event spring clips will not pass over the vertical tabs on regulator, remove regulator and examine both regulator and base for foreign objects causing interference.



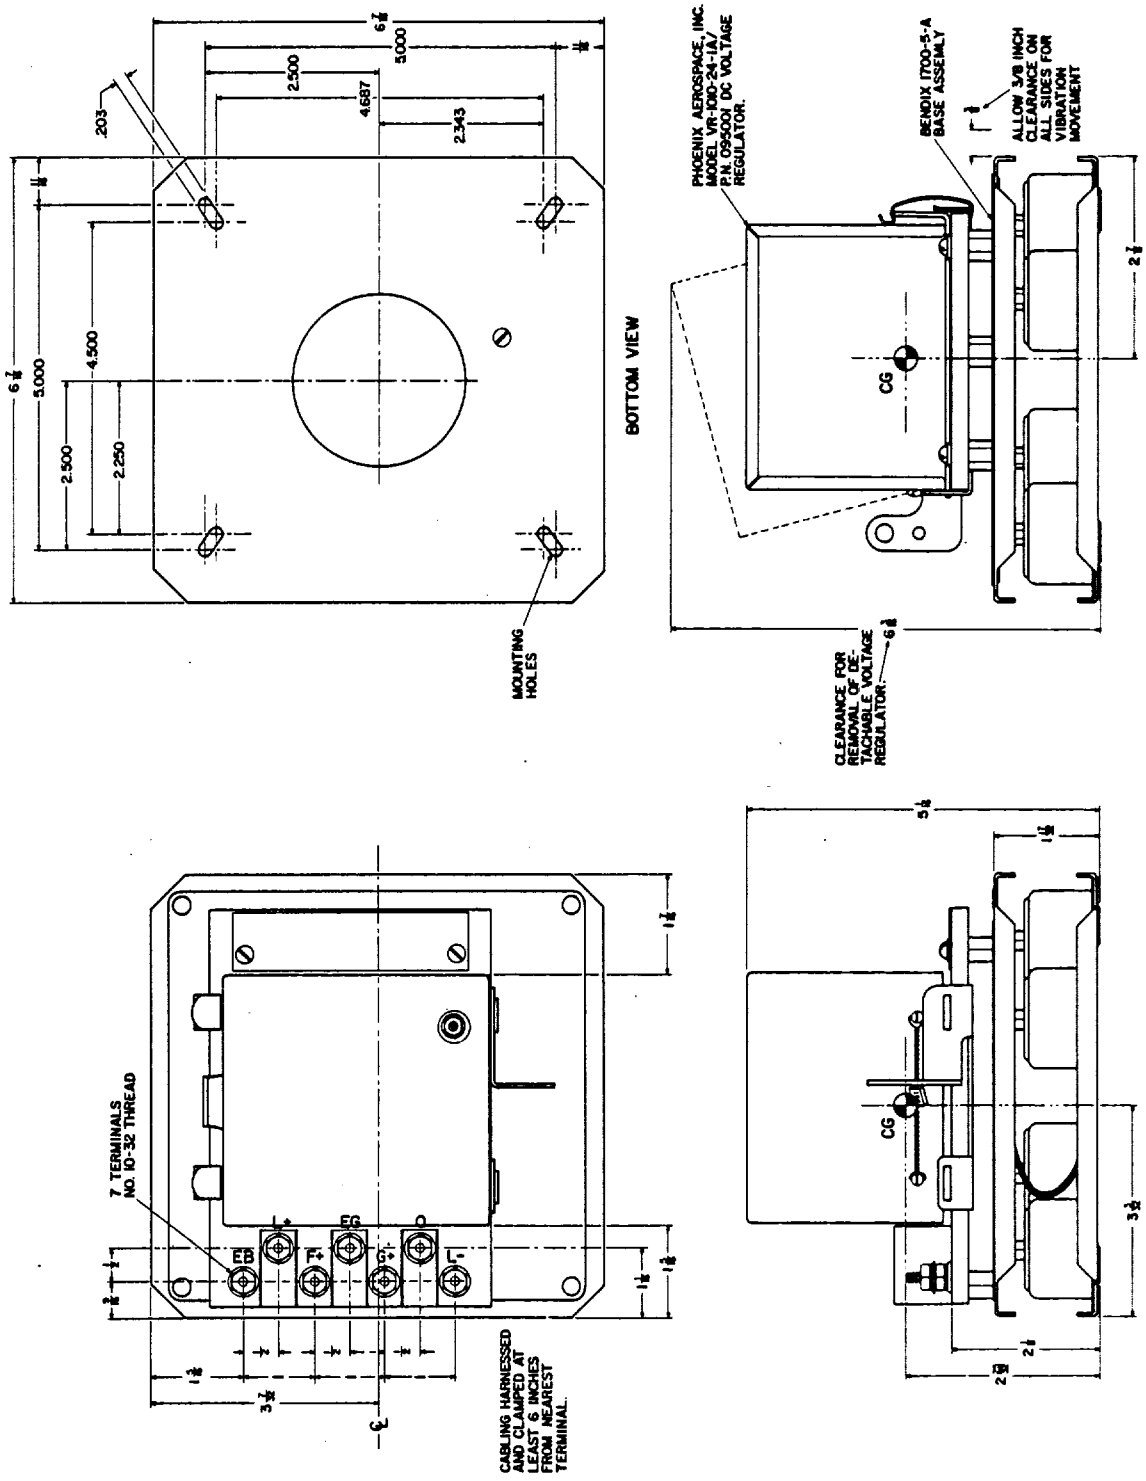
(6) Refer to Fig. 204, Fig. 205, and Fig. 206 and prepare wiring in accordance with system wiring diagrams. Refer to Fig. 205 and Fig. 206 for typical single and dual generator system wiring diagrams, respectively. Figure 207 shows typical retrofit information for typical installation.

(7) After installation and wiring have been completed check to insure that all switches or circuit breakers are in their off positions.



B. Removal.

(1) Place all switches or circuit breakers in their off positions.



(2) Remove unit in reverse order of procedures given in paragraphs 3.A(1) thru (5).

Typical DC Voltage Regulator Retrofit Data
Figure 207

4. ADJUSTMENT/TEST.

The following paragraphs outline test procedures for both installation check-out and a pre-installation bench test if desired or required by maintenance policies.

A. Installation Test.

Complete the following steps to determine that the DC Voltage Regulator and associated generator operate properly.

NOTE: The following checks are performed with the generator operating at, or above minimum rated speed. Observe the engine manufacturer's instructions carefully to prevent overheating when operating the engine on the ground. Upon completion of checking procedure, throttle engine down.

(1) Voltage Check.

(a) Connect a voltmeter with a range of 0 to 30 volts across terminals E and B of the generator, ground and positive terminals, respectively.

(b) Accelerate the engine until the generator is operating, at or above the minimum rated speed as given in the applicable generator manufacturer's handbook. Generator switch and master battery switches are open, OFF.

NOTE: Proper engine speed is determined by dividing the minimum rated generator speed by the ratio of generator speed to engine crankshaft speed as given in the manufacturer's handbook.

(c) Close the generator switch and place all load switches in their OFF positions.

(d) No-load or minimum-load voltage should be between 28.3 and 28.7 volts. In the event limits are exceeded, the regulator is not operating properly and should be removed for repair by the overhaul shop.

(e) The DC Voltage Regulator is preset at the factory for 28.5 volts with generator operating at full load and at MID-RANGE speed (6,000 RPM). In the event adjustment is required at flight line level, perform steps (f) through (h).

(f) Identify the Voltage Set potentiometer, INCREASE, under the plug button on right corner of regulator. Using a 5/16 inch hex nut driver with hollow shaft, loosen the regulation adjustment control locking nut.

(g) Using a small screwdriver, approximately 1/8 inch blade, rotate slotted control shaft to obtain desired voltage on regulated bus.

(h) Using the 5/16 inch hex nut driver, tighten control locking nut. DO NOT overtighten, replace plug button over control access hole.

(i) Operate the generator at minimum rated speed with regulator under test for at least 15 minutes and recheck no-load and full-load voltage, to insure temperature rise does not affect the regulation.

NOTE: The Model VR-1010-24-1A DC Voltage Regulator does not exhibit the characteristic droop of carbon pile regulators when cold. The regulation will be flat over the specified temperature-altitude operating range.

(j) Close Master Battery switch and switch on a DC load to the system.

(k) The generator ammeter should indicate a reading equivalent to the load applied and the voltage reading on the voltmeter connected at the point of regulation on the positive DC bus and negative (ground) Terminal E of generator should indicate 28.5 volts DC.

(l) Switch OFF DC load, Master Battery switch, Generator switch, and engine.

CAUTION: DO NOT ATTEMPT TO DISCONNECT VOLTAGE REGULATOR FROM THE SYSTEM UNLESS GENERATOR IS STOPPED OR THE FIELD IS OPEN. FAILURE TO OBSERVE THIS CAUTION WILL RESULT IN PITTED OR BURNED CONTACT SURFACES.

(m) In the event trouble was experienced, remove the voltage regulator and return to the overhaul shop for repair.

(2) Paralleling Check.

NOTE: Each generator and regulator combination should be checked as outlined in preceding Voltage Check procedure, steps (a) through (m), and adjusted for exactly the same no-load or minimum-load voltage by completion of steps (f) through (h) of the Voltage Check procedure of sub paragraph (1).

(a) Operate all generators at or above minimum rated speed.

(b) Check accuracy of the system ammeters by switching on one generator at a time while a constant load (approximately equal to the full-load rating of one generator) is switched on. Record the ammeter reading of each generator. If ammeter readings are equal, the ammeters are considered to be accurate.

(c) Close all generator switches, all equalizer switches, and with all generators operating at or above minimum rated speed, apply a load approximately equal to the full load rating of any one generator in the parallel system.

(d) Check the individual ammeters for indication that each generator is sharing the load with ±10 per cent of rated output.

NOTE: In the event load sharing does not meet specification of ±10 per cent, switch regulators and repeat preceding steps. If this fails to correct trouble, refer to manufacturer's handbook for the generator and check resistance in equalizing circuits for balance.

B. Pre-installation Test.

Complete the following steps to determine that the DC Voltage Regulator is operating properly before installation in the airframe.

NOTE: The subsequent steps are to be used only in determining proper operation of the DC Voltage Regulator prior to installation in the airframe. The following steps do not authorize flight line repairs to the DC Voltage Regulator other than resetting the voltage regulation point. Tests are performed on a motor driven generator test set similar to the Sun Model AGT-2 Generator Test Set or equivalent and a voltage and metering source as described in subsequent steps.

(1) Refer to Fig. 208 and connect the DC Voltage Regulator to the associated test equipment and the Generator Test Set.

CAUTION: DO NOT ATTEMPT TO CONNECT VOLTAGE REGULATOR TO THE GENERATOR TEST SET WITH THE GENERATOR TEST SET OPERATING.

(2) Proceed as follows to complete pre-installation tests.

(a) Start Generator Test Set and run generator speed up to LOW RANGE (approx. 4,500 RPM) Master Battery and Load switches open, OFF.

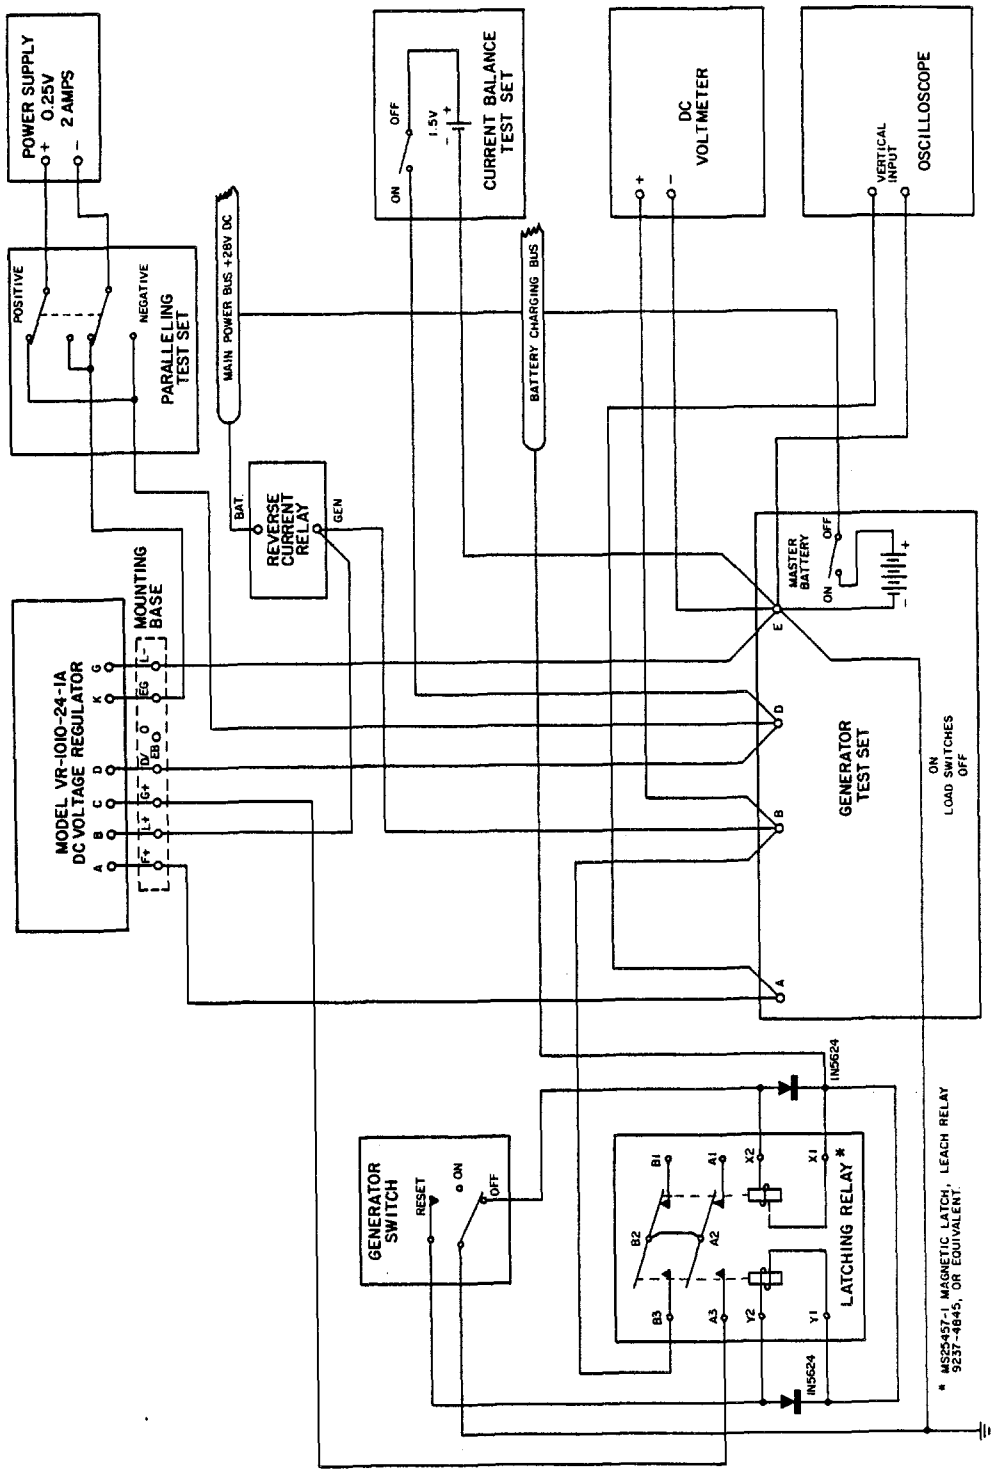
CAUTION: DO NOT OPERATE GENERATOR TEST SET WITHOUT AIRBLAST TO GENERATOR TO PREVENT SERIOUS OVERHEATING OF THE GENERATOR.

(b) No-load or minimum-load voltage should not vary more than ±0.2 volts from the regulated point setting, standard factory setting is 28.5 volts DC. In the event adjustment is required, perform steps (c) through (e).

(c) Identify the Voltage Set potentiometer INCREASE at the lower right corner of regulator under the plug button. Using a 5/16 inch hex nut driver with hollow shaft, loosen the regulation adjustment control locking nut.

(d) Using a small screwdriver, approximately 1/8 inch blade, rotate slotted control shaft to obtain desired voltage on regulated bus, terminal B of the generator.

(e) Using the 5/16 inch hex nut driver, tighten control locking nut. DO NOT overtighten, replace plug button over control access hole.



(f) Close Master Battery switch and Load switches to apply a load of 50 to 100 percent to the system.

(g) Place all Load switches in their OFF positions and Master Battery switch in the OFF position and increase Generator Test Set speed to MID RANGE (approx. 6,000 RPM).

(h) No-load or minimum load voltage should not vary more than ±0.2 volts from the regulated point as determined in preceding step (b).

(i) Close Master Battery switch and Load switches to apply a load of 50 to 100 per cent to the system.

(j) Place all Load switches in their OFF positions and Master Battery switch in the OFF position and increase Generator Test Set speed to HIGH RANGE (approx. 8,000 RPM).

Test Set-Up
Model VR-1010-24-1A, DC Voltage Regulator
Figure 208

(k) No-load or minimum load voltage should not vary more than ±0.2 volts from the regulated point as determined in preceding steps (b) and (h).

(l) Close Master Battery switch and Load switches to apply 50 percent and 100 per cent loads to the generator.

(m) Place all Load switches in their OFF positions and Master Battery switch in the OFF position and decrease Generator Test Set speed to required speed preparatory to stopping Generator Test Set. Stop Generator Test Set completely.

NOTE: Each Voltage Regulator should be checked as outlined in preceding steps and adjusted for exactly the same no-load or minimum-load voltage by completion of steps (c) through (e).

(n) Complete steps (o) throught (t) to check parallel operation.

(o) Start Generator Test Set and run generator speed up to LOW RANGE (approx. 4,500 RPM). Close Master Battery switch and Load switches to apply a 100 per cent load to the system.

(p) Operate Paralleling Test Set switch to NEGATIVE, applying the positive 0.25 volts DC to the equalizer bus, Pin K, of the regulator and the negative 0.25 volts DC to terminal D of the Generator Test Set. Voltmeter reading across the generator output should decrease by at least 2.5 volts. Return switch to the center OFF position.

(q) Place all Load switches in their OFF positions disconnecting all load. Operate Paralleling Test Set switch to NEGATIVE, applying the positive 0.25 volts DC to the equalizer bus, Pin K, of the regulator and the negative 0.25 volts DC to terminal D of the Generator Test Set. Voltmeter reading across the generator output should decrease by at least 2.5 volts. Return switch to center OFF position.

(r) Close Load switches to apply a 100 per cent load to the generator. Operate Paralleling Test Set switch to POSITIVE, applying the negative 0.25 volts DC to the equalizer bus, Pin K, of the regulator and the positive 0.25 volts DC to terminal D of the Generator Test Set. Voltmeter reading across the generator output should increase by at least 2.5 volts. Return switch to the center OFF position.

(s) Place all Load switches in their OFF positions, disconnecting all loads. Operate Paralleling Test Set switch to POSITIVE, applying the negative 0.25 volts DC to the equalizer bus, Pin K, of the regulator and the positive 0.25 volts DC to terminal D of the Generator Test Set. Voltmeter reading across the generator output should increase by at least 2.5 volts. Return switch to center OFF position.

(t) Operate Current Balance Test Set switch to the ON position applying −1.5 volts DC to terminal D on Generator Test Set and +1.5 volts DC to terminal G on Generator Test Set. Voltmeter across the generator output should not indicate a change greater than ±0.15 volts. Return Current Balance Test Set switch to the OFF position.

(u) Place all Load switches in their OFF positions, disconnecting all loads.

(v) Open Master Battery switch and decrease Generator Test Set speed required preparatory to stopping generator. Stop Generator Test Set completely.

CAUTION: DO NOT ATTEMPT TO DISCONNECT VOLTAGE REGULATOR FROM THE GENERATOR TEST SET UNTIL GENERATOR IS STOPPED AND ALL VOLTAGES ARE OFF. FAILURE TO OBSERVE THIS CAUTION WILL RESULT IN POSSIBLE DAMAGE TO THE REGULATOR.

(w) In the event trouble was experienced, remove the voltage regulator and return to overhaul shop for repair.

5. INSPECTION/CHECK.

Visual inspection of external cabling for breaks, and for proper connection at mating connectors, are the only authorized inspection checks. For inspection/check procedures of associated generator refer to the generator manufacturer's handbook. No authority is given for visual or other checks internally or removal of the sealed cover at flight line maintenance levels.

6. CLEANING/PAINTING.

The DC Voltage Regulator requires no periodic cleaning operations under the sealed cover. If readily accessible, exterior dust or dirt may be brushed or wiped off the exterior surfaces.

7. APPROVED REPAIRS.

The only repairs approved for flight line maintenance are those associated with external cabling. No repairs are authorized or approved for flight line maintenance requiring removal of the sealed cover.

8. GENERATOR TEST SET.

The Generator Test Set referenced in preceding paragraph 4B is only one of many types available. Other accessories, such as metering and switching arrangements are fabricated by the user to operate with the test setup as suggested. Test setup may be modified at user's discretion provided tests are completed.

CONTENTS

PHOENIX AEROSPACE INC. STANDARD WARRANTY

1. Sellers Standard Warranty

(a) Phoenix Aerospace, Inc. herein called Seller, warrants that each unit delivered shall, at the time of delivery thereof to Buyer or Buyer's customers, be free from defects in material and workmanship and from defects or faults in design in view of the state of the art at the time of design thereof. Any defect must have become apparent and Buyer must have notified Seller thereof within twenty-four (24) months after installation in aircraft, not to exceed thirty (30) months after date of manufacture on unit nameplate. The extent of Seller's liability is limited to the repair, replacement, overhaul, or modification of any defective unit.

(b) Seller's obligation hereunder is conditioned upon the return as soon as practicable of the defective unit with all transportation charges prepaid to Seller in Phoenix, Arizona. Returned units must be accompanied by properly authorized Purchase Order, specifying the nature of the defect, if known, and containing reasonable proof to Seller that the defect is due to a matter embraced within Seller's warranty. An allowance will be made for inbound transportation charges in the Continental United States, but inbound transportation charges are the responsibility of Buyer outside the limits of the Continental United States. Overhauled or repaired units will be returned via air, transportation charges prepaid to destination anywhere in the world. Removal of the unit from any aircraft and reinstallation shall be at Buyer's expense.

(c) The warranty hereunder shall not apply to any unit installed in any Aircraft if such Aircraft shall not have been operated in accordance with the Federal Aviation Regulations issued by the Federal Aviation Administration, or if such unit shall not have been operated or maintained in accordance with Seller's instructions applicable to such unit, or if such unit shall have been repaired, altered or modified without Seller's approval, or operated with an accessory or part not authorized for use therewith, or if such unit shall have been operated subsequent to its involvement in an accident, or if the unit shall have been subject in any way to improper operation, maintenance, repair, alteration or modification.

(d) THE WARRANTY AND THE OBLIGATIONS AND LIABILITIES OF SELLER HEREUNDER ARE EXCLUSIVE AND IN SUBSTITUTION FOR AND BUYER HEREBY WAIVES ALL OTHER WARRANTIES, EXPRESS OR IMPLIED, ARISING BY LAW OR OTHERWISE (INCLUDING, WITHOUT LIMITATION, THE IMPLIED WARRANTY OR MERCHANTABILITY, ANY IMPLIED WARRANTY ARISING FROM COURSE OF PERFORMANCE, COURSE OF DEALING OR USAGE OF TRADE, ANY IMPLIED WARRANTY OF FITNESS, AND ANY OBLIGATION OF SELLER WITH RESPECT TO INCIDENTAL OR CONSEQUENTIAL DAMAGES), AND SHALL NOT BE EXTENDED, ALTERED OR VARIED EXCEPT BY A WRITTEN INSTRUMENT SIGNED BY SELLER AND BUYER.

2. General Instructions

(a) Overhaul, modification or repair of all Phoenix Aerospace units is authorized only at Seller's facility. Any overhaul, repair, alteration or modification without Seller's approval will negate or void the terms of Seller's Standard Warranty stated herein. Units in need of repair should be shipped directly to:

Phoenix Aerospace Inc.
1022 South 23rd Street
P. O. Box 20804
Phoenix, Arizona 85036

Units in warranty are repaired at the factory under the terms and conditions of Seller's Standard Warranty at no charge. There will be a charge imposed for Units returned within the warranty period which are found not to be defective or for a defect found not to be included within Seller's Standard Warranty or which have been removed or returned as a result of any program of preventive maintenance.

(b) Units out of warranty are repaired at the factory at Seller's standard charge in effect at the time of receipt of unit. Inbound and outbound transportation charges are the responsibility of the Buyer.

VR-1010-24-1A/P.N. 095001

INTRODUCTION

In conformance with A.T.A. Specification No. 100 for Manufacturers' Technical Data, two manuals have been prepared concerning the Model VR-1010-24-1A, DC Voltage Regulator (Solid-State Silicon). These manuals, if used as intended, will facilitate the effective, continued operation of the equipment. Technical data is grouped according to usage in the manual as described.

OVERHAUL MANUAL WITH ILLUSTRATED PARTS CATALOG

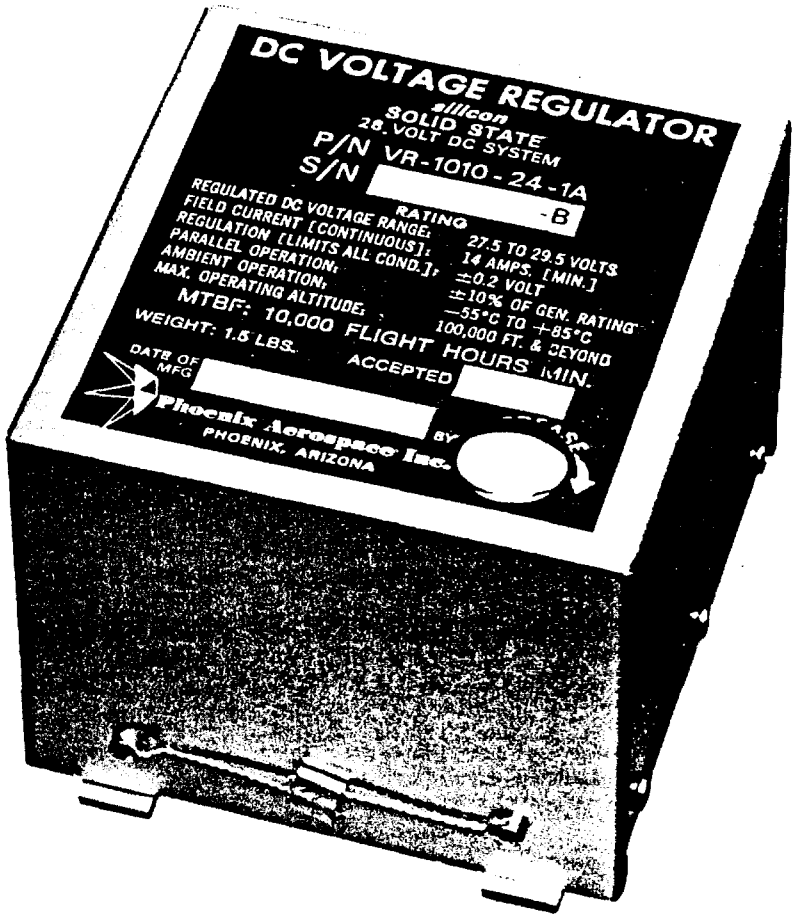
This manual contains all the information required for shop testing, replacement of defective parts, alignment and adjustment, mechanical disassembly, inspection, and reassembly. Detailed circuit theory is given with emphasis on theory that will be especially helpful for effective trouble-shooting. Performance tests as well as functional (go/no-go) checks, which may be used to determine condition of equipment and for retesting after repairs.

The Illustrated Parts Catalog provides a means to determine the manufacturer's part number and the physical location on the equipment of a part if the reference designation is known, or to determine the reference designation and the manufacturer's part number when the physical location of the part is known but no other information is available.

MAINTENANCE MANUAL

This Maintenance Manual is intended for use by flight line and hangar maintenance personnel. A detailed description and operation procedures, including a table of leading particulars are presented for reference. Mounting information and cabling information are presented as an aid to installation. Trouble-shooting information is limited to procedures required to trace a trouble to the overall unit for replacement.

DESCRIPTION AND OPERATION



1. GENERAL.

A. Purpose of Manual.

This manual contains information required for shop testing, replacement of defective parts, adjustment and alignment, mechanical disassembly, inspection, reassembly, and illustrated parts catalog, for the Model VR-1010-24-1A, DC Voltage Regulator, silicon solid-state, illustrated in Fig. 1.

B. Purpose of Equipment

The Model VR-1010-24-1A, DC Voltage Regulator is used to control all 28 volt direct current generators and starter generators conforming to FAA TSO-C56 and/or Military Specification MIL-G-6162. The regulator performs the function of maintaining constant output voltage under varying speed and load conditions in single generator or multiple generator systems.

Model VR-1010-24-1A, DC Voltage Regulator
Figure 1

2. DESCRIPTION.

A. The Model VR-1010-24-1A, DC Voltage Regulator is a compact self-contained unit utilizing state-of-the-art solid-state techniques. The regulated voltage is adjustable through access hole in top cover, by removing chrome plug button, and resetting mechanically locked potentiometer. Operating power for the regulator is obtained from the regulated generator. The regulator automatically adjusts field current to produce a constant voltage at the generator output under varying speeds and loads. The unit mounts in several military and commercial type mounts for ease in installation and retrofit operations.

B. The primary characteristics, capabilities, overall weight, and dimensions are listed in Table of Leading Particulars, Table 1.

GENERAL:

Duty: Continuous, unattended.

Temperature Rise: 15° C (maximum).

Cooling: Self-cooled by natural convection, conduction, and radiation.

Ambient Temperature Range: −85° to +85° C.

Maximum Operating Altitude: 100,000 feet and beyond.

Reliability: 10,000 hours MTBF (minimum).

ELECTRICAL:

Regulated DC Voltage Range: 27.5 to 29.5 VDC, no load to full load, over rated generator speed and temp/alt. operating range.

Field Current (Continuous): 14 Amperes (minimum).

Regulation: ±0.2 Volts, no load to full load, over rated generator speed and temp/alt. operating range.

Voltage Adjustment Limits: 26 VDC to 31 VDC, continuously variable.

Equalizer Circuit: ±2.5 Volts, minimum change, no load to full load, at minimum rated speed for regulation, when 0.25 volts is applied to equalizer bus terminals.

Parallel Operation: ±10 per cent equal division of load, two or more generators operated in parallel, no load to full load, over rated generator speed range.

Table of Leading Particulars
Table 1

ELECTRICAL (cont):

Regulator Equivalent Resistance: High Value—More than 100 ohms.
Low Value—Less than 0.5 ohms.

Current Regulation: Regulation for balancing current between parallel generators in multiple generator systems.

Recovery Time: 0.05 Seconds, full load switched ON-OFF-ON, controlled voltage recovers to and remains within 10 per cent of steady state condition.

Overload Current: 14 Amperes (minimum) for one hour.

Induced Ripple: Less than 1.5 volts peak to peak.

Transient Protection: ±80 volts for 40 milliseconds,
±600 volts for 10 microseconds.

MECHANICAL:

Weight: 1.6 pounds (729.6 grams).

Overall Dimensions: 3-1/2 in. wide (8.89 cm) by
3-3/4 in. long (9.425 cm) by
3 in. high (7.62 cm).

Electrical Connections: Connections made through contactors of associated mounting base, positive spring loaded in base.

Mounting: Unit plugs into MS Bases: AC40D-8445-2, AF49C-7573 and AN3204, Commercial Bases: Bendix Types 1700, 19E04, and 32E04. New applications permit use of Bendix Type 1B38-1 when desired.

Cooling: Self-cooled by natural convection, conduction, and radiation.

Installation: Mounts in any position, without degradation of regulation, heating, operating life, or other operating characteristics.

Adjustment: Voltage set potentiometer, INCREASE, adjusts voltage and paralleling in a single operation, located under removable plug button at top of unit.

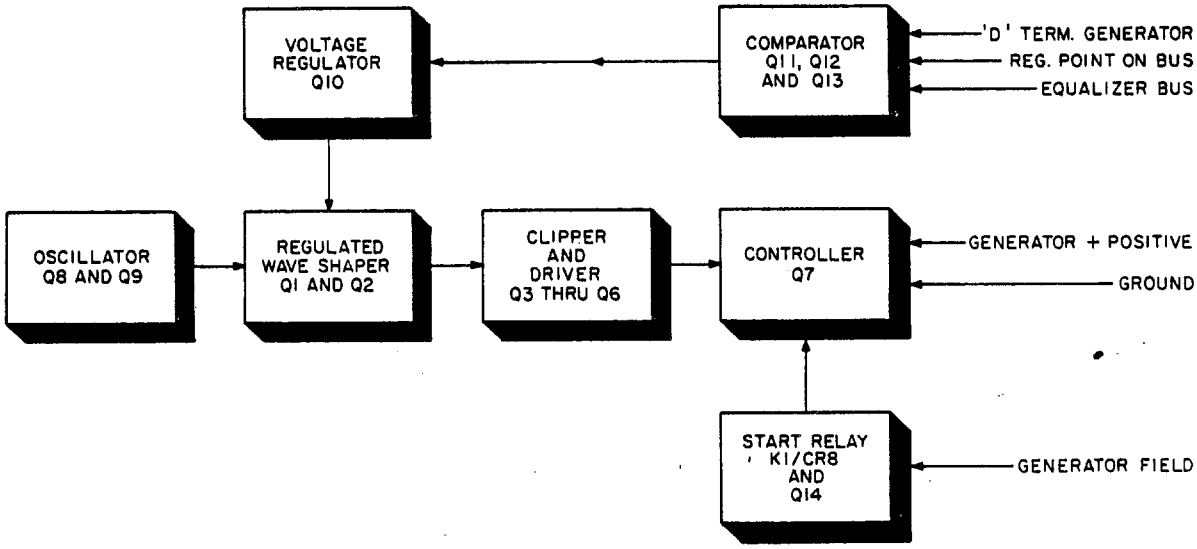


Table of Leading Particulars (cont)
Table 1 (cont)

3. OPERATION.

The subsequent paragraphs cover the theory of operation for the Model VR-1010-24-1A, DC Voltage Regulator. The Block Diagram Theory will aid in conveying the overall circuit operation to non-technical oriented personnel, while the Detailed Circuit Theory will enable the technician to understand in detail the operation of equipment.

A. Block Diagram Theory.

The subsequent paragraphs together with the block diagram of Fig. 2, cover in concise form the signal flow and circuit operation for the Model VR-1010-24-1A, DC Voltage Regulator.

Model VR-1010-24-1A, DC Voltage Regulator
Block Diagram
Figure 2

(1) Generator Start Relay. Relay K1 in the de-energized condition, contacts closed, completes the generator field circuit, until operating speed and voltage output are attained. Relay K1 energizes at a voltage of approximately 20 volts, when Zener diode ZR3 conducts and biases transistor Q14 to turn-on. Relay K1 contacts open, and the generator field circuit is now completed through the controller circuit of the regulator, transistor Q7. Operating power for the regulator circuit is obtained from the generator output.

(2) Stabilized Oscillator. Transistors Q8 and Q9 generate a sine wave signal at a frequency of approximately 400 Hertz. The sine wave signal is coupled through auxiliary windings of oscillator transformer T1 to the input of the regulated wave shaper circuits.

(3) Regulated Wave Shaper. Transistors Q1 and Q2 in a push-pull circuit receive the sine wave signal from the stabilized oscillator. Voltage applied from the voltage regulator circuit determines the shaping operation to control duty cycle and regulator operation. The shaped output is coupled to the input of the clipper circuit.

(4) Clipper and Driver. Transistors Q3, Q4, Q5, and Q6 in cascaded push-pull stages provide additional shaping and amplification of the 400 Hertz signal. The amplified signal is applied to the controller circuits.

(5) Controller. Transistor Q7 and diodes CR2 and CR3 comprise the controller circuitry. Transistor Q7 switches the generator field current at a rate of approximately 800 pulses per second, derived by rectification of the 400 Hertz signal by diodes CR2 and CR3. Variation in the width, duty cycle, determines the amount of field current. Clamp diode CR4 maintains continuous field current.

(6) Voltage Regulator. Transistor Q10 delivers the regulating bias to control pulse width of the regulated wave shaper circuit. Reference and control signals are derived from the voltage comparator circuit.

(7) Voltage Comparator. Transistors Q12 and Q13 are operating as a voltage comparator circuit with temperature stabilized reference voltages and an adjustable set point. Transistor Q11 is a current comparator circuit for paralleling operation.

B. Detailed Circuit Theory.

The following sub-paragraphs cover the individual circuits and their operation. Occasional reference to the overall schematic diagram of the equipment, Fig. 1201, will be necessary to determine circuit configuration.

(1) Generator Start Relay. The generator start relay K1 with normally closed contacts in the de-energized condition allows maximum field current to flow during start-up of generator. When the generator voltage reaches approximately 20 volts, Zener diode ZR3 conducts and biases transistor Q14 to 'turn-on' and permits relay K1 to energize, opening the field current by-passing contacts. The generator field current path is now passing through the controller circuit through transistor Q7. Operating power is supplied from the generator (+), to the control circuits. Diode CR8 across the coil of relay K1 functions as a suppressor diode. Resistors R39 and R40 determine the maximum base current flow of transistor Q14.

(2) Stabilized Oscillator. The stabilized oscillator utilizes transistors Q8 and Q9 in a Hartley oscillator circuit. Toroidal transformer T1 with multiple windings provides the tuned circuit, feedback, and output windings for the oscillator. The tuned circuit is tuned by capacitor C3 to approximately 400 Hertz. Capacitor C8 provides parasitic suppression in the oscillator tank circuit. The feedback winding provides sustained oscillation to the base-collector circuit. Resistors R21 and R22 provide the bias to the base circuits of the transistors to insure starting and sustained oscillation. Resistor R15 provides degeneration for improved stability of the oscillator circuit. Output to the regulated wave shaper circuit is through remaining winding on transformer T1.

(3) Regulated Wave Shaper. The regulated wave shaper receives the 400 Hertz sinusoidal signal from transformer T1. The input signal applied to the bases of transistors Q1 and Q2 is through resistors R1 and R2 to limit the amount of base current. Transistors Q1 and Q2 conduct alternately on positive half-cycles of the input signal. The point of conduction and duration, resultant increase or decrease in duty cycle is determined by the bias supplied to the emitter circuits from transistor Q10, voltage regulator. Diode CR1 serves as a clamp diode to set bias level of transistors Q1 and Q2. The output across the collectors is a quasi-square wave signal and is applied to the input of the clipper circuit.

(4) Clipper and Driver. The clipper and driver circuit provide additional shaping of the signal and amplification for application to the controller circuit. The clipper circuit consists of transistors Q3 and Q4 in a push-pull circuit. The quasi-square wave signal is coupled to the base circuits of transistors Q3 and Q4 through limiting resistors R3 and R5, respectively. The output of the clip-

per circuit is a quasi-square wave with improved rise time. The output is coupled to the base circuits of the driver transistors Q5 and Q6 through resistors R7 and R8, respectively. Resistors R9 and R10 provide a low impedance return for leakage currents. Output in the collector circuit is developed across toroidal transformer T2 and coupled to the controller circuit. Zener diode ZR1 and resistor R14 provide voltage regulation to the clipper and driver circuits.

(5) Controller. The controller circuit comprised of transistor Q7 and diodes CR2 and CR3 control the generator field current to regulate the output voltage of the generator. The quasi-square wave output across transformer T2 is converted to a uni-directional positive voltage by rectification circuit comprised of diodes CR2 and CR3. The positive pulses with a nominal pulse rate of 800 per second are applied to the base of transistor Q7 to control turn on and turn off. Variation of the pulse width, varies in step with the voltage adjustment setting of variable resistor R35, effectively controlling duty cycle. The results of this variation in duty cycle determines the on-off time of transistor Q7 and subsequent variations in generator field current to achieve voltage regulation at the generator output. The regulator operating at a nominal rate of 800 pulses per second in the controller section is adequate to provide proper smoothing of the current to the generator field. The predominate AC component on the DC output of the generator is due primarily to commutator ripple and not from the contribution of the field excitation. RF filter L1 in the collector circuit of transistor Q7 and in series with pin C of the regulator, provides additional filtering of the 800 pulse per second controller output and harmonics of the fundamental frequency. Since the generator field is highly inductive, continuous field current is achieved by the action of clamp diode CR4. The voltage waveform at pin A of the regulator, emitter of transistor Q7, is a positive pulse with an excursion from ground to a positive value approximating generator voltage, typically 27.5 to 29.5 volts. The current flowing in the generator field is constant due to the action of clamp diode CR4. Capacitor C2 and resistor R13 provide a series path for high speed transients which might appear across the collector to emitter circuit of transistor Q7.

(6) Voltage Regulator. The voltage regulator consists of transistor Q10, and associated biasing and time constant circuitry. Resistors R18 and R19 comprise a voltage divider and bias network for the emitter while resistor R17 and capacitor C4 establish the time constant of regulation. Control is applied to the base circuit from the voltage comparator. Output at the collector is applied to the emitter and base circuit of transistors Q1 and Q2, across clamp diode CR1.

(7) Voltage Comparator. The voltage comparator circuit comprised of transistors Q12 and Q13 samples the voltage on the generator bus, pin B of the regulator. The circuit operates as a differential comparator. The base of transistor Q13 receives the voltage from regulation point on generator bus, as adjusted by setting of voltage adjustment increase-EADJ, variable resistor R35, while the base of transistor Q12 is referenced to the temperature compensated Zener voltage at the collector of transistor Q11. Any change in voltage at the regulation point on bus of the generator develops a voltage across resistor R23 in the base of transistor Q10 to apply a change in bias to the voltage regulator. Parallel generator operation is achieved by sampling the voltage between the equalizer bus, pin K of the regulator, and the equalizer sense point, terminal D on generator, pin D of the regulator. The change in voltage appears across resistor R27 and causes a change in the voltage drop across resistor R28 in the collector circuit, and adds in series with the reference voltage derived from temperature compensating diode CR5, CR6, and CR7 in series with Zener diode ZR2. Diode CR9 and resistor R26 establish a reference voltage at the base of transistor Q11. Unequal generator currents cause a change in generator voltage output in a direction to equalize generator currents.

DISASSEMBLY

1. GENERAL.

This section outlines procedures for disassembly of the DC Voltage Regulator. These procedures should be followed in the event it becomes necessary to repair the unit after a malfunction or part failure. Electrical wiring should not be disconnected except when required for complete removal of a component or subassembly or when wiring is found to be defective. When wiring is disconnected, tag each wire and note connection point for ease in identification during reassembly.

2. COVER REMOVAL.

A. Break Phoenix Aerospace, Inc. seal, (7) Fig. 1101, by cutting wire, and remove.

NOTE: In the event DC Voltage Regulator is in warranty, breaking of seal may void warranty unless covered by other contractual agreement.

B. Remove the four screws, (-5 and -6) Fig. 1101, securing cover, (4) Fig. 1101, and remove cover by lifting straight up from regulator. Place hardware and cover aside for reassembly.

3. REMOVAL OF CIRCUIT MODULE, OSCILLATOR/SWITCHING CIRCUITS SUB-ASSEMBLY.

A. GENERAL.

Removal of oscillator/switching circuits sub-assembly, (2) Fig. 1101, is accomplished to gain access to components on the bottom side and connections to contact pins in the base plate and chassis with connector sub-assembly, (1) Fig. 1101. Unless complete oscillator/switching circuit sub-assembly replacement is required or base plate and connector subassembly replacement is required, interconnecting wires should never be disconnected. Proceed as follows to gain access to the under side of sub-assembly.

B. REMOVAL PROCEDURES.

(1) Loosen and remove the three No. 4-40 x 3/8 inch long pan head machine screws, (-3) Fig. 1101, at each side of the base plate and connector sub-assembly.

(2) Carefully swing sub-assembly up to expose the underside of oscillator/switching circuit sub-assembly. DO NOT disconnect wiring unless removal of entire sub-assembly is required.

4. DISASSEMBLY OF OSCILLATOR/SWITCHING CIRCUIT SUB-ASSEMBLY.

A. GENERAL.

Disassembly of the oscillator/switching circuit sub-assembly is required to gain access to components on the oscillator/driver circuit board sub-assembly (1) Fig. 1102, and components on top of switching circuits chassis (4) Fig. 1102. Unless replacement of complete oscillator/driver circuit board sub-assembly is required, interconnecting wires should never be disconnected. Proceed as follows to gain access to components on oscillator/driver circuit board sub-assembly and top of switching circuits chassis.

B. DISASSEMBLY PROCEDURE.

(1) Remove the four No. 4-40 x 1-3/4 inch long round head machine screws, (-2) Fig. 1102, and the four round spacers, (-3) Fig. 1102 at the corners of oscillator/driver circuit board sub-assembly.

(2) Carefully lift board and fold back to expose components and interconnect wiring. DO NOT disconnect wiring between the oscillator/driver circuit board sub-assembly and switching circuits chassis unless complete replacement of either component is necessary.

CLEANING

1. GENERAL.

This section outlines procedures for cleaning the components of the DC Voltage Regulator while disassembled. Cleaning materials are listed in Table 201.

WARNING: PERFORM OPERATION INVOLVING SOLVENT ONLY IN A WELL VENTILATED AREA. AVOID BREATHING OF SOLVENT VAPOR AND CONTINUOUS CONTACT WITH SOLVENT.

Reference to air jet refers to a hand-operated air nozzle supplied with clean, dry, compressed air at a maximum pressure of 28 psi.

WARNING: GOGGLES SHOULD BE WORN WHEN USING AIR JET TO BLOW DUST AND DIRT FROM EQUIPMENT. OTHER PERSONS SHOULD BE WARNED AWAY FROM HAZARDOUS AREA OR WORKING ENCLOSURE.

MATERIAL
Trichloroethylene Solvent
Soft-bristled Brush
Stiff-bristled Brush
Soft, Clean Cloth

List of Cleaning Materials
Table 201

2. PRINTED CIRCUIT BOARDS-WIRED CHASSIS.

Remove dust and dirt from all surfaces with a soft-bristled brush in conjunction with an air jet.

NOTE: When the dress of wiring is disturbed, dressing should be noted, and when cleaning is finished, wiring should be restored to proper dress or position.

3. METAL SURFACES.

Clean with soft cloth moistened in trichloroethylene solvent, and dry with clean, dry cloth.

4. CONNECTORS.

A. Wipe dust and dirt from contacts using trichloroethylene solvent and a soft cloth. Wipe dry with clean, dry cloth.

B. Remove dust from contacts and insulator areas using small, soft-bristled brush in conjunction with air jet.

INSPECTION/CHECK

1. GENERAL.

   This section contains procedures to determine the condition of the DC Voltage Regulator.

2. COVER.

   Inspect cover for deformations, dents, punctures or surfaces which might be wearing due to interference with other components.

3. CONNECTORS.

   A. Inspect for broken parts or other abnormal condition.

   B. Inspect for contacts which are broken, deformed or out of alignment. Check for corrosion and signs of arcing at the contacts and for poorly soldered connections.

4. RESISTORS.

   Inspect resistors for signs of overheating; cracked, broken, or charred insulation; loose, poorly soldered, or corroded terminal connections; and loose mountings.

5. METAL SURFACES AND MECHANICAL.

   Inspect metal surfaces for signs of corrosion. Also check component mountings for mechanical tightness.

6. WIRES.

   Check wires for damaged insulation and for proper dress.

REPAIR

1. GENERAL.

This section outlines instructions for the repair or replacement of damaged or defective parts. Faulty parts are usually detected by inspection, cleaning or trouble shooting. The repair or replacement of damaged or defective parts involves standard repair techniques. Identify each wire before removal of any part requiring unsoldering of several lead wires.

2. COVER AND METAL PARTS.

Straighten any deformation, and retouch scratched or worn surfaces as required.

3. PRINTED CIRCUIT BOARD AND TERMINAL STRIPS.

Remove all traces of corrosion and recoat with clear epoxy resin where broken or removed during repairs.

Before attempting to solder connections, peel away epoxy resin using a sharp knife.

NOTE: The clear epoxy resin is Armstrong Products Inc. Type T-600 or equivalent. Any time the epoxy coating is disturbed, recoating is advised.

4. CONNECTORS.

Check and resolder connections and check insulation. If badly damaged, replace contactor or contact plate (base plate and chassis sub-assembly).

5. SOLDER CONNECTIONS.

Resolder any defective solder joints. Remove all traces of corrosion.

6. WIRING.

Replace any wiring with damaged insulation or broken strands.

7. RESISTORS.

Replace resistors that show signs of overheating or with cracked or broken bodies. Resolder loose, broken or corroded connections.

ASSEMBLY

1. GENERAL.

This section outlines the instructions for assembly of the DC Voltage Regulator. Before assembly of the unit, the Cleaning, Inspection/Check, and Repair Sections should be consulted to determine if all components are properly cleaned and in proper physical and operating condition. Where wiring must be reconnected, good practices must be followed in dressing of wires and soldering connections. Refer to Figures 1101 through 1103 for identification and location of sub-assemblies and component parts.

2. ASSEMBLY OF OSCILLATOR/SWITCHING CIRCUIT SUB-ASSEMBLY.

A. GENERAL.

Assembly of the oscillator/switching circuit sub-assembly requires reference to Figure 1102 for component identification and reference to the schematic diagram, Figure 1201, in the event complete disassembly was necessary and it is necessary to reconnect interwiring. Proceed as follows, eliminating steps where necessary.

B. ASSEMBLY PROCEDURES.

(1) Identify disconnected leads and reconnect to points indicated. Reference to the overall schematic diagram, Figure 1201, should be made for all connections as well as reference to Figures 1102 and 1103 for component identification.

(2) Dress wires and assemble oscillator/driver circuit board sub-assembly, (1) Fig. 1102, to switching circuits chassis, (4) Fig. 1102. Use the four No. 4-40 x 1-3/4 inch long round head machine screws, (-2) Fig. 1102, and the four round spacers, (-3) Fig. 1102.

3. INSTALLATION OF CIRCUIT MODULE, OSCILLATOR/SWITCHING CIRCUITS SUB-ASSEMBLY.

A. GENERAL.

Installation of the oscillator/switching circuits, sub-assembly (2) Fig. 1101 requires reference to the overall schematic diagram, Figure 1201, in the event lead wires between the contact pins in the base plate and chassis with connector sub-assembly, (1) Fig. 1101, were disconnected. Proceed as follows eliminating steps not applicable.

B. INSTALLATION PROCEDURES.

(1) Identify disconnect leads and reconnect to points as tagged. Refer to the overall schematic diagram, Fig. 1201, to insure accuracy of connections and to Figure 1102 for component identification.

(2) Dress wiring to prevent interference with oscillator/switching circuits sub-assembly and return sub-assembly to position at bottom of base plate and chassis with connector sub-assembly.

(3) Secure with the six No. 4-40 x 3/8 inch long pan head screws, (-3) Fig. 1101, three on each side.

4. INSTALLATION OF COVER.

A. Reposition cover over DC Voltage Regulator by sliding cover over unit. Check to see that adjustment screw is accessible under plug button.

B. Secure cover with two No. 4-40 x 3/8 inch long pan head screws, (-5) Fig. 1101, at the end opposite the adjustment access hole.

C. Secure cover with two No. 4-40 x 5/8 inch long (drilled) fillister head screws, (-6) Fig. 1101, at end nearest to adjustment access hole.

D. Place tie wire through drilled holes of fillister head screws and seal with lead seal, (7) Fig. 1101, if available.

VR-1010-24-1A/P.N. 095001

FITS AND CLEARANCES

Not Applicable to Solid State DC Voltage Regulator.
No moving parts required.

TESTING

1. GENERAL.

This section defines test procedures for the Model VR-1010-24-1A DC Voltage Regulator. The procedures given are in sequential step form and test the unit completely. When the results of any step or test are not achieved the Trouble Shooting of this manual should be consulted.

2. PERFORMANCE TESTS.

Performance tests are designed to provide a fast efficient method for complete check-out of the voltage regulator. Subsequent paragraphs contain a list of test equipment required. Minimum performance requirements, and interconnect diagrams to facilitate testing.

A. Test Equipment Required.

The test equipment required to accomplish the performance tests consists of the following: generator test set, oscilloscope, volt-meter, insulation resistance tester and interconnect cabling. This equipment is listed and described in the Special Tools, Fixtures, and Equipment section of this manual.

B. Minimum Performance Requirements.

The minimum performance requirements of the Model VR-1010-24-1A DC Voltage Regulator is to provide regulation of generator field current such that the output voltage of generator is maintained constant. Regulation level is maintained at ±0.2 volts DC at any preset value in the 27.5 to 29.5 volts DC range. Regulation at this preset value is maintained at no load to full load operation and under varying generator speeds, at or above the minimum rated generator speed and temperature-altitude operating range.

C. Preparation for Testing.

(1) Chassis Isolation Test. Perform the following steps using an Associated Research Model 2956, Insulation Resistance Tester to determine unit meets applicable specifications for chassis isolation.

WARNING: The recommended Insulation Resistance Tester produces potentially dangerous voltages. Care in operation must be exercised to prevent possible electrical shock.

(a) Place POWER ON/OFF switch on Insulation Tester in the OFF position and connect line cord, three wire grounding type, to source of 115 volts AC, 60 Hz. Identify VOLTAGE ADJUST control and rotate to the extreme counter-clockwise position. Connect the black lead with a spade lug to the GROUND terminal and connect clip to chassis at one of the screws with tie wire securing the cover in place on the Voltage Regulator. Identify MEGOHM MULTIPLIER control and position to the 100 position. Identify the HIGH VOLTAGE connection and connect test lead for use in subsequent paragraphs.

CAUTION: The Insulation Tester must be connected and operated in accordance with the following procedures to insure accurate testing and adequate protection to the equipment under test. Under no circumstances should the probes be connected to any point other than that specifically directed in the procedures given. In all cases the GROUND lead clip must be connected to the chassis of the unit being tested, (hardware securing cover on Voltage Regulator).

(b) Identify HIGH VOLTAGE clip lead and connect to terminal A, GENERATOR FIELD, on Voltage Regulator. GROUND switch is in the METERED RETURN position. Identify HIGH VOLTAGE CIRCUIT—ENERGIZE switch and operate to the ON position, red HIGH VOLTAGE lamp will light. Identify VOLTAGE ADJUST control and rotate clock-

wise until KILOVOLTS meter indicates .5 KILOVOLT (500 volts). Note reading of the MEGOHM-METER and multiply by the KILOVOLTS meter reading multiplied by the multiplying factor of 1, multiplied by the MEGOHMS MULTIPLIER to obtain reading in Megohms. Return VOLTAGE ADJUST control to the extreme counter-clockwise position and place the HIGH VOLTAGE CIRCUIT—ENERGIZE switch in the OFF position. Disconnect the HIGH VOLTAGE test lead from the unit after metering indicates voltage has dropped to zero. Isolation of terminal A on Voltage Regulator to chassis ground must measure 10,000 megohms, minimum.

(c) Repeat procedures of paragraph (b) connecting HIGH VOLTAGE clip lead to terminal B, VOLTAGE SENSE (Regulation Point on Bus), on Voltage Regulator. Isolation of terminal B on Voltage Regulator to chassis ground must measure 10,000 megohms, minimum.

(d) Repeat procedures of paragraph (b) connecting HIGH VOLTAGE clip lead to terminal C, GENERATOR POSITIVE, on Voltage Regulator. Isolation of terminal C on Voltage Regulator to chassis ground must measure 10,000 megohms, minimum.

(e) Repeat procedures of paragraph (b) connecting HIGH VOLTAGE clip lead to terminal D, EQUALIZER SENSE ("D" terminal of Generator) on Voltage Regulator. Isolation of terminal D on Voltage Regulator to chassis ground must measure 10,000 megohms, minimum.

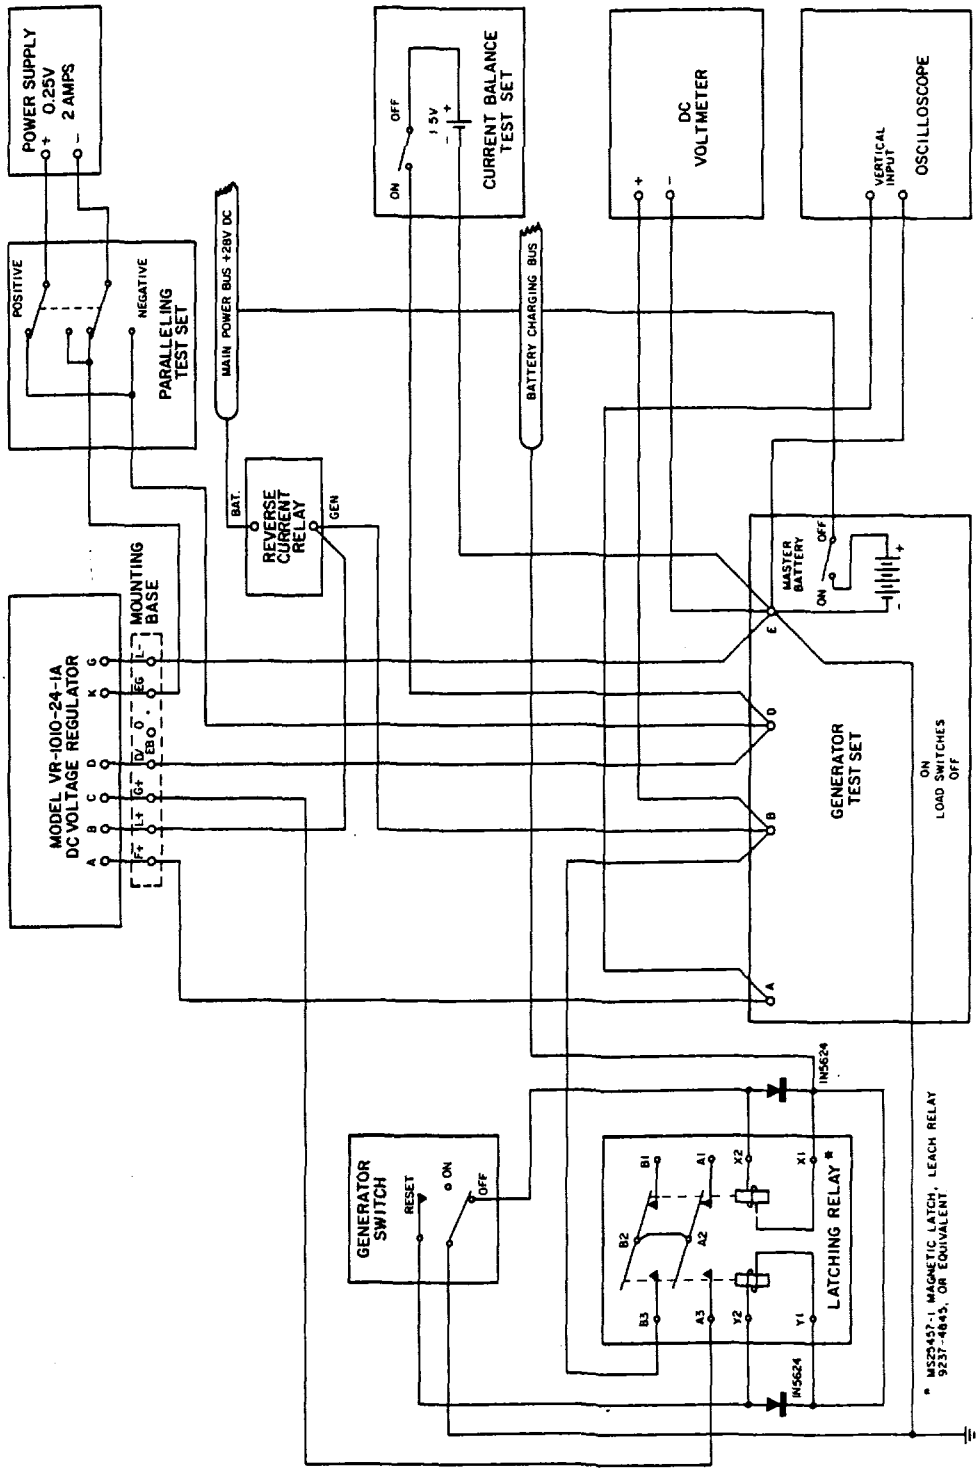
(f) Repeat procedures of paragraph (b) connecting HIGH VOLTAGE clip lead to terminal G, GROUND (Generator Negative), on Voltage Regulator. Isolation of terminal G on Voltage Regulator to chassis ground must measure 10,000 megohms, minimum.

(g) Repeat procedures of paragraph (b) connecting HIGH VOLTAGE clip lead to terminal K, on Voltage Regulator. Isolation of terminal K on Voltage Regulator to chassis ground must measure 10,000 megohms, minimum.

(h) Place POWER switch on the Insulation Tester in the OFF position and disconnect Insulation Tester before proceeding with subsequent performance testing.

(2) Connect the voltmeter across the positive and negative, terminals B and E of the generator, respectively. Set voltmeter to the range required to measure 0 to 30 volts DC.

(3) Connect the Paralleling Test Set, comprised of a polarity reversing switch and appropriate interconnect wiring to an auxiliary power supply to terminal D on the generator and the equalizer bus or pin F of regulator. Set the three position, POSITIVE-OFF-NEGATIVE, switch to the OFF position.



(4) Connect a DC power supply capable of supplying 0.25 volts DC at 2.0 amperes to the input terminals of the Paralleling Test Set. Set output level of supply to 0.25 volts using meter on supply or an accurate voltmeter.

(5) Connect the Current Balance Test Set, comprised of a −1.5 volt DC source and a single pole single throw (ON-OFF) switch, to terminals D and E on the generator. Set the switch on the Current Balance Test Set the OFF position. Check voltage source for accuracy with a suitable meter.

(6) Connect the oscilloscope to terminals A and E on the generator.

D. Performance Test.

The procedures of the performance test listed in numbered steps of Table 701 should be accomplished in the sequence presented. In the event the required result is not obtained, the trouble shooting section should be consulted and the malfunction corrected before proceeding to the next step.

Test Set-up, Model VR-1010-24-1A
DC Voltage Regulator
Figure 701

STEP	SET-UP	PROCEDURE	RESULT
1	Interconnect per Fig. 701 and para. 2.C., (2) Generator Test Set 'stopped' OFF.	(a) Apply power to all measuring equipment and auxiliary power supplies. (b) Check and set accuracy of the .025 volt and −1.5 volt DC sources.	
2	Generator Test Set load switches, and Master Battery switch in OFF positions. Paralleling Test Set, and Current Balance Test switches in their OFF position. Overvoltage Test Set switch in the NORMAL position.	Start Generator Test Set and run speed up to MID-RANGE (approx. 6,000 RPM).	Voltmeter across output indicates regulated voltage at point of regulation on the DC bus. Standard factory setting is 28.5 volts DC after final test.
3	Generator Test Set operating at MID-RANGE (6,000 RPM), Master Battery switch, Paralleling Test Set, and Current Balance Test Set switches in their OFF position. Overvoltage Test Set switch in the NORMAL position.	(a) Operate Generator Test Set LOAD switches to apply a 100 per cent load. (b) Identify the Voltage Set potentiometer, INCREASE, under plug button on the regulator. (c) Using a 5/16 inch hollow shaft nut driver, loosen adjustment locking nut. (d) Using a small screwdriver, approximately 1/8 inch blade, rotate slotted control shaft and set voltage to 28.0 volts DC prior to performing subsequent tests.	Voltmeter indicates regulated voltage point, and adjustment limits. Point of regulation as set becomes reference for subsequent tests. Voltmeter indicates 28.0 volts DC and becomes reference for subsequent tests.
4	Generator Test Set operating at MID-RANGE (approx. 6,000 RPM), Master Battery switch, Paralleling Test Set and Current Balance Test Set switches in their off position. Overvoltage Test Set switch in the NORMAL position.	Operate Generator Test Set Load switches to apply a 50 per cent load.	Voltmeter reading should not vary by an amount greater than plus or minus 0.2 volt from regulation point. Ammeter on Generator Test Set indicates a current equal to 50 per cent of generator full load current rating (typically 200 amperes).
5	Generator Test Set operating at MID-RANGE (approx. 6,000 RPM). Master Battery switch, Paralleling Test Set and Current Balance Test Set switches in their off position. Overvoltage Test Set switch in the NORMAL position.	Operate Generator Test Set Load switches to apply a 100 per cent load.	Voltmeter readings should not vary by an amount greater than plus or minus 0.2 volt from regulation point. Ammeter on Generator Test Set indicates a current equal to 100 per cent of generator full load current rating (typically 400 amperes).

STEP	SET-UP	PROCEDURE	RESULT
6	Generator Test Set operating at MID-RANGE (approx. 6,000 RPM), Paralleling Test Set and Current Balance Test Set switches in their OFF Position. Overvoltage Test Set switch in the NORMAL position. Load switches in 100 per cent Load position.	Close Master Battery switch placing battery across generator output.	Voltmeter reading should be stable at regulation point.
7	RANGE (approx. 6,000 RPM), Paralleling Test Set and Current Balance Test Set switches in their OFF position. Overvoltage Test Set switch in the NORMAL position. Load switches in 100 per cent load position and Master Battery switch ON.	(a) Place Master Battery switch to the OFF position removing battery from circuit. (b) Operate Generator Test Set Load switches to disconnect all load. (c) Increase Generator Test Set speed to HIGH RANGE (approx. 8,000 RPM).	Voltmeter reading should not vary by an amount greater than plus or minus 0.2 volt from regulation point.
8	Generator Test Set operating at HIGH RANGE (approx. 8,000 RPM). Master Battery, Paralleling Test Set, and Current Balance Test Set switches in their OFF Position. Overvoltage Test Set switch in the NORMAL position.	Operate Generator Test Set Load switches to apply a 50 per cent load.	Voltmeter reading should not vary by an amount greater than plus or minus 0.2 volt from regulation point. Ammeter on Generator Test Set indicates a current equal to 100 per cent of generator full load current rating (typically 200 amperes).
9	Generator Test Set operating at HIGH RANGE (approx. 8,000 RPM), Master Battery, Paralleling Test Set and Current Balance Test Set switches in their OFF Position. Overvoltage Test Set in the NORMAL position.	Operate Generator Test Set Load switches to apply a 100 per cent load.	Voltmeter reading should not vary by an amount greater than plus or minus 0.2 volt from regulation point. Ammeter on Generator Test Set indicates a current equal to 100 per cent of generator full load current rating (typically 400 amperes).
10	Generator Test Set operating at HIGH RANGE (approx. 8,000 RPM), Master Battery, Paralleling Test Set and Current Balance Test Set switches in their OFF Position, Overvoltage Test Set in the NORMAL position.	(a) Operate Generator Test Set Load switches to disconnect all load. (b) Decrease Generator Test Set speed to LOW RANGE (approx. 4,500 RPM) by braking.	Voltmeter reading should not vary by an amount greater than plus or minus 0.2 volt from regulation point.

Performance Test Procedure
Table 701 (Sheet 3 of 5)

STEP	SET-UP	PROCEDURE	RESULT
11	Generator Test Set operating at LOW RANGE (approx. 4,500 RPM) Master Battery, Paralleling Test Set and Current Balance Test Set switches in their OFF position. Overvoltage Test Set in the NORMAL position.	Operate Generator Test Set Load switches to apply a 50 per cent load.	Voltmeter reading should not vary by an amount greater than plus or minus 0.2 volt from regulation point. Ammeter on Generator Test Set indicates a current equal to 50 per cent of generator full load current rating (typical 200 amperes).
12	Generator Test Set operating at LOW RANGE (approx. 4,500 RPM) Master Batter, Paralleling Test Set and Current Balance Test Set switches in their OFF position. Overvoltage Test Set in the NORMAL position.	Operate Generator Test Set Load switches to apply a 100 per cent load.	Voltmeter reading should not vary by an amount greater than plus or minus 0.2 volt from regulation point. Ammeter on Generator Test Set indicates a current on Generator Test Set indicates a current equal to 100 per cent of generator full load current rating (typical 400 amperes).
13	Generator Test Set operating at LOW RANGE (approx. 4,500 RPM) Master Battery, Paralleling Test Set, and Current Balance Test Set switches in their OFF position. Overvoltge Test Set in the NORMAL position.	Operate Generator Test Set Load switches to disconnect load.	Voltmeter reading should not vary by an amount greater than plus or minus 0.2 volt from regulation point.
14	Generator Test Set load switches, and Master Battery Switch in OFF position. Paralleling Test Set, and Current Balance Test switches in their OFF position. Overvoltage Test Set switch in the NORMAL position.	Start Generator Test Set and run speed up to MID-RANGE (approx. 6,000 RPM).	Voltmeter across output indicates regulated voltage at point of regulation on the DC bus.
15	Generator Test Set operating at MID-RANGE (6,000 RPM), Master Battery switch, Paralleling Test Set, and Current Balance Test Set switches in their OFF position. Overvoltage Test Set switch in the NORMAL position.	(a) Operate Generator Test Set LOAD switches to apply a 100 per cent load. (b) Identify the Voltage Adjustment control adjacent to connector J1 on the regulator. (c) Using a 5/16 inch hollow shaft nut driver, loosen adjustment locking nut. (d) Using a small screwdriver, approximately 1/8 inch blade, rotate slotted control shaft and set voltage to 28.5 volts DC.	Voltmeter indicates 28.5 volts DC and returns unit to factory setting of 28.5 volts DC.

STEP	SET-UP	PROCEDURE	RESULT
16	Generator Test Set operating at LOW RANGE (approx. 4,500 RPM) Master Battery, Paralleling Test Set, and Current Balance Test Set, switches in their OFF position. Overvoltage Test Set in the NORMAL position.	(a) Operate Paralleling Test Set switch to NEGATIVE position applying the positive 0.25 volts DC to the equalizer bus, pin F, connector J1 of the regulator and the negative 0.25 volts DC to terminal D of the Generator Test Set. (b) Return Paralleling Test Set switch to center OFF position.	Voltmeter reading should decrease by at least 2.5 volts.
17	Generator Test Set operating at MID-RANGE (approx. 4,500 RPM), Master Battery switch, Paralleling Test Set, and Current Balance Test Set, switches in their OFF position. Overvoltage Test Set switch in the NORMAL position.	(a) Operate Generator Test Set Load switches to apply 100 per cent load. (b) Operate Paralleling Test Set switches to NEGATIVE applying the positive 0.25 volts DC to equalizer bus, contact K, of the regulator and the negative 0.25 volts DC to terminal D of the Generator Test Set. (c) Return Paralleling Test Set switch to center OFF position. (d) Operate Generator Test Set Load switches to disconnect load.	Voltmeter reading should decrease by at least 2.5 volts.
18	Generator Test Set operating at LOW RANGE approx. 4,500 RPM), Master Battery switch, Paralleling Test Set, and Current Balance Test Set switches in their OFF position. Overvoltage Test Set switch in the NORMAL Position. Generator Test Set Load switches set to NO LOAD positions.	(a) Operate Paralleling Test Set switch to POSITIVE applying the negative 0.25 volts DC to equalizer bus, contact K, of the regulator and the positive 0.25 volts DC to terminal D of the Generator Test Set. (b) Return Paralleling Test Set switch to center OFF position.	Voltmeter reading should increase by at least 2.5 volts.

STEP	SET-UP	PROCEDURE	RESULT
19	Generator Test Set operating at LOW RANGE (approx. 4,500 RPM), Master Battery switch, Paralleling Test Set, and Current Balance Test Set, switches in their OFF position. Overvoltage Test Set switch in the NORMAL position.	(a) Operate Generator Test Set Load switches to apply 100 per cent load. (b) Operate Paralleling Test Set switches to POSITIVE applying the negative 0.25 volts DC to equalizer bus, contact K, of the regulator and the positive 0.25 volts DC to terminal D of the Generator Test Set. (c) Return Paralleling Test Set switch to center OFF position.	Voltmeter reading should increase by at least 2.5 volts.
20	Generator Test Set operating at LOW RANGE (approx. 4,500 RPM) Master Battery switch, Paralleling Test Set, and Current Balance Test Set, switches in their OFF position. Overvoltage Test Set switch in the NORMAL position. Generator Test Set Load switches set to 100 per cent load.	(a) Operate Current Balance Test Set switch to ON position applying the negative 1.5 volts to terminal D of the Generator Test Set and the positive 1.5 volts to terminal E of the Generator Test Set. (b) Return Current Balance Test Set switch to the OFF position. (c) Operate Generator Test Set Load switches to disconnect Load.	Voltmeter should not indicate a change greater than ±0.15 volts.

TROUBLE SHOOTING

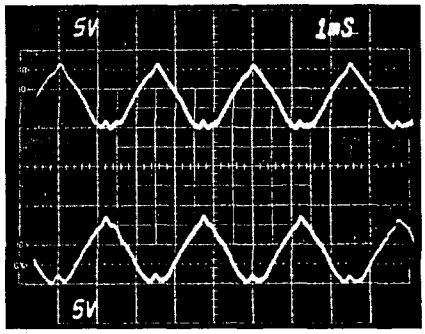
1. GENERAL.

This section outlines in tabular form information for use in localization and isolation of trouble in the Model VR-1010-24-1A DC Voltage Regulator. The trouble shooting procedures, Table 801, together with the information given in preceding section on Testing will in most cases localize and isolate the trouble. Reference to the schematic diagram, Fig. 1201, and the section on Detailed Theory will be necessary and helpful. The voltage measurements of Table 802 in conjunction with the waveforms illustrated in Fig. 801 will aid in isolation of trouble.

2. TROUBLE SHOOTING.

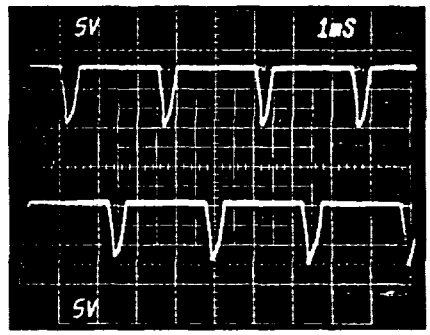
A. Localization.

The trouble shooting table, Table 801, provides a means of localizing malfunctions to a replaceable component or sub-assembly. The table is arranged in the same order of precedence as the performance test, Table 701, in the preceding section. The applicable step of the performance test is shown in parentheses next to the trouble shooting step in the STEP column, in Table 801.



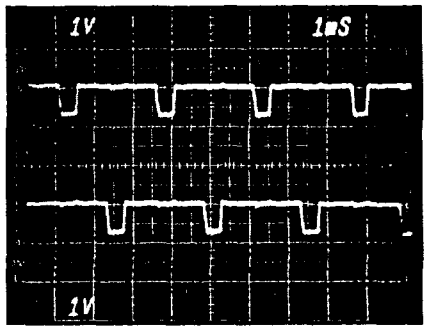
B. Isolation.

The voltage measurements of Table 802 are made using the voltohmmeter described in the Special Tools section of this manual. Reference to the schematic diagram, Fig. 1201, while making voltage measurements will aid in isolation of trouble within the unit.

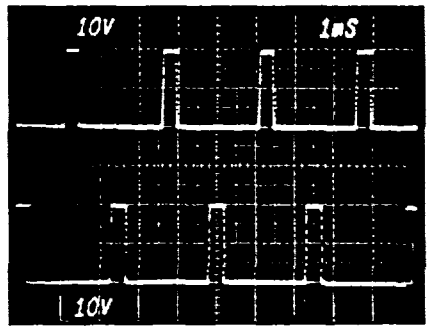


C. Analysis.

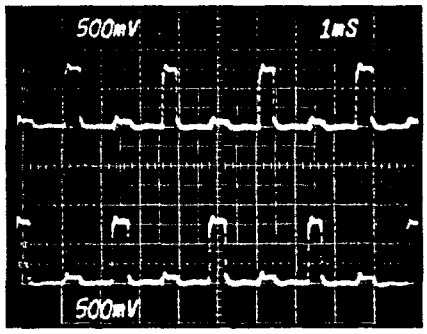
The waveforms pictured in Fig. 801 were made using the oscilloscope described in the Special Tools section of this manual, and will aid in analyzing the equipment performance when trouble shooting procedures are being performed.



STEP	SYMPTOM	PROBABLE CAUSE	CHECK	REMEDY
1	Generator voltage continues to increase.	Relay K1 failed to open, defective transistor Q14, Zener diode ZR3 or diode CR8.	Check transistor Q14, zener diode ZR3, diode CR8, or relay K1.	Replace defective component.
2	Generator output voltage zero, erratic regulation, or erratic paralleling operation.	Open or defective wiring at contactor/base of regulator or at generator terminals.	Continuity of input/output wiring at contactor/base and generator.	Repair or replace. Clean and burnish contacts carefully.
3	Generator output voltage increases to 20 volts and starts dropping to zero causing relay chatter.	Defective drive signal.	Check operation of oscillator transistor Q8 and Q9, and following stages of shaping and amplification, transistors Q1 through Q7.	Replace defective component.
4	Generator output voltage control adjustment on regulator, resistor R35, out of limits.	Defective reference in voltage comparator circuit.	Check zener diode ZR2, resistors R35, R28 and R29, diodes CR5, CR6, and CR7, and transistor Q12.	Replace defective component.
5	Generator will not operate in parallel service within specifications.	Defective reference in current comparator circuit.	Check resistors R26 and R27, and transistor Q11.	Replace defective component.
6	Generator (hunts) voltage rises and falls erractically.	Defective time constant in voltage regulator circuit.	Check capacitors C4 and C5 and zener diode ZR1.	Replace defective component.



A. WAVEFORMS AT BASE OF TRANSISTORS Q1 AND Q2 GENERATOR OPERATING AT LOW RANGE (APPROX. 4,500 RPM), 100 AMP LOAD
VERTICAL SENSITIVITY: 5.0 VOLTS/DIVISION
TIME BASE: 1.0 MILLISECONDS/DIVISION



B. WAVEFORMS AT COLLECTOR OF TRANSISTORS Q1 AND Q2 GENERATOR OPERATING AT LOW RANGE (APPROX. 4,500 RPM), 100 AMP LOAD
VERTICAL SENSITIVITY: 5.0 VOLTS/DIVISION

Q14	***0.64V	***0.06V	***0.00V

TEST POINT	VOLTAGE
Terminal B on regulator (Regulation point on Bus)	28.00V
Terminal C on regulator (Generator + terminal)	28.00V
Junction of Zener diode Z1, resistor R14, and capacitor C5	20.91V

NOTES: Voltage measurements with Triplett VOM Model 800 or equivalent.

All voltages are DC.

Voltage measurements between referenced point and terminal G of regulator (Generator ground terminal).

Regulator adjusted for 28.0 volts regulated output.

Regulator connected generator test set and operating at or above minimum rated generator speed, (6,000 RPM).

*Voltage measurement at emitter will vary with load. Measured value applies to operating regulator on generator test set with 100% load.

**Voltage measurement at this point will vary with DC load on system approximately 4 to 1.

***Voltage measurements at these points taken with Relay K1 energized.

STORAGE INSTRUCTIONS

1. GENERAL.

This section provides information preparing the Model VR-1010-24-1A DC Voltage Regulator, for use from a shipped or stored condition and for packing the unit for storage or shipment.

2. PREPARATION FOR USE.

The Voltage Regulator, when shipped from the factory, is wrapped in cellulose wadding, PPP-C-843, and inserted in a poly bag, LP-278, and enclosed in a corrugated shipping carton, PPP-B-636. To unpack the unit, cut sealing tape and open top of carton by lifting flaps to break adhesive. Remove unit from carton, remove poly bag and cellulose wadding. Visually examine the unit for damage which might have occurred during shipment or storage.

3. PREPARATION FOR STORAGE OR SHIPMENT.

The Voltage Regulator may be stored for short periods of time without packing. If the unit is to be stored for extended periods or is to be shipped, carefullly wrap unit with cellulose wadding, insert in poly bag and place equipment in a corrugated carton. The carton should then be sealed and labeled for storage.

SPECIAL TOOLS, FIXTURES, AND EQUIPMENT

1. GENERAL.

This section provides information on the special tools and test equipment required for overhaul of the Model VR-1010-24-1A, DC Voltage Regulator.

2. STANDARD TEST EQUIPMENT.

Listed in Table 1001 are the items of standard test equipment required for overhaul of the voltage regulator. The listed item or a suitable equivalent may be used if procedures are modified when references to test equipment and setting of test equipment are made.

EQUIPMENT	MANUFACTURER AND MODEL NUMBER
GENERATOR TEST SET	SUN AGT-2 OR EQUIVALENT
OSCILLOSCOPE	HEWLETT-PACKARD MODEL 132A
VOLTOHMMETER	TRIPLETT ELECT. INST. MODEL 800, OR EQUIVALENT. or JOHN FLUKE MODEL 8040A, OR EQUIVALENT.
GENERATOR	PER MIL-G-6162 or EQUIVALENT.
INSULATION RESISTANCE TESTER	ASSOCIATED RESEARCH MODEL 2956

Standard Test Equipment
Table 1001

3. SPECIAL TEST EQUIPMENT.

None required.

VR-1010-24-1A/P.N. 095001

ILLUSTRATED PARTS CATALOG SECTION

1. INTRODUCTION.

This section of the Overhaul Manual provides a complete listing of parts for the Model VR-1010-24-1A DC Voltage Regulator (Solid-State Silicon), as manufactured by Phoenix Aerospace, Inc.

2. PURPOSE.

The information contained in this section is supplied to aid in provisioning, requisitioning, storing, and issuing of the replaceable parts, and to aid in identification of new and reclaimed parts.

3. APPLICATION.

The Illustrated Parts Catalog Section contains three separate listings; Numerical Index, Symbol Index, and Detailed Parts List. The subsequent paragraphs define the content and application of each listing.

A. Numerical Index.

The Numerical Index provides an alpha-numerical listing of the parts listed in the Detailed Parts List. The prime function being to aid in rapid location using the information contained in the various columns.

(1) Part Number Column.

The PART NUMBER column lists part numbers of procurable parts and assemblies as listed in the Detailed Parts List. Parts are listed in alpha-numerical order of precedence starting at the first letter extreme left and reading to the right as follows:

Letters A through Z
Numeral 0 through 9
(Alphabetical 0's are considered as Numerical zeros).

Second and succeeding positions of the part number appear in the order of precedence as follows:

Space (Blank column)
Diagonal (Slant) /
Point (Period)
Dash (-)
Letters A through Z
Numerical 0 through 9
(Alphabetical 0's are considered as numerical zeros).

(2) Airline Part Number Column.

The AIRLINE PART NO. Column is provided to allow insertion where applicable, of the users own part number where available and desired.

(3) Chapter-Section-Unit-Figure-Item Column.

The CH-SECT-UNIT-FIG-ITEM column contains the specific location data where the listed part first appears in the Detailed Parts List and other pertinent data. Example: 24-20-X-1101-18 is indicative of the following:

24 is significant of the Chapter (derived from system identification numbers).
20 is significant of the Section (derived from sub-system identification numbers).
X is significant of the Unit (derived from the application of particular unit).
1101 is significant of the Figure number.
18 is significant of the Item number.

(4) Total Required Column.

The TTL REQ. Column is the total of each item required in the unit whether it be piece part or sub-assembly.

B. Symbol Index.

The Symbol Index enables the location of component parts referenced from the schematic diagram by the reference symbol to a specific Figure and Item number.

(1) Symbol Column.

The SYMBOL column contains an alpha-numerical listing of every component part which carries a reference symbol on the schematic diagram.

(2) Part Number Column.

The PART NUMBER column lists the vendor part number of the symbolized item.

(3) Chapter-Section-Unit-Figure-Item Column./a

The CH-SECT-UNIT-FIG-ITEM column contains the specific location data where the listed part first appears in the Detailed Parts List and other pertinent data. Example: 24-20-X-1101-18 is indicative of the following:

C. Detailed Parts List.

The Detailed Parts List, is a breakdown of the complete unit into sub-assemblies and detailed parts. Each sub-assembly is listed in its order of disassembly and is followed immediately by its component parts properly indented to show its relationship to the assembly.

(1) Figure Item Column.

The FIG. ITEM Column entries key the parts breakdown to the applicable illustration. Items numbered on the Detailed Parts List preceded by a dash (example -1) do not appear on the illustration.

(2) Part Number Column.

The PART NUMBER column lists the applicable Standard part number MS, AN, NAS, etc., vendor part number or Phoenix Aerospace, Inc. part numbers. When more than one part number is assigned to an item the preference shall be Standard MS, AN, NAS, Etc., vendor, or Phoenix Aerospace, Inc., in that order. Vendor part numbers listed in the PART NUMBER Column are subject to change without notice.

(3) Nomenclature Column.

The NOMENCLATURE column describes the assembly, sub-assembly, or component part in a short form description, with the identifying Noun as the first word, followed by the modifiers as required. The indentations denote parts relation to next higher assembly (NHA) or sub-assembly, as applicable. The ATTACHING PARTS entries are listed immediately following the component which they attach.

If a part is purchased by Phoenix Aerospace, Inc. from a vendor, the Federal Supply Code number, preceded by the letter V, is listed in this column, and set off by parentheses. The vendors part number appears in the PART NUMBER column and the Phoenix Aerospace, Inc. part number follows the vendor, FSC number, and is set off in parentheses. If a part number of FSC number does not appear in the NOMENCLATURE column the part number listed in the PART NUMBER column is a Phoenix Aerospace, Inc. number.

(4) Effect From To Column.

The EFFECT FROM TO column provides for entries regarding usage on different models or for field service bulletin entries as applicable. If this column is left blank, parts apply to all models until otherwise noted by revision.

(5) Units Per Assembly Column.

The UNITS PER ASSY Column lists the quantity of sub-assemblies or parts required in the next higher assembly (NHA). The quantities specified, therefore, are not necessarily the total used per equipment. The letters RF denote that the item listed appears on another list and illustration and is referenced for aid in identification only.

4. VENDOR FEDERAL SUPPLY CODE AND NAME INDEX.

The following list is derived by extraction from the Federal Supply Catalog Handbook H4-1. The information is supplied to aid in procurement and identification of the various vendors.

FSC NO. OR CODE	VENDORS NAME AND ADDRESS
01121	Allen Bradley Co. 1201 South 2nd St. Milwaukee, Wisconsin 53204
05277	Westinghouse Electric Corp. Semiconductor Div. Armbrust Road Youngwood, PA 15697
08530	Reliance Mica Corp. 342 39th Street Brooklyn, NY 11232
09214	General Electric Co. Semiconductor Products Dept. Power Semiconductor Products Opn. Sec. W. Genesee St. Suburn, NY 13021
11502	TRW Electronic Components IRC Fixed Resistors Greenway Road Boone, NC 28607
13715	Fairchild Semiconductor, a Div. of Fairchild Camera and Instrument Corp 4300 Redwood Highway San Rafael, CA 94903
14552	Microsemiconductor Corp. 2830 S. Fairview Street Santa Ana, CA 92704
24444	General Semiconductors Industries, Inc. 230 W. 5th Street P. O. Box 3078 Tempe, AZ 85281
25088	Siemens Corp. 186 Wood Ave. S Iselin, NJ 08830
27556	IMB Electronic Products Inc. 15401 E. Carmenita Road Santa Fe Springs, CA 90670
28520	Heyman Manufacturing Co. 147 N. Michigan Ave. Kenilworth, NJ 07033
29632	Phoenix Aerospace, Inc. 1022 South 23rd Street P. O. Box 20804 Phoenix, AZ 85036
44655	Ohmite Manufacturing Co. 3601 W. Howard Street Skokie, IL 60076
56289	Sprague Electric Co. Beaver Street North North Adams, MA 01247
71785	Cinch Mfg. Co., Div. of United Carr-Fastener Corp. Chicago, IL

4. VENDOR FEDERAL SUPPLY CODE AND NAME INDEX. (cont).

FSC NO. OR CODE	VENDORS NAME AND ADDRESS
75042	TRW Electronic Components IRC Fixted Resistors Philadelphia Division 401 N. Broadstreet Philadelphia, PA 19108

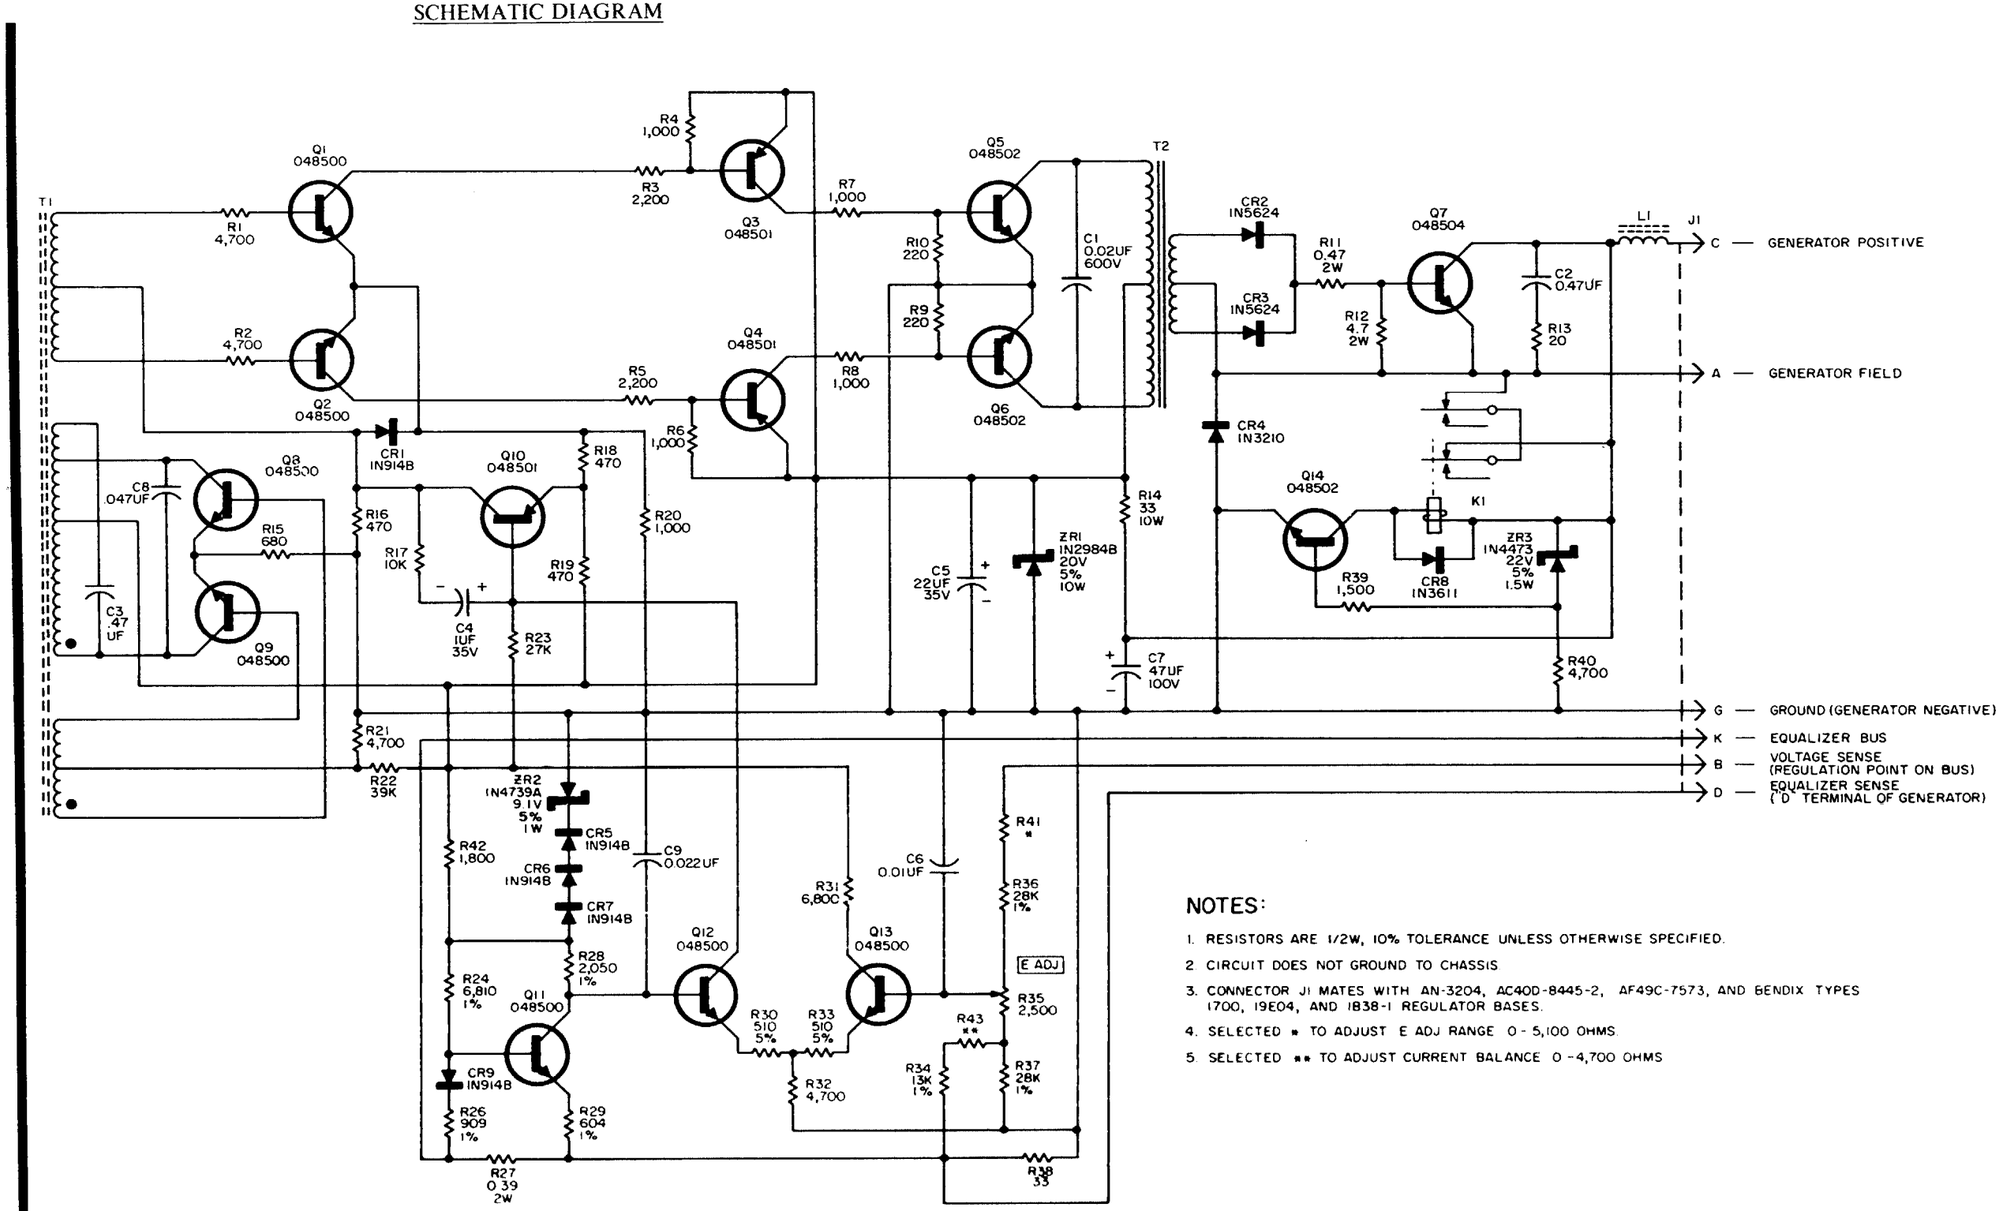
REVISION REFERENCE SHEET

REVISION CODE	REVISION DESCRIPTION	SERIAL NO. EFFECTIVITY
A	RESISTOR R38 CHANGED TO 33 OHMS, ±10%, 1/2W FROM 5.6 OHMS, ±10%, 1/2W.	15 DEC 1967
B	MODIFICATION TO IMPROVE TEMPERATURE COMPENSATION: RESISTOR R24 CHANGED TO 6,810 OHMS, ±1%, 1/8W FROM SELECTED *(3,900-5,100 OHMS); RESISTOR R25 DELETED; RESISTOR R45 ADDED. 1,800 OHMS, ±10%, 1/2W; RESISTOR R26 CHANGED TO 909 OHMS, ±1%, 1/8W FROM 270 OHMS, ±10%, 1/2W; RESISTOR R28 CHANGED TO 2,050 OHMS, ±1%, 1/8W FROM 2,200 OHMS, ±10%, 1/2W; RESISTOR R29 CHANGED TO 604 OHMS, ±1% FROM 620 OHMS, ±10%, 1/2W; RESISTORS R30 AND R33 CHANGED TO 750 OHMS, ±5%, 1/2W FROM 1,000 OHMS, ±10%, 1/2W; RESISTOR R34 CHANGED TO 13K OHMS, ±1% FROM 20K OHMS, ±5%, 1/2W; RESISTORS R36 AND R37 CHANGED TO 28K OHMS, ±1%, 1/8W FROM 16.2K OHMS, ±1%, 1/8W; ZENER DIODE Z2 CHANGED TO 1N4465 FROM 1N4740A.	22 NOV 1968
C	DIODES CR2 AND DR3 CHANGED TO 1N5402 FROM 1N4721. TRANSISTOR Q7 CHANGED TO RCA TYPE NO. 60234 FROM RCA TYPE NO. 2N3772.	10 OCT 1969
D	DIODES CR2 AND CR3 CHANGED TO 1N5624 FROM 1N5402.	22 SEP 1971
E	DIODE CR8 CHANGED TO 1N3611 FROM 1N4002. TRANSISTOR Q7 CHANGED TO RCA TYPE NO. 64497 FROM RCA TYPE NO. 60234. ZENER DIODE Z3 & Z4 CHANGED TO 1N4473 FROM 1N4748A.	22 JUN 1973
F	RF FILTER L1 ADDED IN SERIES WITH PIN C, GENERATOR POSITIVE, OF RECEPTACLE J1.	7 JUN 1974
G	TRANSISTOR Q7 CHANGED TO RCA TYPE NO. 66090 FROM RCA TYPE NO. 64497.	5 MAR 1975

Model VR-1010-24-1A, DC Voltage Regulator,
Revision Reference Sheet, Schematic Diagram,
Figure 1201 (Sheet 1 of 3)



VR-1010-24-1A/P.N. 095001

REVISION REFERENCE SHEET

REVISION CODE	REVISION DESCRIPTION	SERIAL NO. EFFECTIVITY
H	TRANSISTOR Q7 CHANGED TO PAI P.N. 048504 FROM RCA TYPE NO. 66090. TRANSISTORS Q5, Q6, AND Q15 CHANGED TO PAI P.N. 048502 FROM RCA TYPE NO. 40348.	1 DEC 1975
I	TRANSISTORS Q1, Q2, Q8, Q9, Q11, Q12, AND Q13 CHANGED TO PAI P.N. 048500 FROM TYPE 2N3565; TRANSISTORS Q3, Q4, AND Q10 CHANGED TO PAI P.N. 048501 FROM TYPE NO. 2N3638; ZENER DIODE SYMBOLS CHANGED Z1, Z2, AND Z3, TO ZR1, ZR2, AND ZR3; TYPOGRAHICAL ERROR AS READS 1/4W CHANGED TO 1/8W, AS READS 10K CHANGED TO 13K IN REV. B.	1 AUG 1977
J	CAPACITOR C7 CHANGED TO 47UF FROM 50UF. RELAY K1 CONTACTS CORRECTED TO FORM 'C.'	31 MAR 1978
K	ZENER DIODE ZR2 CHANGED TO 1N4739A-9.1V±5%, 1W FROM 1N4465-10V±5%, 1.5W.	30 JUN 1978

Model VR-1010-24-1A, DC Voltage Regulator,
Revision Reference Sheet, Schematic Diagram,
Figure 1201 (Sheet 2 of 3)

SCHEMATIC DIAGRAM

NOTES:

1. RESISTORS ARE 1/2W, 10% TOLERANCE UNLESS OTHERWISE SPECIFIED.
2. CIRCUIT DOES NOT GROUND TO CHASSIS.
3. CONNECTOR J1 MATES WITH AN-3204, AC40D-8445-2, AF49C-7573, AND BENDIX TYPES 1700, 19E04, AND 1838-1 REGULATOR BASES.
4. SELECTED * TO ADJUST E ADJ RANGE 0 - 5,100 OHMS.
5. SELECTED ** TO ADJUST CURRENT BALANCE 0 -4,700 OHMS.

VR-1010-24-2A/P.N. 095027

INTRODUCTION

In conformance with A.T.A. Specification No. 100 for Manufacturers' Technical Data, two manuals have been prepared concerning the Model VR-1010-24-2A DC Voltage Regulator. These manuals, if used as intended, will facilitate the effective, continued operation of the equipment. Technical data is grouped according to usage in the manual as described.

MAINTENANCE MANUAL

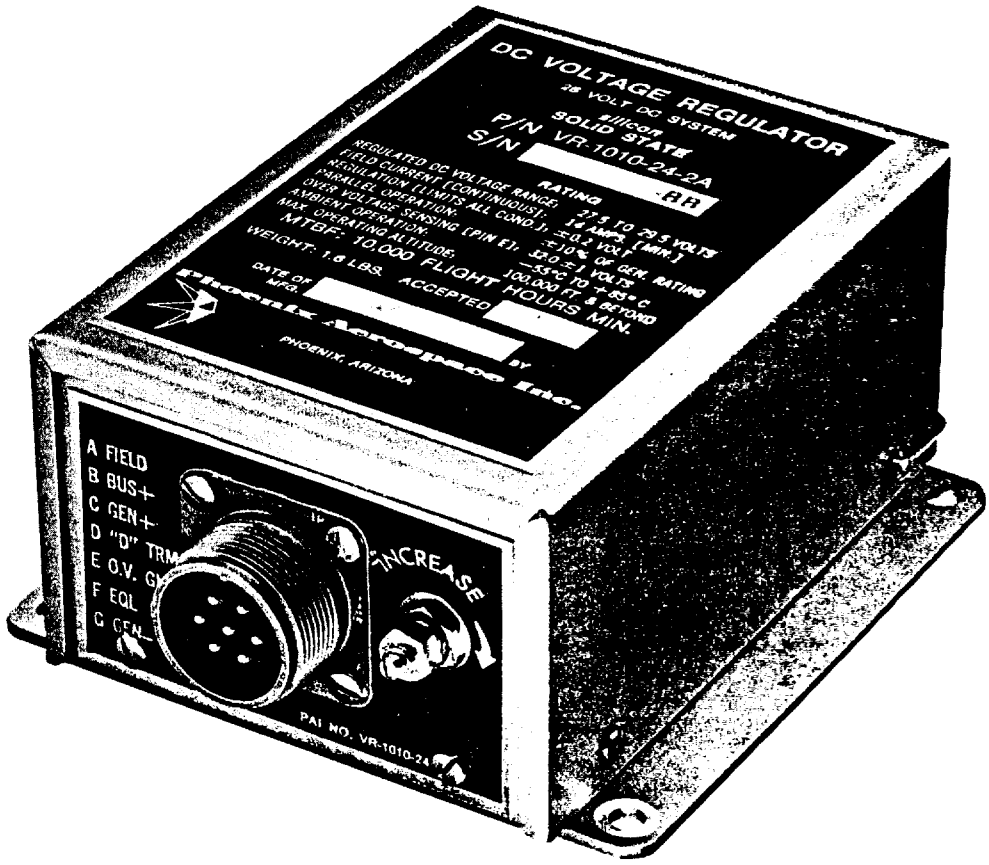
This manual is intended for use by flight line and hangar maintenance personnel. A detailed description and operation procedures, including a table of leading particulars are presented for reference. Mounting information and cabling information are presented as an aid to installation. Trouble-shooting information is limited to procedures required to trace a trouble to the overall unit for replacement.

OVERHAUL MANUAL WITH ILLUSTRATED PARTS CATALOG

The Overhaul Manual contains all the information required for shop testing, replacement of defective parts, alignment and adjustment, mechanical disassembly, inspection, and reassembly. Detailed circuit theory is given with emphasis on theory that will be especially helpful for effective trouble-shooting. Performance tests as well as functional (go/no-go) checks, which may be used to determine condition of equipment and for retesting after repairs.

The Illustrated Parts Catalog provides a means to determine the manufacturer's part number and the physical location on the equipment of a part if the reference designation is known, or to determine the reference designation and the manufacturer's part number when the physical location of the part is known but no other information is available.

DESCRIPTION AND OPERATION



1. GENERAL.

A. Purpose of Manual.

This manual contains maintenance and installation procedures for the Model VR-1010-24-2A, DC Voltage Regulator (Solid-State), illustrated in Fig. 1.

B. Purpose of Equipment.

The Model VR-1010-24-2A, DC Voltage Regulator is used to control all 28 volt direct current generators and starter generators conforming to FAA TSO-C56 and/or Military Specification MIL-G-6162. The regulator performs the function of maintaining constant output voltage under varying speed and load conditions in single generator or multiple generator systems.

Model VR-1010-24-2A, DC Voltage Regulator
Figure 1

2. DESCRIPTION.

A. The Model VR-1010-24-2A, DC Voltage Regulator is a compact self-contained unit utilizing state-of-the-art solid-state techniques. The regulated voltage is adjustable at a mechanically locked potentiometer adjacent to the input/output connector on the end of unit. Operating power for the regulator is obtained from the regulated generator. The regulator automatically adjusts field current to produce a constant voltage at the generator output under varying speeds and loads. The unit mounts directly on a bulkhead or other structural member, equipment rack, or equipment drawer. The unit is compactly packaged to facilitate placement in the aircraft and requires only a single, multi-pin, input/output connector between the unit and the aircraft wiring system.

B. The primary characteristics, capabilities, overall weight, and dimensions are listed in Table of Leading Particulars, Table 1.

GENERAL:

Duty: Continuous, unattended.

Temperature Rise: 15° C (maximum).

Cooling: Self-cooled by natural convection, conduction, and radiation.

Ambient Temperature Range: −85° to +85° C.

Maximum Operating Altitude: 100,000 feet and beyond.

Reliability: 10,000 hours MTBF (minimum).

ELECTRICAL:

Regulated DC Voltage Range: 27.5 to 29.5 VDC, no load to full load, over rated generator speed and temp/alt. operating range.

Field Current (Continuous): 14 Amperes (minimum).

Regulation: ±0.2 Volts, no load to full load, over rated generator speed and temp/alt. operating range.

Voltage Adjustment Limits: 26 VDC to 31 VDC, continuously variable.

Equalizer Circuit: ±2.5 Volts, minimum change, no load to full load, at minimum rated speed for regulation, when 0.25 volts is applied to equalizer bus terminals.

Parallel Operation: ±10 per cent equal division of load, two or more generators operated in parallel, no load to full load, over rated generator speed range.

Table of Leading Particulars
Table 1

Overvoltage Sensing: Overvoltage sensing circuit trips at 32.0 ±1.0 volts independent of the external field relay, placing a ground on pin E of connector J1 to operate an external relay.

Regulator Equivalent Resistance: High Value — More than 100 ohms.
Low Value — Less than 0.5 ohms.

Current Regulation: Regulation for balancing current between parallel generators in multiple generator systems.

Recovery Time: 0.05 Seconds, full load switched ON-OFF-ON, controlled voltage recovers to and remains within 10 per cent of steady state condition.

Overload Current: 14 Amperes (minimum) for one hour.

Induced Ripple: Less than 1.5 volts peak to peak.

Transient Protection: ±80 volts for 40 milliseconds,
±600 volts for 10 microseconds.

MECHANICAL:

Weight: 1.6 pounds (729.6 grams).

Overall Dimensions: 3-1/2 in. wide (8.89 cm) by
5 in. long (12.7 cm) by
2-3/8 in. high (6.03 cm).

Mounting Base Dimensions: 4-5/8 in. long (11.748 cm) by
4-1/2 in. wide (11.43 cm).

Mounting Centers: 4 in. long (10.16 cm) by 4 in. wide (10.16 cm).

Electrical Connectors: Input/Output: MS3102R-16S-1P mating MS3106F-16S-1S.

Cooling: Self-cooled by natural convection, conduction, and radiation.

Installation: Mounts in any position, without degradation of power output, heating, operating life, or other operating characteristics.

Adjustment: Voltage set potentiometer, INCREASE, adjusts voltage and paralleling in a single operation, located adjacent to input/output connector on regulator.

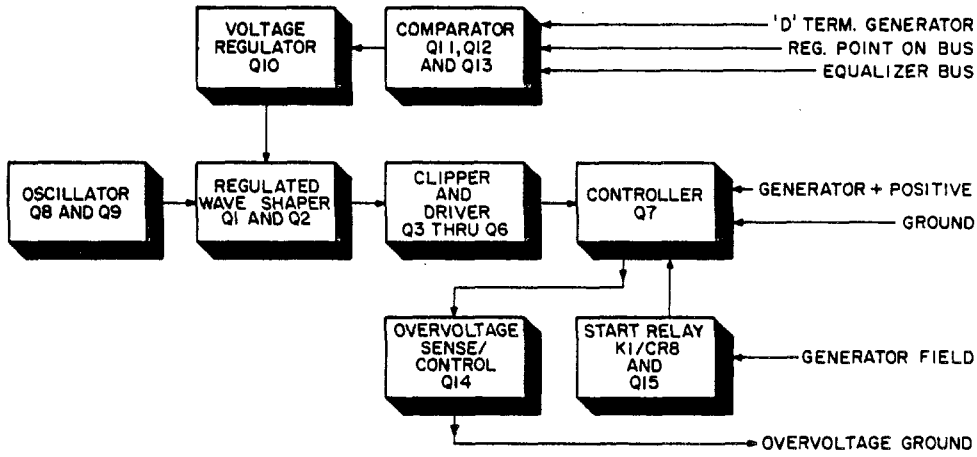


Table of Leading Particulars (Cont)
Table 1 (Cont)

3. OPERATION.

The subsequent paragraphs cover the theory of operation for the Model VR-1010-24-2A, DC Voltage Regulator. The Block Diagram Theory will aid in conveying the overall circuit operation to non-technical oriented personnel, while the Detailed Circuit Theory will enable the technician to understand in detail the operation of equipment.

A. Block Diagram Theory.

The subsequent paragraphs together with the block diagram of Fig. 2, cover in concise form the signal flow and circuit operation for the Model VR-1010-24-2A, DC Voltage Regulator.

Model VR-1010-24-2A, DC Voltage Regulator
Block Diagram
Figure 2

(1) Generator Start Relay. Relay K1 in the de-energized condition, contacts closed, completes the generator field circuit, until operating speed and voltage output are attained. Relay K1 energizes at a voltage of approximately 20 volts, when Zener diode ZR4 conducts and biases transistor Q15 to turn-on. Relay K1 contacts open by-passing the regulator controller circuits and permits the control circuits to function as controller. Operating power for the regulator circuit is obtained from the generator output.

(2) Stabilized Oscillator. Transistors Q8 and Q9 generate a sine wave signal at a frequency of approximately 400 Hertz. The sine wave signal is coupled through auxiliary windings of oscillator transformer T1 to the input of the regulated wave shaper circuits.

(3) Regulated Wave Shaper. Transistors Q1 and Q2 in a push-pull circuit receive the sine wave signal from the stabilized oscillator. Voltage applied from the voltage regulator circuit determines the shaping operation to control duty cycle and regulator operation. The shaped output is coupled to the input of the clipper circuit.

(4) Clipper and Driver. Transistors Q3, Q4, Q5, and Q6 in cascaded push-pull stages provide additional shaping and amplification of the 400 Hertz signal. The amplified signal is applied to the controller circuits.

(5) Controller. Transistor Q7 and diodes CR2 and CR3 comprise the controller circuitry. Transistor Q7 switches the generator field current at a rate of approximately 800 pulses per second, derived by rectification of the 400 Hertz signal by diodes CR2 and CR3. Variation in the width, duty cycle, determines the amount of field current. Clamp diode CR4 maintains continuous field current.

(6) Overvoltage Sense/Control. Transistor Q14 and Zener Diode ZR3 provide a sense and control circuit to operate an external relay to open the positive 28 volts DC supplied to the regulator or the generator Field line to provide overvoltage protection for the generator.

(7) Voltage Regulator. Transistor Q10 delivers the regulating bias to control pulse width of the regulated wave shaper circuit. Reference and control signals are derived from the voltage comparator circuit.

(8) Voltage Comparator. Transistors Q12 and Q13 are operating as a voltage comparator circuit with temperature stabilized reference voltages and an adjustable set point. Transistor Q11 is a current comparator circuit for paralleling operation.

B. Detailed Circuit Theory.

The following sub-paragraphs cover the individual circuits and their operation. Occasional reference to the overall schematic diagram of the equipment, Fig. 3, will be necessary to determine circuit configuration.

(1) Generator Start Relay. The generator start relay K1 with normally closed contacts in the de-energized condition allows maximum field current to flow during start-up of generator. When the generator voltage reaches approximately 20 volts, Zener diode ZR4 conducts and biases transistor Q15 to 'turn-on' and permits relay K1 to energize, opening the field current by-passing contacts. The generator field current path is now passing through the controller circuit through transistor Q7. Operating power is supplied from the generator (+), to the control circuits. Diode CR8 across the coil of relay K1 functions as a suppressor diode. Resistors R39 and R40 determine the maximum base current flow of transistor Q15.

(2) Stabilized Oscillator. The stabilized oscillator utilizes transistors Q8 and Q9 in a Hartley oscillator circuit. Toroidal transformer T1 with multiple windings provides the tuned circuit, feedback, and output windings for the oscillator. The tuned circuit is tuned by capacitor C3 to approximately 400 Hertz. Capacitor C8 provides parasitic suppression in the oscillator tank circuit. The feedback winding provides sustained oscillation to the base-collector circuit. Resistors R21 and R22 provide the bias to the base circuits of the transistors to insure starting and sustained oscillation. Resistor R15 provides degeneration for improved stability of the oscillator circuit. Output to the regulated wave shaper circuit is through remaining winding on transformer T1.

(3) Regulated Wave Shaper. The regulated wave shaper receives the 400 Hertz sinusoidal signal from transformer T1. The input signal applied to the bases of transistors Q1 and Q2 is through resistors R1 and R2 to limit the amount of base current. Transistors Q1 and Q2 conduct alternately on positive half-cycles of the input signal. The point of conduction and duration, resultant increase or decrease in duty cycle is determined by the bias supplied to the emitter circuits from transistor Q10, voltage regulator. Diode CR1 serves as a clamp

diode to set bias level of transistors Q1 and Q2. The output across the collectors is a quasi-square wave signal and is applied to the input of the clipper circuit.

(4) Clipper and Driver. The clipper and driver circuit provide additional shaping of the signal and amplification for application to the controller circuit. The clipper circuit consists of transistors Q3 and Q4 in a push-pull circuit. The quasi-square wave signal is coupled to the base circuits of transistors Q3 and Q4 through limiting resistors R3 and R5, respectively. The output of the clipper circuit is a quasi-square wave with improved rise time. The output is coupled to the base circuits of the driver transistors Q5 and Q6 through resistors R7 and R8, respectively. Resistors R9 and R10 provide a low impedance return for leakage currents. Output in the collector circuit is developed across toroidal transformer T2 and coupled to the controller circuit. Zener diode ZR1 and resistor R14 provide voltage regulation to the clipper and driver circuits.

(5) Controller. The controller circuit comprised of transistor Q7 and diodes CR2 and CR3 control the generator field current to regulate the output voltage of the generator. The quasi-square wave output across transformer T2 is converted to a uni-directional positive voltage by rectification circuit comprised of diodes CR2 and CR3. The positive pulses with a nominal pulse rate of 800 per second are applied to the base of transistor Q7 to control turn on and turn off. Variation of the pulse width, varies in step with the voltage adjustment setting of variable resistor R35, effectively controlling duty cycle. The results of this variation in duty cycle determines the on-off time of transistor Q7 and subsequent variations in generator field current to achieve voltage regulation at the generator output. The regulator operating at a nominal rate of 800 pulses per second in the controller section is adequate to provide proper smoothing of the current to the generator field. The predominate AC component on the DC output of the generator is due primarily to commutator ripple and not from the contribution of the field excitation. RF filter L1 in the collector circuit of transistor Q7 and in series with pin C of connector J1, provides additional filtering of the 800 pulse per second controller output and harmonics of the fundamental frequency. Since the generator field is highly inductive, continuous field current is achieved by the action of clamp diode CR4. The voltage waveform at pin A of connector J1, emitter of transistor Q7, is a positive pulse with an excursion from ground to a positive value approximating generator voltage, typically 27.5 to 29.5 volts. The current flowing in the generator field is constant due to the action of clamp diode CR4. Capacitor C2 and resistor R13 provide a series path for high speed transients which might appear across the collector to emitter circuit of transistor Q7.

(6) Overvoltage Sensing and Control. Transistor Q14 and Zener diode ZR3 provide a sensing and control circuit for overvoltage protection of the generator. If the generator voltage at pin C of connector J1 should rise to 32 volts DC ± 1 volt, Zener diode ZR3 will conduct and bias transistor Q14 to turn on. Transistor Q14 conducts and provides a ground return through pin E of connector J1 and series current limiting resistor R44. The coil of a latching relay, type MS25457-1, Leach No. 9237-4845, or equivalent, connected between pin E of connector J1 and the positive 28 volt DC source, with a coil rating of 1 Ampere or less, will operate instantly to interrupt the positive 28 volts DC to the voltage regulator or the current through the generator field lead, pins C and A, respectively, on connector J1. Reset of the latching relay is accomplished by application of 28 volts DC to the reset winding on the relay coil.

(7) Voltage Regulator. The voltage regulator consists of transistor Q10, and associated biasing and time constant circuitry. Resistors R18 and R19 comprise a voltage divider and

bias network for the emitter while resistor R17 and capacitor C4 establish the time constant of regulation. Control is applied to the base circuit from the voltage comparator. Output at the collector is applied to the emitter and base circuit of transistors Q1 and Q2, across clamp diode CR1.

(8) Voltage Comparator. The voltage comparator circuit comprised of transistors Q12 and Q13 samples the voltage on the generator bus, pin B of connector J1. The circuit operates as a differential comparator. The base of transistor Q13 receives the voltage from regulation point on generator bus, as adjusted by setting of voltage adjustment, variable resistor R35, while the base of transistor Q12 is referenced to the temperature compensated Zener voltage at the collector of transistor Q11. Any change in voltage at the regulation point on bus of the generator develops a voltage across resistor R23 in the base of transistor Q10 to apply a change in bias to the voltage regulator. Parallel generator operation is achieved by sampling the voltage between the equalizer bus, pin F of connector J1, and the equalizer sense point, terminal D on generator, pin D of connector J1. The change in voltage appears across resistor R27 and causes a change in the voltage drop across resistor R28 in the collector circuit, and adds in series with the reference voltage derived from temperature compensating diode CR5, CR6, and CR7 in series with Zener diode ZR2. Diode CR9 and resistor R26 establish a reference voltage at the base of transistor Q11. Unequal generator currents cause a change in generator voltage output in a direction to equalize generator currents.

TROUBLE SHOOTING

1. GENERAL.

The following paragraphs define procedures suitable for determining that a fault exists in the DC Voltage Regulator. These procedures do not cover trouble shooting within the regulator or associated generator. For equipment trouble shooting procedures refer to the overhaul manual and perform only in an overhaul shop.

2. PRELIMINARY SYSTEM CHECK.

Refer to the airframe wiring diagram and the cabling information given in Fig. 203 or 204 as applicable, and check wiring between generator/s and regulator for continuity and proper connection.

3. OPERATIONAL CHECK.

After preliminary checks have been completed an operational check may be made to determine the malfunctioning component of the system. All checks are made with the generator operating at or above minimum rated speed. When performing checks in a parallel system, check one generator and its associated equipment at a time. The remaining generator/s in the system should be off the line.

NOTE: Observe the engine manufacturers' instructions carefully to prevent overheating when operating the engine on the ground. As soon as checks are completed the engine should be throttled down.

Proceed with checks as outlined in Table 101 to determine malfunction.

CAUTION: UNDER NO CIRCUMSTANCES SHOULD THE REGULATOR BE DISASSEMBLED IN THE FIELD FOR REPAIRS. ANY REGULATOR FOUND TO BE DEFECTIVE MUST BE RETURNED TO AN OVERHAUL REPAIR SHOP FOR REPAIR AND RECONDITIONING.

Trouble Shooting Chart
Table 101 (Sheet 1 of 3)

SYMPTOM	PROBABLE CAUSE	CHECK	REMEDY
Generator ammeter reads zero.	Mating connector not connected properly, or open wiring at connector.	Disconnect input/output connector and inspect for defects.	Clean and/or replace defective connector or wiring.
	DC Voltage Regulator not adjusted properly or malfunctioning.		Remove regulator and install tested and properly adjusted regulator. Return malfunctioning unit to overhaul repair chop.
	Defective or damaged generator.	Check and inspect in accordance with generator manufacturer's instructions.	Remove defective generator and install operative unit. Return defective unit to overhaul repair shop.
	Damaged wiring between generator and regulator.	Inspect wiring for shorts and continuity using airframe manufacturer's installation drawings.	Replace defective wiring, check, and secure all connections.
	Defective ammeter.	Check operation and calibration in accordance with manufacturer's instructions.	Replace defective ammeter. Return defective parts to overhaul repair shop.
	Generator cutout open by overvoltage trip circuit action.	Check continuity of cutout by resistance checks.	Operate generator switch to reset position restoring continuity through generator cutout.
		Check cutout in accordance with manufacturer's instructions.	Replace defective generator cutout. Return defective unit to overhaul repair shop.
	Generator main power switch open, fusible link or battery relay open.	Check circuit for continuity and malfunctions.	Replace defective or malfunctioning unit. Return defective unit to overhaul repair shop.
Generator voltage zero.	DC Voltage Regulator malfunctioning.		Remove regulator and install tested and properly adjusted regulator. Return malfunctioning unit to overhaul repair shop.

SYMPTOM	PROBABLE CAUSE	CHECK	REMEDY
Generator voltage zero (cont.).	Damaged wiring between generator and regulator.	Inspect wiring for shorts and continuity using airframe manufacturer's installation drawings.	Replace defective wiring, check, and secure all connections.
	Defective or damaged generator.	Check and inspect in accordance with generator manufacturer's instructions.	Remove defective generator and install operative unit. Return defective unit to overhaul repair shop.
Output voltage too high.	DC Voltage Regulator not adjusted properly or malfunctioning.		Remove regulator and install tested and properly adjusted regulator. Return malfunctioning unit to overhaul repair shop.
	Damaged wiring between generator and regulator.	Inspect wiring for shorts and continuity using airframe manufacturer's installation drawings.	Replace defective wiring check, and secure all connections.
Output voltage too low.	DC Voltage Regulator not adjusted properly or malfunctioning.		Remove regulator and install tested and properly adjusted regulator. Return malfunctioning unit to overhaul repair shop.
	Damaged wiring between generator and regulator.	Inspect wiring for shorts and continuity using airframe manufacturer's installation drawings.	Replace defective wiring, check, and secure all connections.
Voltmeter or ammeter fluctuates rapidly under steady load conditions.	Malfunctioning DC Voltage Regulator.		Remove regulator and install tested and properly adjusted regulator. Return malfunctioning unit to overhaul repair shop.
Output voltage varies with application or removal of load.	Malfunctioning DC Voltage Regulator.		Remove regulator and install tested and properly adjusted regulator. Return malfunctioning unit to overhaul repair shop.
Load division in a parallel system out of limits.	Defective ammeter.	Check operation and calibration in accordance with manufacturer's instructions.	Replace defective ammeter. Return defective parts to overhaul repair shop.

Trouble Shooting Chart
Table 101 (Sheet 2 of 3)

SYMPTOM	PROBABLE CAUSE	CHECK	REMEDY
Load division in a parallel system out of limits (Cont.)	DC voltage regulator not adjusted properly or malfunctioning.		Remove regulator and install tested and properly adjusted regulator. Return malfunctioning unit to overhaul repair shop.
	Damaged wiring between generator and regulator.	Inspect wiring for shorts and continuity using airframe manufacturer's installation drawings.	Replace defective wiring, check, and secure all connections.
	Generator grounding straps not secured.	Check grounding of generator per airframe and generator manufacturer's instructions, and value of resistance specified.	Secure and ground strap generator properly.
	Equalizer switch/relay open-circuited or grounded.	Check switch/relay in accordance with manufacturer's instructions.	Replace defective switch/ relay.
	Equalizer switch/relay wiring shorted or open.	Check wiring in accordance with manufacturer's instructions.	Replace defective wiring and secure all connections.
System voltage drops when a generator in the parallel system is removed from line.	Equalizer switch/relay shorted.	Check switch/relay in accordance with manufacturer's instructions.	Replace defective switch.
	Equalizer switch/relay wiring shorted.	Check wiring in accordance with airframe manufacturer's drawings.	Replace defective wiring and secure all connections.

MAINTENANCE PRACTICES

1. GENERAL.

The following paragraphs cover in detail operations associated with maintenance, installation/removal, etc. of the Model VR-1010-24-2A DC Voltage Regulator.

2. SERVICING.

Periodic servicing or maintenance of the (solid-state) DC Voltage Regulator is not required or recommended. The equipment should not be removed from the airframe unless required by maintenance practices observed by the using agency. The use of solid state devices in a completely transistorized circuit eliminates the major causes of failures and periodic maintenance procedures. In the event a failure occurs refer to the Installation/Removal procedures and remove unit for repair by the overhaul shop or for return to vendor.

3. INSTALLATION/REMOVAL.

The following sub-paragraphs outline the installation and removal procedures for the DC Voltage Regulator.

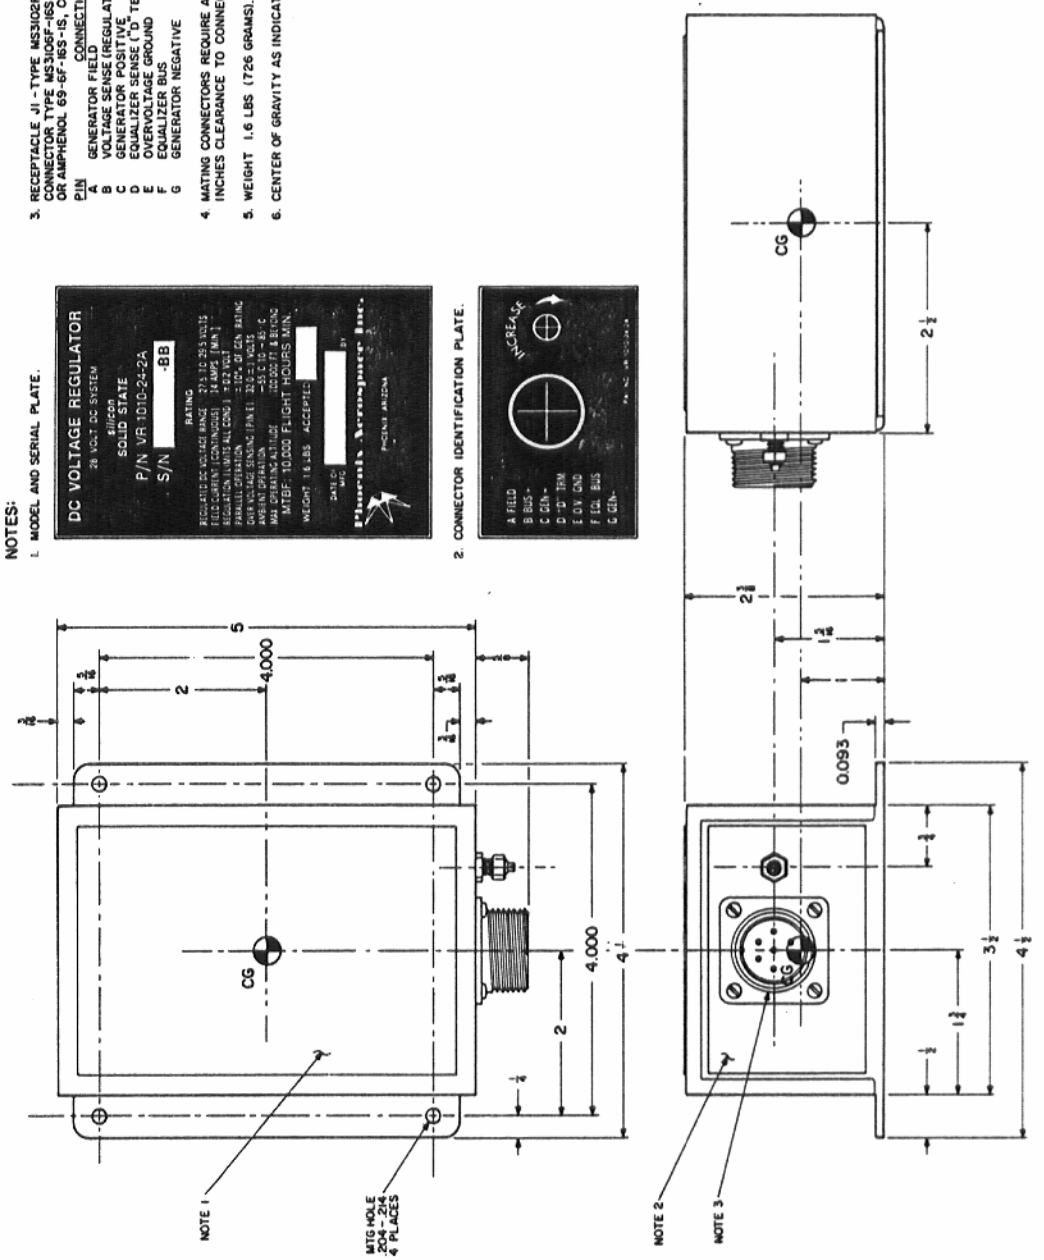
A. Installation.

(1) Refer to Fig. 201 and Fig. 202 to determine clearance and mounting requirements for the DC Voltage Regulator.

CAUTION: USE CARE IN DRILLING OPERATION OF SUBSEQUENT PARAGRAPH, TO PREVENT DAMAGE TO AIRFRAME STRUCTURE, WIRING, OR CONTROLS.

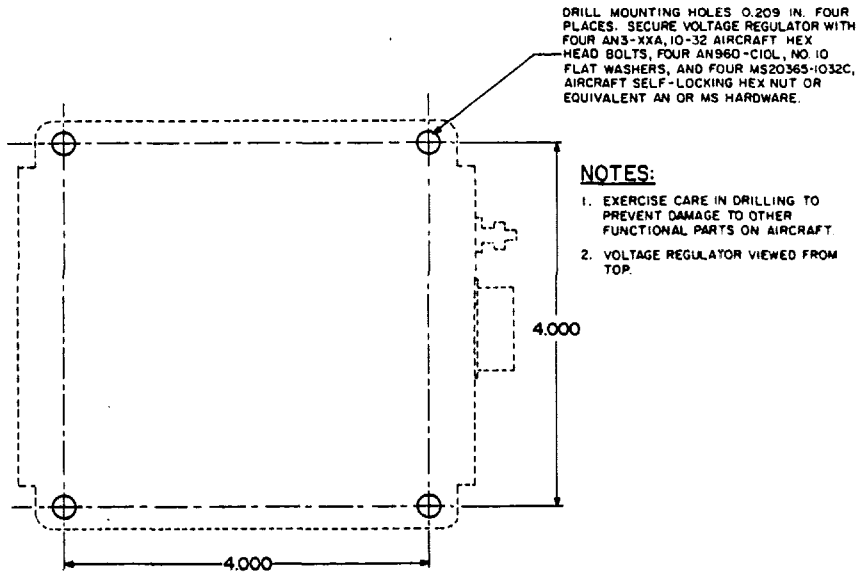
(2) Refer to Fig. 202, mark and drill mounting holes for mounting, typical drilling information is given on Fig. 202.

(3) Install regulator using four, AN3-XXA, 10-32 aircraft hex head bolts, four, AN960-C10L, No. 10 flat washers, and four MS20365-1032C, aircraft self-locking hex nuts or equivalent AN or MS hardware. Length of bolts must be selected for the specific installation for length of grip area, and thread area to insure that at least one and one-half threads showing after installed and securely tightened.



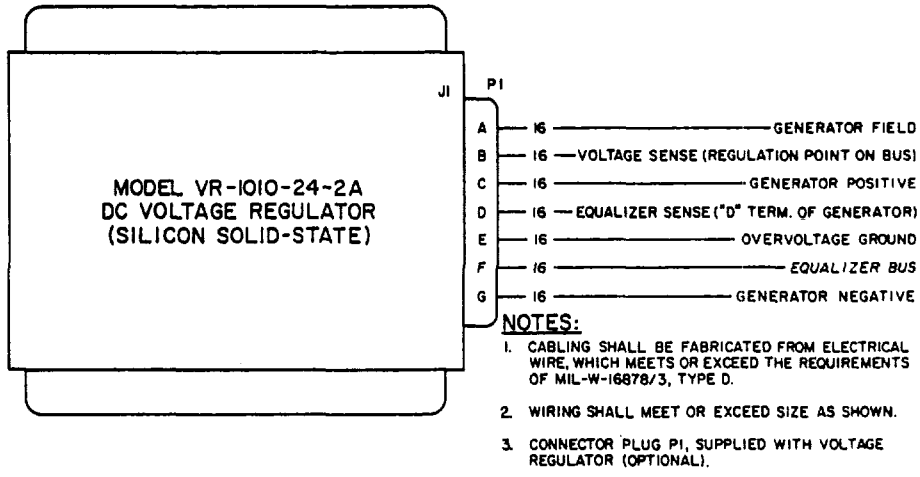
(4) Refer to Fig. 203, Fig. 204, and Fig. 205 and prepare wiring in accordance with system wiring diagrams. Refer to Fig. 204 and Fig. 205 for typical single and dual generator system wiring diagrams, respectively.

(5) After installation and wiring have been completed check to insure that all switches or circuit breakers are in their off positions.



B. Removal.

(1) Place all switches or circuit breakers in their off positions.



(2) Remove unit in reverse order of procedures given in paragraphs 3.A(1) thru (4).

Figure 206

4. ADJUSTMENT/TEST.

The following paragraphs outline test procedures for both installation check-out and a pre-installation bench test if desired or required by maintenance policies.

A. Installation Test.

Complete the following steps to determine that the DC Voltage Regulator and associated generator operate properly.

NOTE: The following checks are performed with the generator operating at, or above minimum rated speed. Observe the engine manufacturer's instructions carefully to prevent overheating when operating the engine on the ground. Upon completion of checking procedure, throttle engine down.

(1) Voltage Check.

(a) Connect a voltmeter with a range of 0 to 30 volts across terminals E and B of the generator, ground and positive terminals, respectively.

(b) Accelerate the engine until the generator is operating, at or above the minimum rated speed as given in the applicable generator manufacturer's handbook. Generator switch and master battery switches are open, OFF.

NOTE: Proper engine speed is determined by dividing the minimum rated generator speed by the ratio of generator speed to engine crankshaft speed as given in the manufacturer's handbook.

(c) Close the generator switch and place all load switches in their OFF positions.

(d) No-load or minimum-load voltage should be between 28.3 and 28.7 volts. In the event limits are exceeded, the regulator is not operating properly and should be removed for repair by the overhaul shop.

(e) The DC Voltage Regulator is preset at the factory for 28.5 volts with generator operating at full load and at MID-RANGE speed (6,000 RPM). In the event adjustment is required at flight line level, perform steps (f) through (h).

(f) Identify the Voltage Set potentiometer, INCREASE, adjacent to the Input/Output connector J1. Using a 5/16 inch hex nut driver with hollow shaft, loosen the regulation adjustment control locking nut.

(g) Using a small screwdriver, approximately 1/8 inch blade, rotate slotted control shaft to obtain desired voltage on regulated bus.

(h) Using the 5/16 inch hex nut driver, tighten control locking nut. DO NOT overtighten.

(i) Operate the generator at minimum rated speed with regulator under test for at least 15 minutes and recheck no-load and full-load voltage, to insure temperature rise does not affect the regulation.

NOTE: The Model VR-1010-24-2A DC Voltage Regulator does not exhibit the characteristic droop of carbon pile regulators when cold. The regulation will be flat over the specified temperature-altitude operating range.

(j) Close Master Battery switch and switch on a DC load to the system.

(k) The generator ammeter should indicate a reading equivalent to the load applied and the voltage reading on the voltmeter connected at the point of regulation on the positive DC bus and negative (ground) Terminal E of generator should indicate 28.5 volts DC.

(l) Switch OFF DC load, Master Battery switch, Generator switch, and engine.

CAUTION: DO NOT ATTEMPT TO DISCONNECT VOLTAGE REGULATOR FROM THE SYSTEM UNLESS GENERATOR IS STOPPED OR THE FIELD IS OPEN. FAILURE TO OBSERVE THIS CAUTION WILL RESULT IN PITTED OR BURNED CONTACT SURFACES.

(m) In the event trouble was experienced, remove the voltage regulator and return to the overhaul shop for repair.

(2) Paralleling Check.

NOTE: Each generator and regulator combination should be checked as outlined in preceding Voltage Check procedure, steps (a) through (m), and adjusted for exactly the same no-load or minimum-load voltage by completion of steps (f) through (h) of the Voltage Check procedure.

(a) Operate all generators at or above minimum rated speed.

(b) Check accuracy of the system ammeters by switching on one generator at a time while a constant load (approximately equal to the full-load rating of one generator) is switched on. Record the ammeter reading of each generator. If ammeter readings are equal, the ammeters are considered to be accurate.

(c) Close all generator switches, all equalizer switches, and with all generators operating at or above minimum rated speed, apply a load approximately equal to the full load rating of any one generator in the parallel system.

(d) Check the individual ammeters for indication that each generator is sharing the load with ± 10 per cent of rated output.

NOTE: In the event load sharing does not meet specification of ± 10 per cent, switch regulators and repeat preceding steps. If this fails to correct trouble, refer to manufacturer's handbook for the generator and check resistance in equalizing circuits for balance.

B. Pre-installation Test.

Complete the following steps to determine that the DC Voltage Regulator is operating properly before installation in the airframe.

NOTE: The subsequent steps are to be used only in determining proper operation of the DC Voltage Regulator prior to installation in the airframe. The following steps do not authorize flight line repairs to the DC Voltage Regulator other than resetting the voltage regulation point. Tests are performed on a motor driven generator test set similar to the Sun Model AGT-2 Generator Test Set or equivalent and a voltage and metering source as described in subsequent steps.

(1) Refer to Fig. 207 and connect the DC Voltage Regulator to the associated test equipment and the Generator Test Set.

CAUTION: DO NOT ATTEMPT TO CONNECT VOLTAGE REGULATOR TO THE GENERATOR TEST SET WITH THE GENERATOR TEST SET OPERATING.

(2) Proceed as follows to complete pre-installation tests.

(a) Start Generator Test Set and run generator speed up to LOW RANGE (approx. 4,500 RPM) Master Battery and Load switches open, OFF.

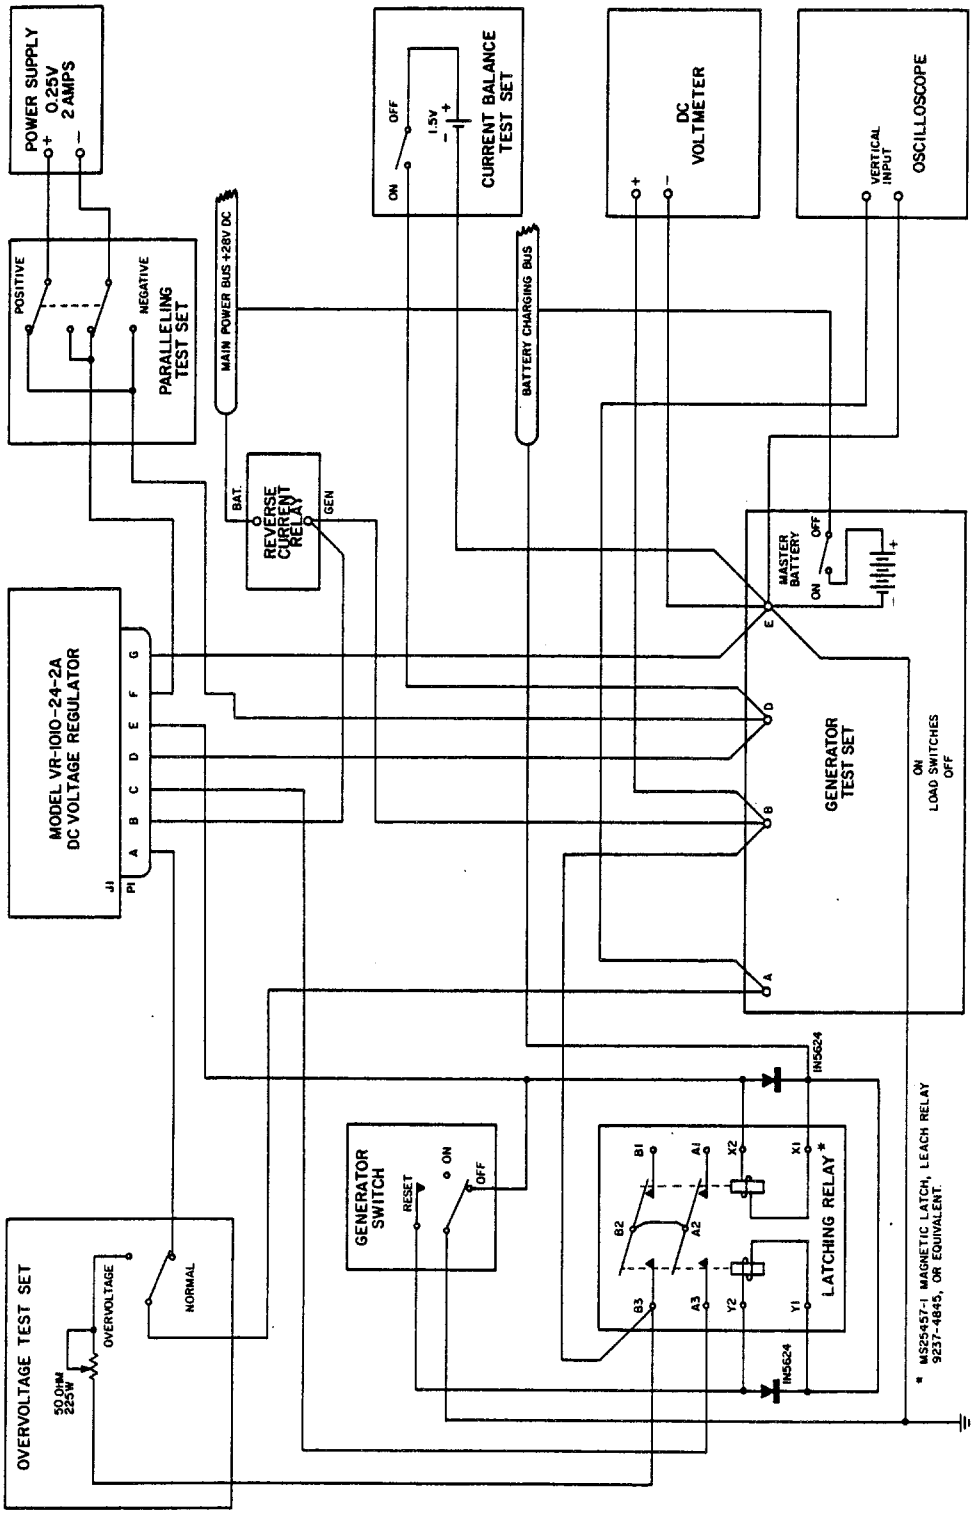
CAUTION: DO NOT OPERATE GENERATOR TEST SET WITHOUT AIRBLAST TO GENERATOR TO PREVENT SERIOUS OVERHEATING OF THE GENERATOR.

(b) No-load or minimum-load voltage should not vary more than ±0.2 volts from the regulated point setting, standard factory setting is 28.5 volts DC. In the event adjustment is required, perform steps (c) through (x).

(c) Identify the Voltage Set potentiometer INCREASE at the connector end of unit. Using a 5/16 inch hex nut driver with hollow shaft, loosen the regulation adjustment control locking nut.

(d) Using a small screwdriver, approximately 1/8 inch blade, rotate slotted control shaft to obtain desired voltage on regulated bus, Pin B of connector J1.

(e) Using the 5/16 inch hex nut driver, tighten control locking nut. DO NOT overtighten.



(f) Close Master Battery switch and Load switches to apply a load of 50 to 100 percent to the generator.

(g) Place all Load switches in their OFF positions and Master Battery switch in the OFF position and increase Generator Test Set speed to MID RANGE (approx. 6,000 RPM).

(h) No-load or minimum load voltage should not vary more than ±0.2 volts from the regulated point as determined in preceding step (b).

(i) Close Master Battery switch and Load switches to apply a load of 50 to 100 per cent to the system.

(j) Place all Load switches in their OFF positions and Master Battery switch in the OFF position and increase Generator Test Set speed to HIGH RANGE (approx. 8,000 RPM).

Generator Test Set Connections to
Model VR-1010-24-2A, DC Voltage Regulator
Figure 207

(k) No-load or minimum load voltage should not vary more than ±0.2 volts from the regulated point as determined in preceding steps (b) and (h).

(l) Close Master Battery switch and Load switches to apply 50 percent and 100 per cent loads to the generator.

(m) Place all Load switches in their OFF positions and Master Battery switch in the OFF position and decrease Generator Test Set speed to required speed preparatory to stopping Generator Test Set. Stop Generator Test Set completely.

NOTE: Each Voltage Regulator should be checked as outlined in preceding steps and adjusted for exactly the same no-load or minimum-load voltage by completion of steps (c) through (e).

(n) Complete steps (o) through (t) to check parallel operation.

(o) Start Generator Test Set and run generator speed up to LOW RANGE (approx. 4,500 RPM). Close Master Battery switch and Load switches to apply a 100 per cent load to the system.

(p) Operate Paralleling Test Set switch to NEGATIVE, applying the positive 0.25 volts DC to the equalizer bus, Pin F, connector J1 of the regulator and the negative 0.25 volts DC to terminal D of the Generator Test Set. Voltmeter reading across the generator output should decrease by at least 2.5 volts. Return switch to the center OFF position.

(q) Place all Load switches in their OFF positions disconnecting all load. Operate Paralleling Test Set switch to NEGATIVE, applying the positive 0.25 volts DC to the equalizer bus, Pin F, connector J1 of the regulator and the negative 0.25 volts DC to terminal D of the Generator Test Set. Voltmeter reading across the generator output should decrease by at least 2.5 volts. Return switch to center OFF position.

(r) Close Load switches to apply a 100 per cent load to the generator. Operate Paralleling Test Set switch to POSITIVE, applying the negative 0.25 volts DC to the equalizer bus, Pin F, connector J1 of the regulator and the positive 0.25 volts DC to terminal D of the Generator Test Set. Voltmeter reading across the generator output should increase by at least 2.5 volts. Return switch to the center OFF position.

(s) Place all Load switches in their OFF positions, disconnecting all loads. Operate Paralleling Test Set switch to POSITIVE, applying the negative 0.25 volts DC to the equalizer bus, Pin F, connector J1 of the regulator and the positive 0.25 volts DC to terminal D of the Generator Test Set. Voltmeter reading across the generator output should increase by at least 2.5 volts. Return switch to center OFF position.

(t) Operate Current Balance Test Set switch to the ON position applying −1.5 volts DC to terminal D on Generator Test Set and +1.5 volts DC to terminal G on Generator Test Set. Voltmeter across the generator output should not indicate a change greater than ±0.15 volts. Return Current Balance Test Set switch to the OFF position.

(u) Close Load switches to apply a 100 per cent load to the system. Operate Overvoltage Test Set switch NORMAL—OVERVOLTAGE by placing switch in the OVERVOLTAGE posi-

tion and adjust field current by varying setting of variable resistor to cause generator output voltage to increase, when the generator voltage reaches 32.0 volts ±1 volt DC the circuit operates a magnetic latching relay opening the field circuit and dropping generator output to zero. Application of 28 volts DC through the RESET switch to the magnetic latching relay restores generator field circuit and generator output, provided field current is returned to normal by resetting of variable resistor.

(v) Place all Load switches in their OFF positions, disconnecting all loads. Operate Overvoltage Test Set switch NORMAL—OVERVOLTAGE by placing switch in the OVERVOLTAGE position and adjust field current by varying setting of variable resistor to cause generator output voltage to increase, when the generator voltages reaches 32.0 volts ±1 volt DC the circuit operates a magnetic latching relay opening the field circuit and dropping generator output to zero. Application of 28 volts DC through the RESET switch to the magnetic latching relay restores generator field circuit and generator output, provided field current is returned to normal by resetting of variable resistor.

(w) Open Master Battery switch and decrease Generator Test Set speed required preparatory to stopping generator. Stop Generator Test Set completely.

CAUTION: DO NOT ATTEMPT TO DISCONNECT VOLTAGE REGULATOR FROM THE GENERATOR TEST SET UNTIL GENERATOR IS STOPPED AND ALL VOLTAGES ARE OFF. FAILURE TO OBSERVE THIS CAUTION WILL RESULT IN POSSIBLE DAMAGE TO THE REGULATOR.

(x) In the event trouble was experienced, remove the voltage regulator and return to overhaul shop for repair.

5. INSPECTION/CHECK.

Visual inspection of external cabling for breaks, and for proper connection at mating connectors, are the only authorized inspection checks. For inspection/check procedures of associated generator refer to the generator manufacturer's handbook. No authority is given for visual or other checks internally or removal of the sealed cover at flight line maintenance levels.

6. CLEANING/PAINTING.

The DC Voltage Regulator requires no periodic cleaning operations under the sealed cover. If readily accessible, exterior dust or dirt may be brushed or wiped off the exterior surfaces.

7. APPROVED REPAIRS.

The only repairs approved for flight line maintenance are those associated with external cabling. No repairs are authorized or approved for flight line maintenance requiring removal of the sealed cover.

8. GENERATOR TEST SET.

The Generator Test Set referenced in preceding paragraph 4B is only one of many types available. Other accessories, such as metering and switching arrangements are fabricated by the user to operate with the test setup as suggested. Test setup may be modified at user's discretion provided tests are completed.

VR-1010-24-2A/P.N. 095027

INTRODUCTION

In conformance with A.T.A. Specification No. 100 for Manufacturers' Technical Data, two manuals have been prepared concerning the Model VR-1010-24-2A DC Voltage Regulator. These manuals, if used as intended, will facilitate the effective, continued operation of the equipment. Technical data is grouped according to usage in the manual as described.

OVERHAUL MANUAL WITH ILLUSTRATED PARTS CATALOG

The Overhaul Manual contains all the information required for shop testing, replacement of defective parts, alignment and adjustment, mechanical disassembly, inspection, and reassembly. Detailed circuit theory is given with emphasis on theory that will be especially helpful for effective trouble-shooting. Performance tests as well as functional (go/no-go) checks, which may be used to determine condition of equipment and for retesting after repairs.

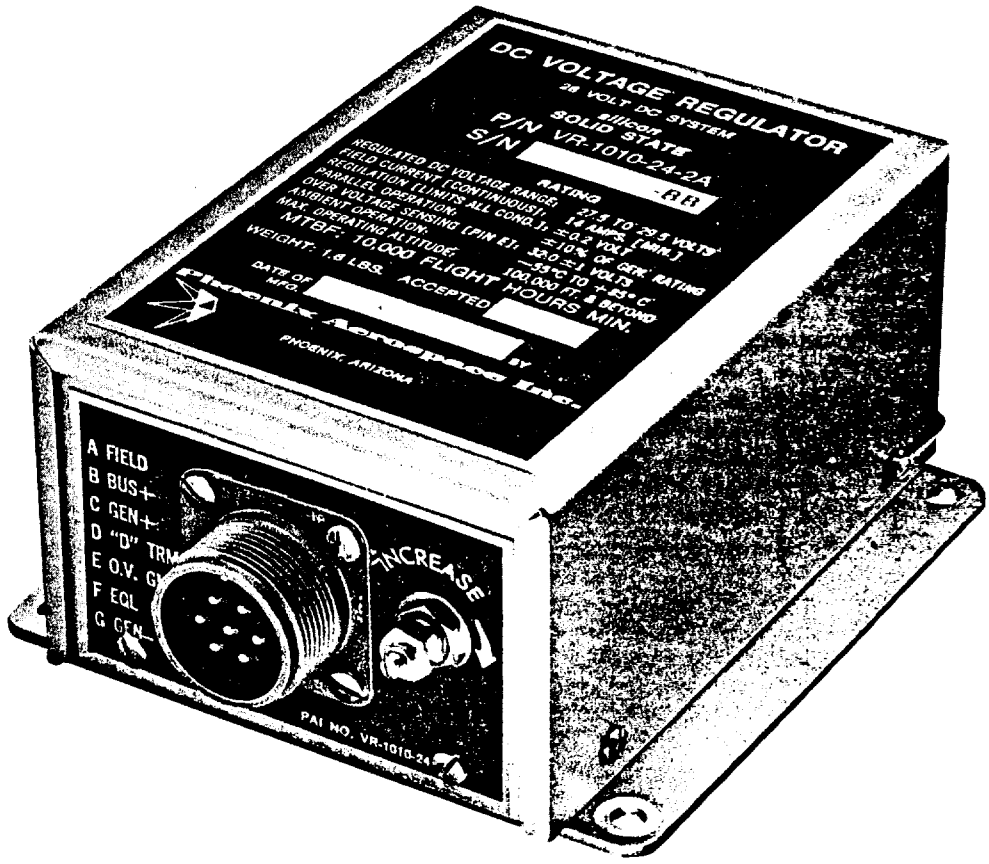
The Illustrated Parts Catalog provides a means to determine the manufacturer's part number and the physical location on the equipment of a part if the reference designation is known, or to determine the reference designation and the manufacturer's part number when the physical location of the part is known but no other information is available.

MAINTENANCE MANUAL

This manual is intended for use by flight line and hangar maintenance personnel. A detailed description and operation procedures, including a table of leading particulars are presented for reference. Mounting information and cabling information are presented as an aid to installation. Trouble-shooting information is limited to procedures required to trace a trouble to the overall unit for replacement.

VR-1010-24-2A/P.N. 095027

DESCRIPTION AND OPERATION



1. GENERAL.

A. Purpose of Manual.

This manual contains overhaul procedures and the illustrated parts catalog for the Model VR-1010-24-2A, DC Voltage Regulator (Solid-State), illustrated in Fig. 1.

B. Purpose of Equipment

The Model VR-1010-24-2A, DC Voltage Regulator is used to control all 28 volt direct current generators and starter generators conforming to FAA TSO-C56 and/or Military Specification MIL-G-6162. The regulator performs the function of maintaining constant output voltage under varying speed and load conditions in single generator or multiple generator systems.

Model VR-1010-24-2A, DC Voltage Regulator
Figure 1

2. DESCRIPTION.

A. The Model VR-1010-24-2A, DC Voltage Regulator is a compact self-contained unit utilizing state-of-the-art solid-state techniques. The regulated voltage is adjustable at a mechanically locked potentiometer adjacent to the input/output connector on the end of unit. Operating power for the regulator is obtained from the regulated generator. The regulator automatically adjusts field current to produce a constant voltage at the generator output under varying speeds and loads. The unit mounts directly on a bulkhead or other structural member, equipment rack, or equipment drawer. The unit is compactly packaged to facilitate placement in the aircraft and requires only a single, multi-pin, input/output connector between the unit and the aircraft wiring system.

B. The primary characteristics, capabilities, overall weight, and dimensions are listed in Table of Leading Particulars, Table 1.

GENERAL:

Duty: Continuous, unattended.

Temperature Rise: 15° C (maximum).

Cooling: Self-cooled by natural convection, conduction, and radiation.

Ambient Temperature Range: −85° to +85° C.

Maximum Operating Altitude: 100,000 feet and beyond.

Reliability: 10,000 hours MTBF (minimum).

ELECTRICAL:

Regulated DC Voltage Range: 27.5 to 29.5 VDC, no load to full load, over rated generator speed and temp/alt. operating range.

Field Current (Continuous): 14 Amperes (minimum).

Regulation: ±0.2 Volts, no load to full load, over rated generator speed and temp/alt. operating range.

Voltage Adjustment Limits: 26 VDC to 31 VDC, continuously variable.

Equalizer Circuit: ±2.5 Volts, minimum change, no load to full load, at minimum rated speed for regulation, when 0.25 volts is applied to equalizer bus terminals.

Parallel Operation: ±10 per cent equal division of load, two or more generators operated in parallel, no load to full load, over rated generator speed range.

Table of Leading Particulars
Table 1

Overvoltage Sensing: Overvoltage sensing circuit trips at 32.0 ±1.0 volts independent of the external field relay, placing a ground on pin E of connector J1 to operate an external relay.

Regulator Equivalent Resistance: High Value — More than 100 ohms.
Low Value — Less than 0.5 ohms.

Current Regulation: Regulation for balancing current between parallel generators in multiple generator systems.

Recovery Time: 0.05 Seconds, full load switched ON-OFF-ON, controlled voltage recovers to and remains within 10 per cent of steady state condition.

Overload Current: 14 Amperes (minimum) for one hour.

Induced Ripple: Less than 1.5 volts peak to peak.

Transient Protection: ±80 volts for 40 milliseconds,
±600 volts for 10 microseconds.

MECHANICAL:

Weight: 1.6 pounds (729.6 grams).

Overall Dimensions: 3-1/2 in. wide (8.89 cm) by
5 in. long (12.7 cm) by
2-3/8 in. high (6.03 cm).

Mounting Base Dimensions: 4-5/8 in. long (11.748 cm) by
4-1/2 in. wide (11.43 cm).

Mounting Centers: 4 in. long (10.16 cm) by 4 in. wide (10.16 cm).

Electrical Connectors: Input/Output: MS3102R-16S-1P mating MS3106F-16S-1S.

Cooling: Self-cooled by natural convection, conduction, and radiation.

Installation: Mounts in any position, without degradation of power output, heating, operating life, or other operating characteristics.

Adjustment: Voltage set potentiometer, INCREASE, adjusts voltage and paralleling in a single operation, located adjacent to input/output connector on regulator.

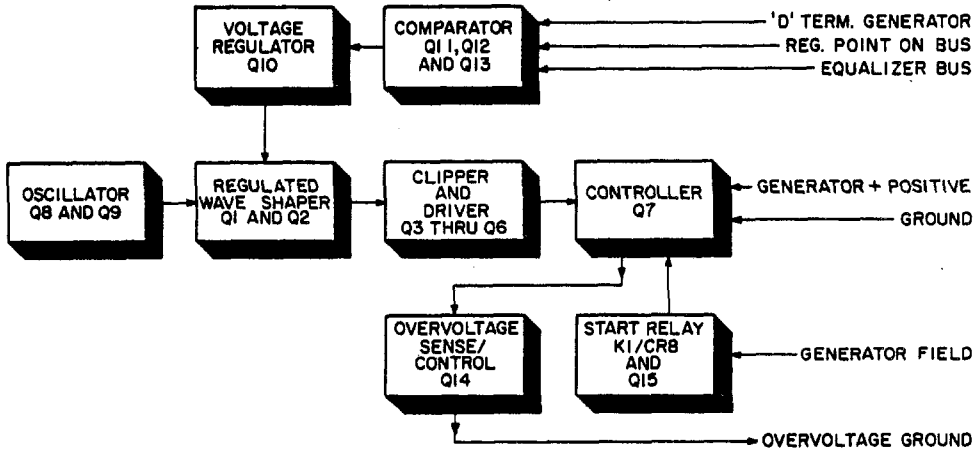


Table of Leading Particulars (Cont)
Table 1 (Cont)

3. OPERATION.

The subsequent paragraphs cover the theory of operation for the Model VR-1010-24-2A, DC Voltage Regulator. The Block Diagram Theory will aid in conveying the overall circuit operation to non-technical oriented personnel, while the Detailed Circuit Theory will enable the technician to understand in detail the operation of equipment.

A. Block Diagram Theory.

The subsequent paragraphs together with the block diagram of Fig. 2, cover in concise form the signal flow and circuit operation for the Model VR-1010-24-2A, DC Voltage Regulator.

Model VR-1010-24-2A, DC Voltage Regulator
Block Diagram
Figure 2

(1) Generator Start Relay. Relay K1 in the de-energized condition, contacts closed, completes the generator field circuit, until operating speed and voltage output are attained. Relay K1 energizes at a voltage of approximately 20 volts, when Zener diode ZR4 conducts and biases transistor Q15 to turn-on. Relay K1 contacts open by-passing the regulator controller circuits and permits the control circuits to function as controller. Operating power for the regulator circuit is obtained from the generator output.

(2) Stabilized Oscillator. Transistors Q8 and Q9 generate a sine wave signal at a frequency of approximately 400 Hertz. The sine wave signal is coupled through auxiliary windings of oscillator transformer T1 to the input of the regulated wave shaper circuits.

(3) Regulated Wave Shaper. Transistors Q1 and Q2 in a push-pull circuit receive the sine wave signal from the stabilized oscillator. Voltage applied from the voltage regulator circuit determines the shaping operation to control duty cycle and regulator operation. The shaped output is coupled to the input of the clipper circuit.

(4) Clipper and Driver. Transistors Q3, Q4, Q5, and Q6 in cascaded push-pull stages provide additional shaping and amplification of the 400 Hertz signal. The amplified signal is applied to the controller circuits.

(5) Controller. Transistor Q7 and diodes CR2 and CR3 comprise the controller circuitry. Transistor Q7 switches the generator field current at a rate of approximately 800 pulses per second, derived by rectification of the 400 Hertz signal by diodes CR2 and CR3. Variation in the width, duty cycle, determines the amount of field current. Clamp diode CR4 maintains continuous field current.

(6) Overvoltage Sense/Control. Transistor Q14 and Zener Diode ZR3 provide a sense and control circuit to operate an external relay to open the positive 28 volts DC supplied to the regulator or the generator Field line to provide overvoltage protection for the generator.

(7) Voltage Regulator. Transistor Q10 delivers the regulating bias to control pulse width of the regulated wave shaper circuit. Reference and control signals are derived from the voltage comparator circuit.

(8) Voltage Comparator. Transistors Q12 and Q13 are operating as a voltage comparator circuit with temperature stabilized reference voltages and an adjustable set point. Transistor Q11 is a current comparator circuit for paralleling operation.

B. Detailed Circuit Theory.

The following sub-paragraphs cover the individual circuits and their operation. Occasional reference to the overall schematic diagram of the equipment, Fig. 1201, will be necessary to determine circuit configuration.

(1) Generator Start Relay. The generator start relay K1 with normally closed contacts in the de-energized condition allows maximum field current to flow during start-up of generator. When the generator voltage reaches approximately 20 volts, Zener diode ZR4 conducts and biases transistor Q15 to 'turn-on' and permits relay K1 to energize, opening the field current by-passing contacts. The generator field current path is now passing through the controller circuit through transistor Q7. Operating power is supplied from the generator (+), to the control circuits. Diode CR8 across the coil of relay K1 functions as a suppressor diode. Resistors R39 and R40 determine the maximum base current flow of transistor Q15.

(2) Stabilized Oscillator. The stabilized oscillator utilizes transistors Q8 and Q9 in a Hartley oscillator circuit. Toroidal transformer T1 with multiple windings provides the tuned circuit, feedback, and output windings for the oscillator. The tuned circuit is tuned by capacitor C3 to approximately 400 Hertz. Capacitor C8 provides parasitic suppression in the oscillator tank circuit. The feedback winding provides sustained oscillation to the base-collector circuit. Resistors R21 and R22 provide the bias to the base circuits of the transistors to insure starting and sustained oscillation. Resistor R15 provides degeneration for improved stability of the oscillator circuit. Output to the regulated wave shaper circuit is through remaining winding on transformer T1.

(3) Regulated Wave Shaper. The regulated wave shaper receives the 400 Hertz sinusoidal signal from transformer T1. The input signal applied to the bases of transistors Q1 and Q2 is through resistors R1 and R2 to limit the amount of base current. Transistors Q1 and Q2 conduct alternately on positive half-cycles of the input signal. The point of conduction and duration, resultant increase or decrease in duty cycle is determined by the bias supplied to the emitter circuits from transistor Q10, voltage regulator. Diode CR1 serves as a clamp

diode to set bias level of transistors Q1 and Q2. The output across the collectors is a quasi-square wave signal and is applied to the input of the clipper circuit.

(4) Clipper and Driver. The clipper and driver circuit provide additional shaping of the signal and amplification for application to the controller circuit. The clipper circuit consists of transistors Q3 and Q4 in a push-pull circuit. The quasi-square wave signal is coupled to the base circuits of transistors Q3 and Q4 through limiting resistors R3 and R5, respectively. The output of the clipper circuit is a quasi-square wave with improved rise time. The output is coupled to the base circuits of the driver transistors Q5 and Q6 through resistors R7 and R8, respectively. Resistors R9 and R10 provide a low impedance return for leakage currents. Output in the collector circuit is developed across toroidal transformer T2 and coupled to the controller circuit. Zener diode ZR1 and resistor R14 provide voltage regulation to the clipper and driver circuits.

(5) Controller. The controller circuit comprised of transistor Q7 and diodes CR2 and CR3 control the generator field current to regulate the output voltage of the generator. The quasi-square wave output across transformer T2 is converted to a uni-directional positive voltage by rectification circuit comprised of diodes CR2 and CR3. The positive pulses with a nominal pulse rate of 800 per second are applied to the base of transistor Q7 to control turn on and turn off. Variation of the pulse width, varies in step with the voltage adjustment setting of variable resistor R35, effectively controlling duty cycle. The results of this variation in duty cycle determines the on-off time of transistor Q7 and subsequent variations in generator field current to achieve voltage regulation at the generator output. The regulator operating at a nominal rate of 800 pulses per second in the controller section is adequate to provide proper smoothing of the current to the generator field. The predominate AC component on the DC output of the generator is due primarily to commutator ripple and not from the contribution of the field excitation. RF filter L1 in the collector circuit of transistor Q7 and in series with pin C of connector J1, provides additional filtering of the 800 pulse per second controller output and harmonics of the fundamental frequency. Since the generator field is highly inductive, continuous field current is achieved by the action of clamp diode CR4. The voltage waveform at pin A of connector J1, emitter of transistor Q7, is a positive pulse with an excursion from ground to a positive value approximating generator voltage, typically 27.5 to 29.5 volts. The current flowing in the generator field is constant due to the action of clamp diode CR4. Capacitor C2 and resistor R13 provide a series path for high speed transients which might appear across the collector to emitter circuit of transistor Q7.

(6) Overvoltage Sensing and Control. Transistor Q14 and Zener diode ZR3 provide a sensing and control circuit for overvoltage protection of the generator. If the generator voltage at pin C of connector J1 should rise to 32 volts DC ± 1 volt, Zener diode ZR3 will conduct and bias transistor Q14 to turn on. Transistor Q14 conducts and provides a ground return through pin E of connector J1 and series current limiting resistor R44. The coil of a latching relay, type MS25457-1, Leach No. 9237-4845, or equivalent, connected between pin E of connector J1 and the positive 28 volt DC source, with a coil rating of 1 Ampere or less, will operate instantly to interrupt the positive 28 volts DC to the voltage regulator or the current through the generator field lead, pins C and A, respectively, on connector J1. Reset of the latching relay is accomplished by application of 28 volts DC to the reset winding on the relay coil.

(7) Voltage Regulator. The voltage regulator consists of transistor Q10, and associated biasing and time constant circuitry. Resistors R18 and R19 comprise a voltage divider and bias network for the emitter while resistor R17 and capacitor C4 establish the time constant of regulation. Control is applied to the base circuit from the voltage comparator. Output at the collector is applied to the emitter and base circuit of transistors Q1 and Q2, across clamp diode CR1.

(8) Voltage Comparator. The voltage comparator circuit comprised of transistors Q12 and Q13 samples the voltage on the generator bus, pin B of connector J1. The circuit operates as a differential comparator. The base of transistor Q13 receives the voltage from regulation point on generator bus, as adjusted by setting of voltage adjustment, variable resistor R35, while the base of transistor Q12 is referenced to the temperature compensated Zener voltage at the collector of transistor Q11. Any change in voltage at the regulation point on bus of the generator develops a voltage across resistor R23 in the base of transistor Q10 to apply a change in bias to the voltage regulator. Parallel generator operation is achieved by sampling the voltage between the equalizer bus, pin F of connector J1, and the equalizer sense point, terminal D on generator, pin D of connector J1. The change in voltage appears across resistor R27 and causes a change in the voltage drop across resistor R28 in the collector circuit, and adds in series with the reference voltage derived from temperature compensating diode CR5, CR6, and CR7 in series with Zener diode ZR2. Diode CR9 and resistor R26 establish a reference voltage at the base of transistor Q11. Unequal generator currents cause a change in generator voltage output in a direction to equalize generator currents.

VR-1010-24-2A/P.N. 095027

DISASSEMBLY

1. GENERAL.

This section outlines procedures for disassembly of the DC Voltage Regulator. These procedures should be followed in the event it becomes necessary to repair the unit after a malfunction or part failure. Electrical wiring should not be disconnected except when required for complete removal of a sub-assembly or when wiring is damaged or defective. When wiring is disconnected, tag each wire and note connection point for ease in identification during reassembly.

2. COVER REMOVAL.

A. Break Phoenix Aerospace, Inc. seal, (-19) Fig. 1101, by cutting wire, and remove.

NOTE: In the event DC Voltage Regulator is in warranty, breaking of seal may void warranty, unless covered by other contractual agreement.

B. Remove the four screws securing cover, (-17) and (-18) Fig. 1101, and remove cover, (16) Fig. 1101, by lifting straight up from base of regulator. Place hardware and cover aside for reassembly.

3. REMOVAL OF OSCILLATOR/AMPLIFIER BOARD AND SWITCHING CIRCUITS CHASSIS SUB-ASSEMBLY.

A. General.

Removal of oscillator/amplifier board and switching circuits chassis subassembly, (12) Fig. 1101, is accomplished to gain access to components on the circuit board, switching chassis, top and bottom sides. Unless an entire board or switching chassis replacement is necessary, interconnecting wires should never be disconnected. Proceed as follows to gain access to the components in the sub-assemblies.

B. Removal Procedures.

(1) Remove the four 4-40 x 1-3/4 inch long, (-14) Fig. 1101, round head machine screws and four .1875 inch O.D. round aluminum spacers, (-15) Fig. 1101, securing oscillator/amplifier circuit board sub-assembly, (40) Fig. 1102. Place hardware aside for reassembly.

(2) Carefully lift oscillator/amplifier circuit board sub-assembly, (40) Fig. 1101, and fold back to expose component side of circuit board and top side of switching circuits chassis pan, (1) Fig. 1102.

(3) Remove the four 4-40 x 7/16 inch long, (-13) Fig. 1101, pan head machine screws securing the switching circuits chassis pan, (1) Fig. 1102, to the regulator base, (2) Fig. 1101. Place hardware aside for reassembly.

(4) Remove switching circuits chassis pan sub-assembly, (1) Fig. 1102, by lifting out of voltage regulator base by grasping sub-assembly at rear edge and lifting out and up to clear connector and voltage adjust potentiometer. Fold back carefully to expose components on underside of sub-assembly.

(5) Carefully swing sub-assemblies into position necessary to gain access to components to be tested or replaced. DO NOT disconnect wiring unless removal of entire sub-assembly is required.

CLEANING

1. GENERAL.

This section outlines procedures for cleaning the components of the DC Voltage Regulator while disassembled. Cleaning materials are listed in Table 201.

WARNING: PERFORM OPERATION INVOLVING SOLVENT ONLY IN A WELL VENTILATED AREA. AVOID BREATHING OF SOLVENT VAPOR AND CONTINUOUS CONTACT WITH SOLVENT.

Reference to air jet refers to a hand-operated air nozzle supplied with clean, dry, compressed air at a maximum pressure of 28 psi.

WARNING: GOGGLES SHOULD BE WORN WHEN USING AIR JET TO BLOW DUST AND DIRT FROM EQUIPMENT. OTHER PERSONS SHOULD BE WARNED AWAY FROM HAZARDOUS AREA OR WORKING ENCLOSURE.

MATERIAL
Trichloroethylene Solvent
Soft-bristled Brush
Stiff-bristled Brush
Soft, Clean Cloth

List of Cleaning Materials
Table 201

2. PRINTED CIRCUIT BOARDS-WIRED CHASSIS.

Remove dust and dirt from all surfaces with a soft-bristled brush in conjunction with an air jet.

NOTE: When the dress of wiring is disturbed, dressing should be noted, and when cleaning is finished, wiring should be restored to proper dress or position.

3. METAL SURFACES.

Clean with soft cloth moistened in trichloroethylene solvent, and dry with clean, dry cloth.

4. CONNECTORS.

A. Wipe dust and dirt from contacts using trichloroethylene solvent and a soft cloth. Wipe dry with clean, dry cloth.

B. Remove dust from connectors using small, soft-bristled brush in conjunction with air jet.

INSPECTION/CHECK

1. GENERAL.

   This section contains procedures to determine the condition of the DC Voltage Regulator.

2. COVER.

   Inspect cover for deformations, dents, punctures or surfaces which might be wearing due to interference with other components.

3. CONNECTORS.

   A. Inspect for broken parts or other abnormal condition.

   B. Inspect for contacts which are broken, deformed or out of alignment. Check for corrosion and signs of arcing at the contacts and for poorly soldered connections.

4. RESISTORS.

   Inspect resistors for signs of overheating; cracked, broken, or charred insulation; loose, poorly soldered, or corroded terminal connections; and loose mountings.

5. METAL SURFACES AND MECHANICAL.

   Inspect metal surfaces for signs of corrosion. Also check component mountings for mechanical tightness.

6. WIRES.

   Check wires for damaged insulation and for proper dress.

REPAIR

1. GENERAL.

This section outlines instructions for the repair or replacement of damaged or defective parts. Faulty parts are usually detected by inspection, cleaning or trouble shooting. The repair or replacement of damaged or defective parts involves standard repair techniques. Identify each wire before removal of any part requiring unsoldering of several lead wires.

2. COVER AND METAL PARTS.

Straighten any deformation, and retouch scratched or worn surfaces as required.

3. PRINTED CIRCUIT BOARD AND TERMINAL STRIPS.

Remove all traces of corrosion and recoat with clear epoxy resin where broken or removed during repairs.

Before attempting to solder connections, peel away epoxy resin using a sharp knife.

NOTE: The clear epoxy resin is Armstrong Products Inc. Type T-600 or equivalent. Any time the epoxy coating is disturbed, recoating is advised.

4. CONNECTORS.

Check and resolder connections and check insulation. If badly damaged, replace connector or contact pin.

5. SOLDER CONNECTIONS.

Resolder any defective solder joints. Remove all traces of corrosion.

6. WIRING.

Replace any wiring with damaged insulation or broken strands.

7. RESISTORS.

Replace resistors that show signs of overheating or with cracked or broken bodies. Resolder loose, broken or corroded connections.

VR-1010-24-2A/P.N. 095027

ASSEMBLY

1. GENERAL.

This section outlines the instructions for assembly of the DC Voltage Regulator. Before assembly of the unit, the Cleaning, Inspection/Check, and Repair Sections should be consulted to determine if all components are properly cleaned and in proper physical and operating condition. Where wiring must be reconnected, good practices must be followed in dressing of wires and soldering connections. Refer to Figures 1101 through 1103 for identification and location of sub-assemblies and component parts.

2. ASSEMBLY OF OSCILLATOR/AMPLIFIER BOARD AND SWITCHING CIRCUITS CHASSIS SUB-ASSEMBLY.

A. General.

Assembly of the oscillator/amplifier board and switching circuits chassis sub-assembly requires reference to Figures 1101 through 1103 for component identification and reference to the schematic diagram, Figure 1201, in the event complete disassembly was necessary and it is necessary to reconnect interwiring. Proceed as follows, eliminating steps where necessary.

B. Assembly Procedures.

(1) Identify disconnected leads and reconnect to points indicated. Reference to the overall schematic diagram, Figure 1201, should be made for all connections as well as references to Figures 1101 through 1103 for component identification.

(2) Dress wires and replace switching circuits chassis pan, (1) Fig. 1101, by inserting front edge under connector and voltage adjustment potentiometer, and pushing gently down and forward to seat chassis pan in base of regulator, (2) Fig. 1101. Secure with four 4-40 x 7/16 inch long pan head machine screws (-13) Fig. 1101.

(3) Dress wires and replace oscillator/amplifier circuit board sub-assembly, (40) Fig. 1101, using four 4-40 x 1-3/4 inch long round head machine screws. (-14) Fig. 1101, and four .1875 inch O.D. round aluminum spacers, (-15) Fig. 1101, tighten securely.

3. INSTALLATION OF COVER.

A. Reposition cover (16) Fig. 1101, over regulator base (2) Fig. 1101, and slide cover into position.

B. Secure cover with two 4-40 x 3/8 inch long pan head machine screws, (-17) Fig. 1101, at the end nearest the connector and voltage adjustment potentiometer.

C. Secure cover with two 4-40 x 3/8 inch long (drilled) fillister head machine screws, (-18) Fig. 1101, at rear of unit, end opposite connector.

D. Place tie wire through drilled holes of fillister head screws and reseal with aluminum or lead seal, (-19) Fig. 1101, if available.

VR-1010-24-2A/P.N. 095027

FITS AND CLEARANCES

Not Applicable to Solid State DC Voltage Regulator.
No moving parts required.

TESTING

1. GENERAL.

This section defines test procedures for the Model VR-1010-24-2A DC Voltage Regulator. The procedures given are in sequential step form and test the unit completely. When the results of any step or test are not achieved the Trouble Shooting of this manual should be consulted.

2. PERFORMANCE TESTS.

Performance tests are designed to provide a fast efficient method for complete check-out of the voltage regulator. Subsequent paragraphs contain a list of test equipment required. Minimum performance requirements, and interconnect diagrams to facilitate testing.

A. Test Equipment Required.

The test equipment required to accomplish the performance tests consists of the following: generator test set, oscilloscope, volt-meter, and interconnect cabling. This equipment is listed and described in the Special Tools, Fixtures, and Equipment Section of this manual.

B. Minimum Performance Requirements.

The minimum performance requirements of the Model VR-1010-24-2A DC Voltage Regulator are as follows:

(1) The regulator provides regulation of generator field current such that the output voltage of generator is maintained constant. Regulation level is maintained at ±0.2 volts DC at any preset value in the 27.5 to 29.5 volts DC range. Regulation at this preset value is maintained at no load to full load operation and under varying generator speeds, at or above the minimum rated generator speed and temperature-altitude operating range.

(2) The regulator provides an overvoltage sense and control, overvoltage trip, which operates at 32 volts DC, ±1.0 volt DC. The circuit operates an external relay, magnetic, latching type, (MS25457-1, Leach Type 9237-48455, or equivalent), which opens the generator field circuit until reset by application of 28 volts DC from the battery bus through a reset startup. Time to trip for a typical aircraft system is shown in Fig. 701. The information given is time versus voltage, and approximates the rise in generator voltage after a malfunction causing loss or regulation. The overvoltage circuit operates instantly however when specified overvoltage is sensed, and opens the generator field within .002 seconds by relay action.

C. Preparation for Testing.

(1) Chassis Isolation Test. Perform the following steps using an Associated Research Model 2956, Insulation Resistance Tester to determine unit meets applicable specifications for chassis isolation.

WARNING: The recommended Insulation Tester produces potentially dangerous voltages. Care in operation must be exercised to prevent possible electrical shock.

(a) Place POWER ON/OFF Switch on Insulation Tester in the OFF Position and connect line cord, three wire grounding type, to source of 115 volts AC, 60 Hz. Identify VOLTAGE ADJUST control and rotate to the extreme counter-clockwise position. Connect the black lead with a spade lug to the GROUND terminal and connect clip to chassis at the spot faced mounting hole on the Voltage Regulator mounting flange. Identify MEGOHM MULTIPLIER control and position to the 100 position. Identify the HIGH VOLTAGE connection and connect test lead for use in subsequent paragraphs.

CAUTION: The Insulation Tester must be connected and operated in accordance with the following procedures to insure accurate testing and adequate protection to the equipment under test. Under no circumstances should the probes be connected to any point other than that specifically directed in the procedures given. In all cases the GROUND lead clip must be connected to the chassis of the unit being tested, (spot faced mounting hole or shell of connector J1).

(b) Identify HIGH VOLTAGE clip lead and connect to pin A of connector J1, GENERATOR FIELD, GROUND switch is in the METERED RETURN position. Identify HIGH VOLTAGE CIRCUIT—ENERGIZE switch and operate to the ON position, red HIGH VOLTAGE lamp will light. Identify VOLTAGE ADJUST control and rotate clockwise until KILOVOLTS meter indicates .5 KILOVOLT (500 volts). Note reading of the MEGOHMMETER and multiply by the KILOVOLTS meter reading multiplied by the multiplying factor of 1, multiplied by the MEGOHMS MULTIPLIER to obtain reading in Megohms. Return VOLTAGE ADJUST control to the extreme counter-clockwise position and place the HIGH VOLTAGE CIRCUIT—ENERGIZE switch in the OFF position. Disconnect the HIGH VOLTAGE test lead from the unit after metering indicates voltage has dropped to zero. Isolation of pin A of connector J1 to chassis ground must measure 10,000 megohms, minimum.

(c) Repeat procedures of paragraph (b) connecting HIGH VOLTAGE clip lead to pin B of connector, J1. Isolation of pin B of connector J1, VOLTAGE SENSE (Regulation Point on Bus), to chassis ground must measure 10,000 megohms, minimum.

(d) Repeat procedures of paragraph (b) connecting HIGH VOLTAGE clip lead to pin C of connector, J1. Isolation of pin C of connector J1, GENERATOR POSITIVE, to chassis ground must measure 10,000 megohms, minimum.

(e) Repeat procedures of paragraph (b) connecting HIGH VOLTAGE clip lead to pin D of connector, J1. Isolation of pin D of connector J1, EQUALIZER SENSE ("D" Terminal of Generator), to chassis ground must measure 10,000 megohms, minimum.

(f) Repeat procedures of paragraph (b) connecting HIGH VOLTAGE clip lead to pin E of connector, J1. Isolation of pin E of connector J1, OVERVOLTAGE GROUND, to chassis ground must measure 10,000 megohms, minimum.

(g) Repeat procedures of paragraph (b) connecting HIGH VOLTAGE clip lead to pin F of connector, J1. Isolation of pin F of connector J1, EQUALIZER BUS, to chassis ground must measure 10,000 megohms, minimum.

(h) Repeat procedures of paragraph (b) connecting HIGH VOLTAGE clip lead to pin G of connector, J1. Isolation of pin G of connector J1, GENERATOR NEGATIVE, to chassis ground must measure 10,000 megohms, minimum.

(i) Place POWER Switch on the Insulation Tester in the OFF Position and disconnect Insulation Tester before proceeding with subsequent performance testing.

(2) Complete the following steps to prepare the voltage regulator for testing. Refer to Fig. 702 for equipment interconnection and referenced test points.

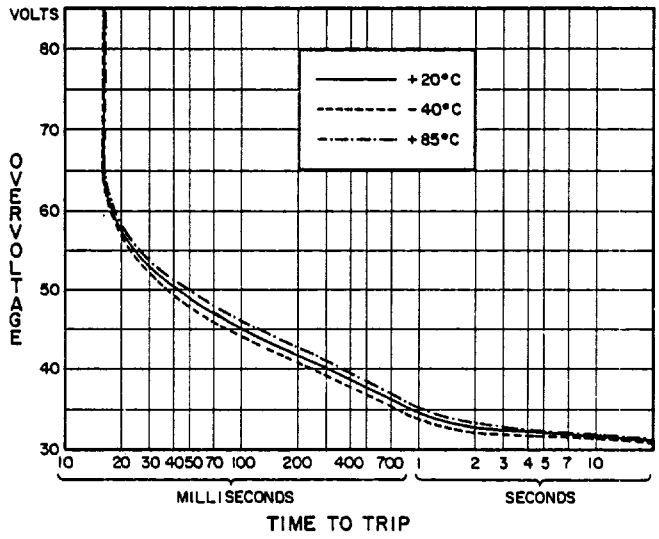
CAUTION: DO NOT ATTEMPT TO CONNECT REGULATOR UNLESS GENERATOR TEST SET IS STOPPED OR THE FIELD IS OPEN. FAILURE TO OBSERVE THIS CAUTION WILL RESULT IN PITTED OR BURNED CONNECTOR PINS.

(a) Connect the DC Voltage Regulator to the generator test set through pendant cable and plug P1 to connector J1 on regulator.

(b) Connect the voltmeter across the positive and negative, terminals B and E on the generator, respectively. Set voltmeter to the range required to measure 0 to 30 volts DC.

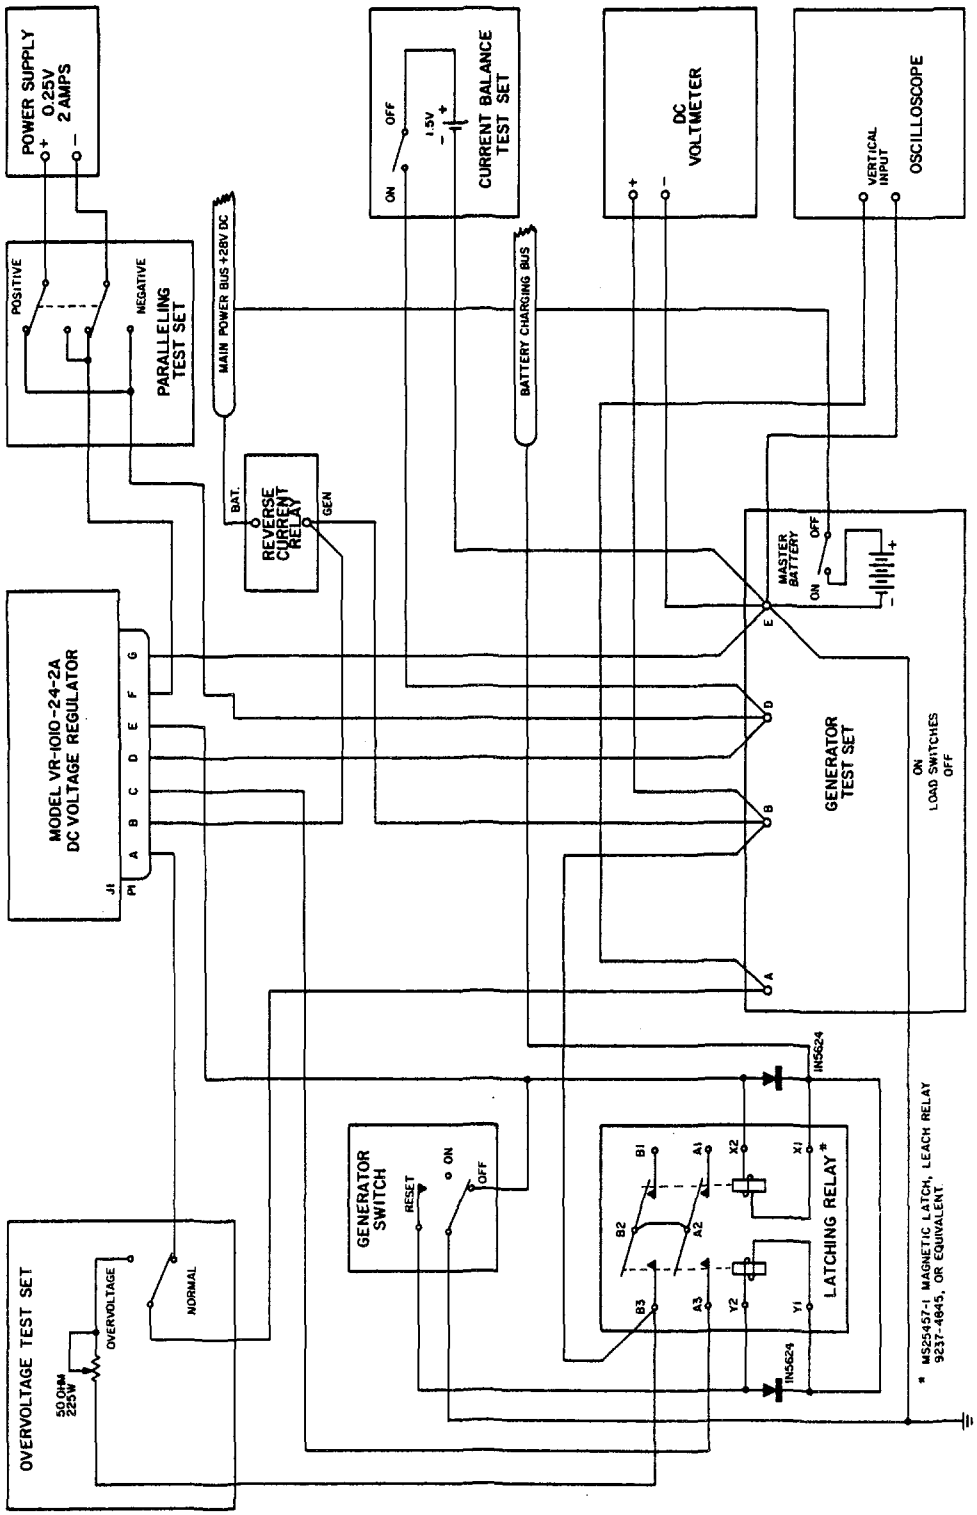
(c) Connect the Paralleling Test Set, comprised of a polarity reversing switch and appropriate interconnect wiring to an auxiliary power supply to terminal D on the generator and the equalizer bus or pin F of connector P1/J1. Set the three position, POSITIVE-OFF-NEGATIVE, switch to the OFF position.

(d) Connect a DC power supply capable of supplying 0.25 volts DC at 2.0 amperes to the input terminals of the Paralleling Test Set. Set output level of supply to 0.25 volts using meter on supply or an accurate voltmeter.



(e) Connect the Current Balance Test Set, comprised of a −1.5 volt DC source and a single pole single throw (ON-OFF) switch, to terminals D and E on the generator. Set the switch on the Current Balance Test Set the OFF position. Check voltage source for accuracy with a suitable meter.

(f) Connect the Overvoltage Test Set, comprised of a variable resistor, and a single pole double throw (NORMAL-OVERVOLTAGE) switch, to terminal B3 of the magnetic latching relay and the overvoltage terminal of the single pole double throw switch, and the remaining two terminals on the Test Set, in series with terminal A of the generator and Pin A of connector P1/J1 on the regulator. Place switch in the NORMAL position.



(g) Connect the oscilloscope to terminals A and E on the generator.

D. Performance Test.

The procedures of the performance test listed in numbered steps of Table 701 should be accomplished in the sequence presented. In the event the required result is not obtained, the trouble shooting section should be consulted and the malfunction corrected before proceeding to the next step.

Overvoltage Protector Trip
Charactistic in a Typical
Aircraft System
Figure 701

Test Set-up, Model VR-1010-24-2A
DC Voltage Regulator
Figure 702

STEP	SET-UP	PROCEDURE	RESULT
1	Interconnect per Fig. 702 and para. 2.C., Generator Test Set 'stopped' OFF.	(a) Apply power to all measuring equipment and auxiliary power supplies. (b) Check and set accuracy of the .025 volt and −1.5 volt DC sources.	
2	Generator Test Set load switches, and Master Battery switch in OFF positions. Paralleling Test Set, and Current Balance Test switches in their OFF position. Overvoltage Test Set switch in the NORMAL position.	Start Generator Test Set and run speed up to MID-RANGE (approx. 6,000 RPM).	Voltmeter across output indicates regulated voltage at point of regulation on the DC bus. Standard factory setting is 28.5 volts DC after final test.
3	Generator Test Set operating at MID-RANGE (6,000 RPM), Master Battery switch, Paralleling Test Set, and Current Balance Test Set switches in their OFF position. Overvoltage Test Set switch in the NORMAL position.	(a) Operate Generator Test Set LOAD switches to apply a 100 per cent load. (b) Identify the Voltage Set potentiometer, INCREASE, adjacent to connector J1 on the regulator. (c) Using a 5/16 inch hollow shaft nut driver, loosen adjustment locking nut. (d) Using a small screwdriver, approximately 1/8 inch blade, rotate slotted control shaft and set voltage to 28.0 volts DC prior to performing subsequent tests.	Voltmeter indicates regulated voltage point, and adjustment limits. Point of regulation as set becomes reference for subsequent tests. Voltmeter indicates 28.0 volts DC and becomes reference for subsequent tests.
4	Generator Test Set operating at MID-RANGE (approx. 6,000 RPM), Master Battery switch, Paralleling Test Set and Current Balance Test Set switches in their off position. Overvoltage Test Set switch in the NORMAL position.	Operate Generator Test Set Load switches to apply a 50 per cent load.	Voltmeter reading should not vary by an amount greater than plus or minus 0.2 volt from regulation point. Ammeter on Generator Test Set indicates a current equal to 50 per cent of generator full load current rating (typically 200 amperes).

STEP	SET-UP	PROCEDURE	RESULT
5	Generator Test Set operating at MID-RANGE (approx. 6,000 RPM). Master Battery switch, Paralleling Test Set and Current Balance Test Set switches in their off position. Overvoltage Test Set switch in the NORMAL position.	Operate Generator Test Set Load switches to apply a 100 per cent load.	Voltmeter readings should not vary by an amount greater than plus or minus 0.2 volt from regulation point. Ammeter on Generator Test Set indicates a current equal to 100 per cent of generator full load current rating (typically 400 amperes).
6	Generator Test Set operating at MID-RANGE (approx. 6,000 RPM), Paralleling Test Set and Current Balance Test Set switches in their OFF position. Overvoltage Test Set switch in the NORMAL position. Load switches in 100 per cent Load position.	Close Master Battery switch placing battery across generator output.	Voltmeter should not indicate in an oscillating manner, reading should remain stable.
7	RANGE (approx. 6,000 RPM), Paralleling Test Set and Current Balance Test Set switches in their OFF Position. Overvoltage Test Set switch in the NORMAL position. Load switches in 100 per cent load position and Master Battery switch ON.	(a) Place Master Battery switch to the OFF position removing battery from circuit. (b) Operate Generator Test Set Load switches to disconnect all load. (c) Increase Generator Test Set speed to HIGH RANGE (approx. 8,000 RPM).	Voltmeter reading should not vary by an amount greater than plus or minus 0.2 volt from regulation point.
8	Generator Test Set operating at HIGH RANGE (approx. 8,000 RPM). Master Battery, Paralleling Test Set, and Current Balance Test Set switches in their OFF position. Overvoltage Test Set switch in the NORMAL position.	Operate Generator Test Set Load switches to apply a 50 per cent load.	Voltmeter reading should not vary by an amount greater than plus or minus 0.2 volt from regulation point.
9	Generator Test Set operating at HIGH RANGE (approx. 8,000 RPM), Master Battery, Paralleling Test Set and Current Balance Test Set switches in their OFF position. Overvoltage Test Set in the NORMAL position.	Operate Generator Test Set Load switches to apply a 100 per cent load.	Ammeter on Generator Test Set indicates a current equal to 50 per cent of generator full load current rating (typically 200 amperes). Voltmeter reading should not vary by an amount greater than plus or minus 0.2 volt from regulation point. Ammeter on Generator Test Set indicates a current equal to 100 per cent of generator full load current rating (typically 400 amperes).

STEP	SET-UP	PROCEDURE	RESULT
10	Generator Test Set operating at HIGH RANGE (approx. 8,000 RPM), Master Battery, Paralleling Test Set and Current Balance Test Set switches in their OFF position, Overvoltage Test Set in the NORMAL position.	(a) Operate Generator Test Set Load switches to disconnect all load. (b) Decrease Generator Test Set speed to LOW RANGE (approx. 4,500 RPM) by braking.	Voltmeter reading should not vary by an amount greater than plus or minus 0.2 volt from regulation point.
11	Generator Test Set operating at LOW RANGE (approx. 4,500 RPM) Master Battery, Paralleling Test Set and Current Balance Test Set switches in their OFF position. Overvoltage Test Set in the NORMAL position.	Operate Generator Test Set Load switches to apply a 50 per cent load.	Voltmeter reading should not vary by an amount greater than plus or minus 0.2 volt from regulation point. Ammeter on Generator Test Set indicates a current equal to 50 per cent of generator full load current rating (typical 200 amperes).
12	Generator Test Set operating at LOW RANGE (approx. 4,500 RPM) Master Battery, Paralleling Test Set and Current Balance Test Set switches in their OFF position. Overvoltage Test Set in the NORMAL position.	Operate Generator Test Set Load switches to apply a 100 per cent load.	Voltmeter reading should not vary by an amount greater than plus or minus 0.2 volt from regulation point. Ammeter on Generator Test Set indicates a current equal to 100 per cent of generator full load current rating (typical 400 amperes).
13	Generator Test Set operating at LOW RANGE (approx. 4,500 RPM) Master Battery, Paralleling Test Set, and Current Balance Test Set switches in their OFF position. Overvoltge Test Set in the NORMAL position.	Operate Generator Test Set Load switches to disconnect load.	Voltmeter reading should not vary by an amount greater than plus or minus 0.2 volt from regulation point.
14	Generator Test Set load switches, and Master Battery switch in OFF positions, Paralleling Test Set, and Current Balance Test switches in their OFF position. Overvoltage Test Set switch in the NORMAL position.	Start Generator Test Set and run speed up to MID-RANGE (approx. 6,000 RPM).	Voltmeter across output indicates regulated voltage at point of regulation on the DC bus.

STEP	SET-UP	PROCEDURE	RESULT
15	Generator Test Set operating at MID-RANGE (6,000 RPM), Master Battery switch, Paralleling Test Set, and Current Balance Test Set switches in their OFF position. Overvoltage Test Set switch in the NORMAL position.	(a) Operate Generator Test Set LOAD switches to apply a 100 per cent load. (b) Identify the Voltage Adjustment control adjacent to connector J1 on the regulator. (c) Using a 5/16 inch hollow shaft nut driver, loosen adjustment locking nut. (d) Using a small screwdriver, approximately 1/8 inch blade, rotate slotted control shaft and set voltage to 28.5 volts DC.	Voltmeter indicates 28.5 volts DC and returns unit to factory setting of 28.5 volts DC.
16	Generator Test Set operating at LOW RANGE (approx. 4,500 RPM) Master Battery, Paralleling Test Set, and Current Balance Test Set, switches in their OFF position. Overvoltage Test Set in the NORMAL position.	(a) Operate Paralleling Test Set switch to NEGATIVE position applying the positive 0.25 volts DC to the equalizer bus, pin F, connector J1 of the regulator and the negative 0.25 volts DC to terminal D of the Generator Test Set. (b) Return Paralleling Test Set switch to center OFF position.	Voltmeter reading should decrease by at least 2.5 volts.
17	Generator Test Set operating at MID-RANGE (approx. 4,500 RPM), Master Battery switch, Paralleling Test Set, and Current Balance Test Set, switches in their OFF position. Overvoltage Test Set switch in the NORMAL position.	(a) Operate Generator Test Set Load switches to apply 100 per cent load. (b) Operate Paralleling Test Set switches to NEGATIVE applying the positive 0.25 volts DC to equalizer bus, pin F, connector J1 of the regulator and the negative 0.25 volts DC to terminal D of the Generator Test Set. (c) Return Paralleling Test Set switch to center OFF position. (d) Operate Generator Test Set Load switches to disconnect load.	Voltmeter reading should decrease by at least 2.5 volts.

STEP	SET-UP	PROCEDURE	RESULT
18	Generator Test Set operating at LOW RANGE (approx. 4,500 RPM), Master Battery switch, Paralleling Test Set, and Current Balance Test Set switches in their OFF position. Overvoltage Test Set switch in the NORMAL position. Generator Test Set Load switches set to NO LOAD positions.	(a) Operate Paralleling Test Set switch to POSITIVE applying the negative 0.25 volts DC to equalizer bus, pin F, connector J1 of the regulator and the positive 0.25 volts DC to terminal D of the Generator Test Set. (b) Return Paralleling Test Set switch to center OFF position.	Voltmeter reading should increase by at least 2.5 volts.
19	Generator Test Set operating at LOW RANGE (approx. 4,500 RPM), Master Battery switch, Paralleling Test Set, and Current Balance Test Set, switches in their OFF position. Overvoltage Test Set switch in the NORMAL position.	(a) Operate Generator Test Set Load switches to apply 100 per cent load. (b) Operate Paralleling Test Set switches to POSITIVE applying the negative 0.25 volts DC to equalizer bus, Pin F, connector J1 of the regulator and the positive 0.25 volts DC to terminal D of the Generator Test Set. (c) Return Paralleling Test Set switch to center OFF position.	Voltmeter reading should increase by at least 2.5 volts.
20	Generator Test Set operating at LOW RANGE (approx. 4,500 RPM) Master Battery switch, Paralleling Test Set, and Current Balance Test Set, switches in their OFF position. Overvoltage Test Set switch in the NORMAL position. Generator Test Set Load switches set to 100 per cent load.	(a) Operate Current Balance Test Set switch to ON position applying the negative 1.5 volts to terminal D of the Generator Test Set and the positive 1.5 volts to terminal E of the Generator Test Set. (b) Return Current Balance Test Set switch to the OFF position. (c) Operate Generator Test Set Load switches to disconnect Load.	Voltmeter should not indicate a change greater than ±0.15 volts.

STEP	SET-UP	PROCEDURE	RESULT
21	Generator Test Set operating at LOW RANGE (approx. 4,500 RPM) Master Battery switch, Paralleling Test Set, and Current Balance Test Set switches in their OFF position. Overvoltage Test Set switch in the NORMAL position.	(a) Operate Overvoltage Test Set placing NORMAL—OVER-VOLTAGE switch to the OVER-VOLTAGE position and rotate ADJUSTMENT potentiometer on Test Set to increase field current to the field of the Generator Test Set. (b) Reduce Generator Test Set speed by braking preparatory to stopping generator. (c) Stop generator Test Set and disconnect the DC Voltage Regulator.	Voltmeter reading will increase in direct relation with change in field current. Generator Test Set output will drop to zero when the voltage rises to 32 volts DC ±1 volt DC.

VR-1010-24-2A/P.N. 095027

TROUBLE SHOOTING

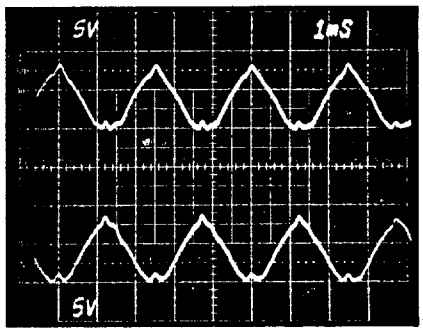
1. GENERAL.

This section outlines in tabular form information for use in localization and isolation of trouble in the Model VR-1010-24-1A DC Voltage Regulator. The trouble shooting procedures, Table 801, together with the information given in preceding section on Testing will in most cases localize and isolate the trouble. Reference to the schematic diagram, Fig. 1201, and the section on Detailed Theory will be necessary and helpful. The voltage measurements of Table 802 in conjunction with the waveforms illustrated in Fig. 801 will aid in isolation of trouble.

2. TROUBLE SHOOTING.

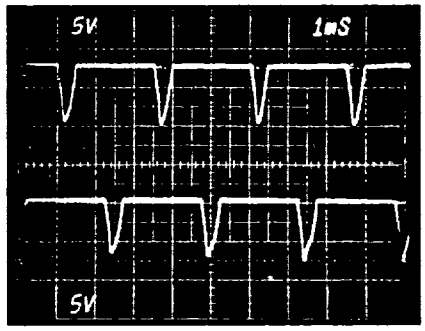
A. Localization.

The trouble shooting table, Table 801, provides a means of localizing malfunctions to a replaceable component or sub-assembly. The table is arranged in the same order of precedence as the performance tests, Table 701, in the preceding section. The applicable step of the performance test is shown in parentheses next to the trouble shooting step in the STEP column, in Table 801.



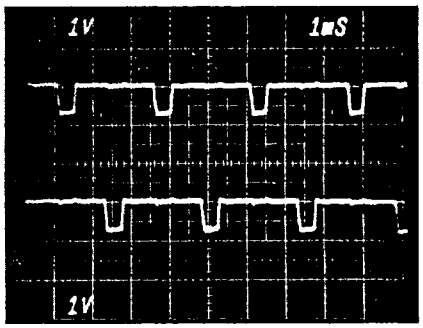
B. Isolation.

The voltage measurements of Table 802 are made using the voltohmmeter described in the Special Tools section of this manual. Reference to the schematic diagram, Fig. 1201, while making voltage measurements will aid in isolation of trouble within the unit.

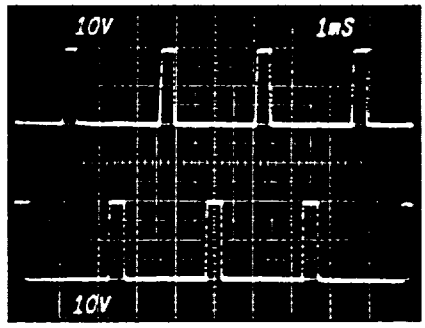


C. Analysis.

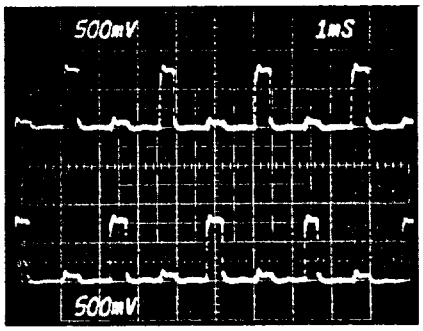
The waveforms pictured in Fig. 801 were made using the oscilloscope described in the Special Tools section of this manual, and will aid in analyzing the equipment performance when trouble shooting procedures are being performed.



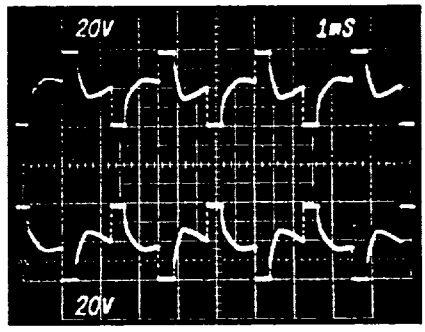
STEP	SYMPTOM	PROBABLE CAUSE	CHECK	REMEDY
1	Generator voltage continues to increase.	Relay K1 failed to open, defective transistor Q15, Zener diode ZR4 or diode CR8.	Check transistor Q15, zener diode ZR4, diode CR8, or relay K1.	Replace defective component.
2	Generator output voltage zero, erratic regulation, or erratic paralleling operation.	Open or defective wiring at connector P1/J1 of regulator or at generator terminals.	Continuity of input/output wiring and connector P1/J1 and generator.	Repair or replace.
3	Generator output voltage increases to 20 volts and starts dropping to zero causing relay chatter.	Defective drive signal.	Check operation of oscillator transistor Q8 and Q9, and following stages of shaping and amplification, transistors Q1 through Q7.	Replace defective component.
4	Generator output voltage control adjustment on regulator, resistor R35, out of limits.	Defective reference in voltage comparator circuit.	Check zener diode ZR2, resistors R35, R28 and R29, diodes CR5, CR6, and CR7, and transistor Q12.	Replace defective component.
5	Generator will not operate in parallel service within specifications.	Defective reference in current comparator circuit.	Check resistors R26 and R27, and transistor Q11.	Replace defective component.
6	Generator (hunts) voltage rises and falls erractically.	Defective time constant in voltage regulator circuit.	Check capacitors C4 and C5 and zener diode ZR1.	Replace defective component.
7	Overvoltage relay cuts generator off line repeatedly.	Defective overvoltage control circuit or defective output circuit, control transistor.	Check transistor Q14, Zener diode ZR3, diode CR10 and transistor Q7.	Replace defective component.



A. WAVEFORMS AT BASE OF TRANSISTORS Q1 AND Q2
GENERATOR OPERATING AT LOW RANGE (APPROX. 4,500 RPM),
100 AMP LOAD
VERTICAL SENSITIVITY: 5.0 VOLTS/DIVISION
TIME BASE: 1.0 MILLISECONDS/DIVISION

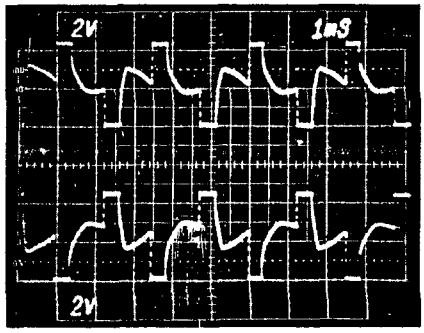


B. WAVEFORMS AT COLLECTOR OF TRANSISTORS Q1 AND Q2
GENERATOR OPERATING AT LOW RANGE (APPROX. 4,500 RPM),
100 AMP LOAD
VERTICAL SENSITIVITY: 5.0 VOLTS/DIVISION
TIME BASE: 1.0 MILLISECONDS/DIVISION

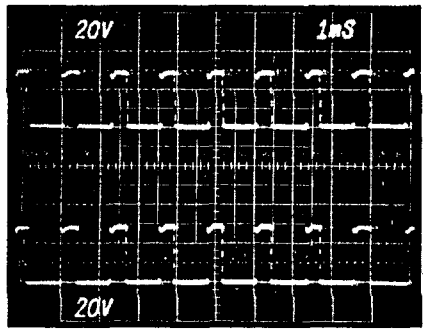


C. WAVEFORMS AT BASE OF TRANSISTORS Q3 AND Q4
GENERATOR OPERATING AT LOW RANGE (APPROX. 4,500 RPM),
100 AMP LOAD
VERTICAL SENSITIVITY: 1.0 VOLTS/DIVISION
TIME BASE: 1.0 MILLISECONDS/DIVISION

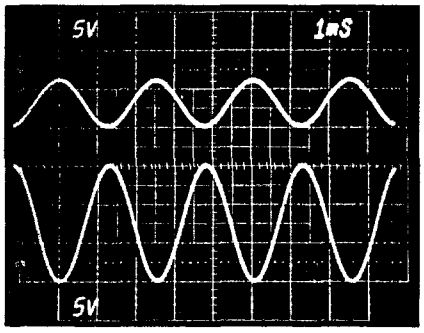
D. WAVEFORMS AT COLLECTOR OF TRANSISTORS Q3 AND Q4
GENERATOR OPERATING AT LOW RANGE (APPROX. 4,500 RPM),
100 AMP LOAD
VERTICAL SENSITIVITY: 10.0 VOLTS/DIVISION
TIME BASE: 1.0 MILLISECONDS/DIVISION



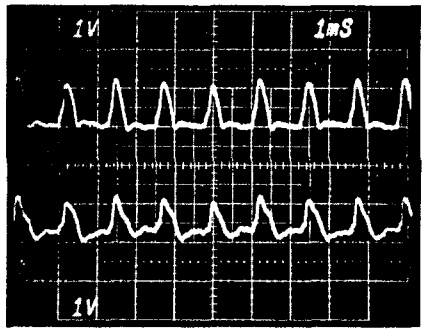
E. WAVEFORMS AT BASE OF TRANSISTORS Q5 AND Q6
GENERATOR OPERATING AT LOW RANGE (APPROX. 4,500 RPM),
100 AMP LOAD
VERTICAL SENSITIVITY: 0.5 VOLTS/DIVISION
TIME BASE: 1.0 MILLISECONDS/DIVISION



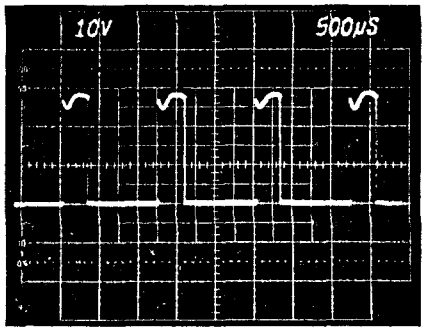
F. WAVEFORMS AT COLLECTOR OF TRANSISTORS Q5 AND Q6
GENERATOR OPERATING AT LOW RANGE (APPROX. 4,500 RPM),
100 AMP LOAD
VERTICAL SENSITIVITY: 20.0 VOLTS/DIVISION
TIME BASE: 1.0 MILLISECONDS/DIVISION



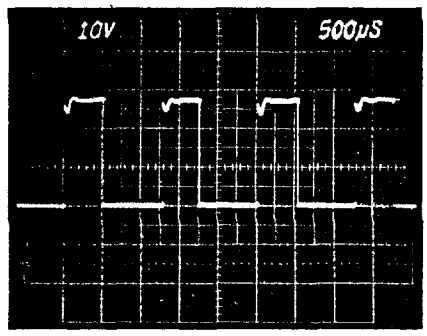
Waveform Measurements, Model VR-1010-24-2A,
DC Voltage Regulator
Figure 801 (Sheet 1 of 3)



G. WAVEFORM AT INPUT TO DIODE CR2, TOP; WAVEFORM AT INPUT TO DIODE CR3, BOTTOM; REFERENCED TO CENTER TAP OF TRANSFORMER T2, GENERATOR OPERATING AT LOW RANGE (APPROX. 4,500 RPM), 100 AMP LOAD
VERTICAL SENSITIVITY: 2.0 VOLTS/DIVISION
TIME BASE: 1.0 MILLISECONDS/DIVISION

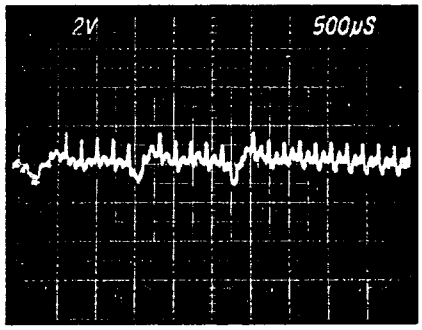


H. WAVEFORM AT JUNCTION OF DIODES CR2 AND CR3, TOP: WAVEFORM AT BASE OF TRANSISTOR Q7, BOTTOM; GENERATOR OPERATING AT LOW RANGE (APPROX. 4,500 RPM), 100 AMP LOAD
VERTICAL SENSITIVITY: 20. VOLTS/DIVISION
TIME BASE: 1.0 MILLISECONDS/DIVISION

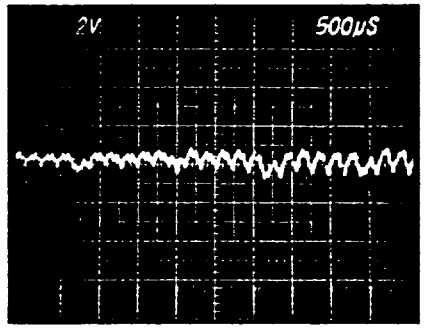


I. WAVEFORM AT BASE OF TRANSISTOR Q8, TOP: WAVEFORM AT COLLECTOR OF TRANSISTOR Q8, BOTTOM; GENERATOR OPERATING AT LOW RANGE (APPROX. 4,500 RPM), 100 AMP LOAD
VERTICAL SENSITIVITY: 5.0 VOLTS/DIVISION
TIME BASE: 1.0 MILLISECONDS/DIVISION

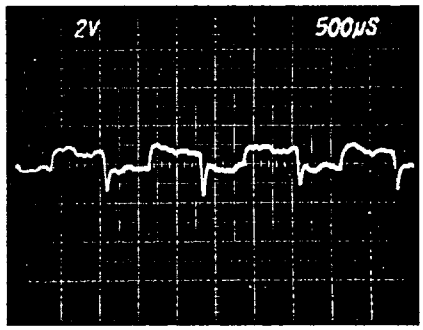
J. WAVEFORM AT EMITTER OF TRANSISTORS Q1 AND Q2, TOP: WAVEFORM AT COLLECTOR OF TRANSISTOR Q10, BOTTOM; GENERATOR OPERATING AT LOW RANGE (APPROX. 4,500 RPM), 100 AMP LOAD
VERTICAL SENSITIVITY: 1.0 VOLTS/DIVISION
TIME BASE: 1.0 MILLISECONDS/DIVISION



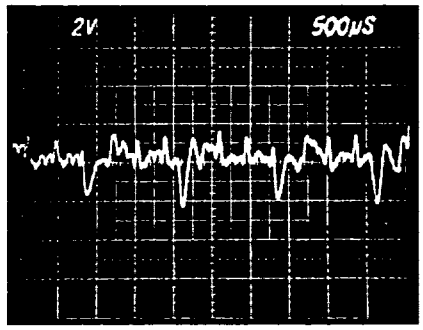
K. WAVEFORM AT PIN A, CONNECTOR J1, GENERATOR FIELD, SWITCHING-WAVEFORM NO-LOAD, GENERATOR OPERATING AT LOW RANGE (APPROX. 4,500 RPM)
VERTICAL SENSITIVITY: 10.0 VOLTS/DIVISION
TIME BASE: 500 MICROSECONDS/DIVISION



L. WAVEFORM AT PIN A, CONNECTOR J1, GENERATOR FIELD, SWITCHING WAVEFORM FULL-LOAD; GENERATOR OPERATING AT LOW RANGE (APPROX. 4,500 RPM)
VERTICAL SENSITIVITY: 10.0 VOLTS/DIVISION
TIME BASE: 500 MICROSECONDS/DIVISION



Waveform Measurements, Model VR-1010-24-2A,
DC Voltage Regulator
Figure 801 (Sheet 2 of 3)



M. WAVEFORM AT PIN C, CONNECTOR J1, GENERATOR +, REGULATOR SWITCHED IN, NO-LOAD GENERATOR OPERATING AT HIGH RANGE (APPROX. 8,000 RPM)
VERTICAL SENSITIVITY: 2.0 VOLTS/DIVISION
TIME BASE: 500 MICROSECONDS/DIVISION

N. WAVEFORM AT PIN C, CONNECTOR J1, GENERATOR +, REGULATOR SWITCHED IN, FULL-LOAD, GENERATOR OPERATING AT HIGH RANGE (APPROX. 8,000 RPM)
VERTICAL SENSITIVITY: 2.0 VOLTS/DIVISION
TIME BASE: 500 MICROSECONDS/DIVISION

O. WAVEFORM AT PIN C, CONNECTOR J1, GENERATOR +, FULL-LOAD, REGULATOR SWITCHED IN, GENERATOR OPERATING AT LOW RANGE (APPROX. 4,500 RPM)
VERTICAL SENSITIVITY: 2.0 VOLTS/DIVISION
TIME BASE: 500 MICROSECONDS/DIVISION

P. WAVEFORM AT PIN C, CONNECTOR J1, GENERATOR +, NO-LOAD, REGULATOR SWITCHED IN, GENERATOR OPERATING AT LOW RANGE (APPROX. 4,500 RPM)
VERTICAL SENSITIVITY: 2.0 VOLTS/DIVISION
TIME BASE: 500 MICROSECONDS/DIVISION

Q15	****0.60V	****0.02V	****0.0V

TEST POINT	VOLTAGE
Pin B, Connector J1 (Regulation point on Bus)	28.0V
Pin C, Connector J1 (Generator + B terminal)	27.85V
Junction of Zener diode ZR1, resistor R14, and capacitor C5	19.9V

NOTES: Voltage measurements with Triplett VOM Model 800 or equivalent.

All voltages are DC.

Voltage measurements between referenced point and terminal G of regulator (Generator ground terminal).

Regulator adjusted for 28.0 volts regulated output.

Regulator connected to generator test set and operating at or above minimum rated generator speed. (6,000 RPM)

*Voltage measurement at emitter will vary with load. Measured value applies to operating regulator on generator test set with 100% load.

**Voltage measurement at this point will vary with DC load on system approximately 4 to 1.

***Voltage measurement when connected to external overvoltage relay.

****Voltage measurements at these points taken with Relay K1 energized.

VR-'010-24-2A/P.N. 095027

STORAGE INSTRUCTIONS

1. GENERAL.

This section provides information preparing the Model VR-1010-24-2A DC Voltage Regulator, for use from a shipped or stored condition and for packing the unit for storage or shipment.

2. PREPARATION FOR USE.

The Voltage Regulator, when shipped from the factory, is wrapped in cellulose wadding, PPP-C-843, and inserted in a poly bag, LP-278, and enclosed in a corrugated shipping carton, PPP-B-636. To unpack the unit, cut sealing tape and open top of carton by lifting flaps to break adhesive. Remove unit from carton, remove poly bag and cellulose wadding. Visually examine the unit for damage which might have occurred during shipment or storage.

3. PREPARATION FOR STORAGE OR SHIPMENT.

The Voltage Regulator may be stored for short periods of time without packing. If the unit is to be stored for extended periods or is to be shipped, carefully wrap unit with cellulose wadding, insert in poly bag and place equipment in a corrugated carton. The carton should then be sealed and labeled for storage.

SPECIAL TOOLS, FIXTURES, AND EQUIPMENT

1. GENERAL.

This section provides information on the special tools and test equipment required for overhaul of the Model VR-1010-24-2A, DC Voltage Regulator.

2. STANDARD TEST EQUIPMENT.

Listed in Table 1001 are the items of standard test equipment required for overhaul of the voltage regulator. The listed item or a suitable equivalent may be used if procedures are modified when references to test equipment and setting of test equipment are made.

EQUIPMENT	MANUFACTURER AND MODEL NUMBER
GENERATOR TEST SET	SUN AGT-2 OR EQUIVALENT
OSCILLOSCOPE	HEWLETT-PACKARD MODEL 132A
VOLTOHMMETER	TRIPLETT ELECT. INST. MODEL 800 OR EQUIVALENT, or JOHN FLUKE MODEL 8040A, OR EQUIVALENT.
GENERATOR	PER MIL-G-6162 or EQUIVALENT.
INSULATION RESISTANCE TESTER	ASSOCIATED RESEARCH MODEL 2956

Standard Test Equipment
Table 1001

3. SPECIAL TEST EQUIPMENT.

None required.

VR-1010-24-2A/P.N. 095027

ILLUSTRATED PARTS CATALOG SECTION

1. INTRODUCTION.

This section of the Overhaul Manual provides a complete listing of parts for the Model VR-1010-24-2A DC Voltage Regulator (Solid-State Silicon), as manufactured by Phoenix Aerospace, Inc.

2. PURPOSE.

The information contained in this section is supplied to aid in provisioning, requisitioning, storing, and issuing of the replaceable parts, and to aid in identification of new and reclaimed parts.

3. APPLICATION.

The Illustrated Parts Catalog Section contains three separate listings; Numerical Index, Symbol Index, and Detailed Parts List. The subsequent paragraphs define the content and application of each listing.

A. Numerical Index.

The Numerical Index provides an alpha-numerical listing of the parts listed in the Detailed Parts List. The prime function being to aid in rapid location using the information contained in the various columns.

(1) Part Number Column.

The PART NUMBER column lists part numbers of procurable parts and assemblies as listed in the Detailed Parts List. Parts are listed in alpha-numerical order of precedence starting at the first letter extreme left and reading to the right as follows:

Letters A through Z
Numerals 0 through 9
(Alphabetical 0's are considered as Numerical zeros).

Second and succeeding positions of the part number appear in the order of precedence as follows:

Space (Blank column)
Diagonal (Slant) /
Point (Period)
Dash (-)
Letters A through Z
Numerical 0 through 9
(Alphabetical 0's are considered as numerical zeros).

(2) Airline Part Number Column.

The AIRLINE PART NO. column is provided to allow insertion where applicable, of the users own part number where available and desired.

24 is significant of the Chapter (derived from system identification numbers).
30 is significant of the Section (derived from sub-system identification numbers).
X is significant of the Unit (derived from the application of particular unit).
1101 is significant of the Figure number.
18 is significant of the Item number.

(4) Total Required Column.

The TTL REQ. column is the total of each item required in the unit whether it be piece part or sub-assembly.

B. Symbol Index.

The Symbol Index enables the location of component parts referenced from the schematic diagram by the reference symbol to a specific Figure and Item number.

(1) Symbol Column.

The SYMBOL column contains an alpha-numerical listing of every component part which carries a reference symbol on the schematic diagram.

(2) Part Number Column.

The PART NUMBER column lists the vendor part number of the symbolized item.

(3) Chapter-Section-Unit-Figure-Item Column.

The CH-SECT-UNIT-FIG-ITEM column contains the specific location data where the listed part appears in the Detailed Parts List and other pertinent data. (See preceding para. 3.A.(3) for example of information.

C. Detailed Parts List.

The Detailed Parts List, is a breakdown of the complete unit into sub-assemblies and detailed parts. Each sub-assembly is listed in its order of disassembly and is followed immediately by its component parts properly indented to show its relationship to the assembly.

(1) Figure Item Column.

The FIG. ITEM Column entries key the parts breakdown to the applicable illustration. Items numbered on the Detailed Parts List preceded by a dash (example -1) do not appear on the illustration.

(2) Part Number Column.

The PART NUMBER column lists the applicable Standard part number NS, AN, NAS, etc., vendor part number or Phoenix Aerospace, Inc. part numbers. When more than one part number is assigned to an item the preference shall be Standard MS, AN, NAS, etc., vendor, or Phoenix Aerospace, Inc., in that order. Vendor part numbers listed in the PART NUMBER column are subject to change without notice.

(2) Part Number Column.

The PART NUMBER column lists the applicable Standard part number MS, AN, NAS, etc., vendor part number or Phoenix Aerospace, Inc. part numbers. When more than one part number is assigned to an item the preference shall be Standard MS, AN, NAS, etc., vendor, or Phoenix Aerospace, Inc., in that order. Vendor part numbers listed in the PART NUMBER column are subject to change without notice.

(3) Nomenclature Column.

The NOMENCLATURE column describes the assembly, sub-assembly, or component part in a short form description, with the identifying Noun as the first word, followed by the modifiers as required. The indentations denote parts relation to next higher assembly (NHA) or sub-assembly, as applicable. the ATTACHING PARTS entries are listed immediately following the component which they attach.

If a part is purchased by Phoenix Aerospace, Inc. from a vendor, the Federal Supply Code number, preceded by the letter V, is listed in this column, and set off by parentheses. The vendors part number appears in the PART NUMBER column and the Phoenix Aerospace, Inc. part number follows the vendor, FSC number, and is set off in parentheses. If a part number or FSC number does not appear in the NOMENCLATURE column the part number listed in the PART NUMBER column is a Phoenix Aerospace, Inc. number.

(4) Effect From To Column.

The EFFECT FROM TO column provides for entries regarding usage on different models or for field service bulletin entries as applicable. If this column is left blank, parts apply to all models until otherwise noted by revision.

(5) Units Per Assembly Column.

The UNITS PER ASSY column lists the quantity of sub-assemblies or parts required in the next higher assembly (NHA). The quantities specified, therefore, are not necessarily tht total used per equipment. The letters RF denote that the item listed appears on another list and illustration and is referenced for aid in identification only.

4. VENDOR FEDERAL SUPPLY CODE AND NAME INDEX.

The following list is derived by extraction from the Federal Supply Catalog Handbook H4-1. The information is supplied to aid in procurement and identification of the various vendors.

FSC NO. OR CODE	VENDORS NAME AND ADDRESS	FSC NO. OR CODE	VENDORS NAME AND ADDRESS
01121	Allen Bradley Co. 1201 South 2nd St. Milwaukee, Wisconsin 53204	05277	Westinghouse Electric Corp. Semiconductor Div. Armburst Road Youngwood, PA 15697

INTRODUCTION

In conformance with A.T.A. Specification No. 100 for Manufacturers' Technical Data, two manuals have been prepared concerning the Model DH-1030-24-600-CS Solid-State Static Inverter (Transverter). These manuals, if used as intended, will facilitate the effective, continued operation of the equipment. Technical data is grouped according to usage in the manual as described.

MAINTENANCE MANUAL

This manual is intended for use by flight line and hangar maintenance personnel. A detailed description and operation procedures, including a table of leading particulars are presented for reference. Mounting information, and cabling information are presented as an aid to installation. Trouble-shooting information is limited to procedures required to trace a trouble to the overall unit for replacement.

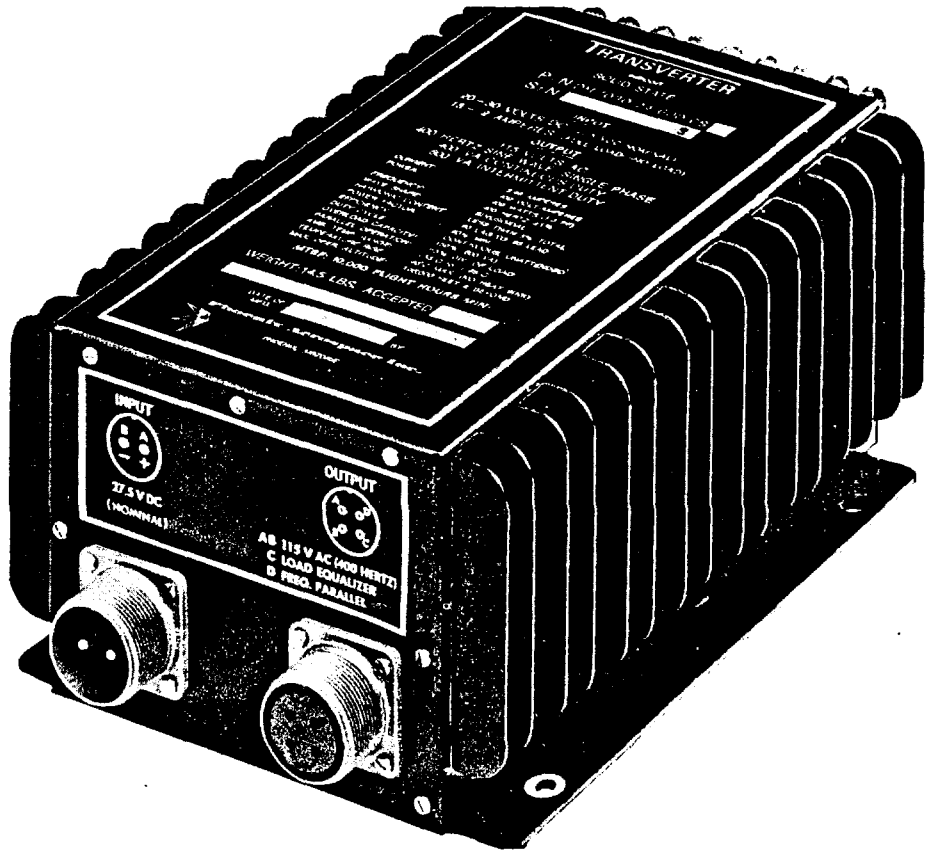
OVERHAUL MANUAL WITH ILLUSTRATED PARTS CATALOG

The Overhaul Manual contains all the information required for shop testing, replacement of defective parts, alignment and adjustment, mechanical disassembly, inspection, and reassembly. Detailed circuit theory is given with emphasis on theory that will be especially helpful for effective trouble-shooting. Performance tests as well as functional (go/no-go) checks, which may be used to determine condition of equipment and for retesting after repairs.

The Illustrated Parts Catalog provides a means to determine the manufacturer's part number and the physical location on the equipment of a part if the reference designation is known, or to determine the reference designation and the manufacturer's part number when the physical location of the part is known but no other information is available.

DH-1030-24-600-CS/P.N. 095032

DESCRIPTION AND OPERATION



1. GENERAL.

A. Purpose of Manual.

This manual contains maintenance procedures for the Model DH-1030-24-600-CS, Solid-State Static Inverter (Transverter), illustrated in Fig. 1.

B. Purpose of Equipment.

The Model DH-1030-24-600-CS Solid-State Static Inverter (Transverter) is used for conversion of electrical power in aircraft for operation of airborne instrumentation and other electrical equipment. The unit provides a continuous source of frequency and voltage regulated, single phase, sine wave, alternating current power from a direct current voltage source. The stable output insures the highest degree of operational reliability under the most adverse service conditions.

Model DH-1030-24-600-CS, Solid-State Static Inverter (Transverter)
Figure 1

2. DESCRIPTION.

A. The Model DH-1030-24-600-CS Solid-State Static Inverter (Transverter) is a self-contained DC to AC inverter using state-of-the-art-solid state techniques. Power from the DC source is changed to a highly stable alternating current power source. The unit is compactly packaged with only input and output connections externally accessible.

B. The primary characteristics, capabilities, overall weight, and dimensions are listed in Table of Leading Particulars, Table 1.

GENERAL:

Input: 20-30 VDC (27.5 VDC nominal), 18.0 - 2.0 Amperes (full load - no load, 27.5 VDC Input).

Output: 115 VAC, 400 Hertz Sine Wave, 1 Phase, 400 VA Continuous Duty, 600 VA Intermittent Duty.

Ambient Temperature Range: −55°C to +85°C.

Temperature Rise: 40°C maximum (no heat sink).

Maximum Operating Altitude: 100,000 feet and beyond.

Reliability: 10,000 hours MTBF (minimum).

ELECTRICAL:

Output:

Volts: 115 VAC ±5% — No load to full load over input and temperature/altitude operating range.

Current: 3.48 Amperes.

Power: 400 Volt-Amperes (Continuous Duty), 600 Volt-Amperes (Intermittent Duty).

Frequency: 400 Hertz ±1% — No load to full load over input and temperature/altitude operating range (frequency is maintained to 10 VDC input, and below).

Wave Shape: Sinusoidal

Harmonic Content: Less than 5% total, (3% typical).

Power Factor: .80° lag to .95° lead.

Efficiency: 80% minimum.

Table of Leading Particulars
Table 1

ELECTRICAL (Cont):

Output (Cont):

Duty Cycle: Continuous, unattended.

Short Circuit Protection: Automatic — Restarts when normal load is restored (No damage, output shorted for 1 minute).

Overload Capacity: 150% for 5 minutes (No damage), (600 VA).

Input:

Volts: 20 - 30 VDC (27.5 VDC nominal) 0 - 36 Volts (No damage).

Current: 18.0 - 1.25 Amperes (full load - no load). Operating at rated load, 27.5 VDC Input, 18.0 Amperes.

Induced Ripple: Less than 1.5 Volts peak to peak.

Overvoltage Protection: 130% for 5 minutes (No damage).

Transient Protection: ±80 volts for 40 milliseconds,
±600 volts for 10 microseconds.

Reverse Polarity Protection: Polarity protect diode.

MECHANICAL:

Weight: 14.5 pounds (6,577 grams).

Overall Dimensions: 10-7/8 in. long (27.623 cm) by
7-3/4 in. wide (19.685 cm) by
5 in. high (12.7 cm).

Mounting Base Dimensions: 10-7/8 in. long (27.623 cm) by
7-3/4 in. wide (19.685 cm).

Mounting Centers: 7 in. long (17.780 cm) by 7 in. wide (17.780 cm).

Electrical Connectors: Input: MS3102R-22-1P mating MS3106F-22-1S.
Output: MS3102R-22-10S mating MS3106F-22-10P.

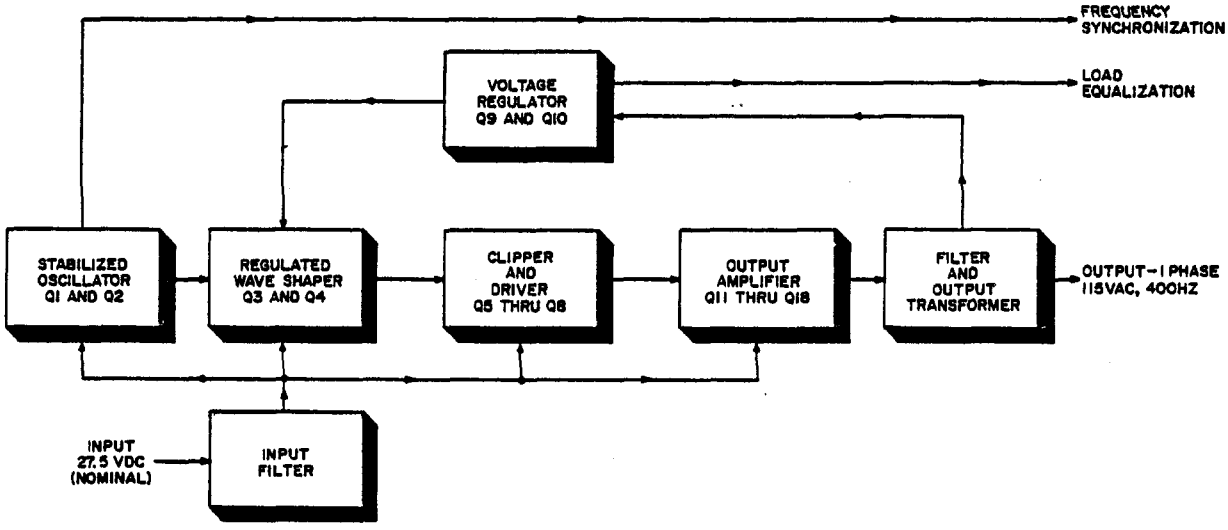
Cooling: Self-cooled by natural convection, conduction and radiation.

Installation: Mounts in any position, without deterioration of power output, heating, operating life, or other operating characteristics.

3. OPERATION.

The subsequent paragraphs cover the theory of operation for the Model DH-1030-24-600-CS Solid-State Static Inverter (Transverter). The Block Diagram Theory will aid in conveying the overall circuit operation to non-technical oriented personnel, while the Detail Circuit Theory will enable the technician to understand in detail the operation of equipment.

A. Block Diagram Theory.



The subsequent paragraphs together with the block diagram of Fig. 2, cover in concise form the signal flow and circuit operation for the Model DH-1030-24-600-CS Solid-State Static Inverter (Transverter).

(1) Input Filter. Power applied through the input filter is free of transients and provided with reverse polarity protection for application to circuits of the Transverter.

(2) Stabilized Oscillator. Transistors Q1 and Q2 generate a 400 Hertz sine wave signal of high stability. The sine wave signal is coupled through auxiliary windings of the oscillator transformer T1 to the input of the regulated wave shaper.

(3) Regulated Wave Shaper. Transistors Q3 and Q4 in a push-pull circuit receive the sine wave signal developed by the stabilized oscillator. Voltage applied from the voltage regulator circuit determines the shaping operation for optimum efficiency, duty cycle and regulation of the output signal. The shaped output is coupled to the input of clipper circuit.

(4) Clipper and Driver. Transistors Q5, Q6, Q7 and Q8 in cascaded push-pull stages provide additional shaping and amplification of the 400 Hertz signal. The amplified signal is applied to the output amplifier.

Model DH-1030-24-600-CS, Solid-State Static Inverter (Transverter), Block Diagram
Figure 2

(5) Output Amplifier. Transistors Q11 through Q18 in a push-pull parallel circuit amplify the 400 Hertz signal to the required level across the output transformers for application to the output filter.

(6) Output Transformers and Filter. The output transformers and associated filter circuitry provide matching and shaping to return the amplified signal to a sinusoidal signal.

(7) Voltage Regulator. Transistors Q9 and Q10 develop the regulating bias by comparison of the rectified negative DC voltage supplied from the output, and adjusted by setting of resistor R22, controlling the Zener controlled voltage to the base of Transistor Q9.

B. Detailed Circuit Theory

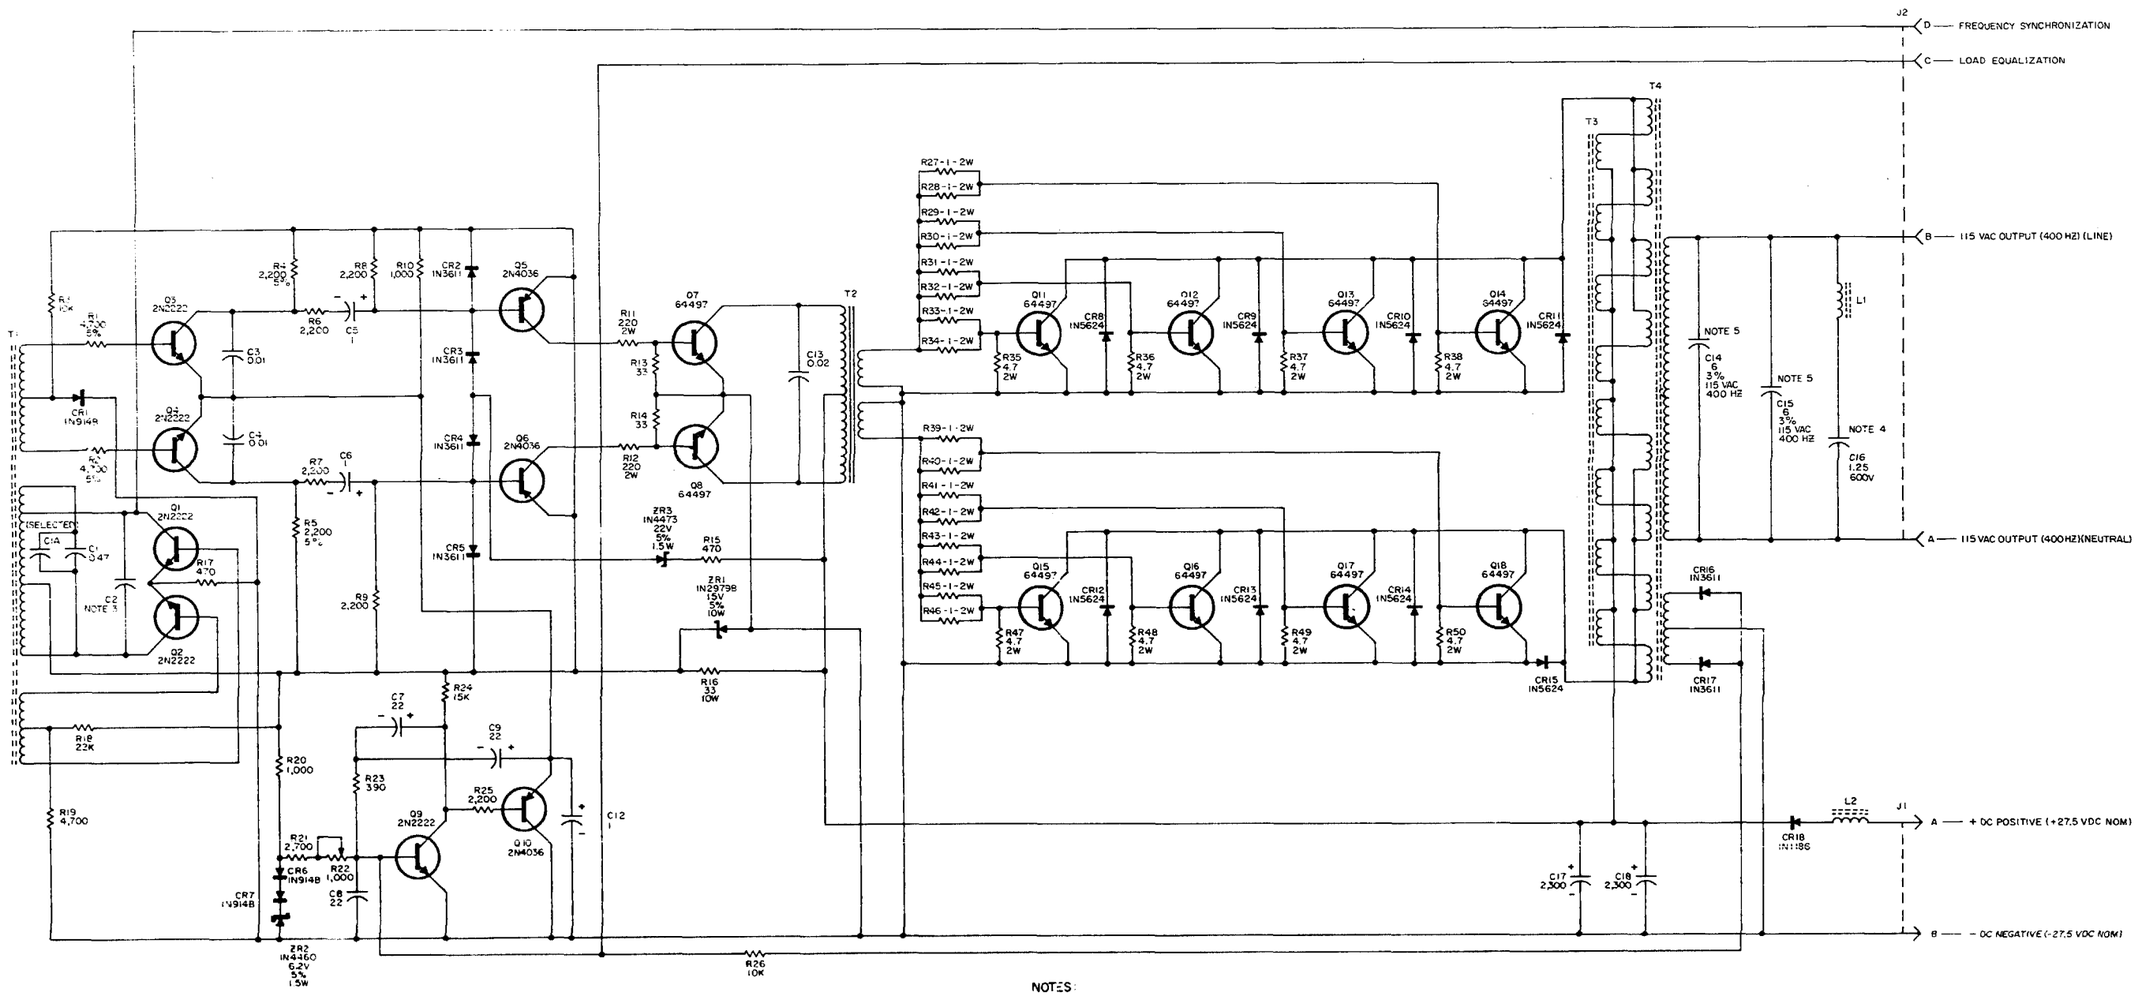
The following sub-paragraphs cover the individual circuits and their operation. Occasional reference to the overall schematic diagram of the Transverter, Fig. 3, will be necessary to determine circuit configuration.

(1) Input Filter. The input filter consists of series reactor L2 and shunt capacitors C17, and C18 providing high speed transient and ripple suppression to the input line. Diode CR19 provides reverse polarity protection for the Transverter circuitry. The input filter and reverse polarity protect diode pass the input current required to maintain rated power output and provide operating voltage and power to Transverter circuits. Over voltage protection for low speed transients is provided by Zener diode. ZR3, resistor R15, and diodes CR2, CR3, CR4, and CR5. If the input voltage exceeds 42 volts, Zener diode ZR3 conducts and applies back bias to transistors Q5 and Q6 through diodes CR3 and CR4, respectively. This bias inhibits switching during over voltage periods and prevents a high voltage from being developed which could damage subsequent amplifier circuits or the output circuit. Diodes CR2 and CR5 protect the base circuits of transistors Q5 and Q6, respectively. Resistor R16 and Zener diode ZR1 provide transient suppression and regulation for the low level stages.

(2) Stabilized Oscillator. The stabilized oscillator utilizes transistors Q1 and Q2 in a Hartley oscillator circuit. Toroidal transformer T1, with multiple windings provides the tuned circuit, feedback, and output windings for the oscillator. The tuned circuit portion is tuned by capacitor C2 to 400 Hertz. Capacitor C1 provides parasitic suppression in the tuned collector circuit. A feedback winding provides the coupling between base-collector circuit to sustain oscillations, resistors R18 and R19 provide bias to the base circuit of transistors Q1 and Q2 to insure positive start and sustained oscillations. Resistor R17 provides degeneration for improved stability of the oscillator circuit. Output to the regulated wave shaper circuit is through the remaining winding on transformer T1. Output direct from the collector of transistor Q1 and tuned circuit is terminated at Pin D of connector J2 for Frequency Synchronization in a multiple inverter system.

(3) Regulated Wave Shaper. The regulated wave shaper receives the 400 Hertz sinusoidal signal from transformer T1 output winding. The input signal is applied to the base circuits of transistors Q3 and Q4 through resistors R1 and R2, respectively, limiting base current which flows in the base circuit. Transistors Q3 and Q4 conduct on alternate half cycles, with the point of conduction determined by the amount of bias supplied by transistor Q10, voltage regulator, to the emitter circuit. The output of this stage is a quasi-square wave and is applied to the input of the clipper circuit.

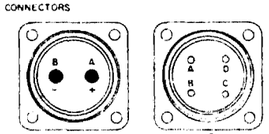
(4) Clipper and Driver. The clipper and driver circuits provide additional shaping of the signal and amplification for application to the output amplifier circuits. The clipper circuit consists of transistors Q5 and Q6 in a push-pull circuit. The quasi-square wave is applied to the base circuits of transistors Q5 and Q6 through limiting resistors R6 and R7, respectively. The output of the clipper circuit results in a quasi-square wave with improved rise time. The output is coupled to the base circuits of the driver transistors Q7 and Q8 through resistors R11 and R12, respectively. Resistors R13 and R14 provide low impedance return for leakage currents. Output of the collector circuits is developed across toroidal driver transformer T2 and coupled to the output amplifier circuits.



(5) Output Amplifiers. The output amplifiers receive the signal through toroidal driver transformer T2. Two output windings are connected in parallel to provide two outputs which drive the eight output transistors Q11 through Q18. Input to the base circuit of each output transistor is through two parallel connected 1 ohm, 2 watt, resistors, providing current limiting to the input. A 4.7 ohm, 2 watt resistor between the base and emitter of each output transistor reduces the impedance during the non-conduction period. The collectors of transistors Q11 through Q18 are parallel connected in groups of four, Q11, Q12, Q13 and Q14 so connected are connected to the high side of transformer T4 while transistors Q15, Q16, Q17, and Q18 are connected to the low side of transformer T4. Diodes CR8 through CR15 connected in parallel with the emitter collector junction of each power transistor provides the path for reverse current flow from the load back to the DC power source under conditions of high reactive loading. Toroidal series reactor transformer T3 is connected across the output transformer T4. The secondary winding of output transformer T4 is connected to the filter circuit.

(6) Output Transformer and Filter. The 400 Hertz quasi-square wave signal developed across toroidal output transformer T4 is high in content of odd order harmonics. Toroidal series reactor transformer T3 in conjunction with the output transformer T4, and the output filter circuit reduce these odd order harmonics. The impedance of the series reactor transformers is low at the 400 Hertz fundamental frequency, but sufficiently high at the frequency of the harmonics to enable the reactor-transformer combination to reduce the harmonic output. The output transformers T4 and T6 appear as a high impedance to the fundamental 400 Hertz signal and a low impedance to the harmonics, thus resulting in optimum power transfer at the fundamental frequency of 400 Hertz. The secondary winding of transformer T4 is tuned to the 400 Hertz fundamental by parallel capacitors C14, and C15, forming a parallel tuned circuit, which reflects a high impedance to the fundamental 400 Hertz signal and a low impedance path to the harmonics. The series tuned circuit comprised of capacitor C16 and toroidal reactor L1 is tuned to the third order harmonic 1200 Hertz, providing a shunting effect to the most predominant harmonic present in the output. The additional winding on transformer T4 is used to derive feedback voltage for the voltage regulator circuit. The derived voltage is rectified by diodes CR16 and CR17 to provide a negative DC potential to the voltage regulator circuit. The filtered output is 115 volts AC at a frequency of 400 Hertz and is available at pins A and B of connector J2.

(7) Voltage Regulator. The voltage regulator consists of transistors Q9 and Q10 and Zener diode ZR2. The positive voltage from Zener diode ZR2 and the negative voltage from diodes CR16 and CR17 are applied to the summing resistors R20, R21, and R22 to derive an error voltage at the base of transistor Q9. A change in output voltage, after the setting of resistor R22 has been determined, causes a change in the voltage applied to the summing circuit, developing an error voltage which is amplified by transistors Q9 and Q10. Output at the collector of transistor Q10 results in a proportional voltage change which is the bias applied to transistors Q3 and Q4. This change in bias controls duty cycle and output voltage by limiting action at the input wave shaper circuit. Output direct from the base of Q9 is terminated at Pin C for load equalization in a multiple inverter system.



REVISION CODE	REVISION DESCRIPTION	SERIAL NO. EFFECTIVITY
A	CR8 THROUGH CR15 CHANGED TO 1N5624	22 SEP 71
B	CHANGED CAPACITOR C16 TO MYLAR FOIL WRAP AND FILL 1.25 UF 600VDC.	18 DEC 71
C	Q7, Q8, Q11, Q12, Q13, Q14, Q15, Q16, Q17 AND Q18 CHANGED TO RCA 64497. REMOVED CAPACITOR C-11 0.1 UF. CHANGED CAPACITORS C14 AND C15 TO 6 UF, ±3%, 115 VAC, 400 HZ, METALIZED POLYCARBONATE.	22 JUN 73
D	REMOVED CAPACITOR C10 1 UF. REMOVED CAPACITOR C19 1400 UF. CHANGED VALUE OF CAPACITORS C17 AND C18 TO 2300 UF. ADDED CAPACITOR C1A (SELECTED).	12 OCT 73

TROUBLE SHOOTING

1. GENERAL.

The following paragraphs define procedures suitable for determining that a fault exists in the Solid-State Static Inverter (Transverter). These procedures do not cover trouble shooting within the Transverter. For equipment trouble shooting procedures refer to the overhaul manual and perform only in overhaul shops.

2. PRELIMINARY SYSTEM CHECK.

Refer to the airframe wiring diagram and the cabling information given in figure 203 in this manual and perform the following checks:

A. Check for input power at primary power source, breaker or fuse, and at pins A and B of input power connector P1. Use a DC voltmeter with a measuring range of 0 to 40 volts. Nominal input voltage of 27.5 volts should be measured between pins A and B.

B. Check for output at connector J2, pins A and B, series breaker or fuse, and at the input of device to which power is supplied. NOTE: When checking for output, check for shorted output at load by opening breaker or removing fuse and rechecking output present at connector J2. Use an AC voltmeter capable of measuring 0 to 150 volts AC at 400 Hertz. Measured voltage should be 115 volts AC between pins A and B plus or minus 5%.

C. Check output current to the load using an AC ammeter to determine that output current is not in excess of 3.48 Amperes on pin B of connector J2.

MAINTENANCE PRACTICES

1. GENERAL.

The following paragraphs cover in detail operations associated with maintenance, installation/removal, etc., of the Model DH-1030-24-600-CS Solid-State Static Inverter (Transverter).

2. SERVICING.

Periodic servicing or maintenance of the Transverter is not required or recommended. The equipment should not be removed from the airframe unless required by maintenance practices observed by the using agency. The use of solid state devices in a completely transistorized circuit, eliminates all moving parts, including relays or contactors. The design therefore eliminates the major cause of failure and maintenance points. In the event failure occurs, refer to the Installation/Removal paragraphs and remove unit for repair by overhaul shop or return to vendor.

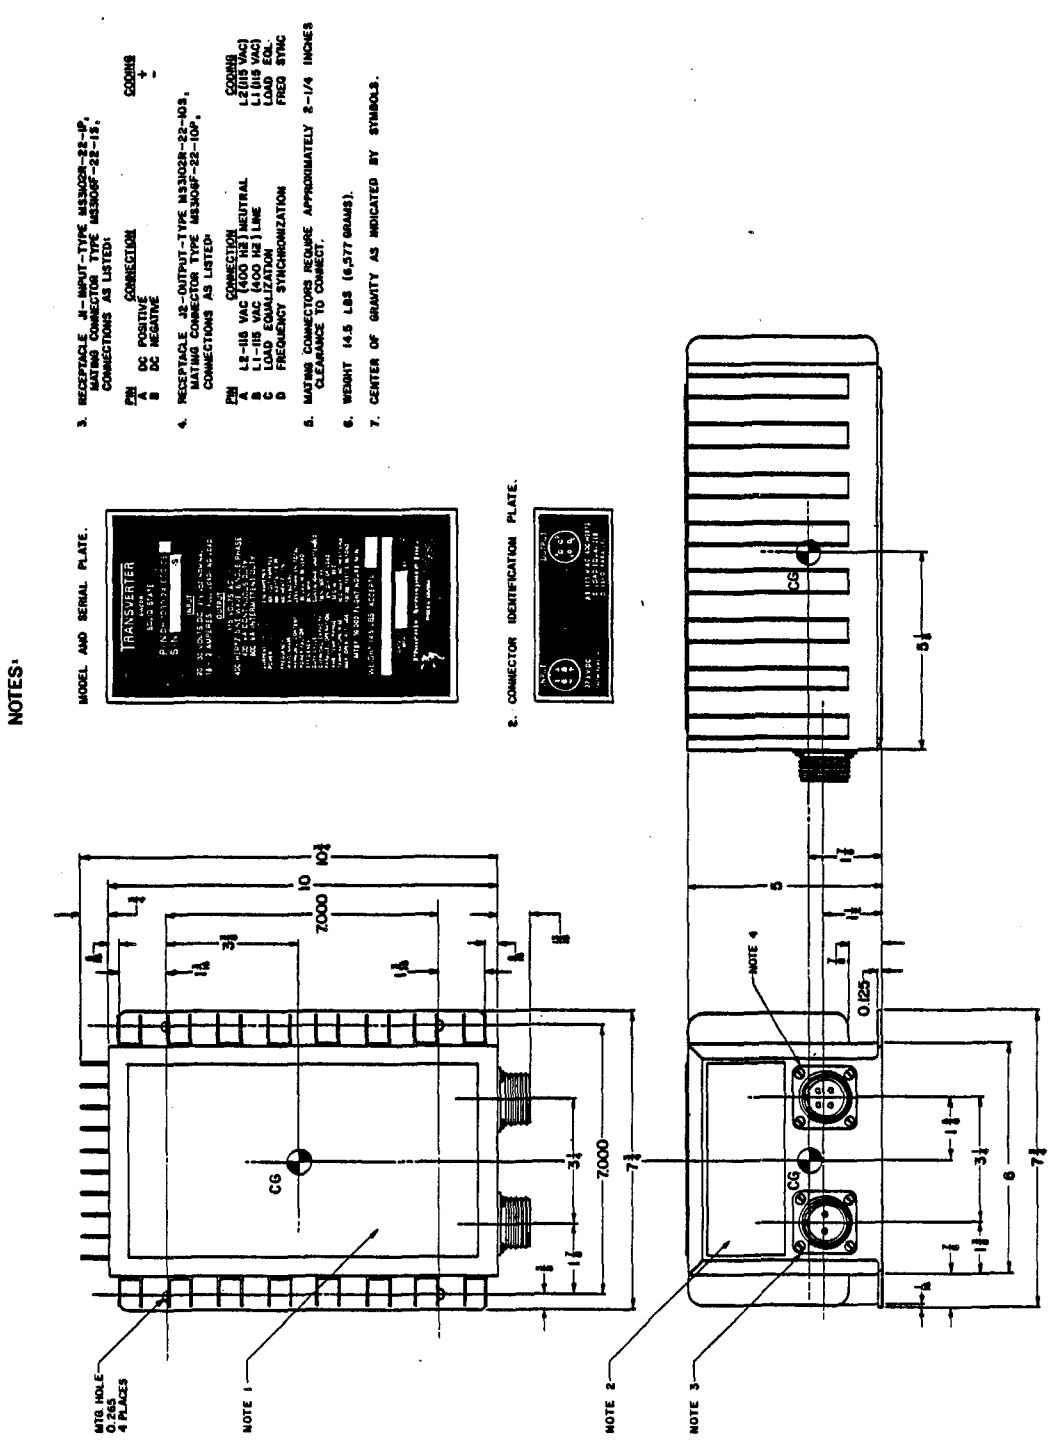
3. INSTALLATION/REMOVAL.

The following sub-paragraphs outline installation and removal procedures.

A. Installation.

(1) Refer to Fig. 201 and determine the clearance requirements for equipment and the associated cabling at selected installation point.

CAUTION: USE CARE IN DRILLING OPERATION OF SUBSEQUENT PARAGRAPH, TO PREVENT DAMAGE TO AIRFRAME STRUCTURE, OTHER WIRING, OR CONTROLS.



(2) Refer to Fig. 202, mark and drill four .265 inch diameter holes to mount equipment to airframe.

NOTE: Paint removal is not required, however, better heat transfer is accomplished if the mounting surface is clean and free from paint. A light coating of Dow Corning #340 Silicone compound applied to the base prior to installation improves the heat transfer from equipment to airframe.

(3) Install Transverter, securing in place with four 1/4-28 hex head cap screws, four 1/4 inch internal tooth lock washers, and four 1/4-28 self-locking hex nuts. All hardware shall meet or exceed applicable MS or AN Specification. Length of screws must be selected at installation and must have at least one and one-half threads showing after installed and tightened securely in place.

(4) Using the two mating connectors supplied, refer to Fig. 203 and prepare input and output cabling between the Transverter and circuit breaker/fuse panel and the powered device.

(5) After completion of cabling, open circuit breakers or remove fuses at power panel and connect the input power cable plug P1, MS3106F-22-1S to input receptacle J1, MS3102R-22-1P. Connect output power cable plug P2, MS3106F-22-10P to output receptacle J2, MS3102R-22-10S.

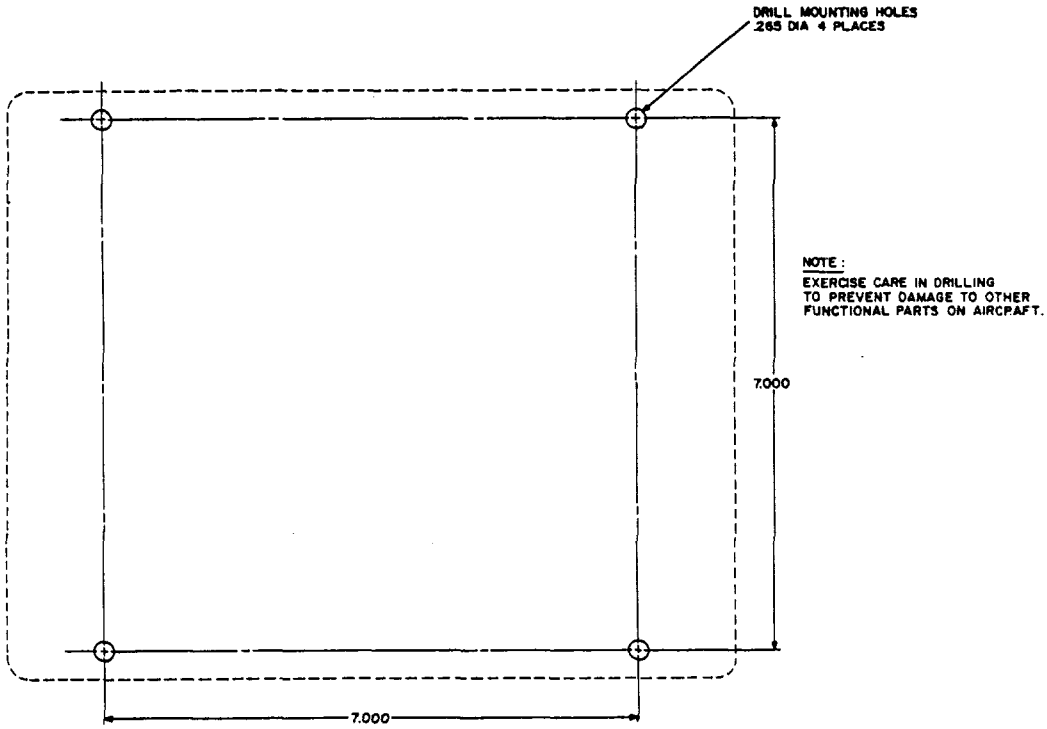
Outline Dimensions, Model DH-1030-24-600-CS
Solid-State Static Inverter (Transverter)
Figure 201

B. Removal.

(1) Identify circuit breakers or fuses at power panel and place circuit breakers in off position or remove fuses.

(2) Refer to cabling diagram Fig. 203 and disconnect input and output connectors P1 and P2, respectively.

(3) Remove the four 1/4-28 hex head screws, 1/4 inch internal tooth lock washers, and 1/4-28 self-locking hex nuts securing the Transverter to airframe.



4. ADJUSTMENT/TEST.

The following paragraphs outline test procedures for both installation check out and a pre-installation bench test if desired or required by maintenance policies. Adjustments are not authorized at flight line maintenance level.

A. Installation Test.

Complete the following steps to determine if Transverter and associated load are operating properly.

(1) Place circuit breakers in the on position or install fuses at power panel in the input circuit.

Drilling Template Mounting Holes,
Model DH-1030-24-600-CS
Solid-State Static Inverter (Transverter)
Figure 202

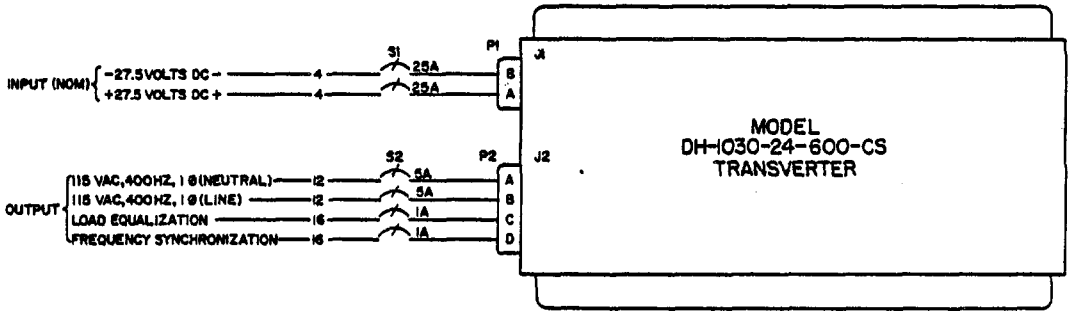
(2) Operate control to apply power to input of device while observing aircraft metering of the DC voltage for any abrupt change in voltage or current. In the event any abrupt change occurs, remove power and check wiring for shorted condition.

(3) Place circuit breakers in the on position or install fuses at power panel in the output circuit.

(4) Operate control or connect device or load to output of Transverter, observing operation of powered device and aircraft metering of the DC voltage for any change in voltage or current. In the event any appreciable change occurs, remove power at input and check output wiring and the associated load for short or other malfunction.

B. Pre-installation Check.

Complete the following steps to determine that Transverter is operable and capable of supplying power to a specific load.



(1) Refer to Fig. 204 and connect Transverter to the Test Set and associated DC Power Supply.

(2) Place selector switch on Test Set to 400 WATTS 1.0-UNITY position.

(3) Connect output of DC Power Supply to input of Test Set observing the polarity carefully.

(4) Adjust output of DC Power Supply to 27.5 volts DC and observe current meters in both the input and output circuits for proper operation.

Input Current: 18.0 Amperes Input Voltage: 27.5 VDC
Output Current: 3.48 Amperes Output Voltage: 115 VAC±5%

NOTES:

1. CIRCUIT BREAKER S1 AND S2 ARE NOT SUPPLIED. THE BREAKERS MAY BE REPLACED WITH FUSES IF DESIRED. THE INPUT POWER LINE REQUIRES PROTECTION OF 25 AMPERES, S1 WHILE THE OUTPUT LINE REQUIRES PROTECTION OF 5 AMPERES, S2 CONTROL LINES MAY BE PROTECTED BY 1 AMPERE BREAKERS OR FUSES.
2. CABLING SHALL BE FABRICATED FROM ELECTRICAL WIRE WHICH MEETS OR EXCEEDS REQUIREMENTS OF MIL-W-16878/3, TYPE D.
3. WIRING SHALL MEET OR EXCEED THE FOLLOWING SIZE REQUIREMENTS:

INPUT P1/J1		OUTPUT P2/J2	
PIN A	#4	PIN A	#12
PIN B	#4	PIN B	#12
		PIN C	#16
		PIN D	#16

4. CONNECTOR PLUGS, P1 AND P2 ARE SUPPLIED WITH TRANSVERTER (OPTIONAL).

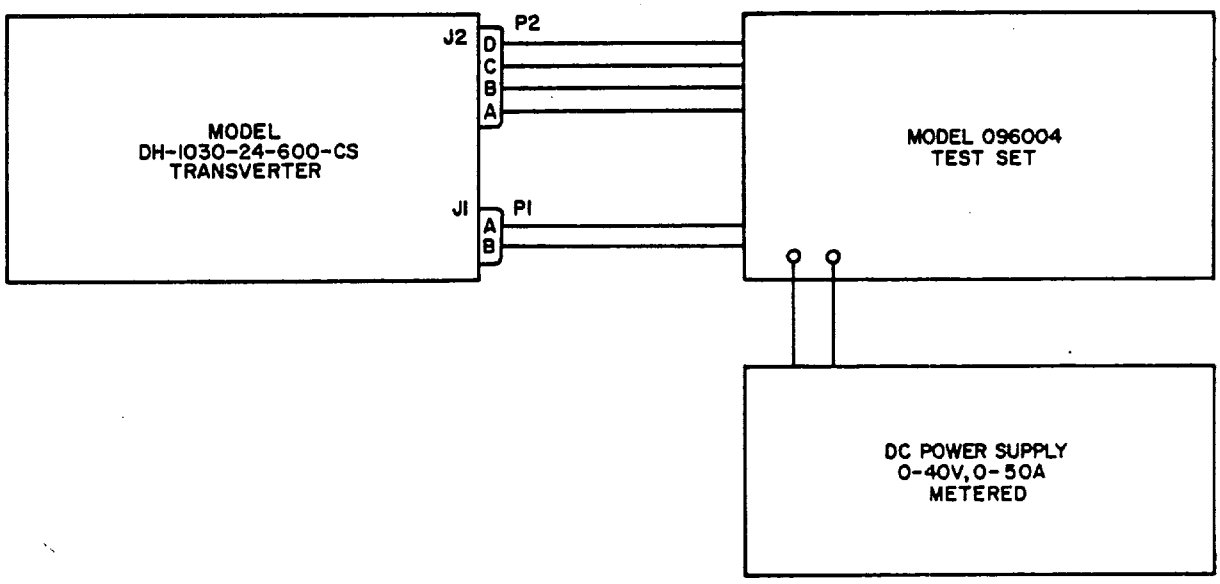
Cabling Diagram, Model DH-1030-24-600-CS
Solid-State Static Inverter (Transverter)
Figure 203

(5) Change input voltage from DC Power Supply varying between 20 and 30 volts and note stability of output voltage and current, no change is indicative of proper operation.

(6) Return input voltage to zero and disconnect Transverter from Test Set, completing pre-installation or bench tests.

NOTE: In the event Transverter under test does not meet requirements outlined in step (5), unit should be returned to stores for replacement and forwarded to overhaul or returned to vendor for repairs.

5. INSPECTION/CHECK.

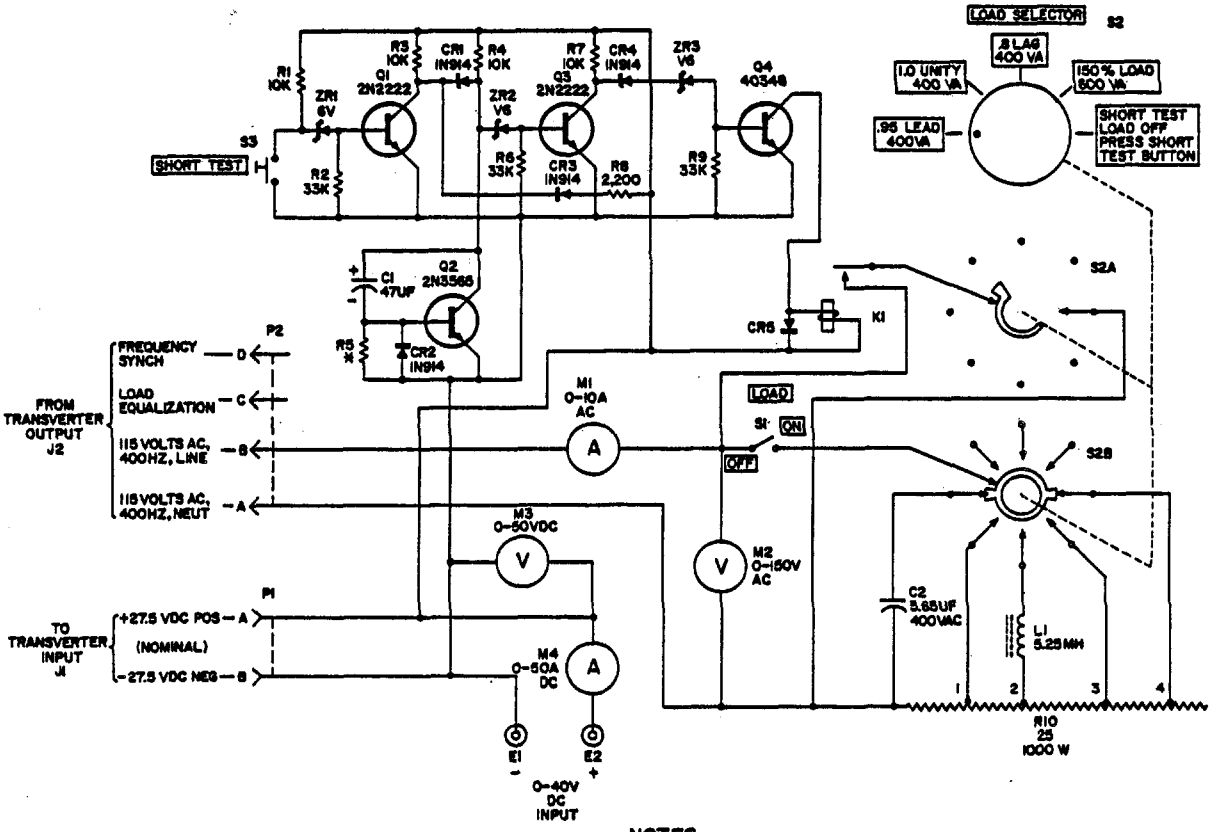


Visual inspection of external cabling for arcing at contacts of connectors, and associated load are the only authorized inspection/checks. No authority is given for visual or other checks internally or even removal of the sealed cover at flight line maintenance levels.

6. CLEANING/PAINTING.

The Transverter requires no periodic cleaning operations under the sealed cover. If readily accessible, exterior dirt may be removed with a brush or cloth and the connector pins may be burnished if corrosion should be apparent during visual inspection check of paragraph 5.

7. APPROVED REPAIRS.



The only repairs approved for flight line maintenance are those associated with external cabling. No repairs are authorized or approved for flight line maintenance requiring removal of the sealed cover.

Bench Test Set-Up, Model DH-1030-24-600-CS
Solid-State Static Inverter (Transverter)
Figure 204

8. ACCESSORY TEST SET, MODEL 096004

The Test Set referenced in preceding paragraph 4.B is available from Phoenix Aerospace as a complete unit or in part as desired by the user. All parts other than the toroidal power reactor are available from local parts jobbers. The schematic diagram for the Test Set is shown in Fig. 205.

NOTES

1. RESISTOR R10 TAP#1 = 14.55Ω; TAP#2 = 17.6Ω; TAP#3 = 22.0Ω; TAP#4 = 23.15Ω.

DH-1030-24-600-CS/P.N. 095032

INTRODUCTION

In conformance with A.T.A. Specification No. 100 for Manufacturers' Technical Data, two manuals have been prepared concerning the Model DH-1030-24-600-CS Solid-State Static Inverter (Transverter). These manuals, if used as intended, will facilitate the effective, continued operation of the equipment. Technical data is grouped according to usage in the manual as described.

OVERHAUL MANUAL WITH ILLUSTRATED PARTS CATALOG

The Overhaul Manual contains all the information required for shop testing, replacement of defective parts, alignment and adjustment, mechanical disassembly, inspection, and reassembly. Detailed circuit theory is given with emphasis on theory that will be especially helpful for effective trouble-shooting. Performance tests as well as functional (go/no-go) checks, which may be used to determine condition of equipment and for retesting after repairs.

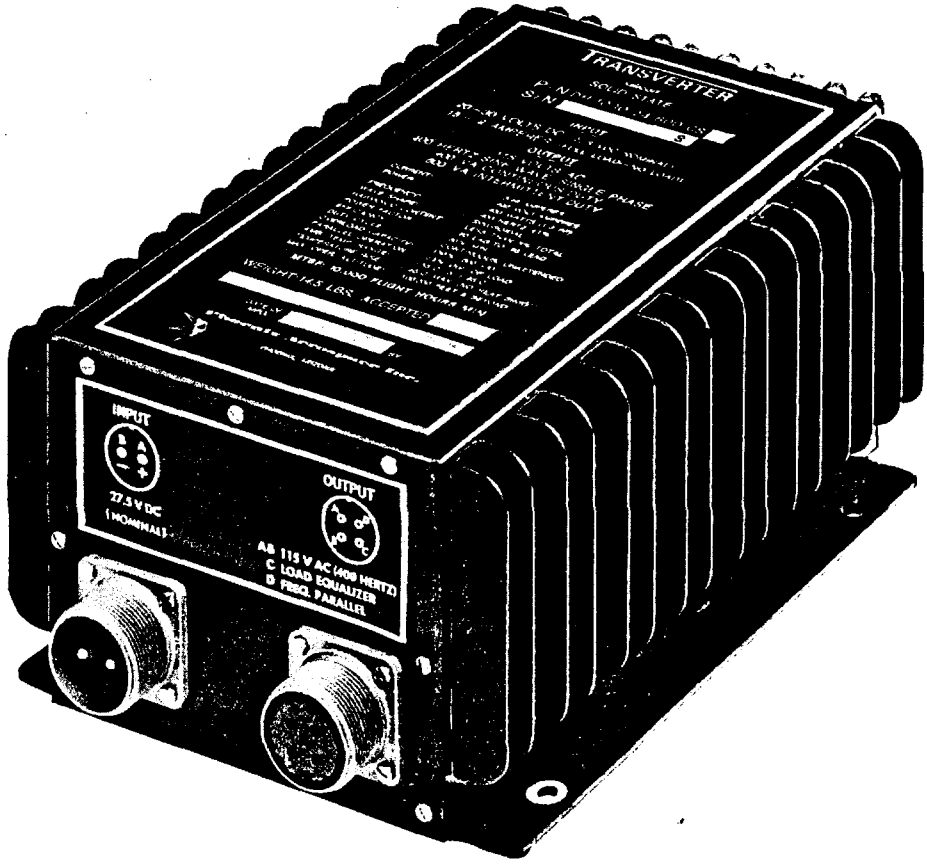
The Illustrated Parts Catalog provides a means to determine the manufacturer's part number and the physical location on the equipment of a part if the reference designation is known, or to determine the reference designation and the manufacturer's part number when the physical location of the part is known but no other information is available.

MAINTENANCE MANUAL

This manual is intended for use by flight line and hangar maintenance personnel. A detailed description and operation procedures, including a table of leading particulars are presented for reference. Mounting information, and cabling information are presented as an aid to installation. Trouble-shooting information is limited to procedures required to trace a trouble to the overall unit for replacement.

DH-1030-24-600-CS/P.N. 095032

DESCRIPTION AND OPERATION



1. GENERAL.

A. Purpose of Manual.

This manual contains instructions covering overhaul, and the illustrated parts catalog for the Model DH-1030-24-600-CS, Solid-State Static Inverter (Transverter), illustrated in Fig. 1.

B. Purpose of Equipment.

The Model DH-1030-24-600-CS, Solid-State Static Inverter (Transverter), is used for conversion of electrical power in aircraft for operation of airborne instrumentation and other electrical equipment. The unit provides a continuous source of frequency and voltage regulated, single phase, sine wave, alternating current power from a direct current voltage source. The stable output insures the highest degree of operational reliability under the most adverse service conditions.

Model DH-1030-24-600-CS, Solid-State Static Inverter (Transverter)
Figure 1

2. DESCRIPTION.

A. The Model DH-1030-24-600-CS Solid-State Static Inverter (Transverter) is a self-contained DC to AC inverter using state-of-the-art-solid state techniques. Power from the DC source is changed to a highly stable alternating current power source. The unit is compactly packaged with only input and output connections externally accessible.

B. The primary characteristics, capabilities, overall weight, and dimensions are listed in Table of Leading Particulars, Table 1.

GENERAL:

Input: 20 - 30 VDC (27.5 VDC nominal), 18.0 - 2.0 Amperes (full load - no load, 27.5 VDC Input).

Output: 115 VAC, 400 Hertz Sine Wave, 1 Phase, 400 VA Continuous Duty, 600 VA Intermittent Duty.

Ambient Temperature Range: −55°C to +85°C.

Temperature Rise: 40°C maximum (no heat sink).

Maximum Operating Altitude: 100,000 feet and beyond.

Reliability: 10,000 hours MTBF (minimum).

ELECTRICAL:

Output:

Volts: 115 VAC ±5% — No load to full load over input and temperature altitude operating range.

Current: 3.48 Amperes.

Power: 400 Volt-Amperes (Continuous Duty), 600 Volt-Amperes (Intermittent Duty)

Frequency: 400 Hertz ±1% — No load to full load over input and temperature/altitude operating range (frequency is maintained to 10 VDC input, and below).

Wave Shape: Sinusoidal

Harmonic Content: Less than 5% total, (3% typical).

Power Factor: .80° lag to .95° lead.

Efficiency: 80% minimum.

Table of Leading Particulars
Table 1

ELECTRICAL (Cont):

Output (Cont):

Duty Cycle: Continuous, unattended.

Short Circuit Protection: Automatic — Restarts when normal load is restored (No damage, output shorted for 1 minute).

Overload Capacity: 150% for 5 minutes (No damage), 600 VA.

Input:

Volts: 20 - 30 VDC (27.5 VDC nominal) 0 - 36 Volts (No damage).

Current: 18.0 - 2.0 Amperes (full load - no load). Operating at rated load, 27.5 VDC Input, 18.0 Amperes.

Induced Ripple: Less than 1.5 Volts peak to peak.

Overvoltage Protection: 130% for 5 minutes (No damage).

Transient Protection: ±80 volts for 40 milliseconds,
±600 volts for 10 microseconds.

Reverse Polarity Protection: Polarity protect diode.

MECHANICAL:

Weight: 14.5 pounds (6,577 grams).

Overall Dimensions: 10-7/8 in. long (27.623 cm) by
7-3/4 in. wide (19.685 cm) by
5 in. high (12.700 cm).

Mounting Base Dimensions: 10-7/8 in. long (27.623 cm) by
7-3/4 in. wide (19.685 cm).

Mounting Centers: 7 in. long (17.780 cm) by 7 in. wide (17.780 cm).

Electrical Connectors: Input: MS3102R-22-1P mating MS3106F-22-1S.
Output: MS3102R-22-10S mating MS3106F-22-10P.

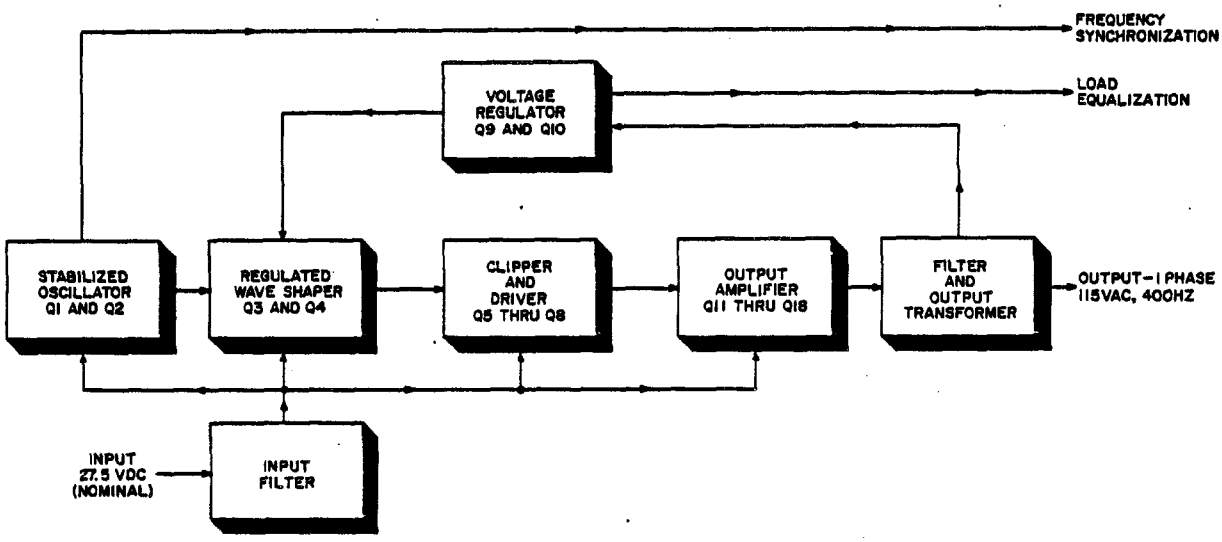
Cooling: Self-cooled by natural convection, conduction and radiation.

Installation: Mounts in any position, without deterioration of power output, heating, operating life, or other operating characteristics.

3. OPERATION.

The subsequent paragraphs cover the theory of operation for the Model DH-1030-24-600-CS Solid-State Static Inverter (Transverter). The Block Diagram Theory will aid in conveying the overall circuit operation to non-technical oriented personnel, while the Detail Circuit Theory will enable the technician to understand in detail the operation of equipment.

A. Block Diagram Theory.



The subsequent paragraphs together with the block diagram of Fig. 2, cover in concise form the signal flow and circuit operation for the Model DH-1030-24-600-CS Solid-State Static Inverter (Transverter).

(1) Input Filter. Power applied through the input filter is free of transients and provided with reverse polarity protection for application to circuits of the Transverter.

(2) Stabilized Oscillator. Transistors Q1 and Q2 generate a 400 Hertz sine wave signal of high stability. The sine wave signal is coupled through auxiliary windings of the oscillator transformer T1 to the input of the regulated wave shaper.

(3) Regulated Wave Shaper. Transistors Q3 and Q4 in a push-pull circuit receive the sine wave signal developed by the stabilized oscillator. Voltage applied from the voltage applied from the voltage regulator circuit determines the shaping operation for optimum efficiency, duty cycle and regulation of the output signal. The shaped output is coupled to the input of clipper circuit.

(4) Clipper and Driver. Transistors Q5, Q6, Q7 and Q8 in cascaded push-pull stages provide additional shaping and amplification of the 400 Hertz signal. The amplified signal is applied to the output amplifier.

Model DH-1030-24-1200-CS, Solid-State Static Inverter (Transverter), Block Diagram
Figure 2

(5) Output Amplifier. Transistors Q11 through Q18 in a push-pull parallel circuit amplify the 400 Hertz signal to the required level across the output transformers for application to the output filter.

(6) Output Transformers and Filter. The output transformers and associated filter circuitry provide matching and shaping to return the amplified signal to a sinusoidal signal.

(7) Voltage Regulator. Transistors Q9 and Q10 develop the regulating bias by comparison of the rectified negative DC voltage supplied from the output, and adjusted by setting of resistor R22, controlling the Zener controlled voltage to the base of transistor Q9.

B. Detailed Circuit Theory

The following sub-paragraphs cover the individual circuits and their operation. Occasional reference to the overall schematic diagram of the Transverter, Fig. 3, will be necessary to determine circuit configuration.

(1) Input Filter. The input filter consists of series reactor L2 and shunt capacitors C17, and C18 providing high speed transient and ripple suppression to the input line. Diode CR19 provides reverse polarity protection for the Transverter circuitry. The input filter and reverse polarity protect diode passes the input current required to maintain rated power output and provide operating voltage and power to Transverter circuits. Over voltage protection for low speed transients is provided by Zener diode. ZR3, resistor R15, and diodes CR2, CR3, CR4, and CR5. If the input voltage exceeds 42 volts, Zener diode ZR3 conducts and applies back bias to transistors Q5 and Q6 through diodes CR3 and CR4, respectively. This bias inhibits switching during over voltage periods and prevents a high voltage from being developed which could damage subsequent amplifier circuits or the output circuit. Diodes CR2 and CR5 protect the base circuits of transistors Q5 and Q6, respectively. Resistor R16 and Zener diode ZR1 provide transient suppression and regulation for the low level stages.

(2) Stabilized Oscillator. The stabilized oscillator utilizes transistors Q1 and Q2 in a Hartley oscillator circuit. Toroidal transformer T1, with multiple windings provides the tuned circuit, feedback, and output windings for the oscillator. The tuned circuit portion is tuned by capacitor C2 to 400 Hertz. Capacitor C1 provides parasitic suppression in the tuned collector circuit. A feedback winding provides the coupling between base-collector circuit to sustain oscillations, resistors R18 and R19 provide bias to the base circuit of transistors Q1 and Q2 to insure positive start and sustained oscillations. Resistor R17 provides degeneration for improved stability of the oscillator circuit. Output to the regulated wave shaper circuit is through the remaining winding on transformer T1. Output direct from the collector of transistor Q1 and tuned circuit is terminated at Pin D of connector J2 for Frequency Synchronization in a multiple inverter system.

(3) Regulated Wave Shaper. The regulated wave shaper receives the 400 Hertz sinusoidal signal from transformer T1 output winding. The input signal is applied to the base circuits of transistors Q3 and Q4 through resistors R1 and R2, respectively, limiting base current which flows in the base circuit. Transistors Q3 and Q4 conduct on alternate half cycles, with the point of conduction determined by the amount of bias supplied by transistor Q10, voltage regulator, to the emitter circuit. The output of this stage is a quasi-square wave and is applied to the input of the clipper circuit.

(4) Clipper and Driver. The clipper and driver circuits provide additional shaping of the signal and amplification for application to the output amplifier circuits. The clipper circuit consists of transistors Q5 and Q6 in a push-pull circuit. The quasi-square wave is applied to the base circuits of transistors Q5 and Q6 through limiting resistors R6 and R7, respectively. The output of the clipper circuit results in a quasi-square wave with improved rise time. The output is coupled to the base circuits of the driver transistors Q7 and Q8 through resistors R11 and R12, respectively. Resistors R13 and R14, provide low impedance return for leakage currents. Output of the collector circuits is developed across toroidal driver transformer T2 and coupled to the output amplifier circuits.

(5) Output Amplifiers. The output amplifiers receive the signal through toroidal driver transformer T2. Four output windings are connected in parallel to provide two outputs which drive the sixteen output transistors Q11 through Q18. Input to the base circuit of each output transistor is through two parallel connected 1 ohm, 2 watt, resistors, providing current limiting to the input. A 4.7 ohm, 2 watt resistor between the base and emitter of each output transistor reduces the impedance during the non-conduction period. The collectors of transistors Q11 through Q18 are parallel connected in groups of four. Q11, Q12, Q13, and Q14 so connected are connected to the high side of transformer T4 while transistors Q15, Q16, Q17, and Q18 are connected to the low side of transformer T4. Diodes CR8 through CR15 connected in parallel with the emitter collector junction of each power transistor provides the path for reverse current flow from the load back to the DC power source under conditions of high reactive loading. Toroidal series reactor transformer T3 is connected across the output transformer T4. The secondary winding of output transformer T4 is connected to the filter circuit.

(6) Output Transformer and Filter. The 400 Hertz quasi-square wave signal developed across toroidal output transformer T4 is high in content of odd order harmonics. Toroidal series reactor transformer T3 in conjunction with the output transformer T4, and the output filter circuit reduce these odd order harmonics. The impedance of the series reactor transformers is low at the 400 Hertz fundamental frequency, but sufficiently high at the frequency of the harmonics to enable the reactor-transformer combination to reduce the harmonic output. The output transformer T4 appears as a high impedance to the fundamental 400 Hertz signal and a low impedance to the harmonics, thus resulting in optimum power transfer at the fundamental frequency of 400 Hertz. The secondary winding of transformer T4 is tuned to the 400 Hertz fundamental by parallel capacitors C14, and C15, forming a parallel tuned circuit, which reflects a high impedance to the fundamental 400 Hertz signal and a low impedance path to the harmonics. The series tuned circuit comprised of capacitor C16 and toroidal reactor L1 is tuned to the third order harmonic 1200 Hertz, providing a shunting effect to the most predominant harmonic present in the output. The additional winding on transformer T4 is used to derive feedback voltage for the voltage regulator circuit. The derived voltage is rectified by diodes CR16 and CR17 to provide a negative DC potential to the voltage regulator circuit. The filtered output is 115 volts AC at a frequency of 400 Hertz and is available at pins A and B of connector J2.

(7) Voltage Regulator. The voltage regulator consists of transistors Q9 and Q10 and Zener diode ZR2. The positive voltage from Zener diode ZR2 and the negative voltage from diodes CR16 and CR17 are applied to the summing resistors R20, R21, and R22 to derive an error voltage at the base of transistor Q9. A change in output voltage, after the setting of resistor R22 has been determined, causes a change in the voltage applied to the summing circuit, developing an error voltage which is amplified by transistors Q9 and Q10. Output at the collector of transistor Q10 results in a proportional voltage change which is the bias applied to transistors Q3 and Q4. This change in bias controls duty cycle and output voltage by limiting action at the input wave shaper circuit. Output direct from the base of Q9 is terminated at Pin C for load equalization in a multiple inverter system.

DISASSEMBLY

1. GENERAL.

This section outlines procedures for disassembly of the Transverter. The procedures should be followed in the event it becomes necessary to repair the unit after a malfunction or part failure. Electrical wiring should not be disconnected except when required for complete removal of a component or sub-assembly or when wiring is found to be defective. When wiring is disconnected, tag each wire and note connection point for ease in identification during reassembly.

2. COVER AND INPUT AND OUTPUT CONNECTIONS NAMEPLATE REMOVAL.

A. Break Phoenix Aerospace, Inc. seal wire, (-65) Fig. 1101, by cutting and remove.

NOTE: In the event Transverter is in warranty, breaking of seal may void warranty unless covered by other contractual agreement.

B. Remove the twenty-eight screws securing cover, (-61), (-62), (-63) Fig. 1101, and remove cover by lifting straight up from base. Place hardware aside for reassembly.

NOTE: Careful attention should be given to the length of screws removed, particularly the lower row on both sides, which are 5/8 inch long. The remaining 20 screws are 3/8 inches long, while the two fillister head screws are 3/8 inches long.

C. Remove input and output connections nameplate, (59) Fig. 1101, lifting at edge of plate, not at the corners, to release adhesive. Place aside for reassembly operation.

CAUTION: DO NOT PLACE NAMEPLATE WITH ADHESIVE SIDE TOWARD PAPER OR AN OILY SURFACE.

3. REMOVAL OF CIRCUIT MODULE-OSCILLATOR/AMPLIFIER/DRIVER SUB-ASSEMBLY.

A. General.

Removal of the Oscillator/Amplifier/Driver Sub-assembly, (52) Fig. 1101, is accomplished to gain access to component side of circuit board or other sub-assemblies of the Transverter Unless board replacement is required interconnecting wires should never be disconnected. Proceed as follows to gain access to the component side of sub-assembly.

B. Removal Procedure.

(1) Loosen and remove the five No. 4-40 x 1/2 inch long flat head, 82° countersink, machine screws, (-53) Fig. 1101, at the connector end of Transverter.

NOTE: These screws were concealed by the Input and Output Connection Nameplate removed in preceding paragraph 2.

(2) Loosen and remove the five No. 4-40 x 1/2 inch long pan head machine screws, (-54) Fig. 1101, at the opposite end of Transverter.

(3) Carefully swing loosened sub-assembly up and over to the side to expose component side of circuit board. DO NOT disconnect wiring unless removal of entire sub-assembly is required.

4. DISASSEMBLY OF OSCILLATOR/AMPLIFIER/DRIVER SUB-ASSEMBLY.

A. General.

Disassembly of the Oscillator/Amplifier/Driber Sub-Assembly is not required unless a printed circuit board, (44) Fig. 1103, is damaged beyond repair and necessitates removal and replacement.

B. Disassembly Procedure.

(1) Carefully identify, disconnect, and tag all wires leading to or from the printed circuit board, (44) Fig. 1103.

(2) Remove the printed circuit board, (44) Fig. 1103, by loosening and removing the four No. 4-40 x 1/2 inch long pan head machine screws, four 5/16 inch long aluminum spacers, four No. 4 internal tooth lock washers, and four No. 4-40 hex nuts, (-45), (-46), (-47), and (-48), Fig. 1103. Place hardware removed aside for use during reassembly.

5. REMOVAL OF INPUT AND OUTPUT FILTER CIRCUIT BOARD SUB-ASSEMBLY.

A. General.

Removal of the Input and Output Filter Circuit Board Sub-Assembly (49) Fig. 1101, is required to gain access to the underside of printed circuit board when parts removal and replacement is required. It is not necessary to remove board completely, therefore, DO NOT disconnect wiring unless board is physically damaged beyond repair.

B. Removal Procedure.

(1) Loosen and remove the four No. 6-32 x 1/2 inch long pan head machine screws, and six No. 6 internal tooth lock washers, (-50), and (-51) Fig. 1101, securing sub-assembly in place. Place hardware aside for use during reassembly.

(2) Carefully lift board to expose underside of printed circuit for component removal and replacement. DO NOT disconnect wiring to board unless sub-assembly removal is required.

6. REMOVAL OF TRANSFORMERS AND REACTORS, TRANSFORMER MOUNTING CHASSIS PAN.

A. General.

Removal of transformers and reactors, (8), (11), (14), and (17) Fig. 1101, should never be accomplished unless replacement is required. In the event replacement is required,

recommended practice would be to replace all four devices and to return the defective part or parts to the factory for repair.

B. Removal Procedure.

(1) Identify and remove Input and Output Filter Circuit Board Sub-Assembly, (49) Fig. 1101, following procedures of preceding paragraph 5.

(2) Disconnect all leads and tag for aid in identification of terminals during reassembly.

(3) Identify and remove the two terminal strips (-37) Fig. 1101, disconnect leads necessary only to remove defective part, identifying carefully all terminals with tags for aid in reassembly.

(4) Identify and remove the six No. 6-32 x 3/8 inch long flat head, 82° countersink, machine screws, (-31), (-33), Fig. 1101, securing the Transformer Mounting Chassis Pan. (4) Fig. 1101, to the Static Inverter (Transverter) Base, (3) Fig. 1101.

(5) Identify the transformer or reactor mounting screw, (-5), (-6), and (-7), Fig. 1101, washer, (-9), (-12), (-15) and (-18), Fig. 1101, and nut (-10), (-13), (-16) and (-19), Fig. 1101, and remove to permit removal from the potting compound.

NOTE: To remove transformers or reactors, potting compound must be broken away before device will separate from Transformer Mounting Chassis Pan. Use care to prevent damage to components not requiring replacement.

CLEANING

1. GENERAL.

This section outlines procedures for cleaning the components of the Transverter while disassembled. Cleaning materials are listed in Table 201.

WARNING: PERFORM OPERATION INVOLVING SOLVENT ONLY IN A WELL VENTILATED AREA. AVOID BREATHING OF SOLVENT VAPOR AND CONTINUOUS CONTACT WITH SOLVENT.

Reference to air jet refers to a hand-operated air nozzle supplied with clean, dry, compressed air at a maximum pressure of 28 psi.

WARNING: GOGGLES SHOULD BE WORN WHEN USING AIR JET TO BLOW DUST AND DIRT FROM EQUIPMENT. OTHER PERSONS SHOULD BE AWARNED AWAY FROM HAZARDOUS AREA OR WORKING ENCLOSURE.

MATERIAL
Trichloroethylene Solvent
Soft-bristled Brush
Stiff-bristled Brush
Soft, Clean Cloth

List of Cleaning Materials
Table 201

2. PRINTED CIRCUIT BOARDS-WIRED CHASSIS.

Remove dust and dirt from all surfaces with a soft-bristled brush in conjunction with an air jet.

NOTE: When the dress of wiring is disturbed, dressing should be noted, and when cleaning is finished, wiring should be restored to proper dress or position.

3. METAL SURFACES.

Clean with soft cloth moistened in trichloroethylene solvent, and dry with clean, dry cloth.

4. CONNECTORS.

A. Wipe dust and dirt from shells using trichloroethylene solvent and a soft cloth. Wipe dry with clean, dry cloth.

B. Remove dust from inserts using small, soft-bristled brush in conjunction with air jet.

INSPECTION/CHECK

1. GENERAL.

This section contains procedures to determine the condition of Transverter.

2. COVER.

Inspect cover for deformations, dents, punctures or surfaces which might be wearing due to interference with other components.

3. CONNECTORS.

A. Inspect for broken parts, damaged shell, and any other abnormal condition.

B. Inspect for broken, cracked, or damaged inserts and for contacts which are broken, deformed, out of alignment. Check for corrosion and signs of arcing at the contacts and for poorly soldered connections.

4. RESISTORS.

Inspect resistors for signs of overheating; cracked, broken, or charred insulation; loose, poorly soldered, or corroded terminal connections; and loose mountings.

5. METAL SURFACES AND MECHANICAL.

Inspect metal surfaces for signs of corrosion. Also check component mountings for mechanical tightness.

6. WIRES.

Check wires for damaged insulation and for proper dress.

REPAIR

1. GENERAL.

This section outlines instructions for the repair or replacement of damaged or defective parts. Faulty parts are usually detected by inspection, cleaning or trouble shooting. The repair or replacement of damaged or defective parts involves standard repair techniques. Identify each wire before removal of any part requiring unsoldering of several lead wires.

2. COVER.

Straighten any deformation, and retouch scratched or worn surfaces.

3. CHASSIS.

Remove all traces of corrosion and recoat with clear epoxy resin where broken or removed during repairs.

Before attempting to solder connections, peel away epoxy resin using a sharp knife.

NOTE: The clear epoxy resin is Armstrong Products Inc. Type T-600 or equivalent. Any time the epoxy coating is disturbed, recoating is advised.

4. CONNECTORS.

Straighten bent pins. Resolder connection and check insulation. If badly damaged, replace connector or insert.

5. SOLDER CONNECTIONS.

Resolder any defective solder joints. Remove all traces of corrosion.

6. WIRING.

Replace any wiring with damaged insulation or broken strands.

7. RESISTORS.

Replace resistors that show signs of overheating or with cracked or broken bodies. Resolder loose, broken or corroded connections.

ASSEMBLY

1. GENERAL.

This section outlines the instructions for assembly of the Transverter. Before assembly of the unit, the Cleaning, Inspection/Check, and Repair Sections should be consulted to determine if all components are properly cleaned and in proper physical and operating condition. Where wiring must be reconnected, good practices must be followed in dressing of wires and soldering connections. Refer to Fig. 1101 for identification and location of sub-assemblies and component parts.

2. INSTALLATION OF TRANSFORMERS AND REACTORS, TRANSFORMER MOUNTING CHASSIS PAN.

A. General.

Assembly of transformers and reactors (8), (11), (14) and (17) Fig. 1101, requires the use of epoxy resin similar to Dow Corning Type D.E.R. 330 with aluminum oxide filler and Dow Corning curing agent. The epoxy resin replaces any removed during the removal of transformers or reactors, and must be replaced to properly heat sink the unit and the transformers and reactors. In the event complete removal was not necessitated, disregard those steps not applicable and complete assembly procedures.

B. Assembly Procedures.

(1) Identify the appropriate mounting screw for the transformer and/or reactor and mount through chassis pan. Secure in place using the No. 10 internal tooth lock washer and No. 10-32 hex nut or No. 8 internal tooth lock washer and No. 8-32 hex nut. DO NOT overtighten hardware.

(2) Replace epoxy resin by preparing the resin in accordance with manufacturer's instructions and adding the aluminum oxide filler in a ratio of 30% by weight. Block ends of Transformer Mounting Chassis Pan to prevent compound from running out and fill to approximately 1/4 inch deep with potting compound. Allow curing to take place and proceed with subsequent steps.

(3) Assemble Transformer Mounting Chassis Pan to Static Inverter (Transverter) Base. Place a thin layer of Dow Corning No. 4 Compound, silicone lubricant between chassis pan and base. Secure, using the six No. 6-32 x 3/8 inch long flat head, 82° countersink, machine screws into the spacer blocks on the chassis pan.

(4) Identify the two terminal strips and position over the 1-1/16 inch high aluminum spacer posts. These units are secured by hardware which will be installed in subsequent paragraphs.

(5) Identify the Input and Output Filter Circuit Board Sub-Assembly, (49) Fig. 1101, and reinstall per procedures of subsequent paragraph 3. B.

(6) Identify leads disconnected during removal procedures and carefully reconnect and solder at the proper points.

3. INSTALLATION OF INPUT AND OUTPUT FILTER CIRCUIT BOARD SUB-ASSEMBLY.

A. General.

Installation of Input and Output Filter Circuit Board Sub-Assembly, (67) Fig. 1101, requires care in reconnecting of leads disconnected during disassembly procedures.

B. Assembly Procedures.

(1) Carefully reconnect leads disconnected during disassembly or removal.

(2) Identify the four No. 6-32 x 3/8 inch long pan head machine screws, four No. 6 internal tooth lock washers, (-50), and (-51) Fig. 1101, align with holes in the two terminal strips positioned in preceding paragraph 2B.(4), (-37) Fig. 1101, and secure to aluminum spacers on Transformer Mounting Chassis Pan.

4. ASSEMBLY OF OSCILLATOR/AMPLIFIER/DRIVER SUB-ASSEMBLY.

A. General.

Assembly of the Oscillator/Amplifier/Driver Sub-Assembly, (53) Fig. 1101, consists of mounting the Oscillator/Amplifier/Driver Circuit Board Sub-Assembly, (Fig. 1103, and reconnection of the leads disconnected during removal procedures.

B. Assembly Procedures.

(1) Identify the four No. 4-40 x 1/2 inch long pan head machine screws, four .1875 inch x 5/16 inch long aluminum spacers, four No. 4 internal tooth lock washers, and four No. 4-40 hex nuts, (-45), (-46), (-47), and (-48), Fig. 1103, and use to secure the Oscillator/Amplifier/Driver Circuit Board Sub-Assembly, (52) Fig. 1101.

(2) Identify and reconnect leads disconnected at time of disassembly.

5. INSTALLATION OF CIRCUIT MODULE OSCILLATOR/AMPLIFIER/DRIVER SUB ASSEMBLY.

A. General.

Reinstallation of the Circuit Module-Oscillator/Amplifier/Driver Sub-Assembly, (52) Fig. 1101, is completed as follows.

B. Assembly Procedures.

(1) Reconnect any wires removed during disassembly and restore lead dress.

(2) Carefully swing sub-assembly over and down between ends of Transverter Base, (3) Fig. 1101, with components on circuit board toward interior of Transverter, and the exterior of transistors up toward cover.

(3) Identify the five No. 4-40 x 1/2 inch long flat head, 82° countersink, machine screws, (-53) Fig. 1101, and secure sub-assembly from connector end, tighten securely.

(4) Identify the five No. 4-40 x 1/2 inch long pan head machine screws, (-54) Fig. 1101, and secure sub-assembly from opposite end of unit, tighten securely.

INSTALLATION OF INPUT AND OUTPUT CONNECTIONS NAMEPLATE.

A. Carefully center Input and Output Connections Nameplate above the input and output connectors and press firmly in place to cause adhesive to stick to metal surface.

B. Place cover over unit and secure in place with hardware removed during disassembly in the following sequence:

(1) Identify the six No. 4-40 x 5/8 inch long pan head machine screws and install at the bottom edge of cover.

(2) Identify the two No. 4-40 x 3/8 inch long fillister head (drilled) machine screws at the front, connector end, lower edge left and right.

(3) Identify the twenty No. 4-40 x 3/8 inch long pan head machine screws and completely secure cover to Transverter base.

CAUTION: UNDER NO CIRCUMSTANCES SHOULD HARDWARE LONGER THAN 3/8 INCH BE USED AT THE CENTER ROW, LEFT AND RIGHT SIDE, TO SECURE COVER.

(4) Place new PAI Warranty Lead Seal tie wire through the drilled holes on fillister head screws and seal by crimping.

FITS AND CLEARANCES

Not Applicable to Solid-State Static Inverter.

No moving parts required.

TESTING

1. GENERAL.

This section defines test procedures for the Model DH-1030-24-600-CS Solid-State Static Inverter (Transverter). The procedures given are in sequential step form and test the unit completely. When the results of any step or test are not achieved the trouble shooting section of this manual should be consulted.

2. PERFORMANCE TESTS.

Performance tests are designed to provide a fast efficient method for complete check-out of the Transverter. Included in this paragraph is a list of test equipment required, the minimum performance requirements of the unit and procedures for connecting the unit for test.

A. Test Equipment Required.

The test equipment required to accomplish the performance tests consist of the following: Specially designed Test Set; 0-40 volt, 50 Ampere DC Power Supply; Oscilloscope; Distortion Analyzer; Frequency Counter; and Voltohmmeter. This equipment is listed and described in the Special Tools Section of this manual.

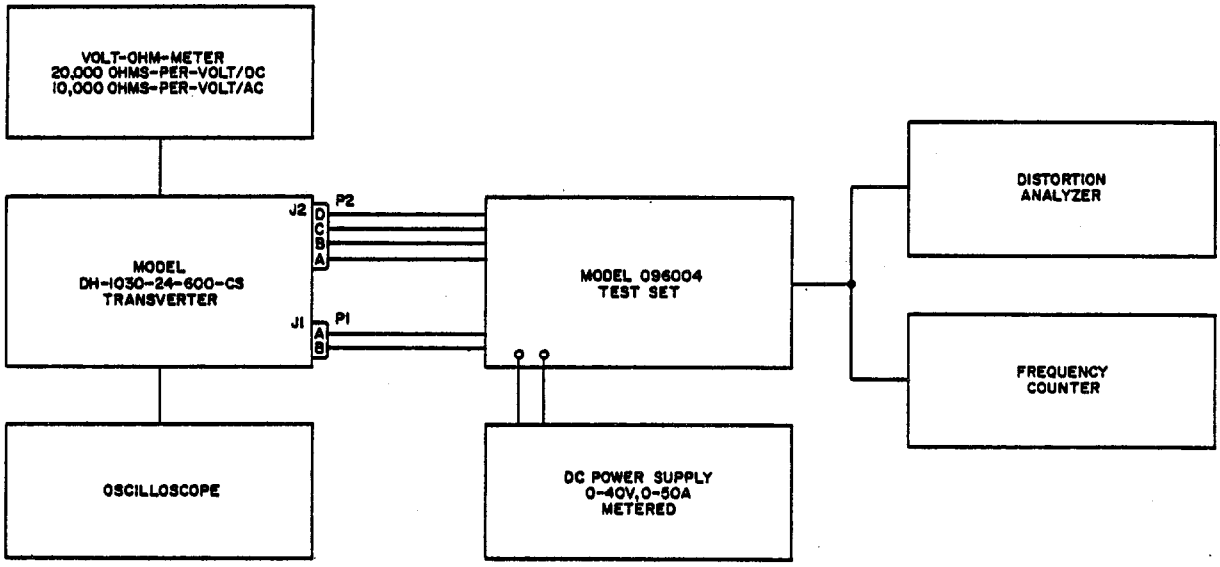
B. Minimum Performance Requirements.

The minimum performance requirements of the Model DH-1030-24-600-CS Solid-State Static Inverter (Transverter) is to supply 115 volts, 400 Hertz sine wave, single phase, alternating current at 400 VA to operate aircraft instrumentation devices. Input power of 27.5 volts DC (nominal) is obtained from the aircraft's storage battery.

C. Preparation for Testing.

Complete the following steps to prepare Transverter for testing. Refer to Fig. 701 for equipment and interconnection.

(1) Connect Test Set to Transverter, LOAD switch in OFF position on Test Set. LOAD SELECTOR switch in 400 VA 1.0 - UNITY position.



(2) Connect DC Power Supply to Test Set terminals E1 and E2, output set to zero. Note polarity when connecting.

(3) Connect Distortion Analyzer to Test Set, connecting across AC voltmeter M2. FUNCTION switch at DISTORTION, FREQUENCY RANGE at X10 position, METER RANGE as required to read distortion level, FREQUENCY, COARSE at 40.

(4) Connect Frequency Counter to Test Set, connecting across AC voltmeter M2. Set to measure frequency of 400 Hertz ±4 Hertz per second.

D. Performance Test.

The procedures of the performance test listed in numbered steps in Table 701 should be accomplished in the sequence presented. In the event the required result is not obtained, the trouble shooting section should be consulted and the malfunction corrected before proceeding to the next step.

Test Set-up, Model DH-1030-24-600-CS
Solid-State Static Inverter (Transverter)
Figure 701

STEP	SET-UP	PROCEDURE	RESULT
1	Interconnect per Fig. 701 and para. 2.C. LOAD switch in OFF position on test set.	(a) Apply power to all measuring equipment for warm-up. (b) Check polarity of DC Power Supply and connection to Test Set.	
2	LOAD switch in OFF position on Test Set.	Increase DC Power Supply Voltage to 27.5 volts DC as indicated on DC VOLTS meter M3 on Test Set.	Input current as indicated by DC AMPERES meter M4 on Test Set should not exceed 2.0 Amperes.
3	LOAD SELECTOR switch set to 1.0 UNITY-400 WATTS position. LOAD switch in ON position on Test Set.	(a) Input voltage set at 27.5 volts DC. (b) Adjust resistor R22 as required for reading 115 volts AC. (c) Vary input voltage from 20 to 30 volts DC.	Input current as indicated by DC AMPERES meter M4 on Test Set should not exceed 18.0 Amperes. Output voltage of pins A and B as indicated by AC VOLTS meter M2 on Test Set should be 115 volts AC. Output current of pin B as indicated by AC AMPERES meter M1 on Test Set should be approximately 3.48 Amperes. Input current as indicated by DC AMPERES meter M4 should vary from 16.0 to 18.0 Amperes with changing input voltage.
4	LOAD SELECTOR switch set to 1.0 UNITY-400 WATTS position. LOAD switch in ON position on Test Set. Frequency counter across AC VOLTS meter M2 on Test Set per para. 2.C.(4).	(a) Input voltage set at 27.5 volts DC. (b) Adjust frequency by selection of capacitor C5 in oscillator circuit.	Input current as indicated by DC AMPERES meter M4 on Test Set should not exceed 18.0 Amperes. Frequency Counter should read 400 Hertz ±4 Hertz.
5	LOAD SELECTOR switch set to 1.0 UNITY-400 WATTS position. LOAD switch in ON position on Test Set. Distortion Analyzer across AC VOLTS meter M2 on Test Set per para. 2.C.(3).	(a) Input voltage set at 27.5 volts DC. (b) Vary input voltage from 20 to 30 volts DC. Take readings at 20, 22, 24, 26, 28 and 30 volts DC.	Distortion Analyzer should read less than 5% distortion with changing input voltage, typical reading 2.0 to 3.9%. Distortion Analyzer should always read less than 5% distortion with changing input voltage, typical reading 2.0 to 3.9%.

STEP	SET-UP	PROCEDURE	RESULT
6	LOAD switch in OFF position on Test Set.	Input voltage set at 27.5 volts DC.	Input current as indicated by DC AMPERES meter M4 should not exceed 2.0 Amperes. Output voltage as indicated by AC VOLTS meter M2 should not exceed 120 volts AC. Frequency Counter should read 400 Hertz ±4 Hertz. Distortion Analyzer should read less than 5% distortion, typical reading 2.5 to 3.5%.
7	LOAD SELECTOR switch set to .8 LAG-400 VA position. LOAD switch in ON position on Test Set. Frequency Counter and Distortion Analyzer connected as in preceding steps 4 and 5.	Input voltage set at 27.5 volts DC.	Input current as indicated by DC AMPERES meter M4 should not exceed 15.0 Amperes. Output voltage as indicated by AC VOLTS meter M2 should be 115 volts AC ±2 volts, typical reading 114 to 115 volts AC. Frequency Counter should read 400 Hertz ±4 Hertz. Distortion Analyzer should indicate less than 5% distortion, typical reading 2.5%.
8	LOAD SELECTOR switch set to .95 LEAD-400 VA position. LOAD switch in ON position on Test Set. Frequency Counter and Distortion Analyzer connected as in preceding steps 4 and 5.	Input voltage set at 27.5 volts DC.	Input current as indicated by DC AMPERES meter M4 should not exceed 18.0 Amperes. Output voltage as indicated by AC VOLTS meter M2 should be 115 volts AC ±2 volts, typical reading 116 volts to 117 volts AC. Frequency Counter should read 400 Hertz ±4 Hertz. Distortion Analyzer should indicate less than 5% distortion, typical reading 3.0%.
9	LOAD SELECTOR switch set to 150% LOAD-600 WATTS position. LOAD switch in ON position on Test Set. Frequency Counter and Distortion Analyzer connected as in preceding steps 4 and 5.	Input voltage set at 27.5 volts DC.	Input current as indicated by DC AMPERES meter M4 should not exceed 25.0 Amperes. Output voltage as indicated by AC VOLTS meter M2 should drop to approximately 110 volts AC, typical reading 109 to 112 volts AC. AC AMPERES meter M1 on Test should not exceed 5.5 Amperes. Frequency Counter should read 400 Hertz ±4 Hertz. Distortion Analyzer should indicate less than 5% distortion, typical reading 3.5%.
10	LOAD SELECTOR switch set to 115V AC SHORT 5 SEC MAX. LOAD switch in ON position on Test Set.	Input voltage set at 27.5 volts DC. Press SHORT button and release.	Input current as indicated by DC AMPERES meter M4 should indicate between 30 to 40 Amperes. AC Amperes should be between 6 to 9 Amperes on AC AMPERES meter M1.

TROUBLE SHOOTING

1. GENERAL.

This section outlines in tabular form information for use in localization and isolation of trouble in the Model DH-1030-24-600-CS Solid-State Static Inverter (Transverter). The trouble shooting procedures, Table 801, together with the information given in preceding section on Testing will in most cases localize and isolate the trouble. Reference to the schematic diagram, Fig. 1201, and the section on Detailed Theory will be necessary and helpful. The voltage measurements of Table 802 in conjunction with the waveforms illustrated in Fig. 801 will aid in isolation of trouble.

TROUBLE SHOOTING.

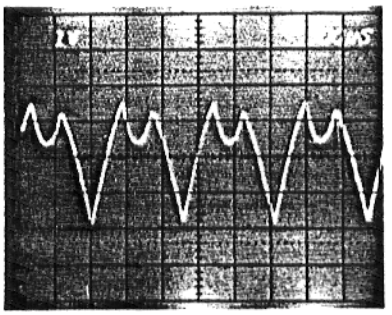
A. Localization.

The trouble shooting table, Table 801, provides a means of localizing malfunctions to a replaceable component or sub-assembly. The table is arranged in the same order of precedence as the performance tests, Table 701, in the preceding section. The applicable step of the performance test is shown in parentheses next to the trouble shooting step in the STEP column, in Table 801.

B. Isolation.

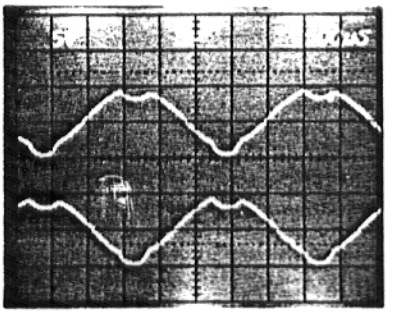
The voltage measurements of Table 802 are made using the voltohmmeter described in the Special Tools Section of this manual. Reference to the schematic diagram while making voltage measurements will aid in isolation of trouble within the unit.

C. Analysis.



The waveforms pictured in Fig. 801 were made using the oscilloscope described in the Special Tools Section of this manual, and will aid in analyzing the equipment performance when trouble shooting procedures are being performed.

Trouble Shooting Chart
Table 801 (Sheet 1 of 2)



STEP	SYMPTOM	PROBABLE CAUSE	CHECK	REMEDY
1(2)	No current drain.	Transistor Q1 or Q2 inoperative.	Check voltage at base, collector, and emitter of Transistors Q1 and Q2 for proper voltage.	Replace defective transistors.
		Input polarity reversed.	Check connection of DC Power Supply and polarity of output.	Reverse input connection.
		Polarity protect Diode CR18 open.	Check continuity of circuit through Diode CR19 and Reactor L2.	Replace defective diode.
2(2)	High current drain.	Transistors Q7 or Q8 defective, shorted.	Check voltages at base, collector, and emitter of Transistors Q7 and Q8 for proper voltage.	Replace defective transistors.
3(3)	AC output voltage high or low, no load.	Resistor R20 not adjusted.	Check operation of Resistor R22 by adjustment noting change in output voltage.	Adjust Resistor R22 to obtain proper output.
		Transistor Q9 or Q10 defective.	Check voltages at base, collector, and emitter of Transistors Q9 and Q10 for proper voltage.	Replace defective transistor.
		Zener Diode ZR2 defective.	Check voltage at Zener Diode ZR2.	Replace defective Zener diode.
		Diodes CR16 and CR17 defective.	Check for presence of negative voltage at junction of Diodes CR16 and CR17 and Resistor R22.	Replace defective diode.
4(4)	Frequency high or low.	Capacitor C1 defective or of improperly selected value.	Check value and test by substitution for proper value.	Replace defective capacitor.
5(5)	Distortion above 5%.	Zener Diode ZR1, or Capacitors C14, C15, or C16 defective.	Check voltage at junction of Zener Diode ZR1, and Resistors R20, R21, and R22 for proper value 15 volts ±5%.	Replace defective Zener diode.
			Check capacitors for excess leakage or open condition.	Replace defective capacitor.
6(6)	AC output voltage high or low, with 800 VA 1.0-UNITY P.F. Load.	Repeat preceding step 3(3).	Repeat preceding step 3(3).	Repeat preceding step 3(3).

STEP	SYMPTOM	PROBABLE CAUSE	CHECK	REMEDY
7	AC output voltage cannot be increased to 115 volts AC.	Defect in control circuit, Transistor Q10, Resistor R22, Diodes CR16 and CR17, or Zener Diode ZR3.	Short emitter of Q3 and Q4 to negative buss or -27.5 volt DC point, voltage will increase to approximately 135 volts AC.	Replace defective component in control circuit.
8	Transistors Q7 and/or Q8 operate with high heat rise.	Transistors Q5 and/or Q6 low output or inoperative.	Check voltages and waveforms at transistor elements.	Replace defective transistor or pair of transistors.
9	Transverter output drops off when input voltage exceeds 26 to 28 volts DC.	Zener Diode ZR3 shorted.	Check voltages at Zener Diode ZR3 and resistor network associated with diode.	Replace defective Zener diode.
10	Transverter operates on pre-installation check, will not operate in aircraft.	Defect in aircraft wiring.	Check for voltage at breaker and primary power source in aircraft.	Correct wiring defect.
			Check for shorted load by opening breaker to AC load in aircraft while power is applied to input.	Correct short in line or load.
		Defective Transformer T4 shorted primary to secondary.	Check transformer for short between primary and secondary winding.	Replace defective transformer.

STORAGE INSTRUCTIONS

1. GENERAL.

This section provides information preparing the Model DH-1030-24-600-CS Solid-State Static Inverter Transverter) for use from a shipped or stored condition and for packing the unit for storage or shipment.

2. PREPARATION FOR USE.

The Transverter, when shipped from the factory, is wrapped in cellulose wadding, PPP-C-843, and inserted in a poly bag, LP-378, and enclosed in a corrugated shipping carton, PPP-B-636. To unpack the unit, cut sealing tape and open top of carton by lifting flaps to break adhesive. Remove unit from carton, remove poly bag and cellulose wadding. Visually examine the unit for damage which might have occurred during shipment or storage.

3. PREPARATION FOR STORAGE OR SHIPMENT.

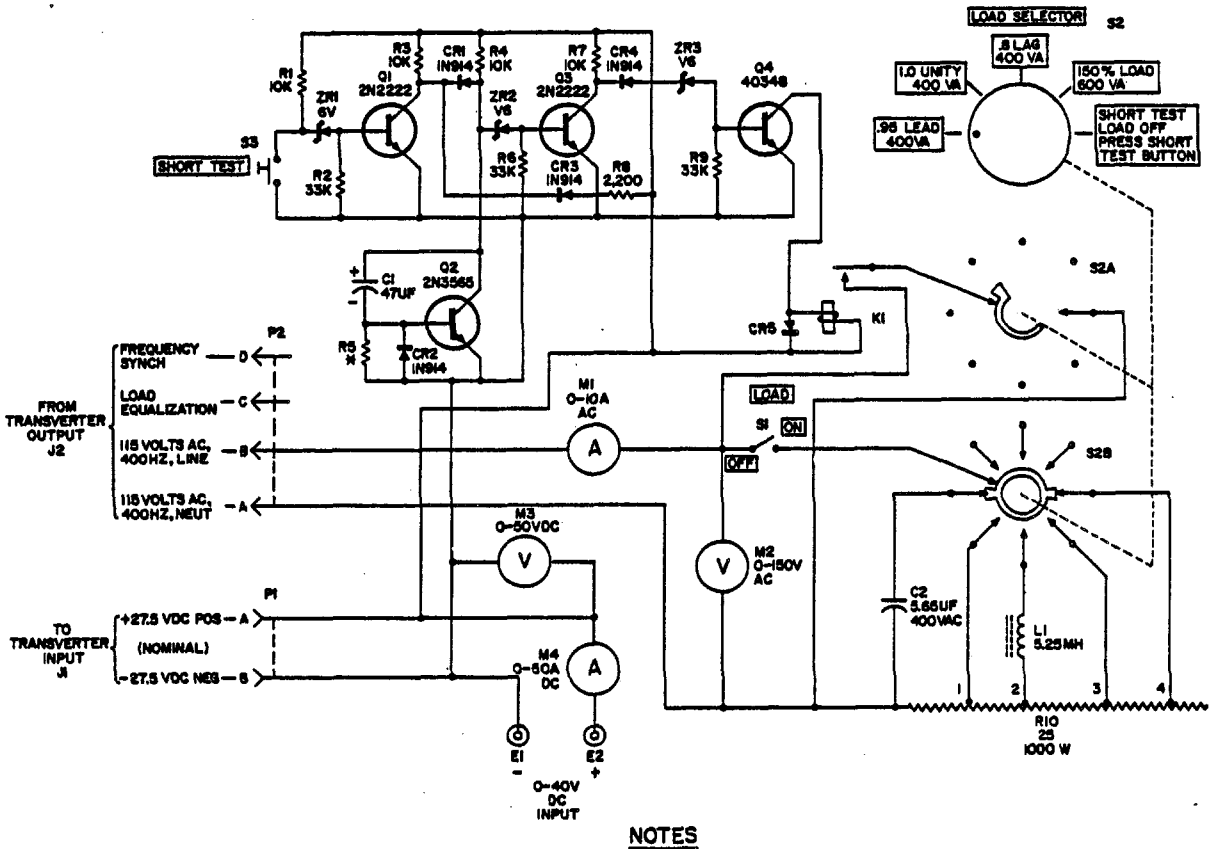
The Transverter may be stored for short periods of time without packing. If the unit is to be stored for extended periods or is to be shipped, carefully wrap unit with cellulose wadding, insert in poly bag and place equipment in a corrugated carton. The carton should then be sealed and labeled for storage.

SPECIAL TOOLS, FIXTURES AND EQUIPMENT

1. GENERAL.

This section provides information on the special tools and test equipment required for overhaul of the Model DH-1030-24-600-CS Solid-State Static Inverter (Transverter).

2. STANDARD TEST EQUIPMENT.



Listed in Table 1001 are the items of standard test equipment required for overhaul of the Transverter. The listed item or suitable equivalent may be used if procedures are modified when references to test equipment are made.

EQUIPMENT	MANUFACTURER AND MODEL NUMBER	
OSCILLOSCOPE	HEWLETT-PACKARD	MODEL 132A
DISTORTION ANALYZER	HEWLETT-PACKARD	MODEL 333A
FREQUENCY COUNTER	HEWLETT-PACKARD	MODEL 5512A
VOLTOHMMETER	TRIPLETT ELECT. INST.	MODEL 800
DC POWER SUPPLY	0-40 VOLTS DC 0-50 AMPERES	

Standard Test Equipment
Table 1001

3. SPECIAL TEST EQUIPMENT.

The special test equipment consists of only one item. This is a Test Set available either from Phoenix Aerospace, Inc. or readily fabricated locally. The toroidal reactor is available separately from Phoenix Aerospace, Inc. when the user desires to fabricate the Test Set. The schematic diagram is shown in Fig. 1001. All parts are listed with values and ratings to aid in local procurement for fabrication.

NOTES

1. RESISTOR R10 TAP#1 = 14.55Ω; TAP#2 = 17.6Ω; TAP#3 = 22.0Ω; TAP#4 = 23.15Ω.
2. P1, PENDANT CONNECTOR PLUG MS3106F-24-9S MATES WITH RECEPTACLE J1, MS3102R-24-9P.
3. P2, PENDANT CONNECTOR PLUG, MS3106F-24-22P, MATES WITH RECEPTACLE J2, MS3102R-24-22S.
4. INDUCTOR L1, PHOENIX AEROSPACE, INC. PART NO. 038014, REACTOR, POWER, TOROIDIAL.

Figure 1001

ILLUSTRATED PARTS CATALOG SECTION

1. INTRODUCTION.

This section of the Overhaul Manual provides a complete listing of parts for the Model DH-1030-24-600-CS Solid-State Static Inverter (Transverter), as manufactured by Phoenix Aerospace, Inc.

2. PURPOSE.

The information contained in this section is supplied to aid in provisioning, requisitioning, storing, and issuing of the replaceable parts, and to aid in identification of new and reclaimed parts.

3. APPLICATION.

The Illustrated Parts Catalog Section contains three separate listings; Numerical Index, Symbol Index, and Detailed Parts List. The subsequent paragraphs define the content and application of each listing.

A. Numerical Index.

The Numerical Index provides an alpha-numerical listing of the parts listed in the Detailed Parts List. The prime function being to aid in rapid location using the information contained in the various columns.

(1) Part Number Column.

The PART NUMBER column lists part numbers of procurable parts and assemblies as listed in the Detailed Parts List. Parts are listed in alpha-numerical order of precedence starting at the first letter extreme left and reading to the right as follows:

Letters A through Z
Numerals 0 through 9
(Alphabetical 0's are considered as Numerical zeros).

Second and succeeding positions of the part number appear in the order of precedence as follows:

Space (Blank column)
Diagonal (Slant) /
Point (Period)
Dash (-)
Letters A through Z
Numerical 0 through 9
(Alphabetical 0's are considered as numerical zeros).

(2) Airline Part Number Column.

The AIRLINE PART NO. column is provided to allow insertion where applicable, of the users own part number where available and desired.

(3) Chapter-Section-Unit-Figure-Item Column.

The CH-SECT-UNIT-FIG-ITEM column contains the specific location data where the listed part first appears in the Detailed Parts List and other pertinent data. Example: 24-20-X-1101-18 is indicative of the following:

24 is significant of the Chapter (derived from system identification numbers).
20 is significant of the Section (derived from sub-system identification numbers).
X is significant of the Unit (derived from the application of particular unit).
1101 is significant of the Figure number.
18 is significant of the Item number.

(4) Total Required Column.

The TTL REQ. column is the total of each item required in the unit whether it be piece part or sub-assembly.

B. Symbol Index.

The Symbol Index enables the location of component parts referenced from the schematic diagram by the reference symbol to a specific Figure and Item number.

(1) Symbol Column.

The SYMBOL column contains an alpha-numerical listing of every component part which carries a reference symbol on the schematic diagram.

(2) Part Number Column.

The PART NUMBER column lists the vendor part number of the symbolized item.

(3) Chapter-Section-Unit-Figure-Item Column.

The CH-SECT-UNIT-FIG-ITEM column contains the specific location data where the listed part appears in the Detailed Parts List and other pertinent data. (See preceding para. 3.A.(3) for example of information.

C. Detailed Parts List.

The Detailed Parts List, is a breakdown of the complete unit into sub-assemblies and detailed parts. Each sub-assembly is listed in its order of disassembly and is followed immediately by its component parts properly indented to show its relationship to the assembly.

(1) Figure Item Column.

The FIG. ITEM Column entries key the parts breakdown to the applicable illustration. Items numbered on the Detailed Parts List preceded by a dash (example -1) do not appear on the illustration.

(2) Part Number Column.

The PART NUMBER column lists the applicable Standard part number MS, AN, NAS, etc., vendor part number or Phoenix Aerospace, Inc. part numbers. When more than one part number is assigned to an item the preference shall be Standard MS, AN, NAS, etc., vendor, or Phoenix Aerospace, Inc., in that order. Vendor part numbers listed in the PART NUMBER column are subject to change without notice.

(3) Nomenclature Column.

The NOMENCLATURE column describes the assembly, sub-assembly, or component part in a short form description, with the identifying Noun as the first word, followed by the modifiers as required. The indentations denote parts relation to next higher assembly (NHA) or sub-assembly, as applicable. The ATTACHING PARTS entries are listed immediately following the component which they attach.

If a part is purchased by Phoenix Aerospace, Inc. from a vendor, the Federal Supply Code number, preceded by the letter V, is listed in this column, and set off by parentheses. The vendors part number appears in the PART NUMBER column and the Phoenix Aerospace, Inc. part number follows the vendor, FSC number, and is set off in parentheses. If a part number or FSC number does not appear in the NOMENCLATURE column the part number listed in the PART NUMBER column is a Phoenix Aerospace, Inc. number.

(4) Effect From To Column.

The EFFECT FROM TO column provides for entries regarding usage on different models or for field service bulletin entries as applicable. If this column is left blank, parts apply to all models until otherwise noted by revision.

(5) Units Per Assembly Column.

The UNITS PER ASSY column lists the quantity of sub-assemblies or parts required in the next higher assembly (NHA). The quantities specified, therefore, are not necessarily the total used per equipment. The letters RF denote that the item listed appears on another list and illustration and is referenced for aid in identification only.

4. VENDOR FEDERAL SUPPLY CODE AND NAME INDEX.

The following list is derived by extraction from the Federal Supply Catalog Handbook H4-1. The information is supplied to aid in procurement and identification of the various vendors.

FSC NO. OR CODE	VENDORS NAME AND ADDRESS
01121	Allen Bradley Co. 1201 South 2nd St. Milwaukee, Wisconsin 53204
01281	Electronics Components TRW Semiconductors, Div. 14520 Aviation Blvd. Lawndale, California 90260

4. VENDOR FEDERAL SUPPLY CODE AND NAME INDEX. (Cont.).

FSC NO. OR CODE	VENDORS NAME AND ADDRESS
01295	Texas Instruments, Inc. Semi-Cond-Comp Div. 13500 North Central Expressway Dallas, Texas 75231
02735	RCA Corp., Solid State Div. Route 202 Sommerville, N. J. 08876
07263	Fairchild Semiconductor, A Div. of Fairchild Camera & Instr. Corp. 4300 Redwood Highway San Rafael, California 94903

REVISION CODE	REVISION DESCRIPTION	SERIAL NO. EFFECTIVITY
A	CR8 THROUGH CR15 CHANGED TO 1N5624	22 SEP 71
B	CHANGED CAPACITOR C16 TO MYLAR FOIL WRAP AND FILL 1.25 UF 600VDC.	18 DEC 71
C	Q7, Q8, Q11, Q12, Q13, Q14, Q15, Q16, Q17 AND Q18 CHANGED TO RCA 64497. REMOVED CAPACITOR C-11 0.1 UF. CHANGED CAPACITORS C14 AND C15 TO 6 UF, ±3%, 115 VAC, 400 HZ, METALIZED POLYCARBONATE.	22 JUN 73
D	REMOVED CAPACITOR C10 1 UF. REMOVED CAPACITOR C19 1400 UF. CHANGED VALUE OF CAPACITORS C17 AND C18 TO 2300 UF. ADDED CAPACITOR C1A (SELECTED).	12 OCT 73

Model DH-1030-24-600-CS, Solid-State Static Inverter
(Transverter) Revision Reference Sheet
Figure 1201 (Sheet 1 of 2)

NOTES:

1. RESISTORS ARE 1/2W, 10% TOLERANCE UNLESS OTHERWISE SPECIFIED. CAPACITOR VALUES ARE IN UF (MICROFARADS) UNLESS OTHERWISE SPECIFIED.
2. CIRCUIT DOES NOT GROUND TO CHASSIS.
3. CAPACITOR C2 SELECTED TO TUNE OSCILLATOR TO 400 HZ. VALUE FROM 0.02 TO 0.047 UF.
4. CAPACITOR C16 IS MYLAR FOIL WRAP AND FILL. DO NOT SUBSTITUTE.
5. CAPACITORS C14, C15 ARE 6.0 UF ± 3%, 115 VAC, 400 HZ, METALIZED POLYCARBONATE.
6. CONNECTORS

PHOENIX AEROSPACE INC. STANDARD WARRANTY

1. Sellers Standard Warranty

(a) Phoenix Aerospace, Inc. herein called Seller, warrants that each unit delivered shall, at the time of delivery thereof to Buyer or Buyer's customers, be free from defects in material and workmanship and from defects or faults in design in view of the state of the art at the time of design thereof. Any defect must have become apparent and Buyer must have notified Seller thereof within twenty-four (24) months after installation in aircraft, not to exceed thirty (30) months after date of manufacture on unit nameplate. The extent of Seller's liability is limited to the repair, replacement, overhaul, or modification of any defective unit.

(b) Seller's obligation hereunder is conditioned upon the return as soon as practicable of the defective unit with all transportation charges prepaid to Seller in Kansas City, Missouri. Returned units must be accompanied by properly authorized Purchase Order, specifying the nature of the defect, if known, and containing reasonable proof to Seller that the defect is due to a matter embraced within Seller's warranty. An allowance will be made for inbound transportation charges in the Continental United States, but inbound transportation charges are the responsibility of Buyer outside the limits of the Continental United States. Overhauled or repaired units will be returned via air, transportation charges prepaid to destination anywhere in the world. Removal of the unit from any aircraft and reinstallation shall be at Buyer's expense.

(c) The warranty hereunder shall not apply to any unit installed in any Aircraft if such Aircraft shall not have been operated in accordance with the Federal Aviation regulations issued by the Federal Aviation Administration, or if such unit shall not have been operated or maintained in accordance with seller's instructions applicable to such unit, or if such unit shall have been repaired, altered or modified without Seller's approval, or operated with an accessory or part not authorized for use therewith, or if such unit shall have been operated subsequent to its involvement in an accident, or if the unit shall have been subject in any way to improper operation, maintenance, repair, alteration or modification.

(d) THE WARRANTY AND THE OBLIGATIONS AND LIABILITIES OF SELLER HEREUNDER ARE EXCLUSIVE AND IN SUBSTITUTION FOR AND BUYER HEREBY WAIVES ALL OTHER WARRANTIES, EXPRESS OR IMPLIED, ARISING BY LAW OR OTHERWISE (INCLUDING, WITHOUT LIMITATION, THE IMPLIED WARRANTY OR MERCHANTABILITY, ANY IMPLIED WARRANTY ARISING FROM COURSE OF PERFORMANCE, COURSE OF DEALING OR USAGE OF TRADE, ANY IMPLIED WARRANTY OF FITNESS, AND ANY OBLIGATION OF SELLER WITH RESPECT TO INCIDENTAL OR CONSEQUENTIAL DAMAGES). AND SHALL NOT BE EXTENDED, ALTERED OR VARIED EXCEPT BY A WRITTEN INSTRUMENT SIGNED BY SELLER AND BUYER.

2. General Instructions

(a) Overhaul, modification or repair of all Phoenix Aerospace units is authorized only at Seller's facility. Any overhaul, repair, alteration or modification without Seller's approval will negate or void the terms of Seller's Standard Warranty stated herein. Units in need of repair should be shipped directly to:

Phoenix Aerospace Inc.
220 West 80th Terrace
Kansas City, Missouri 64114
U.S.A.

Units in warranty are repaired at the factory under the terms and conditions of Seller's Standard Warranty at no charge. There will be a charge imposed for Units returned within the warranty period which are found not to be defective or for a defect found not to be included within Seller's Standard Warranty or which have been removed or returned as a result of any program of preventive maintenance.

(b) Units out of warranty are repaired at the factory at Seller's standard charge in effect at the time of receipt of unit. Inbound and outbound transportation charges are the responsibility of the Buyer.

PHOENIX AEROSPACE INC.

TABLE OF CONTENTS

INTRODUCTION

In conformance with A.T.A. Specification No. 100 for Manufacturers' Technical Data, two manuals have been prepared concerning the PAI P.N. DH-1030-24-600-CS, Type IIB, Solid-State Static Inverter (Transverter). These manuals, if used as intended, will facilitate the effective, continued operation of the equipment. Technical data is grouped according to usage in the manual as described.

MAINTENANCE MANUAL

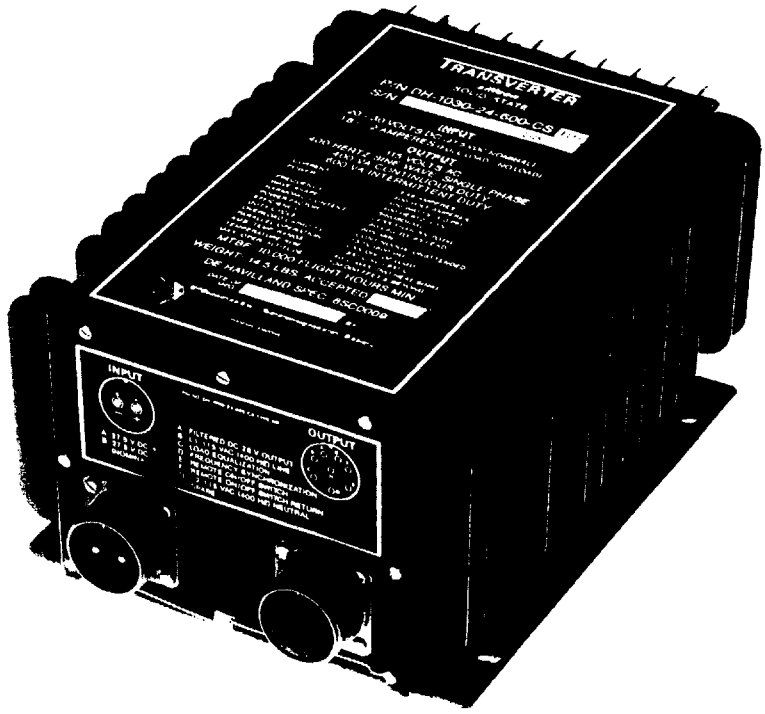
This manual is intended for use by flight line and hangar maintenance personnel. A detailed description and operation, including a table of leading particulars are presented for reference. Mounting and cabling information are presented as an aid to installation. Troubleshooting information is limited to procedures required to trace a trouble to the overall unit for replacement,

OVERHAUL MANUAL WITH ILLUSTRATED PARTS CATALOG

The Overhaul Manual contains all the information required for shop testing, replacement of defective parts, adjustment, mechanical disassembly, inspection, and reassembly. Detailed circuit theory is given with emphasis on theory that will be especially helpful for effective troubleshooting. Performance tests as well as functional (go/no-go) checks, which may be used to determine condition of equipment and for retesting after repairs.

The Illustrated Parts Catalog provides a means to determine the manufacturer's part number and the physical location on the equipment of a part if the reference designation is known, or to determine the reference designation and the manufacturer's part number when the physical location of the part is known but no other information is available.

DESCRIPTION AND OPERATION



1. GENERAL.

A. Purpose of Manual.

This manual contains maintenance procedures, installation procedures, and basic system troubleshooting procedures for use by flight line and hangar maintenance personnel for the PAI P.N. DH-1030-24-600-CS, Type IIB, Solid-State Static Inverter (Transverter), illustrated in Figure 1.

B. Purpose of Equipment.

The PAI P.N. DH-1030-24-600-CS, Type IIB, Solid-State Static Inverter (Transverter) is used for conversion of electrical power in aircraft for operation of airborne instrumentation and other electrical equipment. The unit provides a continuous source of frequency and voltage regulated, single phase, sine wave, alternating current power from a direct current voltage source. The stable output insures the highest degree of operational reliability under the most adverse service conditions.

PAI P.N. DH-1030-24-600-CS, Type IIB, Solid-State Static Inverter (Transverter)
Figure 1

2. DESCRIPTION.

A. The PAI P.N. DH-1030-24-600-CS, Type IIB, Solid-State Static Inverter (Transverter) is a self-contained DC to AC inverter using state-of-the-art-solid state techniques. Power from the DC source is changed to a highly stable alternating current power source. The unit is compactly packaged with only input and output connections externally accessible.

B. The primary characteristics, capabilities, overall weight, and dimensions are listed in Table of Leading Particulars, Table 1.

GENERAL:	
Input:	20-30 VDC (27.5 VDC nominal), 18.0 - 2.0 Amperes (full load - no load, 27.5 VDC Input)
Output:	115 VAC, 400 Hertz Sine Wave, 1 Phase, 400 VA Continuous Duty, 600 VA Intermittent Duty.
Ambient Temperature Range:	-85°C to +85°C
Temperature Rise:	40°C maximum (no heat sink).
Parallel Operation:	±5% equal division of load, multiple inverters operated in parallel mode, no load to full load over input and temperature/altitude operating range
Maximum Operating Altitude:	100,000 feet and beyond.
Reliability:	10,000 hours MTBF (minimum).
ELECTRICAL:	
Output:	
Volts:	115 VAC ±5% (24 - 30V DC) ± 20% (20 - 24V DC) No load to full load over input and temperature/altitude operating range.
Current:	3.48 Amperes.
Power:	400 Volt-Amperes (Continuous Duty) - 115 VAC, 600 Volt-Amperes (Intermittent Duty),
Frequency:	400 Hertz ±1% -No load to full load over input and temperature/altitude operating range (frequency is maintained to 10 VDC input, and below).

Table of Leading Particulars
Table 1

ELECTRICAL (Cont):	
Output (Cont):	
Wave Shape:	Sinusoidal
Harmonic Content:	Less than 5% total, (3% typical).
Power Factor:	.80 lagging to .95 leading.
Efficiency:	75% minimum.
Duty Cycle:	Continuous, unattended.
Short Circuit Current:	2.0 times full load current (min).
Short Circuit Protection:	Automatic - Restarts when normal load is restored (No damage, output shorted for 1 minute).
Overload Capacity:	150% for 5 minutes (No damage), (600 VA), (no heat sink) 110% for 2 hours (no damage), (440 VA), (no heat sink)
Input:	
Volts:	20 - 30 VDC (27.5 VDC nominal) 0 - 36 Volts (No damage).
Current:	18.0 - 2.0 Amperes (full load - no load). Operating at rated load, 27.5 VDC Input.
Induced Ripple:	Less than 1.5 Volts peak to peak, (50 millivolts typical).
Short Circuit Current:	36 - 50 Amperes (typical 45.0 Amperes).
Overvoltage Protection:	130% for 5 minutes (No damage).
Transient Protection:	±80 volts for 40 milliseconds, ±600 volts for 10 microseconds.
Reverse Polarity Protection	Polarity protect diode.
MECHANICAL:	
Weight:	14.5 pounds (6,577 grams).

Table of Leading Particulars (Cont)
Table 1 (Cont)

MECHANICAL (Cont):	
Overall Dimensions:	10-3/4 in. long (27.305 cm) by 7-3/4 in. wide (19.685 cm) by 5 in. high (12.700 cm).
Mounting Base Dimensions:	9-3/8 in. long (23,813 cm) by 7-3/4 in. wide (19.685 cm).
Mounting Centers:	7 in. long (17.780 cm) by 7 in. wide (17.780 cm)
Electrical Connectors: Input/Output:	Input: MS3102R-22-1P mating MS3106F-24-11S. Output:MS3102-R-22-18S mating MS3106F-22-18P
Cooling:	Self-cooled by natural convection, conduction and radiation.
Installation:	Mounts in any position, without deterioration of power output, heating, operating life, or other operating characteristics.

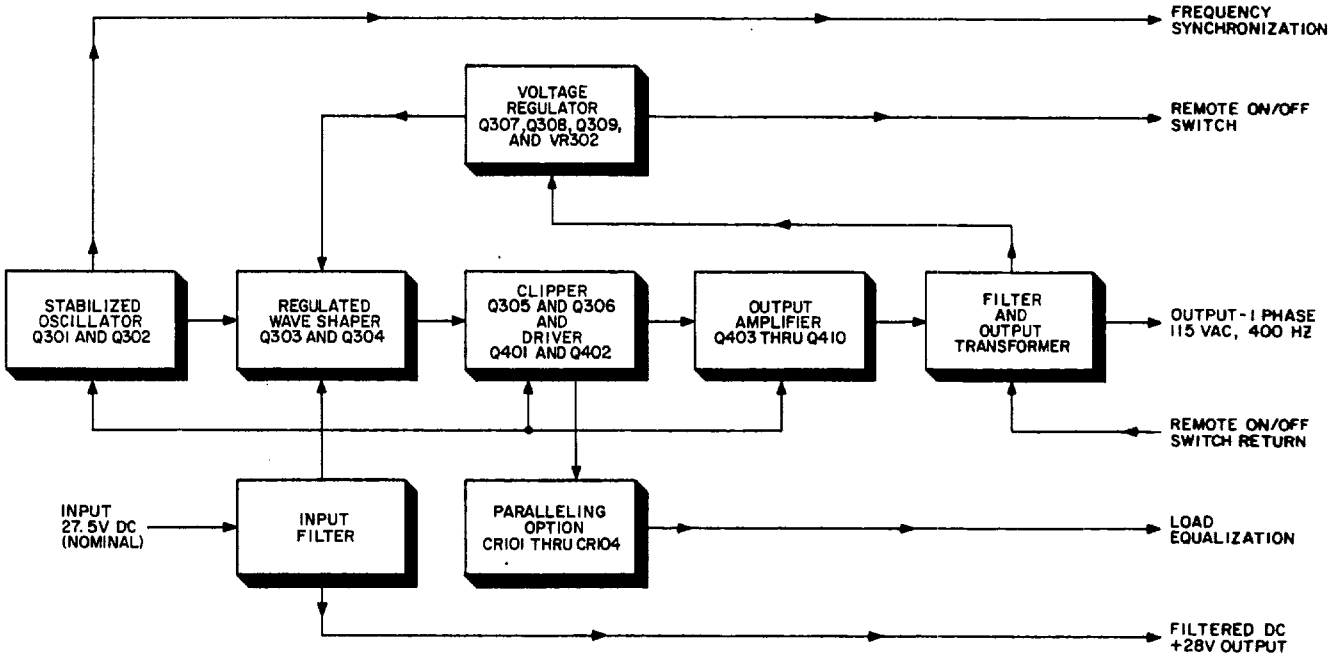
Table I (Cont)

3. OPERATION

The subsequent paragraphs cover the theory of operation for the PAI P.N. DH-1030-24-600-CS, Type IIB, Solid-State Static Inverter (Transverter). The Block Diagram Theory will aid in conveying the overall circuit operation to non-technical oriented personnel, while the Detailed Circuit Theory will enable the technician to understand in detail the operation of equipment.

A. Block Diagram Theory

The subsequent paragraphs together with the block diagram of Fig. 2, cover in concise form the signal flow and circuit operation for the DH-1030-24-600-CS, Type IIB, Solid-State Static Inverter (Transverter).



(1) Input Filter. Power applied through the input filter is free of transients and is provided with reverse polarity protection for application to circuits of the Transverter. A filtered +28V DC output connection is also provided for use in parallel operation of the inverter.

(2) Stabilized Oscillator. Transistors Q301 and Q302 generate a 400 Hertz sine wave signal of high stability. The sine wave signal is coupled through auxiliary windings of the oscillator transformer T301 to the input of the regulated wave shaper.

(3) Regulated Wave Shaper. Transistors Q303 and Q304 in a push-pull circuit receive the sine wave signal developed by the stabilized oscillator. Voltage applied from

the voltage regulator circuit determines the shaping operation for control of duty cycle and regulation of the output voltage. The shaped quasi-square wave output is coupled to the input of the clipper and driver circuit.

(4) Clipper and Driver. Transistors Q305, Q306, Q401, and Q402 in cascaded push-pull stages provide additional shaping and amplification of the 400 Hertz signal. The amplified quasi-square wave signal is applied to the output amplifier.

PAI P.N.DH-1030-24-600-CS, Type IIB, Solid-State Static Inverter (Transverter), Block Diagram
Figure 2

(5) Output Amplifier. Transistors Q403 through Q410 in a push-pull parallel circuit amplify the 400 Hertz signal to the required level across the output transformers for application to the output filter.

(6) Output Transformers and Filter. The output transformers and associated filter circuitry provide matching and shaping to return the amplified signal to a sinusoidal waveform.

(7) Voltage Regulator. Transistors Q308 and Q309 develop the regulating bias by comparison of the rectified negative DC voltage supplied from the output, and adjusted by setting of resistor R324, controlling the Zener regulated voltage to the base of Transistor Q308.

(8) Paralleling Circuit. Coupling transformer T101 provides a voltage to diodes CR101 through CR104 from the collector circuit of transistors Q401 and Q402. The rectified signal is adjusted to provide an output voltage for load equalization when operating inverter in a parallel system.

(9) Remote Turn-On/Turn-Off. Remote turn-on/turn-off of the inverter is accomplished by external control of the collector circuit of transistor Q309, ground return.

B. Detailed Circuit Theory.

The following sub-paragraphs cover the individual circuits and their operation. Occasional reference to the overall schematic diagram of the Transverter, Fig. 3, will be necessary to determine circuit configuration.

(1) Input Filter. The input filter consists of series reactor L2 and shunt capacitors C201, C202, and C203 providing high speed transient and ripple suppression to the input line. Diode CR9 provides reverse polarity protection for the Transverter circuitry. The input filter and reverse polarity protect diode passes the input current required to maintain rated power output and provide operating voltage to Transverter circuits. Over-voltage protection for low speed transients is provided by Zener diode VR301, resistor R313, and diodes CR302, CR303, and CR304. If the input voltage exceeds 39 volts, ±2 volts, Zener diode VR301 conducts and applies back bias to transistors Q305 and Q306 through diodes CR303 and CR304, respectively. This bias inhibits switching during over voltage periods and prevents a high voltage from being developed which could damage subsequent amplifier circuits or the output circuit. Diode CR302 protects the base circuits of transistors Q305 and Q306. Resistor R201 and Zener diode VR401 provide transient suppression and regulation for the low level stages. Diode CR105 located on the Paralleling Circuit Board, across terminals E101 and E102, provides filtered, positive 28 volts DC output at pin A of connector J2.

(2) Stabilized Oscillator. The stabilized oscillator utilizes transistors Q301 and Q302 in a Hartley oscillator circuit. Toroidal transformer T301, with multiple windings provides the tuned circuit, feedback, and output windings for the oscillator. The tuned circuit portion is tuned by capacitors C301, C302, and C303 to 400 Hertz. Capacitor C303 provides parasitic suppression in the tuned collector circuit. A feedback winding provides the coupling between base- collector circuit to sustain oscillations, resistors R318 and R319 provide bias to the base circuit of transistors Q301 and Q302 to insure positive start and sustained oscillations. Resistor R304 provides degeneration for improved stability of the oscillator circuit. Output to the regulated wave shaper circuit is through the remaining winding on transformer T301. Output from the collector of transistor Q302 and tuned circuit is terminated at Pin D of connector J2 for Frequency Synchronization in a multiple inverter system.

(3) Regulated Wave Shaper. The regulated wave shaper receives the 400 Hertz sinusoidal signal from transformer T301 output winding. The input signal is applied to the base circuits of transistors Q303 and Q304 through resistors R301 and R302, respectively, limiting base current which flows in the base circuit. Transistors Q303 and Q304 conduct on alternate half cycles, with the point of conduction determined by the amount of bias supplied by transistor Q309, voltage regulator, to the emitter circuit. Resistor R307 adjusts the output of transistors Q303 and Q304 for minimum second harmonic content in the inverter output. The output of this stage is a quasi-square wave and is applied to the input of the clipper circuit.

(4) Clipper and Driver. The clipper and driver circuits provide additional shaping of the signal and amplification for application to the output amplifier circuits. The clipper circuit consists of transistors Q305 and Q306 in a push-pull circuit. The quasi-square wave is applied to the base circuits of transistors Q305 and Q306 through current limiting resistors R308 and R309 and coupling capacitors C307 and C308, respectively. The output of the clipper circuit results in a quasi-square wave with improved rise time. The output is coupled to the base circuits of the driver transistors Q401 and Q402 through resistors R314 and R315, respectively. Resistors R316 and R317 provide a low impedance return for leakage currents. Output of the collector circuits is developed across toroidal driver transformer T401 and coupled to the output amplifier circuits. Capacitor C401 across the primary winding suppresses transients which might appear across the output.

(5) Output Amplifiers. The output amplifiers receive the quasi-square wave signal through toroidal driver transformer T401. Four output windings are connected in parallel to provide two outputs which drive the eight output transistors Q403 through Q410. Input to the base circuit of each output transistor is through two paralleled 1 Ohm, 2 Watt, resistors, providing current limiting to the input. A 4.7 Ohm, 2 watt resistor between the base and emitter of each output transistor reduces the impedance during the non-conduction period. The collectors of transistors Q403 through Q410 are parallel connected in groups of four, Q403, Q404, Q405, and Q406 are connected to the high side of transformer T2, terminals E1-14, E1-8, E2-14, and E2-8, respectively, while transistors Q407, Q408, Q409, and Q410 are connected to the low side of transformer T2 terminals E2-3, E2-9, E1-3, and E1-9, respectively. Diodes CR1 through CR8 connected in parallel with the emitter and collector terminals of each power transistor provide the reverse current flow from the load back to the DC power source under conditions of high reactive loading. Toroidal series reactor transformer T1 is connected in series with the primary windings of the output transformer T2. The secondary winding of output transformer T2 is connected to the filter circuit.

(6) Output Transformer and Filter. The 400 Hertz quasi-square wave signal developed across toroidal output transformer T2 is high in content of odd order harmonics. Toroidal series reactor transformer T1 in conjunction with the output transformer T2, and the output filter circuit reduce these odd order harmonics. The impedance of the series reactor transformer T1 is low at the 400 Hertz fundamental frequency, but sufficiently high at the frequency of the harmonics to enable the reactor-transformer combination to filter the harmonic content. The output filter appears as a high impedance to the fundamental 400 Hertz signal and a low impedance to the harmonics, thus resulting in optimum power transfer at the fundamental frequency of 400 Hertz. The secondary winding of transformer T2 is tuned to the 400 Hertz fundamental by parallel capacitors C204 and C205, forming a parallel tuned circuit, which reflects a high impedance to the fundamental 400 Hertz signal and a low impedance path to the harmonics. The series tuned circuit comprised of capacitor C206 and toroidal reactor L1 is tuned to the third order harmonic 1,200 Hertz, providing a shunting effect to the most predominant harmonic present in the output. The filtered output is 115 volts AC at a frequency of 400 Hertz and is available at pins B and G of connector J2. The additional winding on transformer T2 is used to derive feedback voltage for the voltage regulator circuit. The derived voltage is rectified by diodes CR305 and CR306 to provide a negative DC potential to the voltage regulator circuit.

(7) Voltage Regulator. The voltage regulator consists of transistors Q307, Q308, and Q309, and Zener diode VR302. The positive voltage from Zener diode VR302 through temperature compensating transistor Q307 and the negative voltage from diodes CR305 and CR306 are applied to the summing resistors R323, R324, R325, and R347 to derive an error voltage at the base of transistor Q308. A change in output voltage, after the setting of resistor R324 has been determined, causes a change in the current applied to the summing circuit, developing an error voltage which is amplified by transistors Q308 and Q309. Output at the emitter of transistor Q309 results in a proportional voltage change which is the bias applied to transistors Q303 and Q304. This change in bias controls duty cycle and output voltage by limiting action in the regulated wave shaper circuit.

(8) Paralleling Circuit. The paralleling circuit operates from voltages derived in the collector circuits of transistors Q401 and Q402, Driver Transistors, conducting on alternate half-cycles. The derived output is applied to a step-down coupling transformer for application to a bridge rectifier circuit comprised of diodes CR101 through CR104. The rectified output voltage developed across load resistor R102 and filter capacitor C101, together with the summed voltage from the base circuit of transistor Q308, applied to connection point B, is adjusted to desired level by variable resistor R103. The preset level becomes the reference voltage which is

delivered from connection point A on the Paralleling Circuit Board to pin C of connector J2 for application to load equalization circuits for automatic control of multiple inverter systems.

(9) Remote Turn-On/Turn-Off. Remote turn-on/turn-off of the inverter is accomplished by external control of the collector return of transistor Q309. to ground. This control requires completion of the circuit between pins E and F of connector J2 through an ancillary switch.

PAI P.N. DH-1030-24-600-CS, Type IIB, Solid-State Static Inverter (Transverter), Schematic Diagram
Figure 3 (Sheet 4 of 4)

TROUBLESHOOTING

1. GENERAL.

The following paragraphs define procedures suitable for determining that a fault exists in the Solid-State Static Inverter (Transverter). These procedures do not cover troubleshooting within the Transverter. For equipment troubleshooting procedures refer to the overhaul manual and perform only in overhaul shops.

2. PRELIMINARY SYSTEM CHECK.

Refer to the airframe wiring diagram and the cabling information given in Figure 203 and 204 in this manual and perform the following checks:

A. Check for input power at primary power source, breaker or fuse, and at positive pin A, and negative at pin B of input power connector J1. Use a DC voltmeter with a measuring range of 0 to 40 volts. Nominal input voltage of 27.5 volts should be measured across the positive and negative leads at connector J1.

B. Check for output at connector J2, pins B and G, series breaker or fuse, and at the input of device to which power is supplied.

NOTE

When checking for output, check for shorted output at load by opening breaker or removing fuse and rechecking output present at connector J2.

Use an AC voltmeter capable of measuring 0 to 150 volts AC at 400 Hertz. Measured voltage should be 115 volts AC ±5%, between pins B and G.

NOTE

A jumper Is required between pins E and F, Remote ON/OFF switch, of connector J2 to permit inverter (Transverter) to operate, if J2 measurements are being made at output of connector

C. Check output current to the load using an AC ammeter to determine that output current is not in excess of 3.48 Amperes on pin B of connector J2.

MAINTENANCE PRACTICES

1. GENERAL.

The following paragraphs cover in detail operations associated with maintenance, installation/removal, etc., of the PAI P.N. DH-1030-24-600-CS, Type IIB, Solid-State Static Inverter (Transverter).

2. SERVICING.

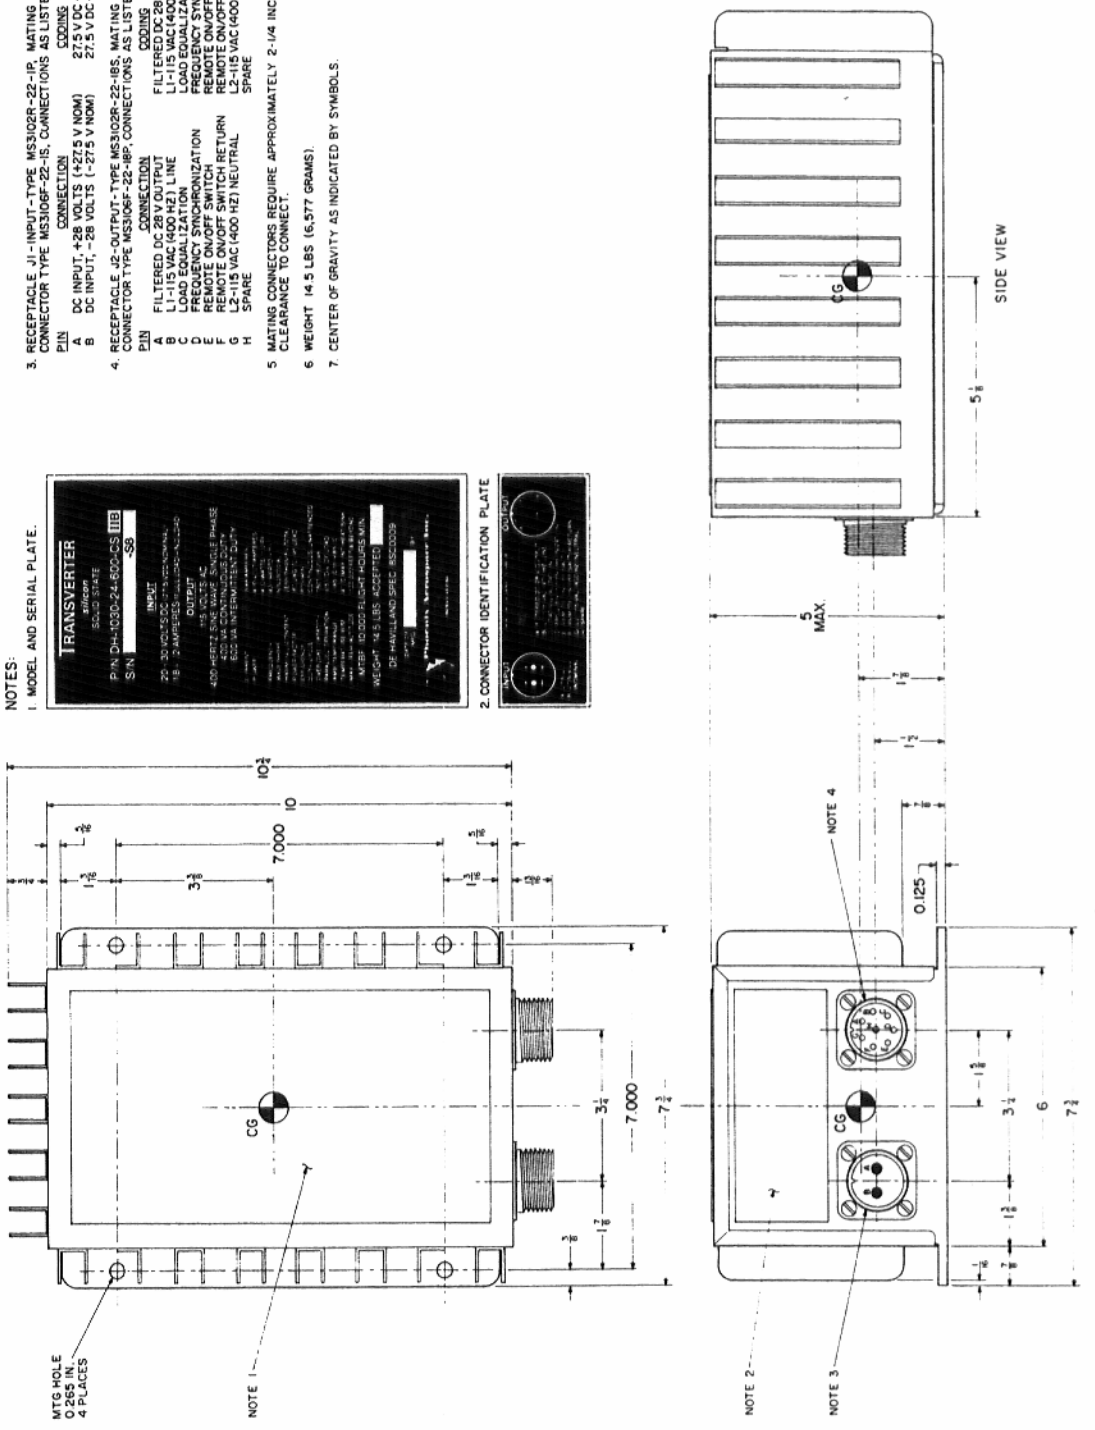
Periodic servicing or maintenance of the Transverter is not required or recommended. The equipment should not be removed from the airframe unless required by maintenance practices observed by the using agency. The use of solid state devices in a completely transistorized circuit, eliminates all moving parts, including relays or contactors. The design therefore eliminates the major cause of failure and maintenance points. In the event failure occurs, refer to the Installation/Removal paragraphs and remove unit for repair by overhaul shop or return to vendor.

3. INSTALLATION/REMOVAL.

The following sub-paragraphs outline installation and removal procedures.

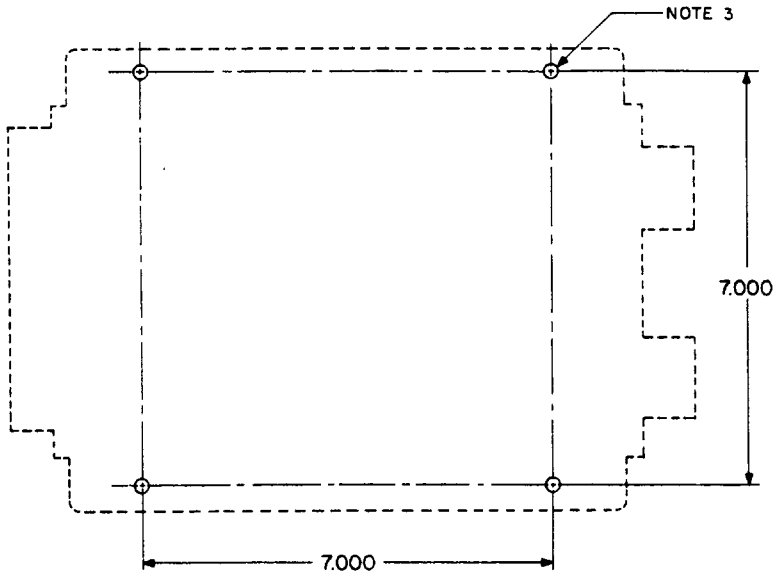
A. Installation.

(1) Refer to Fig. 201 and determine the clearance requirements for equipment and the associated cabling at selected installation point.



CAUTION

USE CARE IN DRILLING OPERATION OF SUBSEQUENT PARAGRAPH, TO PREVENT DAMAGE TO AIRFRAME STRUCTURE, OTHER WIRING, OR CONTROLS.



(2) Refer to Fig. 202, mark and drill four .265 inch diameter holes to mount equipment to airframe.

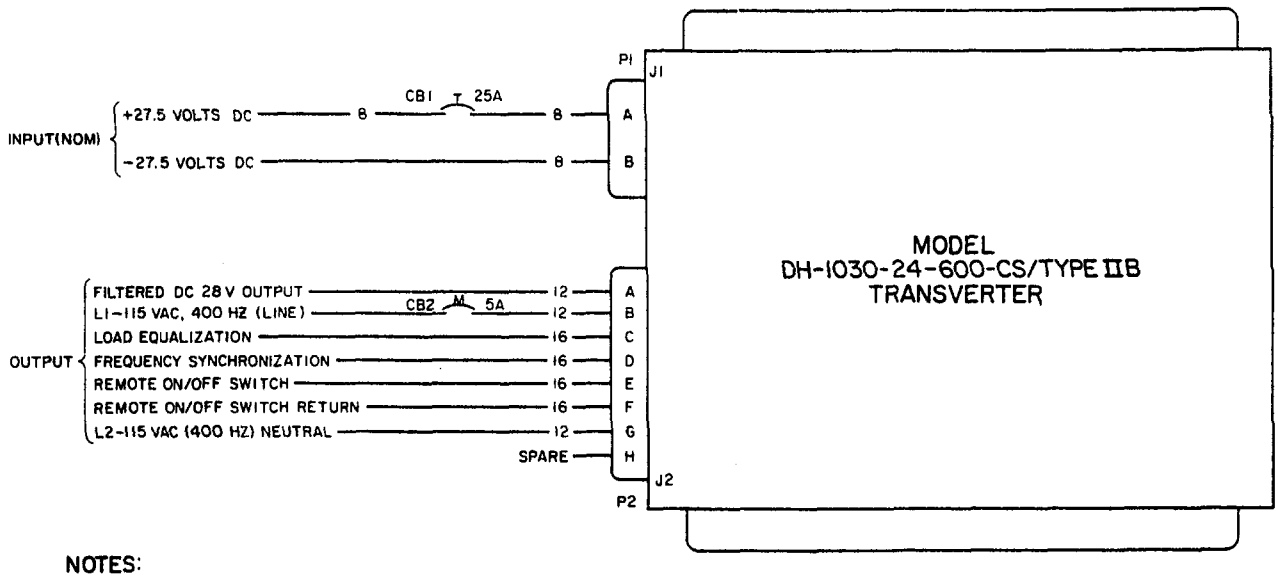
NOTE

Paint removal is not required, however, better heat transfer is accomplished if the mounting surface is clean and free from paint. A light coating of Dow Corning #340 Silicone compound applied to the base prior to installation improves the heat transfer from equipment to airframe.

Outline Dimensions, PAI P.N. DH-1030-24-600-CS, Type IIB, Solid-State Static Inverter (Transverter)
Figure 201

1. EXERCISE CARE IN DRILLING TO PREVENT DAMAGE TO OTHER FUNCTIONAL PARTS ON AIRCRAFT.
2. PAINT REMOVAL IS NOT REQUIRED, HOWEVER, BETTER HEAT TRANSFER IS ASSURED IF THE MOUNTING SURFACE IS CLEAN AND FREE OF PAINT.
3. DRILL FOUR 0.265 IN DIA MOUNTING HOLES.
4. A LIGHT COATING OF GENERAL ELECTRIC # G641 OR #G635 SILICONE COMPOUND APPLIED TO THE BASE PRIOR TO INSTALLATION IMPROVES THE HEAT TRANSFER FROM THE INVERTER TO THE AIRFRAME.
5. SECURE INVERTER (TRANSVERTER) AT THE FOUR MOUNTING HOLES WITH AN4-XXA, 1/4-28, AIRCRAFT, HEX HEAD BOLT; AN960-416, 1/4 IN. FLAT WASHER, AND MS20365-428C, 1/4-28, AIRCRAFT, SELF-LOCKING HEX NUT, OR EQUIVALENT AN OR MS HARDWARE.
6. LENGTH OF BOLTS -XX MUST BE SELECTED FOR THE SPECIFIC INSTALLATION, DETERMINING - LENGTH OF GRIP AREA AND LENGTH OF THREADS TO INSURE AT LEAST ONE AND ONE-HALF THREADS AND NOT MORE THAN THREE THREADS ARE SHOWING AFTER TIGHTENED.

Drilling Template Mounting Holes,
PAI P.N. DH-1030-24-600-CS, Type IIB
Solid-State Static Inverter (Transverter)
Figure 202



(3) Install Transverter using four, AN4-XXA, 1/4-28 aircraft hex head bolts, four, AN960-416, 1/4 in. flat washers, and four MS20365-428C, aircraft self-locking hex nuts, or equivalent AN or MS hardware. Length of bolts must be selected for the specific installation for length of grip area, and thread area to insure that at least one and one-half threads and not more than three threads are showing after the hardware is securely tightened.

(4) Using the two recommended mating connectors P1, MS3106F-22-1S and P2, MS3106F-22-18P, refer to Fig. 203 and prepare input and output cabling between the Transverter and circuit breaker/fuse panel and the powered device. Typical Wiring Diagrams of an AC Power Distribution System utilizing three Phoenix Aerospace Inc. Transverters (Static Inverters) in parallel operation are shown in Figures 204 and 205.

(5) After completion of cabling, open circuit breakers or remove fuses at power panel and connect the input power cable plug P1, MS3106F-22-1S to input receptacle J1, MS3102R-22-1P. Connect output power cable plug P2, MS3106F-22-18P to output receptacle J2, MS3102R-22-18S.

B. Removal.

(1) Identify circuit breakers or fuses at power panel and place circuit breakers in off position or remove fuses.

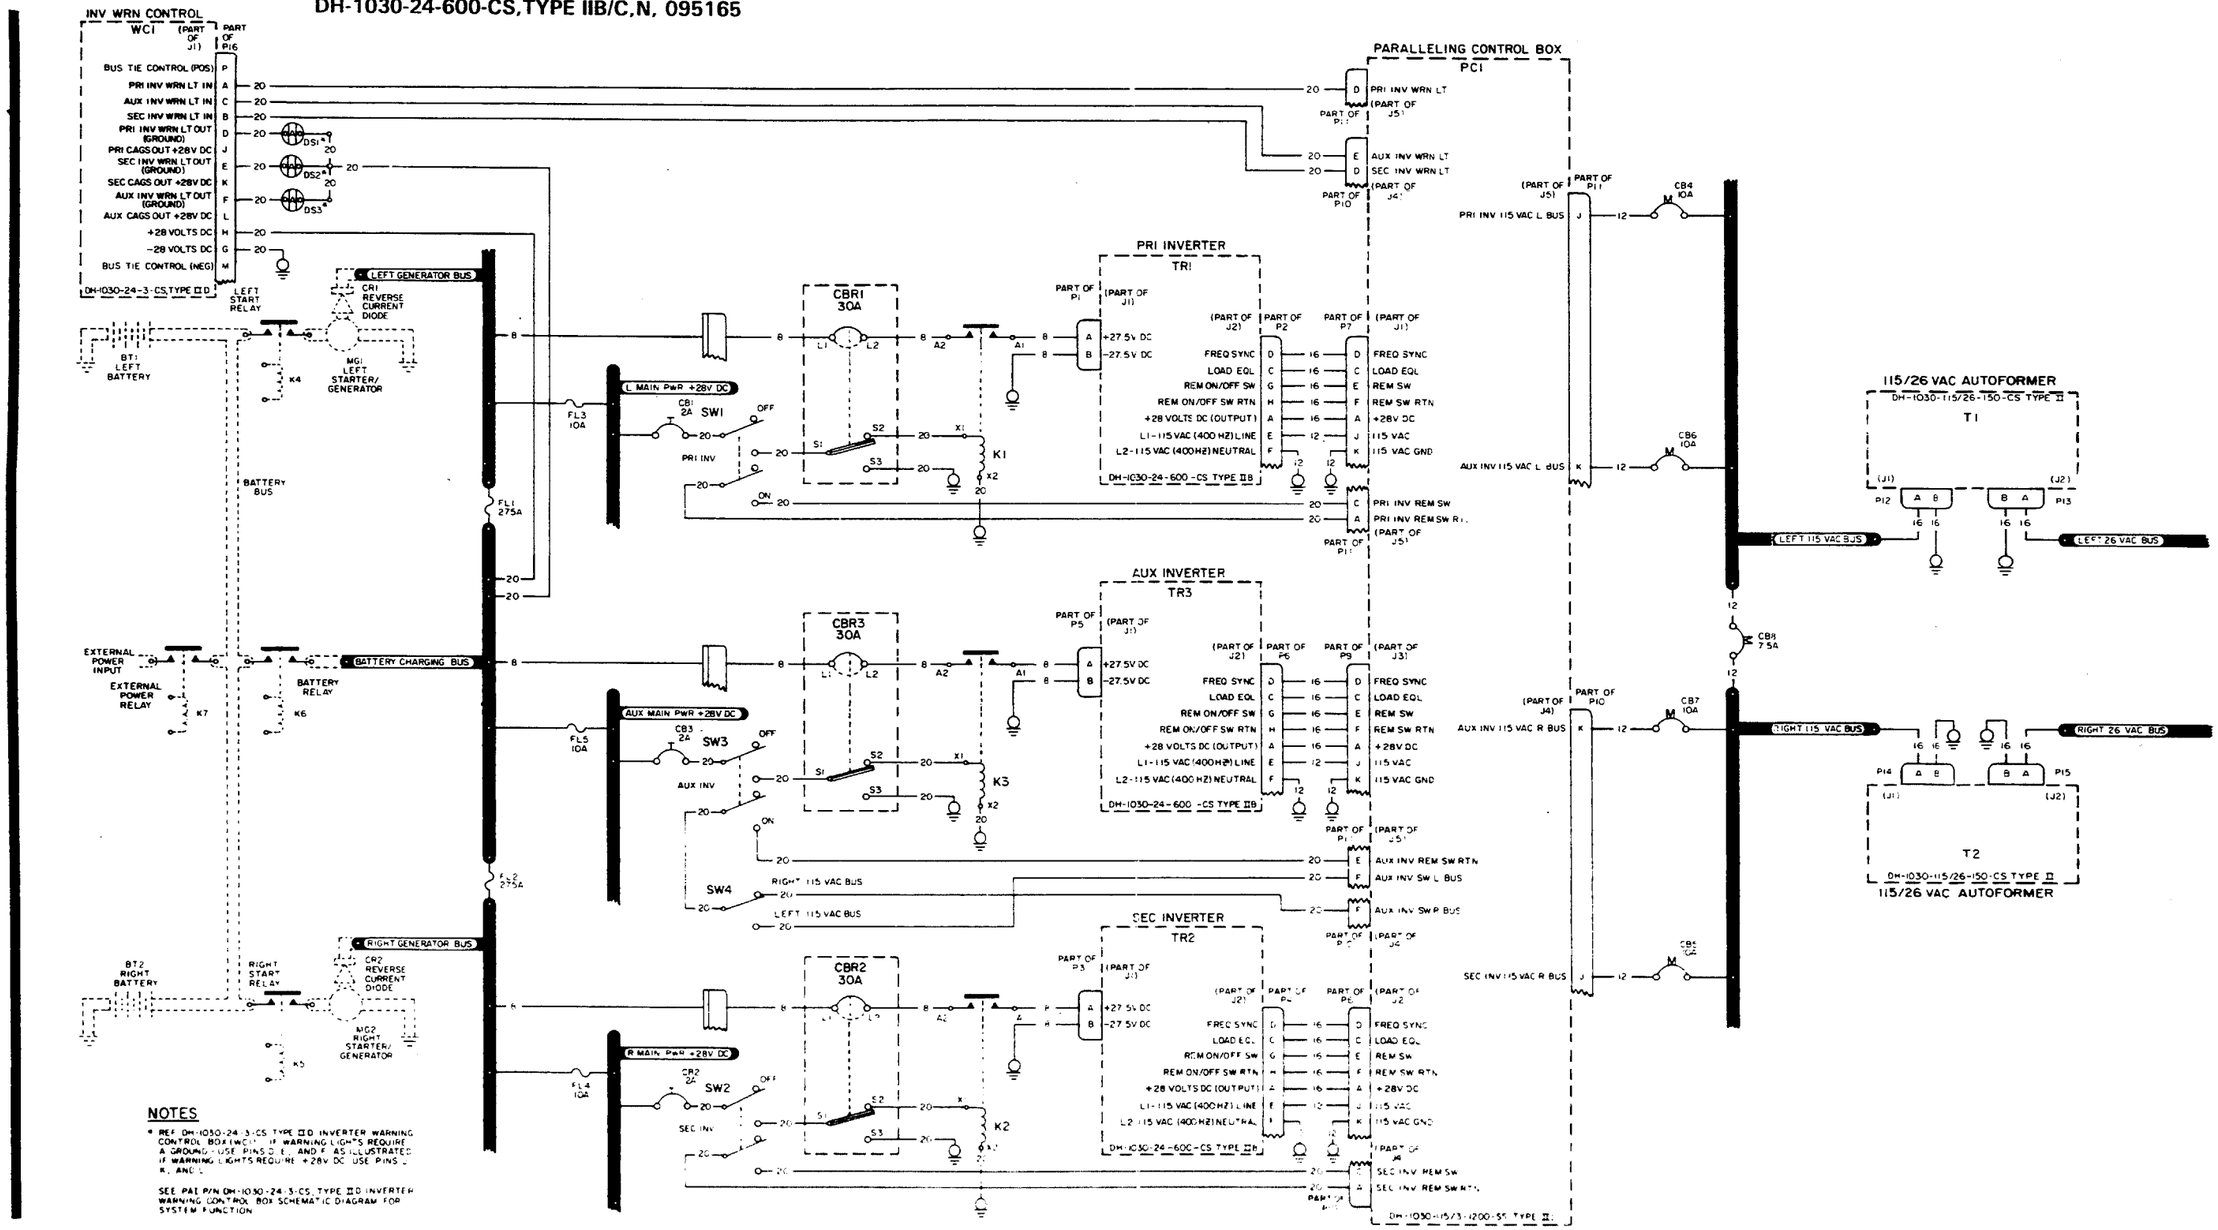
NOTES:

1. CIRCUIT BREAKER CB1 IS NOT SUPPLIED, USE KLIXON 7235-1-25, 25 AMPERES, THERMAL BREAKER, OR EQUIVALENT.
2. CIRCUIT BREAKER CB2 IS NOT SUPPLIED, USE KLIXON 7MC1-201-5, 5 AMPERES, MAGNETIC BREAKER, OR EQUIVALENT.
3. INVERTER REMOTE ON/OFF SWITCH IS NOT SUPPLIED, USE SPST SWITCH, MAXIMUM CURRENT 1 AMPERE, TO OPEN OR CLOSE CIRCUIT BETWEEN PINS E AND F, CONNECTOR PLUG P2/J2.
4. CABLING SHALL BE FABRICATED FROM ELECTRICAL WIRE WHICH MEETS OR EXCEEDS THE REQUIREMENTS OF MIL-W-16878/3, TYPE D.
5. WIRING SHALL MEET OR EXCEED SIZES SHOWN.
6. CONNECTOR PLUGS: P1 - MS3106F-22-1S - INPUT; P2 - MS3106F-22-18P - OUTPUT; ARE NOT SUPPLIED WITH THE INVERTER (TRANSVERTER).

Cabling Diagram, PAI P.N. DH-1030-24-600-CS, Type IIB, Solid-State Static Inverter (Transverter)
Figure 203

(2) Refer to cabling diagram Fig. 203 and disconnect input and output connectors P1 and P2, respectively.

(3) Remove the four AN4-XXA 1/4-28 aircraft hex head bolts, AN960-416 1/4 inch flat washers, and MS20365-428 1/4-28 self-locking hex nuts securing the Transverter to airframe.



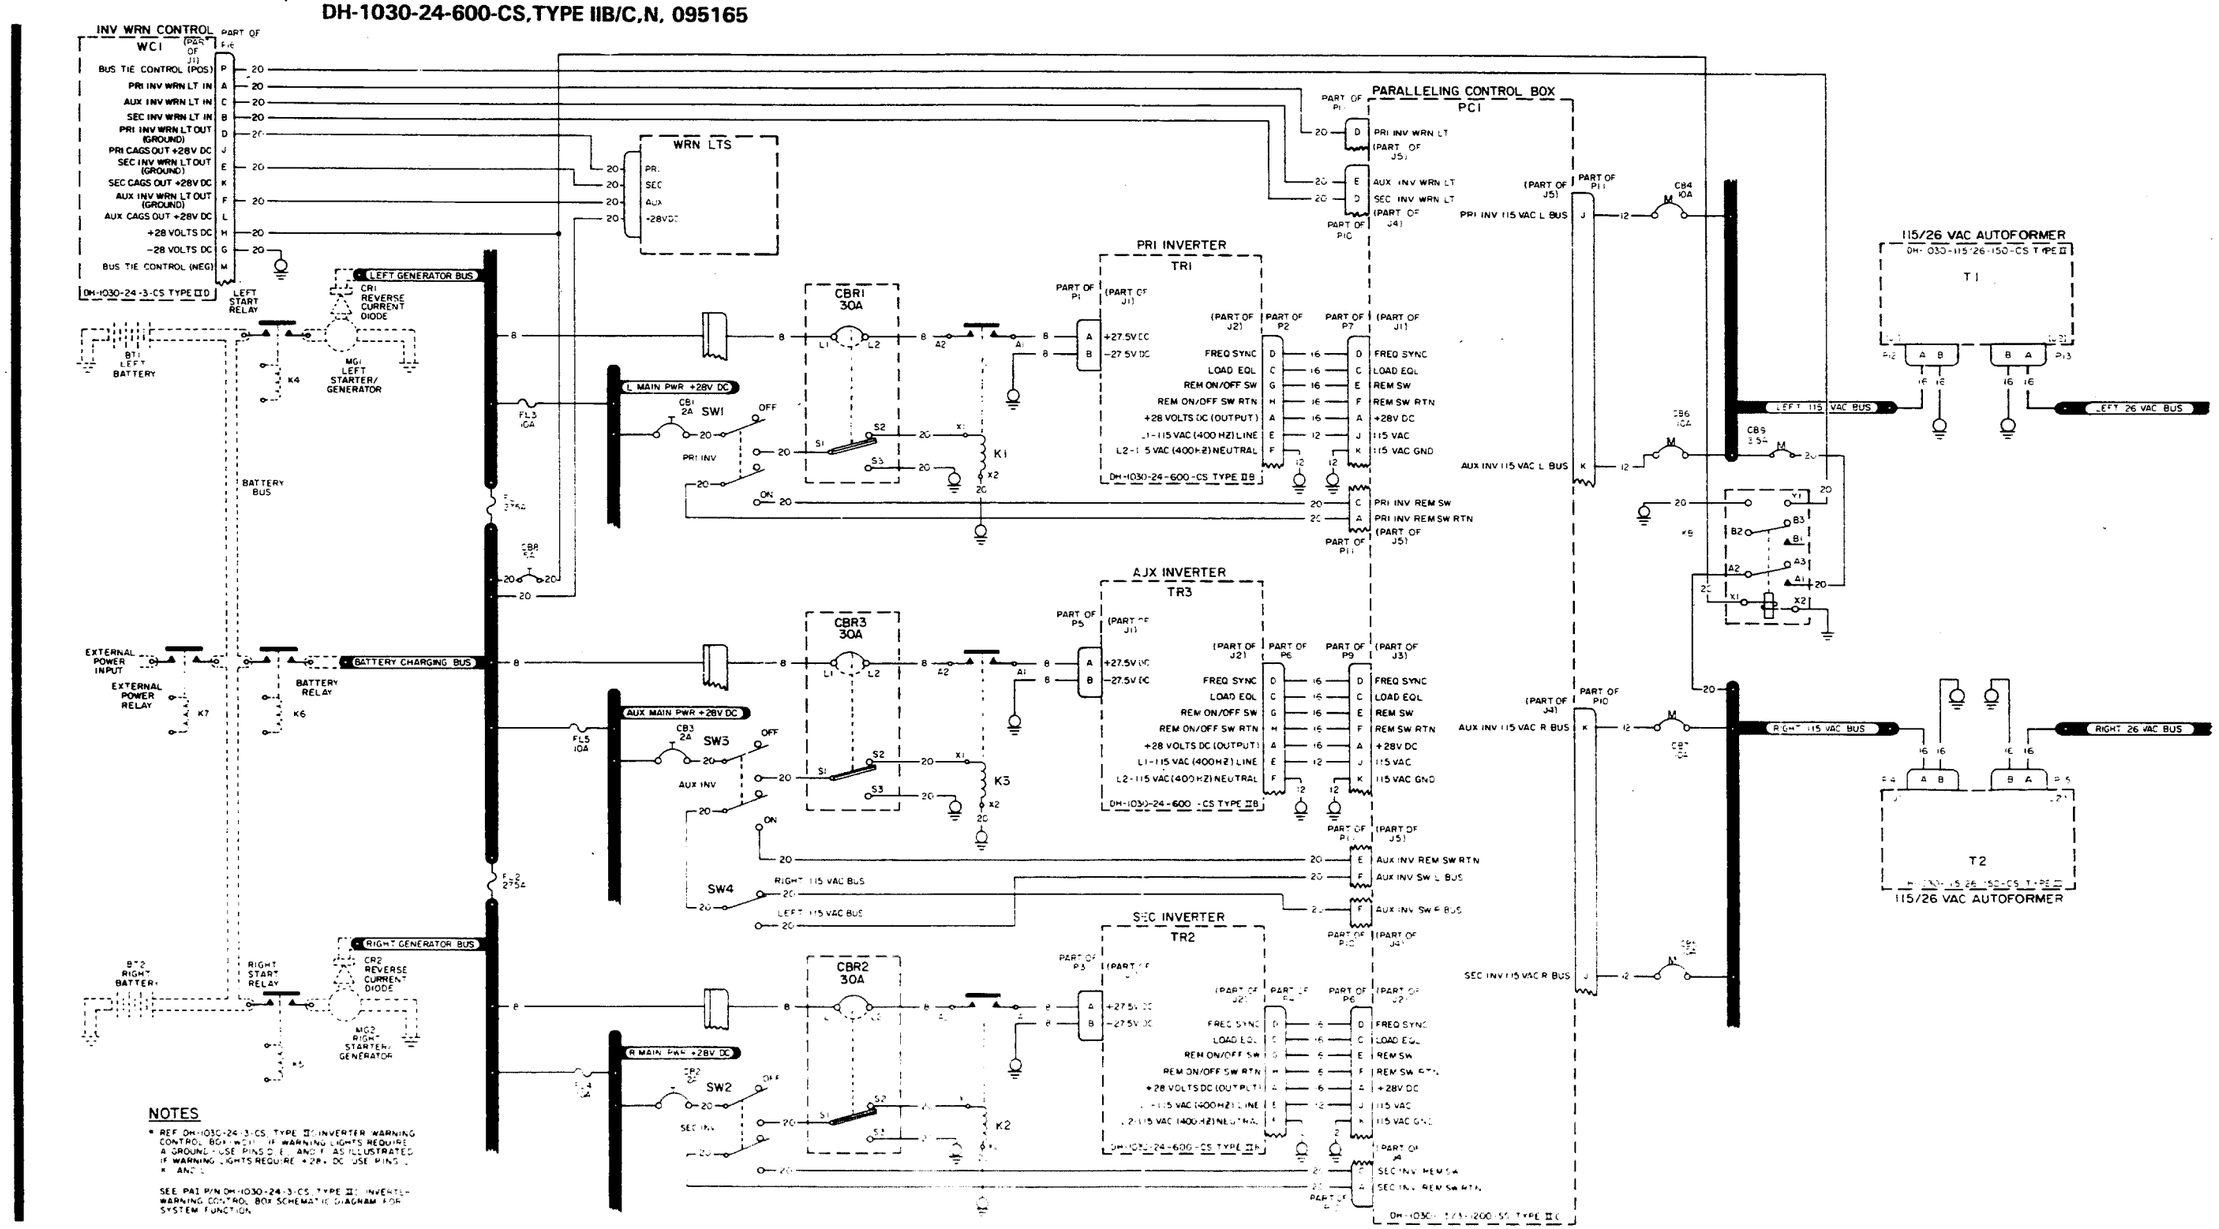
4. ADJUSTMENT/TEST.

The following paragraphs outline test procedures for both installation check out and a pre-installation bench test if desired or required by maintenance policies. Adjustments are not authorized at flight line maintenance level.

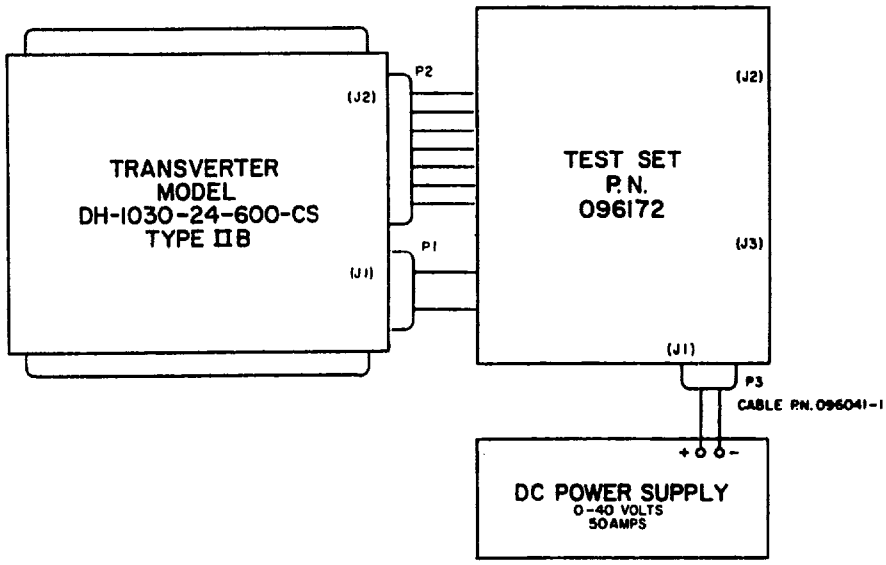
A. Installation Test.

Complete the following steps to determine if Transverter and associated load are operating properly.

(1) Place circuit breakers in the on position or install fuses at power panel in the input circuit.



NOTES



* REF DH-1030-24-3-CS TYPE IID INVERTER WARNING CONTROL BOX (WC1). IF WARNING LIGHTS REQUIRE A GROUND, USE PINS D, E, AND F AS ILLUSTRATED. IF WARNING LIGHTS REQUIRE +28V DC USE PINS J, K, AND L.

SEE PAT P/N DH-1030-24-3-CS, TYPE IID INVERTER WARNING CONTROL BOX SCHEMATIC DIAGRAM FOR SYSTEM FUNCTION.

Wiring Diagram, Typical AC Power Distribution System, Utilizing Three Phoenix Aerospace Inc. Transverters (Static Inverters) in Parallel Operation
Figure 204

Wiring Diagram, Typical AC Power Distribution System, Utilizing Three Phoenix Aerospace Inc. Transverters (Static Inverters) in Parallel Operation, Delayed Bus-Tie
Figure 205

Bench Test Set-Up, PAI P.N. DH-1030-24-600-CS, Type IIB, Solid-State Static Inverter (Transverter)
Figure 206

(2) Operate control to apply power to input of device while observing aircraft metering of the DC voltage for any abrupt change in voltage or current. In the event any abrupt change occurs, remove power and check wiring for shorted condition.

(3) Place circuit breakers in the on position or install fuses at power panel in the output circuit.

(4) Operate control and/or connect device or load to output of Transverter, observing operation of powered device and aircraft metering of the DC voltage for any change in voltage or current. In the event any appreciable change occurs, remove power at input and check output wiring and the associated load for short circuit or other malfunction.

B. Pre-installation Check.

Complete the following steps to determine that Transverter is operable and capable of supplying power to a specific load.

(1) Refer to Fig. 207 and the Inverter Test Set, PAI P.N. 096172, and place push button A in the OFF position, pressed.

(2) Place ON/OFF switch on the DC Power Supply in the OFF position.

(3) Identify the Accessory Interconnect Cable P.N. 096172-1, attaching positive lead to the positive terminal and the negative lead to the negative terminal on the DC Power Supply.

(4) Place ON/OFF switch on the DC Power Supply in the ON position, and increase output of DC Power Supply to 27.5 volts DC.

(5) Press push button D - 400 VA UNITY - lamp DS4 will light and observe DC AMPERES meter M4, DC VOLTS meter M3, AC AMPERES meter M1, and AC VOLTS meter M2 for voltages as noted below

Input Current: 18.0 Amperes (nominal)
Output Current: 3.48 Amperes (nominal)

Input Voltage: 27.5 VDC
Output Voltage: 115 VAC ±5%

(6) Change input voltage from DC Power Supply varying between 20 and 30 volts and note stability of output voltage and current, indicative of proper operation.

(7) Return input voltage to zero and place ON/OFF switch on the DC Power Supply in the OFF position.

(8) Disconnect the Inverter (Transverter) from the Inverter Test Set completing the pre-installation or bench tests.

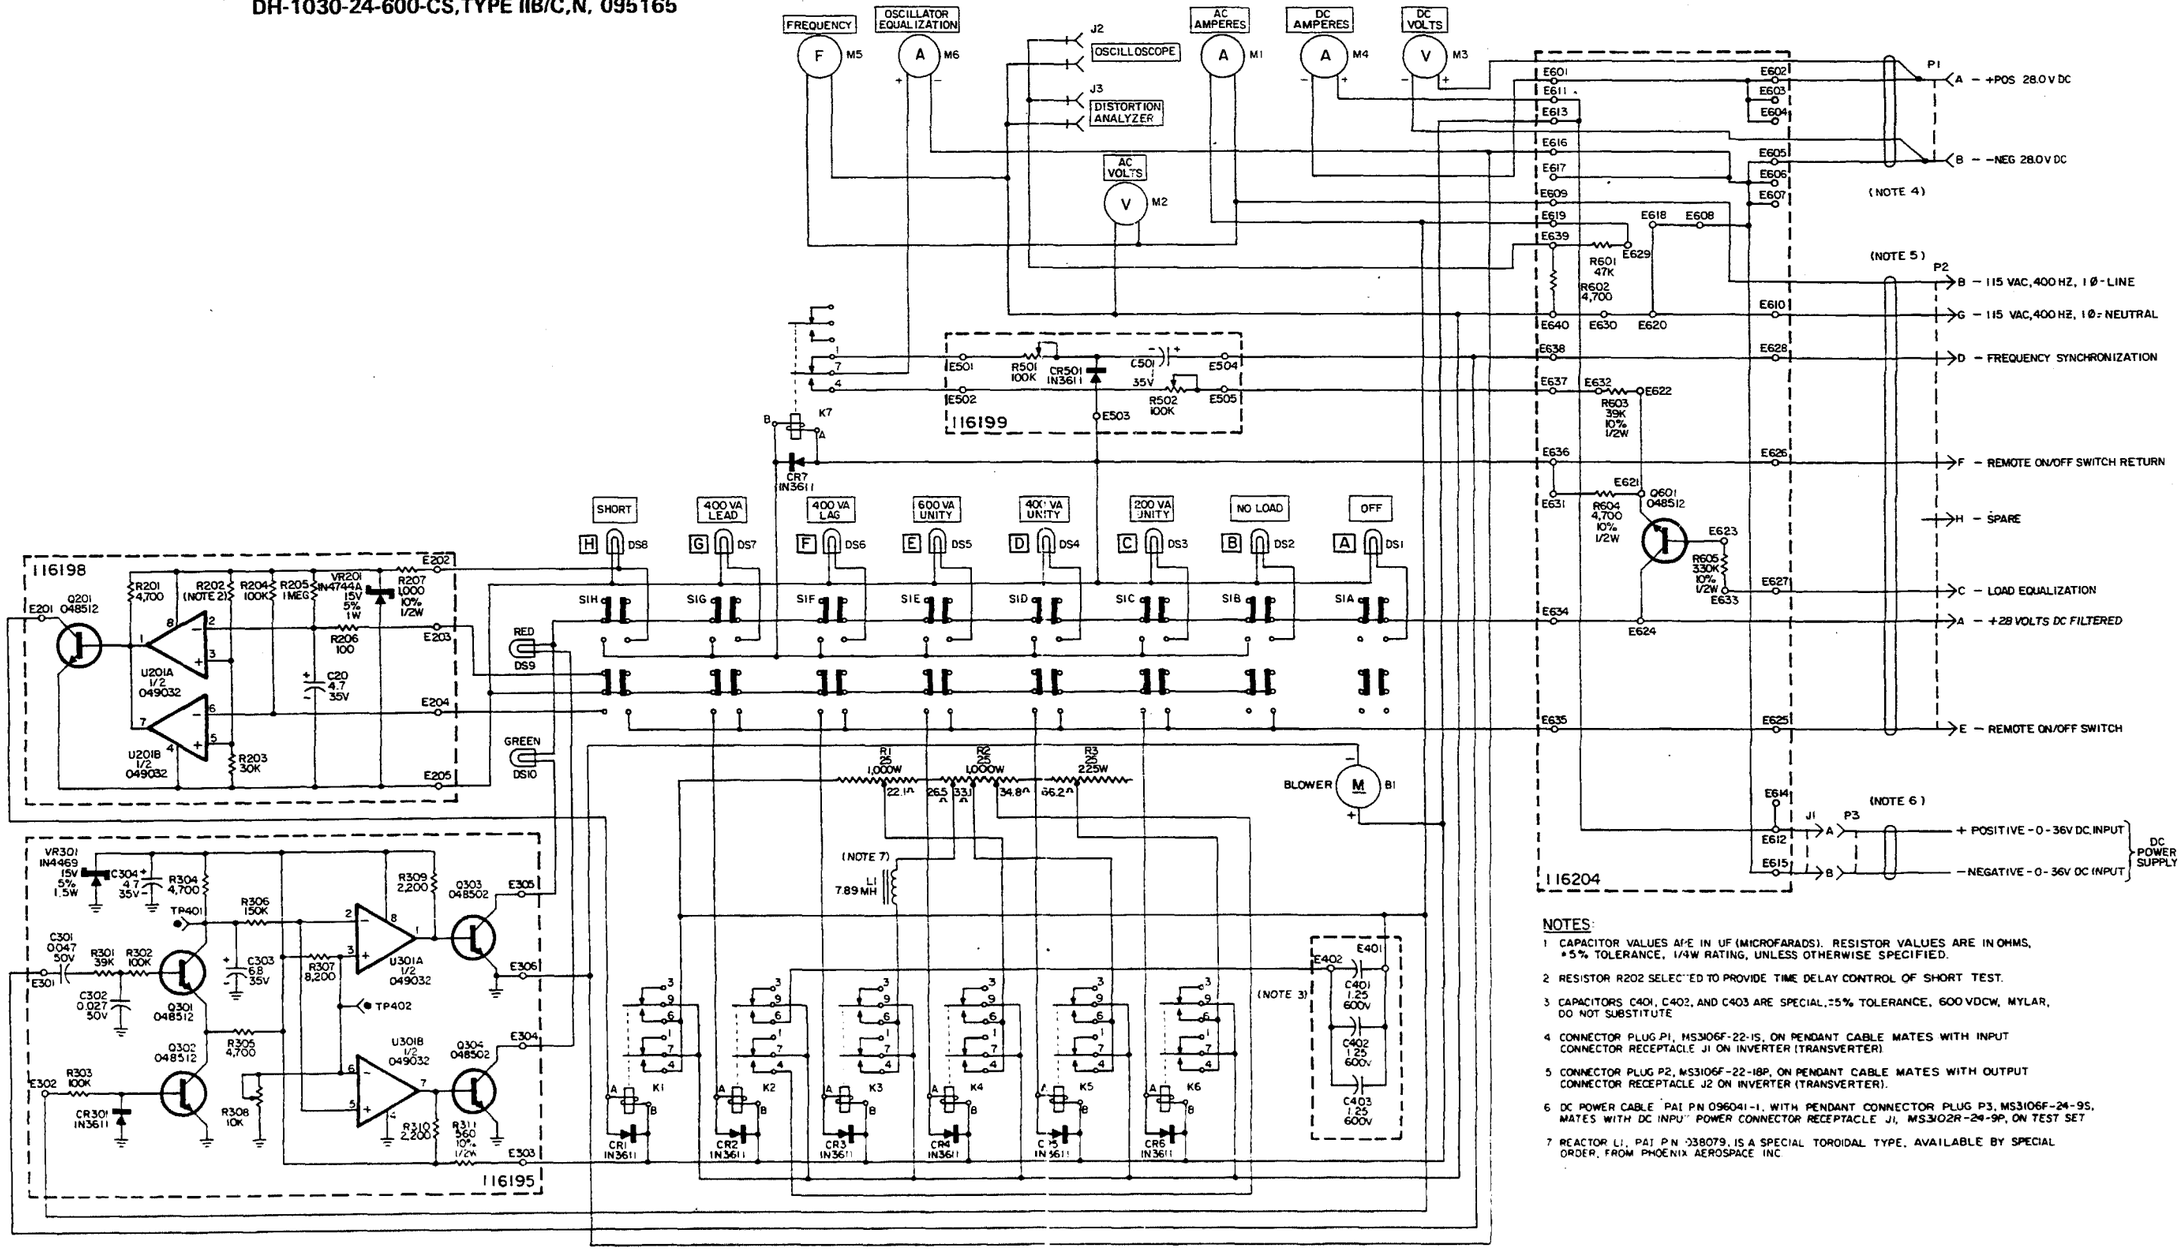
NOTE

In the event Transverter under test does not perform as outlined in step (5), unit should be returned to stores for replacement and forwarded to overhaul or returned to vendor for repairs.

5. INSPECTION/CHECK.

Visual inspection of external cabling for arcing at contacts of connectors, and associated load are the only authorized inspection/checks. No authority is given for visual or other checks internally or even removal of the sealed cover at flight line maintenance levels.

6. CLEANING/PAINTING.



The Transverter requires no periodic cleaning operations under the sealed cover. If readily accessible, exterior dirt may be removed with a brush or cloth and the connector pins may be burnished if corrosion should be apparent during visual inspection check of paragraph 5.

7. APPROVED REPAIRS.

The only repairs approved for flight line maintenance are those associated with external cabling. No repairs are authorized or approved for flight line maintenance requiring removal of the sealed cover.

8. INVERTER TEST SET, PAI P.N.096172.

The Inverter Test Set referenced in preceding paragraph 4.B. is available from Phoenix Aerospace Inc. as a complete unit. The schematic diagram for the Test Set is shown in Fig. 207.

NOTES:

1. CAPACITOR VALUES ARE IN UF (MICROFARADS). RESISTOR VALUES ARE IN OHMS, ±5% TOLERANCE, 1/4W RATING, UNLESS OTHERWISE SPECIFIED.
2. RESISTOR R202 SELECTED TO PROVIDE TIME DELAY CONTROL OF SHORT TEST.

Phoenix Aerospace Inc.

PHOENIX AEROSPACE INC. STANDARD WARRANTY

1. Sellers Standard Warranty

(a) Phoenix Aerospace, Inc. herein called Seller, warrants that each unit delivered shall, at the time of delivery thereof to Buyer or Buyer's customers, be free from defects in material and workmanship and from defects or faults in design in view of the state of the art at the time of design thereof. Any defect must have become apparent and Buyer must have notified Seller thereof within twenty-four (24) months after installation in aircraft, not to exceed thirty (30) months after date of manufacture on unit nameplate. The extent of Seller's liability is limited to the repair, replacement, overhaul, or modification of any defective unit.

(b) Seller's obligation hereunder is conditioned upon the return as soon as practicable of the defective unit with all transportation charges prepaid to Seller in Kansas City, Missouri. Returned units must be accompanied by properly authorized Purchase Order, specifying the nature of the defect, if known, and containing reasonable proof to Seller that the defect is due to a matter embraced within Seller's warranty. An allowance will be made for inbound transportation charges in the Continental United States, but inbound transportation charges are the responsibility of Buyer outside the limits of the Continental United States. Overhauled or repaired units will be returned via air, transportation charges prepaid to destination anywhere in the world. Removal of the unit from any aircraft and reinstallation shall be at Buyer's expense.

(c) The warranty hereunder shall not apply to any unit installed in any Aircraft if such Aircraft shall not have been operated in accordance with the Federal Aviation regulations issued by the Federal Aviation Administration, or if such unit shall not have been operated or maintained in accordance with seller's instructions applicable to such unit, or if such unit shall have been repaired, altered or modified without Seller's approval, or operated with an accessory or part not authorized for use therewith, or if such unit shall have been operated subsequent to its involvement in an accident, or if the unit shall have been subject in any way to improper operation, maintenance, repair, alteration or modification.

(d) THE WARRANTY AND THE OBLIGATIONS AND LIABILITIES OF SELLER HEREUNDER ARE EXCLUSIVE AND IN SUBSTITUTION FOR AND BUYER HEREBY WAIVES ALL OTHER WARRANTIES, EXPRESS OR IMPLIED, ARISING BY LAW OR OTHERWISE (INCLUDING, WITHOUT LIMITATION, THE IMPLIED WARRANTY OR MERCHANTABILITY, ANY IMPLIED WARRANTY ARISING FROM COURSE OF PERFORMANCE, COURSE OF DEALING OR USAGE OF TRADE, ANY IMPLIED WARRANTY OF FITNESS, AND ANY OBLIGATION OF SELLER WITH RESPECT TO INCIDENTAL OR CONSEQUENTIAL DAMAGES), AND SHALL NOT BE EXTENDED, ALTERED OR VARIED EXCEPT BY A WRITTEN INSTRUMENT SIGNED BY SELLER AND BUYER.

2. General Instructions

(a) Overhaul, modification or repair of all Phoenix Aerospace units is authorized only at Seller's facility. Any overhaul, repair, alteration or modification without Seller's approval will negate or void the terms of Seller's Standard Warranty stated herein. Units in need of repair should be shipped directly to:

Phoenix Aerospace Inc.
220 West 80th Terrace
Kansas City, Missouri 64114
U.S.A.

Units in warranty are repaired at the factory under the terms and conditions of Seller's Standard Warranty at no charge. There will be a charge imposed for Units returned within the warranty period which are found not to be defective or for a defect found not to be included within Seller's Standard Warranty or which have been removed or returned as a result of any program of preventive maintenance.

(b) Units out of warranty are repaired at the factory at Seller's standard charge in effect at the time of receipt of unit. Inbound and outbound transportation charges are the responsibility of the Buyer.

INTRODUCTION

In conformance with A.T.A. Specification No. 100 for Manufacturers' Technical Data, two manuals have been prepared concerning the PAI P.N. DH-1030-24-600-CS, Type IIB, Solid-State Static Inverter (Transverter). These manuals, if used as intended, will facilitate the effective, continued operation of the equipment. Technical data is grouped according to usage in the manual as described.

OVERHAUL MANUAL WITH ILLUSTRATED PARTS CATALOG

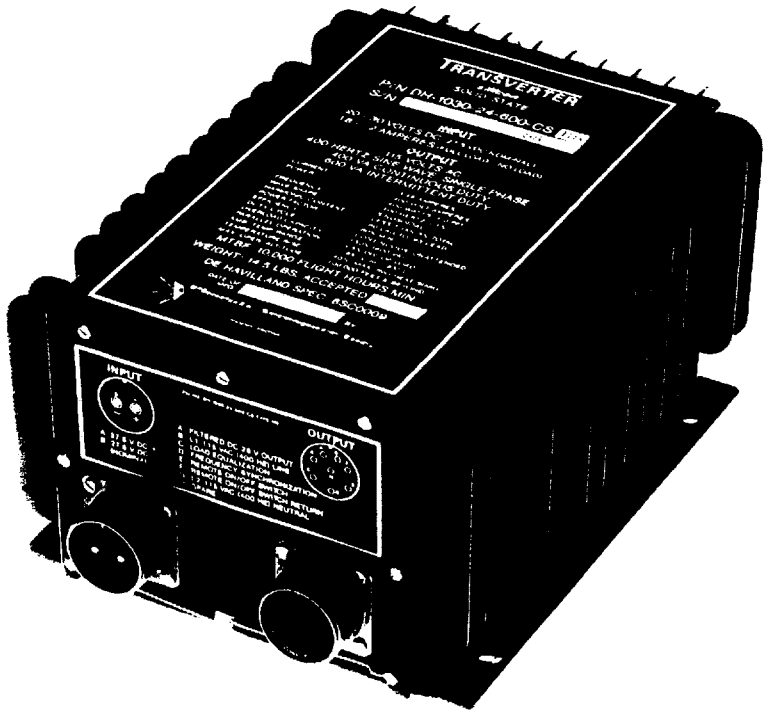
The Overhaul Manual contains all the information required for shop testing, replacement of defective parts, adjustment, mechanical disassembly, inspection, and reassembly. Detailed circuit theory is given with emphasis on theory that will be especially helpful for effective troubleshooting. Performance tests as well as functional (go/no-go) checks, which may be used to determine condition of equipment and for retesting after repairs.

The Illustrated Parts Catalog provides a means to determine the manufacturer's part number and the physical location on the equipment of a part if the reference designation is known, or to determine the reference designation and the manufacturer's part number when the physical location of the part is known but no other information is available.

MAINTENANCE MANUAL

This manual is intended for use by flight line and hangar maintenance personnel. A detailed description and operation, including a table of leading particulars are presented for reference. Mounting and cabling information are presented as an aid to installation. Troubleshooting information is limited to procedures required to trace a trouble to the overall unit for replacement,

DESCRIPTION AND OPERATION



1. GENERAL.

A. Purpose of Manual.

This manual contains information for shop testing, replacement of defective parts, adjustment and alignment, mechanical disassembly, inspection, reassembly, and the Illustrated Parts Catalog for the PAI P.N. DH-1030-24-600-CS, Type IIB, Solid-State Static Inverter (Transverter), illustrated in Figure 1.

B. Purpose of Equipment.

The PAI P.N. DH-1030-24-600-CS, Type IIB, Solid-State Static Inverter (Transverter) is used for conversion of electrical power in aircraft for operation of airborne instrumentation and other electrical equipment. The unit provides a continuous source of frequency and voltage regulated, single phase, sine wave, alternating current power from a direct current voltage source. The stable output insures the highest degree of operational reliability under the most adverse service conditions.

PAI P.N. DH-1030-24-600-CS, Type IIB,
Solid-State Static Inverter (Transverter)
Figure 1

2. DESCRIPTION.

A. The PAI P.N. DH-1030-24-600-CS, Type IIB, Solid-State Static Inverter (Transverter) is a self-contained DC to AC inverter using state-of-the-art-solid state techniques. Power from the DC source is changed to a highly stable alternating current power source. The unit is compactly packaged with only input and output connections externally accessible.

B. The primary characteristics, capabilities, overall weight, and dimensions are listed in Table of Leading Particulars, Table 1.

GENERAL:	
Input:	20-30 VDC (27.5 VDC nominal), 18.0 - 2.0 Amperes (full load - no load, 27.5 VDC Input)
Output:	115 VAC, 400 Hertz Sine Wave, 1 Phase, 400 VA Continuous Duty, 600 VA Intermittent Duty.
Ambient Temperature Range:	-85°C to +85°C
Temperature Rise:	40°C maximum (no heat sink).
Parallel Operation:	±5% equal division of load, multiple inverters operated in parallel mode, no load to full load over input and temperature/altitude operating range
Maximum Operating Altitude:	100,000 feet and beyond.
Reliability:	10,000 hours MTBF (minimum).
ELECTRICAL:	
Output:	
Volts:	115 VAC ±5% (24 - 30V DC) ± 20% (20 - 24V DC) No load to full load over input and temperature/altitude operating range.
Current:	3.48 Amperes.
Power:	400 Volt-Amperes (Continuous Duty) - 115 VAC, 600 Volt-Amperes (Intermittent Duty),
Frequency:	400 Hertz ±1% -No load to full load over input and temperature/altitude operating range (frequency is maintained to 10 VDC input, and below).

Table of Leading Particulars
Table 1

ELECTRICAL (Cont):	
Output (Cont):	
Wave Shape:	Sinusoidal
Harmonic Content:	Less than 5% total, (3% typical).
Power Factor:	.80 lagging to .95 leading.
Efficiency:	75% minimum.
Duty Cycle:	Continuous, unattended.
Short Circuit Current:	2.0 times full load current (min).
Short Circuit Protection:	Automatic - Restarts when normal load is restored (No damage, output shorted for 1 minute).
Overload Capacity:	150% for 5 minutes (No damage), (600 VA), (no heat sink) 110% for 2 hours (no damage), (440 VA), (no heat sink)
Input:	
Volts:	20 - 30 VDC (27.5 VDC nominal) 0 - 36 Volts (No damage).
Current:	18.0 - 2.0 Amperes (full load - no load). Operating at rated load, 27.5 VDC Input.
Induced Ripple:	Less than 1.5 Volts peak to peak, (50 millivolts typical).
Short Circuit Current:	36 - 50 Amperes (typically 45 Amperes).
Overvoltage Protection:	130% for 5 minutes (No damage).
Transient Protection:	±80 volts for 40 milliseconds, ±600 volts for 10 microseconds.
Reverse Polarity Protection	Polarity protect diode.
MECHANICAL:	
Weight:	14.5 pounds (6,577 grams).

Table of Leading Particulars (Cont)
Table 1 (Cont)

MECHANICAL (Cont):	
Overall Dimensions:	10-3/4 in. long (27.305 cm) by 7-3/4 in. wide (19.685 cm) by 5 in. high (12.700 cm).
Mounting Base Dimensions:	9-3/8 in. long (23,813 cm) by 7-3/4 in. wide (19.685 cm).
Mounting Centers:	7 in. long (17.780 cm) by 7 in. wide (17.780 cm)
Electrical Connectors: Input/Output:	Input: MS3102R-22-1P mating MS3106F-24-11S. Output: MS3102-R-22-18S mating MS3106F-22-18P
Cooling:	Self-cooled by natural convection, conduction and radiation.
Installation:	Mounts in any position, without deterioration of power output, heating, operating life, or other operating characteristics.

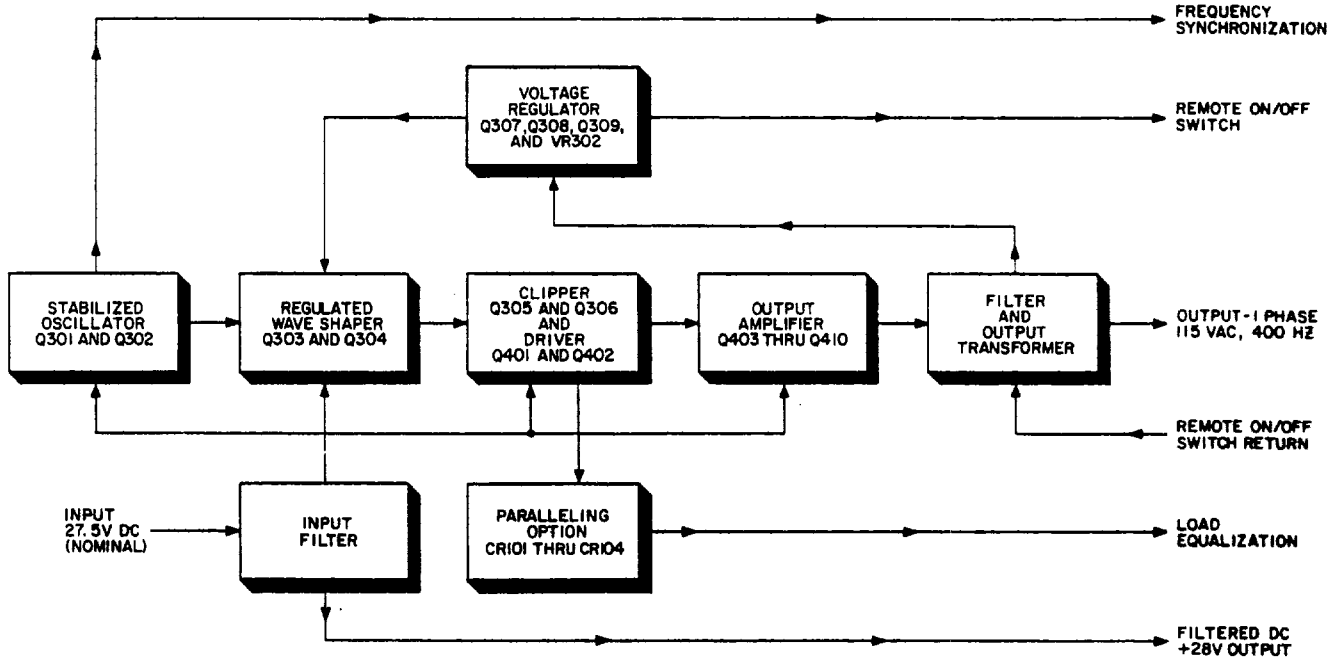
Table of Leading Particulars (Cont)
Table I (Cont)

3. OPERATION

The subsequent paragraphs cover the theory of operation for the PAI P.N. DH-1030-24-600-CS, Type IIB, Solid-State Static Inverter (Transverter). The Block Diagram Theory will aid in conveying the overall circuit operation to non-technical oriented personnel, while the Detailed Circuit Theory will enable the technician to understand in detail the operation of equipment.

A. Block Diagram Theory

The subsequent paragraphs together with the block diagram of Fig. 2, cover in concise form the signal flow and circuit operation for the DH-1030-24-600-CS, Type IIB, Solid-State Static Inverter (Transverter).



(1) Input Filter. Power applied through the input filter is free of transients and is provided with reverse polarity protection for application to circuits of the Transverter. A filtered +28V DC output connection is also provided for use in parallel operation of the inverter.

(2) Stabilized Oscillator. Transistors Q301 and Q302 generate a 400 Hertz sine wave signal of high stability. The sine wave signal is coupled through auxiliary windings of the oscillator transformer T301 to the input of the regulated wave shaper.

(3) Regulated Wave Shaper. Transistors Q303 and Q304 in a push-pull circuit receive the sine wave signal developed by the stabilized oscillator. Voltage applied from

the voltage regulator circuit determines the shaping operation for control of duty cycle and regulation of the output voltage. The shaped quasi-square wave output is coupled to the input of the clipper and driver circuit.

(4) Clipper and Driver. Transistors Q305, Q306, Q401, and Q402 in cascaded push-pull stages provide additional shaping and amplification of the 400 Hertz signal. The amplified quasi-square wave signal is applied to the output amplifier.

PAI P.N.DH-1030-24-600-CS, Type IIB, Solid-State Static Inverter (Transverter), Block Diagram
Figure 2

(5) Output Amplifier. Transistors Q403 through Q410 in a push-pull parallel circuit amplify the 400 Hertz signal to the required level across the output transformers for application to the output filter.

(6) Output Transformers and Filter. The output transformers and associated filter circuitry provide matching and shaping to return the amplified signal to a sinusoidal waveform.

(7) Voltage Regulator. Transistors Q308 and Q309 develop the regulating bias by comparison of the rectified negative DC voltage supplied from the output, and adjusted by setting of resistor R324, controlling the Zener regulated voltage to the base of Transistor Q308.

(8) Paralleling Circuit. Coupling transformer T101 provides a voltage to diodes CR101 through CR104 from the collector circuit of transistors Q401 and Q402. The rectified signal is adjusted to provide an output voltage for load equalization when operating inverter in a parallel system.

(9) Remote Turn-On/Turn-Off. Remote turn-on/turn-off of the inverter is accomplished by external control of the collector circuit of transistor Q309, ground, return.

B. Detailed Circuit Theory.

The following sub-paragraphs cover the individual circuits and their operation. Occasional reference to the overall schematic diagram of the Transverter, Fig. 1201, will be necessary to determine circuit configuration.

(1) Input Filter. The input filter consists of series reactor L2 and shunt capacitors C201, C202, and C203 providing high speed transient and ripple suppression to the input line. Diode CR9 provides reverse polarity protection for the Transverter circuitry. The input filter and reverse polarity protect diode passes the input current required to maintain rated power output and provide operating voltage to Transverter circuits. Over-voltage protection for low speed transients is provided by Zener diode VR301, resistor R313, and diodes CR302, CR303, and CR304. If the input voltage exceeds 39volts ±2 volts, Zener diode VR301 conducts and applies back bias to transistors Q305 and Q306 through diodes CR303 and CR304, respectively. This bias inhibits switching during over voltage periods and prevents a high voltage from being developed which could damage subsequent amplifier circuits or the output circuit. Diode CR302 protects the base circuits of transistors Q305 and Q306. Resistor R201 and Zener diode VR401 provide transient suppression and regulation for the low level stages. Diode CR105 located on the Paralleling Circuit Board, across terminals E101 and E102, provides filtered, positive 28 volts DC output at pin A of connector J2.

(2) Stabilized Oscillator. The stabilized oscillator utilizes transistors Q301 and Q302 in a Hartley oscillator circuit. Toroidal transformer T301, with multiple windings provides the tuned circuit, feedback, and output windings for the oscillator. The tuned circuit portion is tuned by capacitors C301, C302, and C303 to 400 Hertz. Capacitor C303 provides parasitic suppression in the tuned collector circuit. A feedback winding provides the coupling between base- collector circuit to sustain oscillations, resistors R318 and R319 provide bias to the base circuit of transistors Q301 and Q302 to insure positive start and sustained oscillations. Resistor R304 provides degeneration for improved stability of the oscillator circuit. Output to the regulated wave shaper circuit is through the remaining winding on transformer T301. Output from the collector of transistor Q302 and tuned circuit is terminated at Pin D of connector J2 for Frequency Synchronization in a multiple inverter system.

(3) Regulated Wave Shaper. The regulated wave shaper receives the 400 Hertz sinusoidal signal from transformer T301 output winding. The input signal is applied to the base circuits of transistors Q303 and Q304 through resistors R301 and R302, respectively, limiting base current which flows in the base circuit. Transistors Q303 and Q304 conduct on alternate half cycles, with the point of conduction determined by the amount of bias supplied by transistor Q309, voltage regulator, to the emitter circuit. Resistor R307 adjusts the output of transistors Q303 and Q304 for minimum second harmonic content in the inverter output. The output of this stage is a quasi-square wave and is applied to the input of the clipper circuit.

(4) Clipper and Driver. The clipper and driver circuits provide additional shaping of the signal and amplification for application to the output amplifier circuits. The clipper circuit consists of transistors Q305 and Q306 in a push-pull circuit. The quasi-square wave is applied to the base circuits of transistors Q305 and Q306 through current limiting resistors R308 and R309 and coupling capacitors C307 and C308, respectively. The output of the clipper circuit results in a quasi-square wave with improved rise time. The output is coupled to the base circuits of the driver transistors Q401 and Q402 through resistors R314 and R315, respectively. Resistors R316 and R317 provide a low impedance return for leakage currents. Output of the collector circuits is developed across toroidal driver transformer T401 and coupled to the output amplifier circuits. Capacitor C401 across the primary winding suppresses transients which might appear across the output.

(5) Output Amplifiers. The output amplifiers receive the quasi-square wave signal through toroidal driver transformer T401. Four output windings are connected in parallel to provide two outputs which drive the eight output transistors Q403 through Q410. Input to the base circuit of each output transistor is through two paralleled 1 Ohm, 2 Watt, resistors, providing current limiting to the input. A 4.7 Ohm, 2 watt resistor between the base and emitter of each output transistor reduces the impedance during the non-conduction period. The collectors of transistors Q403 through Q410 are parallel connected in groups of four, Q403, Q404, Q405, and Q406 are connected to the high side of transformer T2, terminals E1-14, E1-8, E2-14, and E2-8, respectively, while transistors Q407, Q408, Q409, and Q410 are connected to the low side of transformer T2 terminals E2-3, E2-9, E1-3, and E1-9, respectively. Diodes CR1 through CR8 connected in parallel with the emitter and collector terminals of each power transistor provide the reverse current flow from the load back to the DC power source under conditions of high reactive loading. Toroidal series reactor transformer T1 is connected in series with the primary windings of the output transformer T2. The secondary winding of output transformer T2 is connected to the filter circuit.

(6) Output Transformer and Filter. The 400 Hertz quasi-square wave signal developed across toroidal output transformer T2 is high in content of odd order harmonics. Toroidal series reactor transformer T1 in conjunction with the output transformer T2, and the output filter circuit reduce these odd order harmonics. The impedance of the series reactor transformer T1 is low at the 400 Hertz fundamental frequency, but sufficiently high at the frequency of the harmonics to enable the reactor-transformer combination to filter the harmonic content. The output filter appears as a high impedance to the fundamental 400 Hertz signal and a low impedance to the harmonics, thus resulting in optimum power transfer at the fundamental frequency of 400 Hertz. The secondary winding of transformer T2 is tuned to the 400 Hertz fundamental by parallel capacitors C204 and C205, forming a parallel tuned circuit, which reflects a high impedance to the fundamental 400 Hertz signal and a low impedance path to the harmonics. The series tuned circuit comprised of capacitor C206 and toroidal reactor L1 is tuned to the third order harmonic 1,200 Hertz, providing a shunting effect to the most predominant harmonic present in the output. The filtered output is 115 volts AC at a frequency of 400 Hertz and is available at pins B and G of connector J2. The additional winding on transformer T2 is used to derive feedback voltage for the voltage regulator circuit. The derived voltage is rectified by diodes CR305 and CR306 to provide a negative DC potential to the voltage regulator circuit

(7) Voltage Regulator. The voltage regulator consists of transistors Q307, Q308, and Q309, and Zener diode VR302. The positive voltage from Zener diode VR302 through temperature compensating transistor Q307 and the negative voltage from diodes CR305 and CR306 are applied to the summing resistors R323, R324, R325, and R347 to derive an error voltage at the base of transistor Q308. A change in output voltage, after the setting of resistor R324 has been determined, causes a change in the current applied to the summing circuit, developing an error voltage which is amplified by transistors Q308 and Q309. Output at the emitter of transistor Q309 results in a proportional voltage change which is the bias applied to transistors Q303 and Q304. This change in bias controls duty cycle and output voltage by limiting action in the regulated wave shaper circuit.

(8) Paralleling Circuit. The paralleling circuit operates from voltages derived in the collector circuits of transistors Q401 and Q402, Driver Transistors, conducting on alternate half-cycles. The derived output is applied to a step-down coupling transformer for application to a bridge rectifier circuit comprised of diodes CR101 through CR104. The rectified output voltage developed across load resistor R102 and filter capacitor C101, together with the summed voltage from the base circuit of transistor Q308, applied to connection point B. is adjusted to desired level by

variable resistor R103. The preset level becomes the reference voltage which is delivered for application to load equalization circuits for automatic control of multiple inverter systems.

(9) Remote Turn-On/Turn-Off. Remote turn-on/turn-off of the inverter is accomplished by external control of the collector return of transistor Q309, to ground. This control requires completion of the circuit between pins E and F of connector J2 through an ancillary switch.

DISASSEMBLY

1. GENERAL.

This section outlines procedures for disassembly of the Transverter. The procedures should be followed in the event it becomes necessary to repair the unit after a malfunction or part failure. Electrical wiring should not be disconnected except when required for complete removal of a component or sub-assembly or when wiring is found to be defective. When wiring is disconnected, tag each wire and note connection point for ease in identification during reassembly.

2. COVER AND INPUT AND OUTPUT CONNECTIONS NAMEPLATE REMOVAL.

A. Break Phoenix Aerospace, Inc. safety tie wire (seal), (-26) Fig. 1101, by cutting and remove.

NOTE

In the event Transverter is in warranty, breaking of seal may void warranty unless covered by other contractual agreement.

B. Remove the twenty-eight screws securing cover, (-23), (-24), and (-25) Fig. 1101, and remove cover by lifting straight up from base. Place hardware aside for reassembly.

NOTE

Careful attention should be given to the length of screws removed, particularly the lower row on both sides, are 5/8 inch long, the remaining 22 screws are 3/8 inches long.

C. Remove input and output connections nameplate, (21) Fig. 1101, lifting at edge of plate, not at the corners, to release adhesive. Place aside for reassembly operation.

CAUTION

DO NOT PLACE NAMEPLATE WITH ADHESIVE SIDE TOWARD PAPER OR AN OILY SURFACE.

3. REMOVAL OF OSCILLATOR/AMPLIFIER/DRIVER CIRCUIT MODULE SUB-ASSEMBLY

A. General.

Removal of the Oscillator/Amplifier/Driver Circuit Module Sub-assembly, (13) Fig. 1101, is accomplished to gain access to component side of circuit board or other sub-assemblies

of the Transverter. Unless board replacement is required interconnecting wires should never be disconnected. Proceed as follows to gain access to the component side of sub-assembly.

B. Removal Procedure.

(1) Loosen and remove the five No. 4-40 x 1/2 inch long flat head, 82° countersink, machine screws, (-14) Fig. 1101, at the connector end of Transverter.

NOTE

These screws were concealed by the Input and Output Connections Nameplate removed in preceding paragraph 2.

(2) Loosen and remove the five No. 4-40 x 1/2 inch long binder head machine screws, (-15) Fig. 1101, at the opposite end of Transverter.

(3) Carefully swing loosened sub-assembly up and over to the side to expose component side of circuit board. DO NOT disconnect wiring unless removal of entire sub-assembly is required.

4. DISASSEMBLY OF OSCILLATOR/AMPLIFIER/DRIVER CIRCUIT MODULE SUB-ASSEMBLY.

A. General.

Disassembly of the Oscillator/Amplifier/Driver Circuit Module Sub-assembly is not required unless a printed circuit board, (45) Fig. 1107, is damaged beyond repair and necessitates removal and replacement.

B. Disassembly Procedure.

(1) Carefully identify, disconnect, and tag all wires leading to or from the Oscillator/Amplifier/Driver Circuuit Board Sub-assembly, (45) Fig. 1107.

(2) Remove the Oscillator/Amplifier/Driver Circuit Board Sub-assembly, (45) Fig. 1107, by loosening and removing the four No. 4-40 x 1/2 inch long binder head machine screws, four .1875 inch O.D. x 1/4 inch long aluminum spacers, four No. 4 internal tooth lock washers, and four No. 4-40 hex nuts, (-46), (-47), (-48), and (-49) Fig. 1107. Place hardware removed aside for use during reassembly.

5. REMOVAL OF INPUT AND OUTPUT FILTER CIRCUIT BOARD SUB-ASSEMBLY.

A. General.

Removal of the Input and Output Filter Circuit Board Sub-assembly (9) Fig. 1101, is required to gain access to the underside of printed circuit board when parts removal and replacement is required. **It is not necessary to remove board completely, therefore, DO NOT disconnect wiring unless board is physically damaged beyond repair.**

B. Removal Procedure.

(1) Loosen and remove the two No. 6-32 x 1/2 inch long binder head machine screws, two No. 6-32 x 3/8 inch long binder head machine screws, and four No. 6 internal tooth lock washers, (-10), (-11), and (-12) Fig. 1101, securing sub-assembly in place. Place hardware aside for use during reassembly.

(2) Carefully lift board to expose underside of printed circuit for component removal and replacement. **DO NOT disconnect wiring to board unless sub-assembly removal is required.**

6. REMOVAL OF PARALLELING CIRCUIT BOARD SUB-ASSEMBLY.

A. General.

Removal of the Paralleling Circuit Board Sub-Assembly (10) Fig. 1104, is required to gain access to both sides of the printed circuit board when parts replacement is required. It is not necessary to remove board completely, therefore, DO NOT disconnect wiring unless board is damaged beyond repair. The Parallelling Circuit Board Mounting (Bracket (-6), Fig. 1104, should not be removed unless it is necessary to complete procedures of paragraphs 7 or 8.

B. Removal Procedure.

(1) Identify the three No. 4-40 X 3/8 in. long, binder head, machine screws, (-11) Fig. 1104, securing the Paralleling Control Circuit Board to the circuit board mounting Bracket, (-6), Fig. 1104, remove the hardware to permit circuit board to swing free. Place hardware aside for use during reassembly.

(2) Should removal be necessary, tag and identify leads during removal to facilitate reinstallation.

7. REMOVAL OF TRANSFORMER MOUNTING CHASSIS PAN SUB-ASSEMBLY.

A. General.

Removal of the Transformer Mounting Chassis Pan Sub-Assembly (7), Fig 1101, is required only when it should become necessary to relace a transformer or reactor mounted on this sub-assembly.

B. Removal Procedure.

(1) Identify and remove Input and Output Filter Circuit Board Sub-Assembly, (9), Fig. 1101, following procedures of preceding paragraph 5.

(2) Disconnect all leads and tag for aid in identification during reassembly.

(3) Identify the six No. 6-32 X 3/8 inch long flat head 82° countersink, machine screws, (-8), Fig. 1101, securing the Transformer Mounting Chassis Pan Sub-Assembly to the Static Inverter Base (1), Fig. 1101, and remove.

8. REMOVAL OF TRANSFORMERS AND REACTOR, TRANSFORMER MOUNTING CHASSIS PAN.

A. General.

Removal of transformers and reactor, (12), (17), (22), and (27) Fig. 1104, should never be accomplished unless replacement is required. In the event replacement is required, recommended practice would be to return unit to the factory for repair. If field repairs are to be made proceed as follows.

B. Removal Procedure.

(1) Identify and remove Input/Output Filter Circuit Board Sub-Assembly, (9) Fig. 1101, following procedures of preceding paragraph 5.

(2) Identify and remove the two terminal strips (34) and (35) Fig. 1104, secured in place by two No. 6-32 x 3/8 inch long binder head machine screws,and two No. 6 internal tooth lock washers (-36) and (-37), Fig. 1104, disconnect leads necessary only to remove defective part, identifying carefully all terminals with tags for aid in reassembly.

(3) Identify and remove the six No. 6-32 x 3/8 inch long flat head, 82° countersink, machine screws, (-8), Fig. 1101, securing the Transformer Mounting Chassis Pan, (7) Fig. 1101, to the Static Inverter (Transverter) Base, (1) Fig. 1101.

(4) Identify the transformer or reactor mounting screw, (-14), (-19), (-24), and (-29), Fig. 1104, washer,(-15), (-20), (-25), and (-30), Fig. 1104, and nut (-16), (-21), (-26), and(-31), Fig. 1104, and remove to permit removal from the potting compound.

NOTE

To remove transformers or reactor potting compound must be broken away before device will separate from Transformer Mounting Chassis Pan. Use care to prevent damage to components not requiring replacement.

CLEANING

1. GENERAL.

This section outlines procedures for cleaning the components of the Transverter while disassembled. Cleaning materials are listed in Table 201.

WARNING

PERFORM OPERATION INVOLVING SOLVENT ONLY IN A WELL VENTILATED AREA. AVOID BREATHING OF SOLVENT VAPOR AND CONTINUOUS CONTACT WITH SOLVENT.

Reference to air jet refers to a hand-operated air nozzle supplied with clean, dry, compressed air at a maximum pressure of 28 psi.

WARNING

GOGGLES SHOULD BE WORN WHEN USING AIR JET TO BLOW DUST AND DIRT FROM EQUIPMENT. OTHER PERSONS SHOULD BE WARNED AWAY FROM HAZARDOUS AREA OR WORKING ENCLOSURE.

MATERIAL
Perchloroethylene Solvent/Non-Aqueous
Soft-bristled Brush
Soft, Clean Cloth

List of Cleaning Materials
Table 201

2. PRINTED CIRCUIT BOARDS-WIRED CHASSIS.

Remove dust and dirt from all surfaces with a soft-bristled brush in conjunction with an air jet.

NOTE

When the dress of wiring is disturbed, dressing should be noted, and when cleaning is finished, wiring should be restored to proper dress or position.

3. METAL SURFACES.

Clean with soft cloth moistened in trichloroethylene solvent, and dry with clean, dry cloth.

4. CONNECTORS.

A. Wipe dust and dirt from shell using trichloroethylene solvent and a soft cloth. Wipe dry with clean, dry cloth.

B. Remove dust from insert using small, soft-bristled brush in conjunction with air jet.

INSPECTION/CHECK

1. GENERAL.

This section contains procedures to determine the condition of Transverter.

2. COVER.

Inspect cover for deformations, dents, punctures or surfaces which might be wearing due to interference with other components.

3. CONNECTORS.

A. Inspect for broken parts, damaged shell, and any other abnormal condition.

B. Inspect for broken, cracked, or damaged insert and for contacts which are broken, deformed, out of alignment. Check for corrosion and signs of arcing at the contacts and for poorly soldered connections.

4. RESISTORS.

Inspect resistors for signs of overheating; cracked, broken, or charred insulation; loose, poorly soldered, or corroded terminal connections; and loose mountings.

5. METAL SURFACES AND MECHANICAL.

Inspect metal surfaces for signs of corrosion. Also check component mountings for mechanical tightness.

6. WIRES.

Check wires for damaged insulation and for proper dress.

REPAIR

1. GENERAL.

This section outlines instructions for the repair or replacement of damaged or defective parts. Faulty parts are usually detected by inspection, cleaning or troubleshooting. The repair or replacement of damaged or defective parts involves standard repair techniques. Identify each wire before removal of any part requiring unsoldering of several lead wires.

2. COVER.

Straighten any deformation, and retouch scratched or worn surfaces.

3. CHASSIS.

Remove all traces of corrosion and recoat with clear epoxy resin where broken or removed during repairs.

Before attempting to solder connections, peel away epoxy resin using a sharp knife.

NOTE

The clear epoxy resin is Armstrong Products Inc. Type T-600 or equivalent. Any time the epoxy coating is disturbed, recoating is advised.

4. CONNECTORS.

Straighten bent pins. Resolder connection and check insulation. If badly damaged, replace connector.

5. SOLDER CONNECTIONS.

Resolder any defective solder joints. Remove all traces of corrosion.

6. WIRING.

Replace any wiring with damaged insulation or broken strands.

7. RESISTORS.

Replace resistors that show signs of overheating or with cracked or broken bodies. Resolder loose, broken or corroded connections.

ASSEMBLY

1. GENERAL.

This section outlines the instructions for assembly of the Transverter. Before assembly of the unit, the Cleaning, Inspection/Check, and Repair Sections should be consulted to determine if all components are properly cleaned and in proper physical and operating condition. Where wiring must be reconnected, good practices must be followed in dressing of wires and soldering connections. Refer to Figures 1101, 1103, 1104, 1105, 1106 and 1107 for identification and location of sub-assemblies and component parts. Refer to Figures 501, 502, and 503, for wiring information.

2. INSTALLATION OF TRANSFORMERS AND REACTOR, ON TRANSFORMER MOUNTING CHASSIS PAN SUB-ASSEMBLY.

A. General.

Assembly of transformers and reactor (12), (17), (22) and (27) Fig. 1104, requires the use of epoxy resin similar to Dow Corning Type D.E.R. 330 with aluminum oxide filler and Dow Corning curing agent. The epoxy resin replaces any removed during the removal of transformers or reactors, and must be replaced to properly heat sink the unit and the transformers and reactors. In the event complete removal was not necessitated, disregard those steps not applicable and complete assembly procedures.

NOTE

Insulating disks, (-13), (-18), (-23), and (-28), Fig. 1104, must be replaced if damaged. Insulating Disks are used between the Chassis Pan and transformer or reactor.

B. Assembly Procedure.

(1) Identify the appropriate mounting screw for the transformer and/or reactor and mount through chassis pan. Secure in place using the No. 10 internal tooth lock washer and No. 10-24 hex nut. **DO NOT overtighten hardware.**

(2) The Polarity Protect Diode Sub-Assembly, (2) Fig. 1104, would not be replaced unless bracket has been damaged. Replacement of the diode, (2) Fig. 1102, is easily accomplished by reference to Fig. 1102 and Fig. 501.

(3) Replace epoxy resin by preparing the resin in a ratio of 1 to 1 by weight in accordance with manufacturer's instructions, and adding the aluminum oxide filler in a ratio of 30% by weight. Block ends of Transformer Mounting Chassis Pan to prevent compound from running out and fill to approximately 1/4 inch deep with potting compound. Allow curing to take place and proceed with subsequent steps.

(4) Assemble Transformer Mounting Chassis Pan to Static Inverter (Transverter) Base. Place a thin layer of Dow Corning No. 4 Compound, silicone lubricant between chassis pan and base. Secure, using the eight No. 6-32 x 3/8 inch long flat head, 82° countersink, machine screws, (-8) Fig. 1101, into the spacer blocks on the chassis pan.

(5) Identify the two terminal strips, (34) and (35) Fig. 1104, and position over the position over the 1-11/16 inch high aluminum spacer posts (32) Fig. 1104, and secure by hardware using one No. 6-32 X 3/8 inch long, binder head, machine screw (-36) Fig. 1104, and one No. 6 internal tooth lock washer, (-37) Fig. 1104, at the rear end of the Transverter Mounting Chassis Pan Sub-Assembly, the two other screws retaining the terminal strips will be installed in subsequent paragraphs.

(6) Identify leads disconnected during removal procedures and carefully reconnect and solder at the proper points. Reference to Fig. 501 will aid in identifying and reconnecting leads.

3. INSTALLATION OF TRANSFORMER MOUNTING CHASSIS PAN SUB-ASSEMBLY.

A. General.

Refer to Fig. 1101 and Fig. 501 for aid in installation of the Transformer Mounting Chassis Pan Sub-Assembly, (9) Fig. 1101, to the Static Inverter Base, (1) Fig. 1101.

B. Installation Procedure.

(1) Place a thin layer of Dow Corning, No 4 Compound, silicone lubricant on the bottom of the Transformer Mounting Chassis Pan Sub-Assembly and the Static Inverter Base.

(2) Identify the six No. 6-32 X 3/8 inch long 82° countersink, machine screws, (-8) Fig. 1101, and secure through the Static Inverter Base into the aluminum spacer posts, (-32), and (-33) Fig. 1104, on the Transformer Mounting Chassis Pan Sub-Assembly.

(3) Install all leads disconnected during disassembly and restore lead dress. Reference to Fig. 501 will aid in reconnecting the various leads along with the identification tags used during disassembly.

4. INSTALLATION OF PARALLELING CONTROL CIRCUIT BOARD SUB-ASSEMBLY.

A. General.

Refer to Fig. 1104 and Fig. 501 for aid in reinstallation of the Paralleling Control Circuit Board Sub-Assembly, (10) Fig. 1104, and complete as follows:

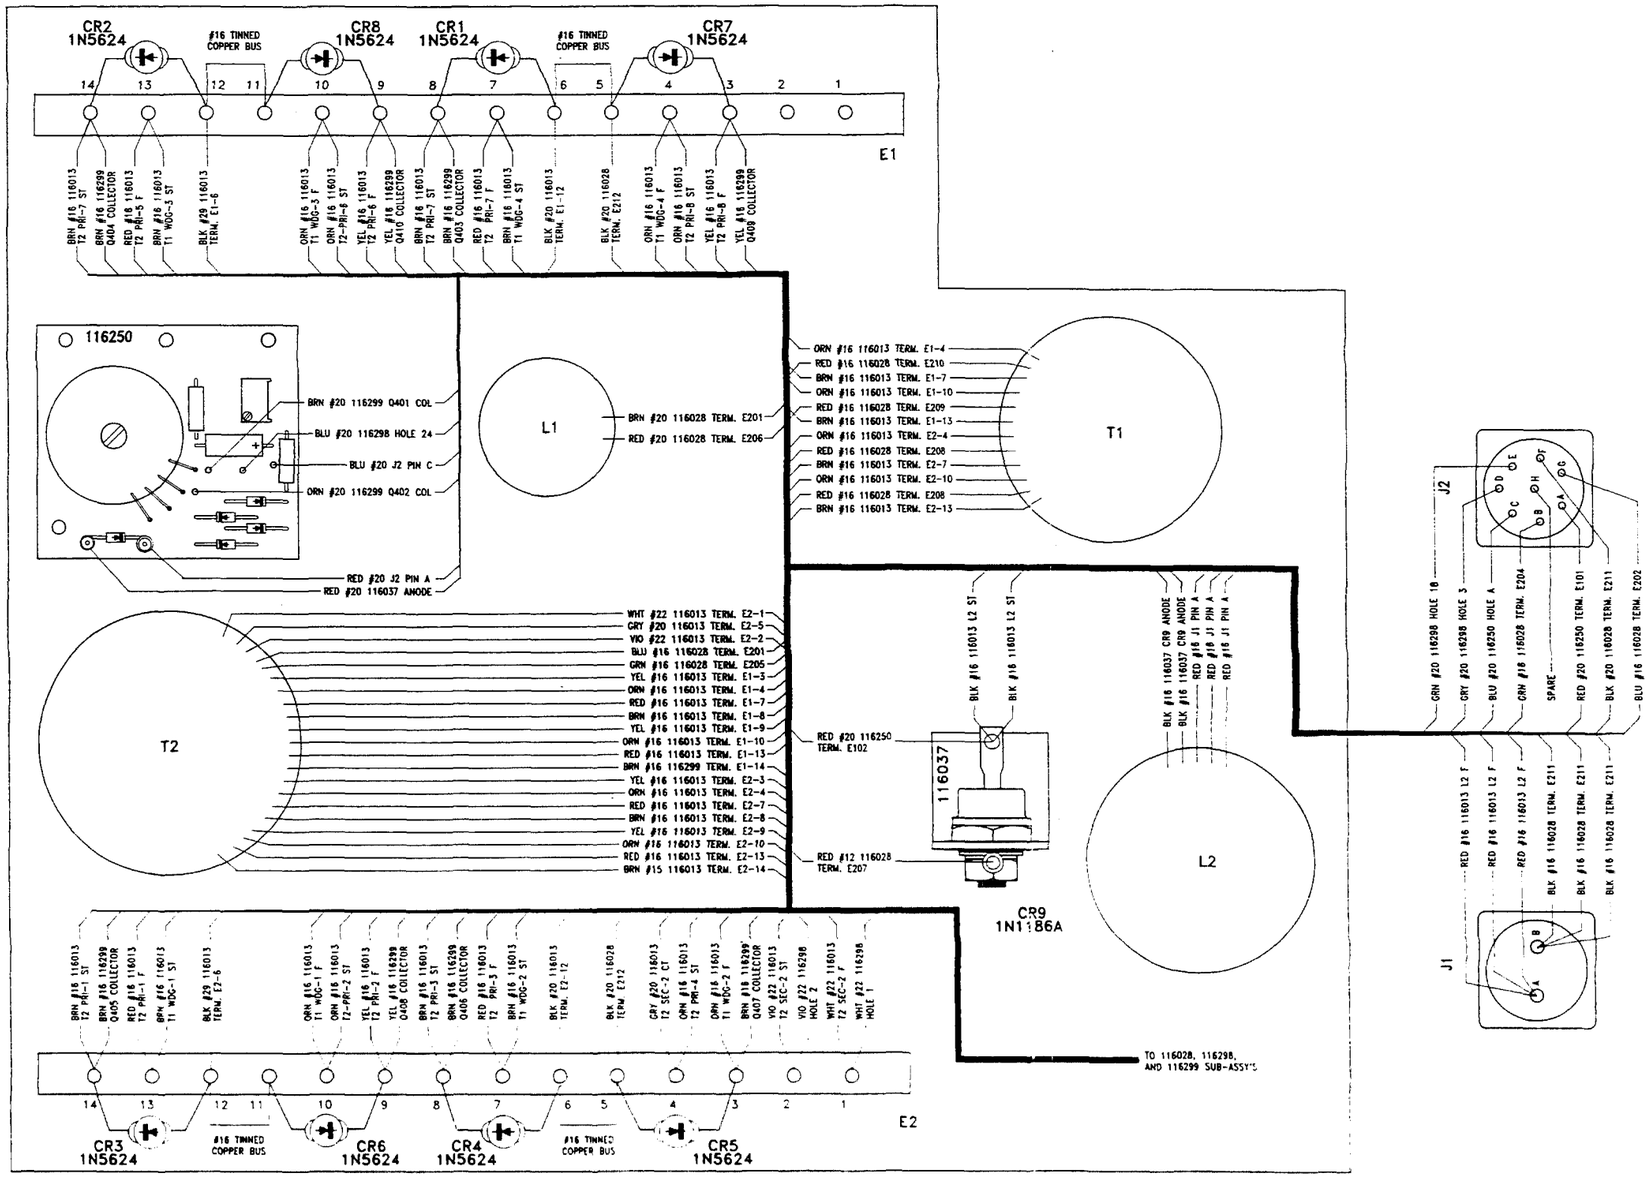


Figure 501. Wiring Diagram, Transformers and Reactors Mounting Chassis Pan Sub-Assembly
Figure 501

B. Installation Procedure.

(1) Refer to Fig. 501 for identification of wire leads and reconnect any wires removed during disassembly and restore lead dress.

(2) Carefully position Paralleling Control Circuit Board Sub-Assembly, (10) Fig. 1104, over mounting bracket, (-6) Fig. 1104. Reinstall using three No. 4-40 X 3/8 inch long, binder head, machine screws, (-11) Fig. 1104.

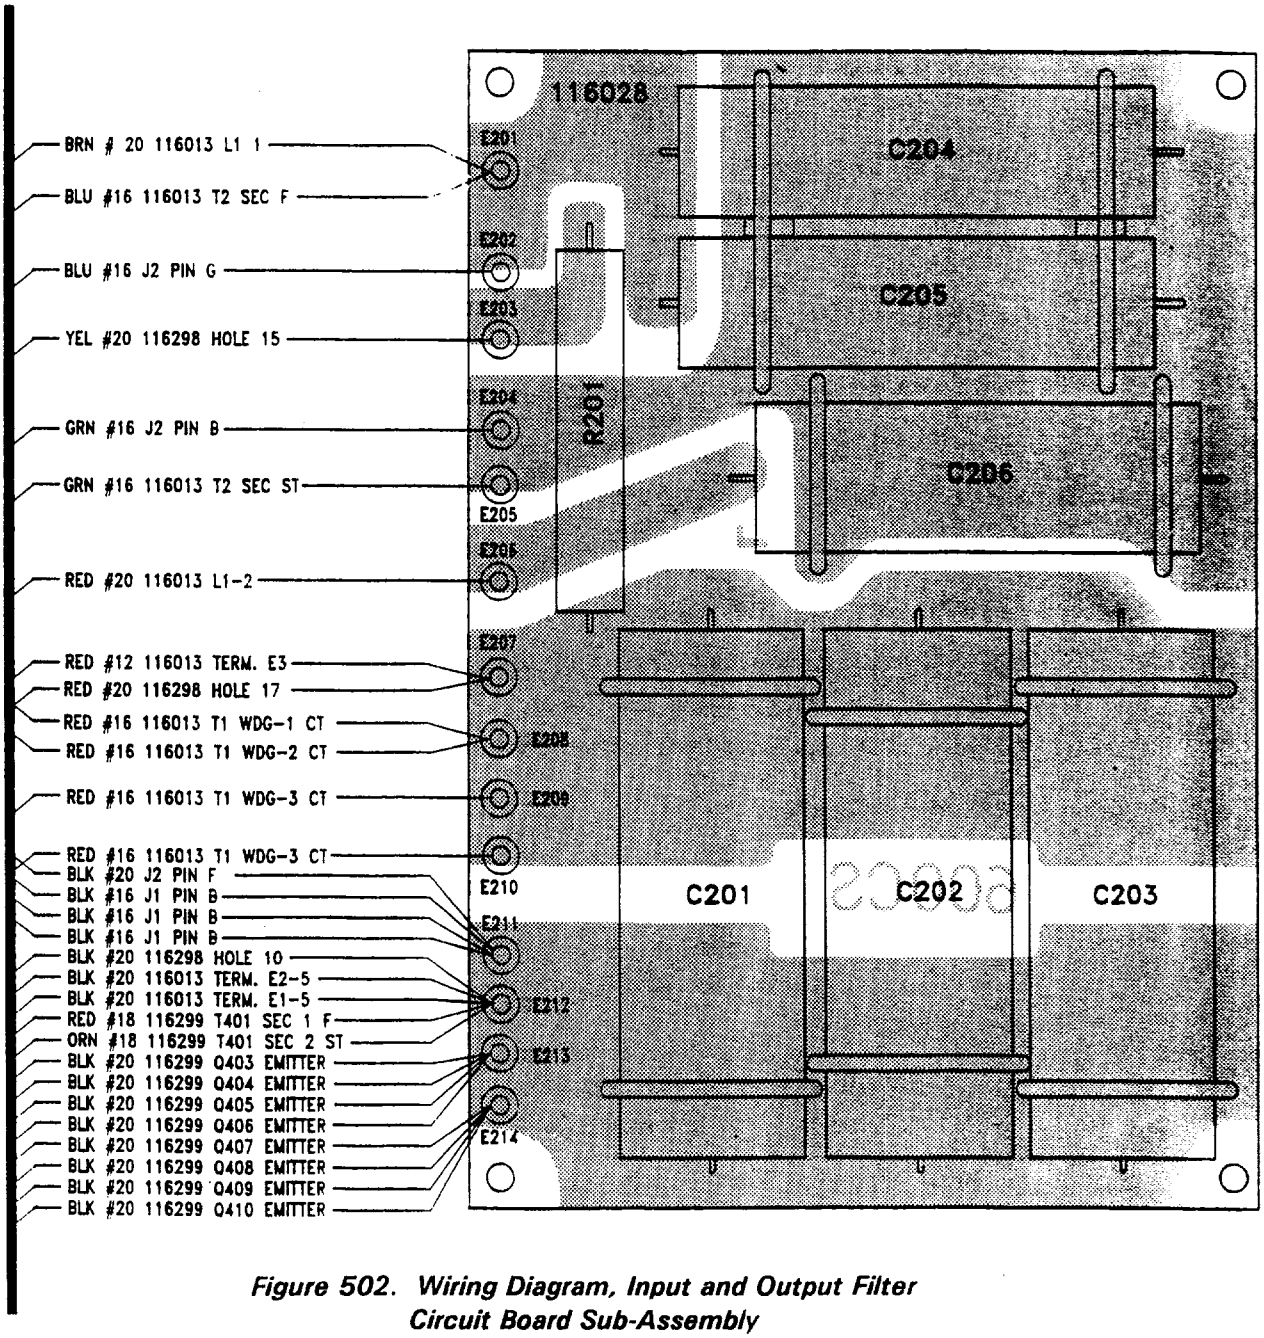

Figure 502. Wiring Diagram, Input and Output Filter Circuit Board Sub-Assembly
Figure 502

5. INSTALLATION OF INPUT AND OUTPUT FILTER CIRCUIT BOARD SUB-ASSEMBLY.

A. General.

Installation of Input and Output Filter Circuit Board Sub-Assembly, (9) Fig. 1101, requires care in reconnecting of leads disconnected during disassembly procedures.

B. Assembly Procedure.

(1) Carefully reconnect leads disconnected during disassembly or removal. Reference to Fig. 502 will aid in reconnecting and identifying leads.

(2) Identify the two No. 6-32 X 1 /2 inch long binder head machine screws, two No. 6-32 x 3/8 inch long binder head machine screws, and four No. 6 internal tooth lock washers, (-10), (-11), and (-12) Fig. 1101, align circuit board with holes in the two terminal strips positioned in preceding paragraph 2B.(4), (34) and (35) Fig. 1104, and using the two 6-32 x 1/2 inch long screws at the board edge over the two terminal strips and the two 6-32 x 3/8 inch long screws at the edge of board over the two aluminum spacers and secure to Transformer Mounting Chassis Pan.

6. ASSEMBLY OF OSCILLATOR/AMPLIFIER/DRIVER CIRCUIT MODULE SUB-ASSEMBLY.

A. General.

Assembly of the Oscillator/Amplifier/Driver Circuit Module Sub-Assembly, (13) Fig. 1101, consists of mounting the Oscillator/Amplifier/Driver Circuit Board Sub-Assembly, (45) Fig. 1107, and reconnection of the leads disconnected during removal procedures.

B. Assembly Procedure.

(1) Identify the four No. 4-40 x 5/8 inch long binder head machine screws, four .0.1875 inch O.D.x 1/4 inch long aluminum spacers, four No. 4 internal tooth lock washers, and four No. 4-40 hex nuts. (-46), (-47), (-48), and (-49) Fig. 1107, and use to secure the Oscillator/Amplifier/Driver Circuit Board Sub-Assembly, (45) Fig. 1107.

(2) Identify and reconnect leads disconnected at time of disassembly. Refer to Figures 502 and 503 for help in reconnecting wires disconnected during disassembly.

7. INSTALLATION OF CIRCUIT MODULE OSCILLATOR/AMPLIFIER/DRIVER SUB-ASSEMBLY.

A. General.

Reinstallation of the Circuit Module-Oscillator/Amplifier/Driver Sub-Assembly, (13) Fig. 1101, is completed as follows.

B. Assembly Procedure.

(1) Reconnect any wires removed during disassembly and restore lead dress. Reference to Figures 501,502, and 503 will be helpful in reconnecting the wires and restoring lead dress.

(2) Carefully swing sub-assembly over and down between ends of Transverter Base, (1) Fig. 1101, with components on circuit board toward interior of Transverter.

(3) Identify the five No. 4-40 x 1/2 inch long flat head, 82° countersink, machine screws, (-14) Fig. 1101, and secure sub-assembly from connector end, tighten securely.

(4) Identify the five No. 4-40 x 1/2 inch long binder head machine screws, (-15) Fig. 1101, and secure sub-assembly from opposite end of unit, tighten securely.

8. INSTALLATION OF INPUT AND OUTPUT CONNECTIONS NAMEPLATE

Carefully center Input and Output Connections Nameplate, (21) Fig. 1101, above the input and output connectors and press firmly in place to cause adhesive to stick to metal surface.

9. INSTALLATION OF COVER.

A. General.

Refer to Fig. 1101 and proceed as follows:

B. Installation Procedure.

(1) Places a thin coating of Dow Corning , No. 4 Compound, silicone lubricant on the edges of the Oscillator/Amplifier/Driver Circuit Module Sub-Assembly and the Transformer Mounting Chassis Pan Sub-Assembly.

(2) Place cover over unit and secure in place with hardware removed during disassembly in the following sequence.

(3) Identify the six No. 4-40 x 5/8 inch long binder head machine screws, (-23) Fig. 1101, and install at the bottom edge of cover.

CAUTION

UNDER NO CIRCUMSTANCES SHOULD HARDWARE LONGER THAN 3/8 INCH BE USED AT UPPER ROW, LEFT AND RIGHT SIDE, TO SECURE COVER.

(2) Identify the two No. 4-40 x 3/8 inch long fillister head (drilled) screws, (-25) Fig. 1101, and install at the front, connector end, lower, left and right edge of cover.

(3) Identify the twenty No. 4-40 x 3/8 inch long binder head machine screws, (-24) Fig. 1101, and completely secure cover to Transverter base.

(4) Place new PAI Warranty Seal, (-27) and Safety Tie Wire, (-26), Fig. 1101, through the drilled holes on No. 4-40 X 3/8 inch long, fillister head (drilled) screws, (-25) Fig 1101, and seal by crimping the Warranty Seal..

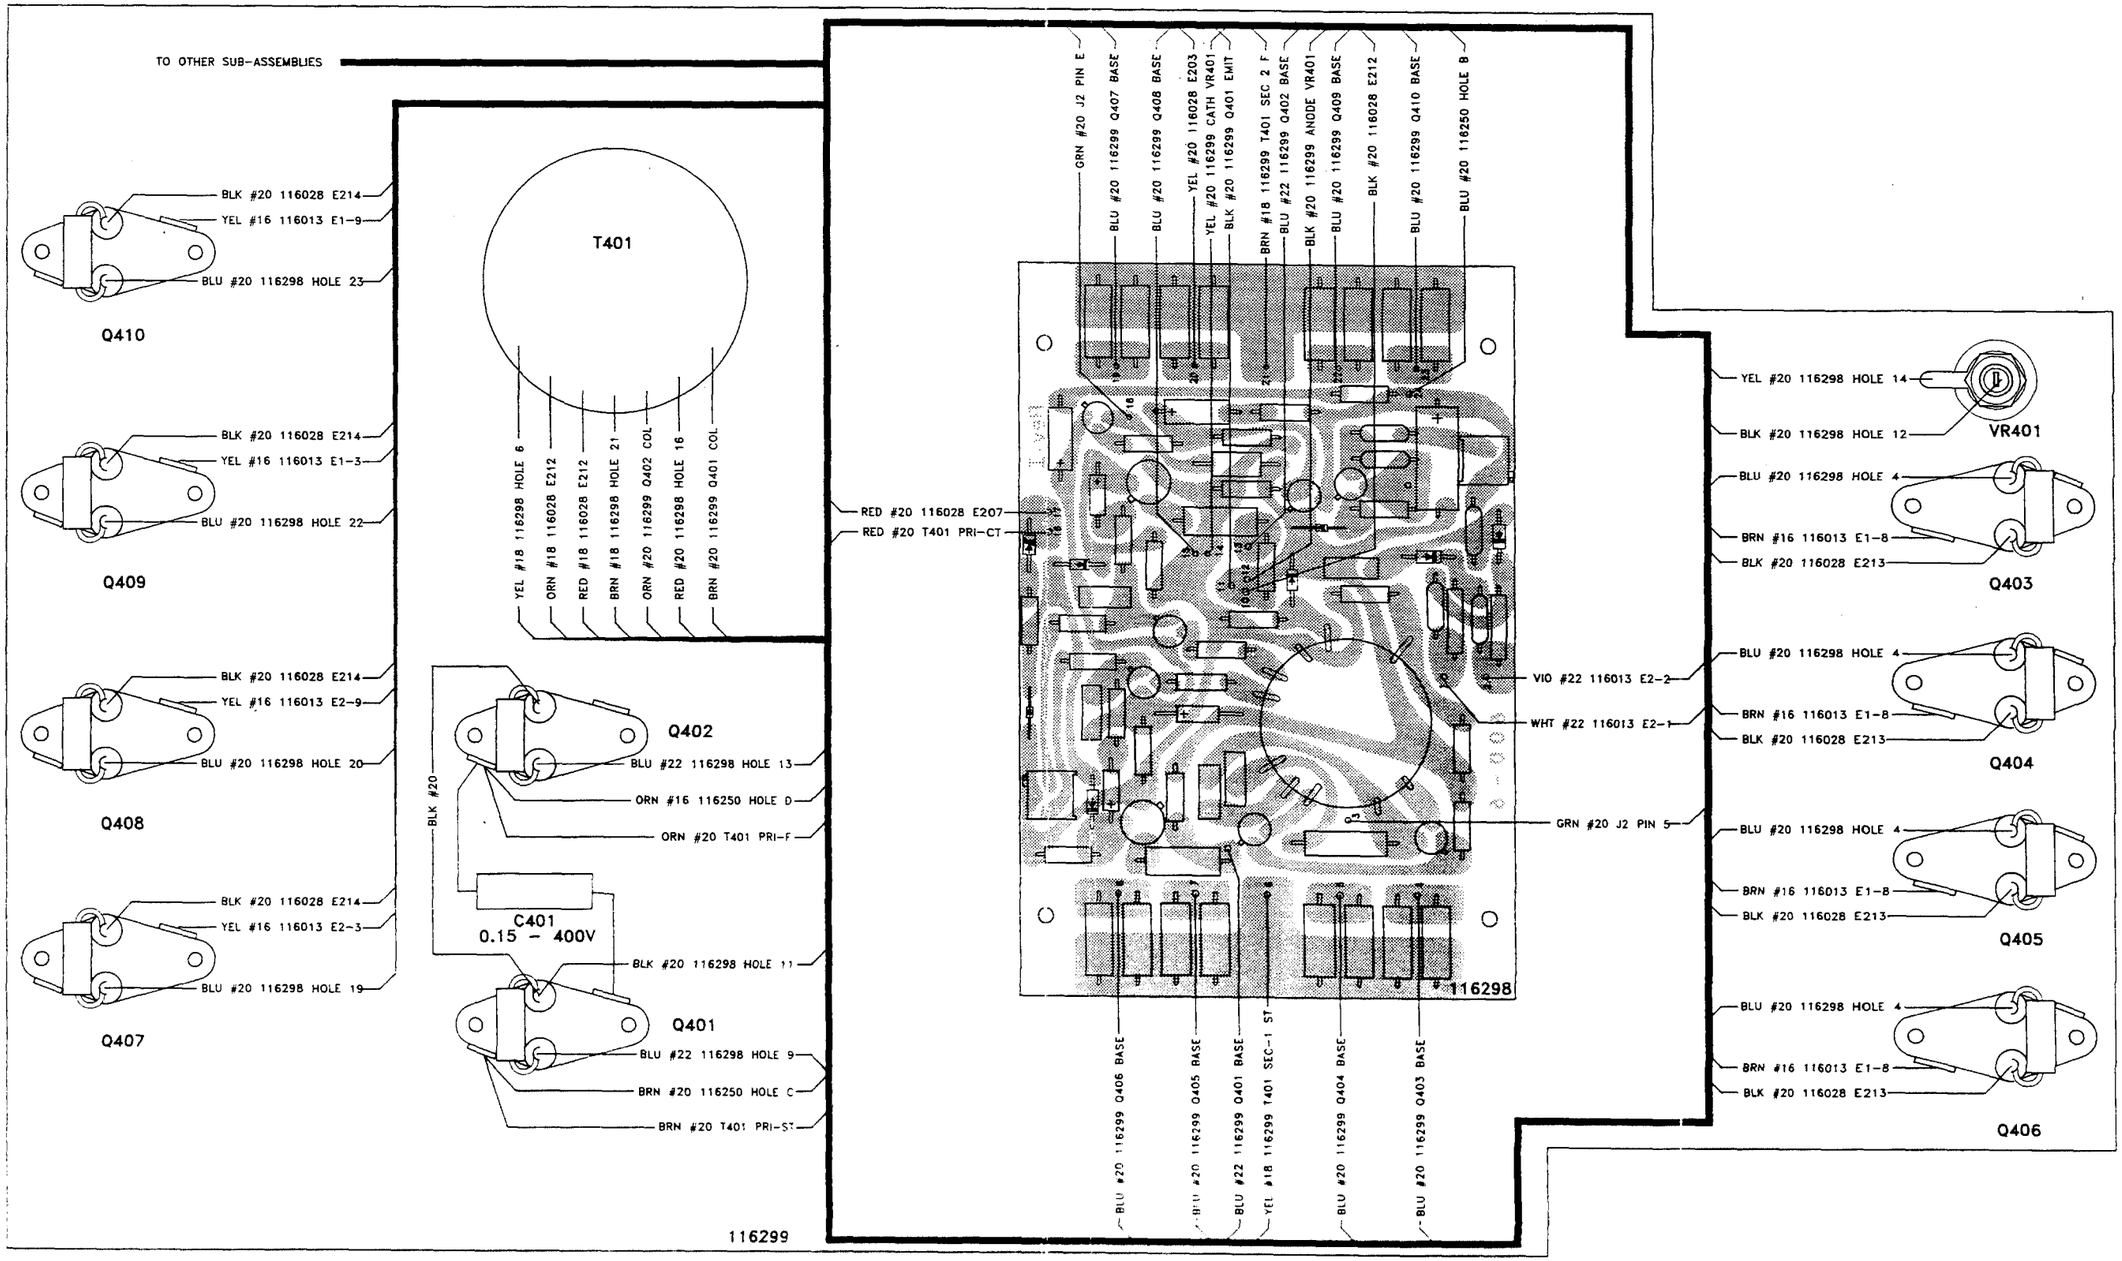

Figure 503. Wiring Diagram, Oscillator/Amplifier/Driver Circuit Module Sub-Assembly Figure 503

FITS AND CLEARANCES

Not Applicable to Solid-State Static Inverter.

No moving parts.

TESTING

1. GENERAL.

This section defines test procedures for the PAI P.N. DH-1030-24-600-CS, Type IIB, Solid-State Static Inverter (Transverter). The procedures given are in sequential step form and test the unit completely. When the results of any step or test are not achieved the troubleshooting section of this manual should be consulted.

2. PERFORMANCE TESTS.

Performance tests are designed to provide a fast efficient method for complete check-out of the Transverter. Included in this paragraph is a list of test equipment required, the minimum performance requirements of the unit and procedures for connecting the unit for test.

A. Test Equipment Required.

The test equipment required to accomplish the performance tests consist of the following: Specially designed Test Set; 0-40 volt, 100 Ampere DC Power Supply; Oscilloscope; Insulation Resistance Tester; Distortion Analyzer; Frequency Counter; and Voltohmmeter. This equipment is listed and described in the Special Tools Section of this manual.

B. Minimum Performance Requirements.

The minimum performance requirement of the PAI P.N. DH-1030-24-600-CS, Type IIB, Solid-State Static Inverter (Transverter) is to supply 115 volts, 400 Hertz sine wave, single phase, alternating current at 400 VA to operate aircraft instrumentation devices. Input power of 27.5 volts DC (nominal) is obtained from the aircraft's main DC power bus. The Performance Test Procedure of Fig. 701 defines the manufacturer's performance specifications with varying input, power factor, and load.

C. Preparation for Testing.

(1) Chassis Isolation Test. Perform the following steps to determine unit meets applicable specifications for chassis isolation.

WARNING

THE RECOMMENDED INSULATION TESTER PRODUCES POTENTIALLY DANGEROUS VOLTAGES. CARE IN OPERATION MUST BE EXERCISED TO PREVENT POSSIBLE ELECTRICAL SHOCK.

(a) Place POWER ON/OFF switch on Insulation Tester in the OFF position and connect line cord, three wire grounding type, to source of 115 volts AC, 60 Hz. Identify VOLTAGE ADJUST control and rotate to the extreme counterclockwise position. Connect the black lead with a spade mounting hole on the Transverter mounting flange. Identify MEGOHM MULTIPLIER control and position to the 100 position. Identify the HIGH VOLTAGE connection and connect test lead for use in subsequent paragraphs.

CAUTION

The Insulation Resistance Tester must be connected and operated in accordance with the following procedures to insure accurate testing and adequate protection to the equipment under test. Under no circumstances should the probes be connected to any point other than that specifically directed in the procedures given. In all cases the GROUND lead clip must be connected to the chassis of the unit being tested, (spot faced mounting hole on base or shell of connector).

(b) Identify HIGH VOLTAGE clip lead and connect to pin A of connector J1, +DC POSITIVE (+27.5V DC NOM), GROUND switch on Tester in the METERED RETURN position. Identify HIGH VOLTAGE CIRCUIT-ENERGIZE switch and operate to the ON position, red HIGH VOLTAGE lamp will light. Identify VOLTAGE ADJUST control and rotate clockwise until KILOVOLTS meter indicates .5 KILOVOLT (500 volts). Note reading of the MEGOHMMETER and multiply by the KILOVOLTS meter multiplied by the multiplying factor of 1, multiplied by the MEGOHMS MULTIPLIER to obtain reading in megohms. Return VOLTAGE ADJUST control to the extreme counter-clockwise position and place the HIGH VOLTAGE CIRCUIT-ENERGIZE switch in the OFF position. Disconnect the HIGH VOLTAGE test lead from the unit after metering indicates voltage has dropped to zero. Isolation of pin A of connector J1 to chassis ground must measure 5,000 megohms, minimum.

(c) Repeat procedures of paragraph (b) connecting HIGH VOLTAGE clip lead to pin B of connector J1. Isolation of pin B of connector J1, -DC NEGATIVE (-27.5V DC NOM), to chassis ground must measure 5,000 megohms, minimum.

(d) Repeat procedures of paragraph (b) connecting HIGH VOLTAGE clip lead to pin A of connector J2. Isolation of pin A of connector J2, FILTERED DC +28V OUTPUT, to chassis ground must measure 5,000 megohms, minimum.

(e) Repeat procedures of paragraph (b) connecting HIGH VOLTAGE clip lead to pin B of connector J2. Isolation of pin B of connector J2, L1-115 VAC (400 HZ) LINE, to chassis ground must measure 5,000 megohms, minimum.

(f) Repeat procedures of paragraph (b) connecting HIGH VOLTAGE clip lead to pin C of connector J2. Isolation of pin C of connector J2, LOAD EQUALIZATION to chassis ground must measure 5,000 megohms, minimum.

(g) Repeat procedures of paragraph (b) connecting HIGH VOLTAGE clip lead to pin D of connector J2. Isolation of pin D of connector J2, FREQUENCY SYNCHRONIZATION, to chassis ground must measure 5,000 megohms, minimum.

(h) Repeat procedures of paragraph (b) connecting HIGH VOLTAGE clip lead to pin E of connector J2. Isolation of pin E of connector J2, REMOTE ON/OFF SWITCH, to chassis ground must measure 5,000 megohms, minimum.

(i) Repeat procedures of paragraph (b) connecting HIGH VOLTAGE clip lead to pin F of connector J2. Isolation of pin F of connector J2, REMOTE ON/OFF SWITCH RETURN, to chassis ground must measure 5,000 megohms, minimum.

(j) Repeat procedures of paragraph (b) connecting HIGH VOLTAGE clip lead to pin G of connector J2. Isolation of pin G of connector J2, L2-115 VAC (400 HZ) NEUTRAL, to chassis ground must measure 5,000 megohms, minimum.

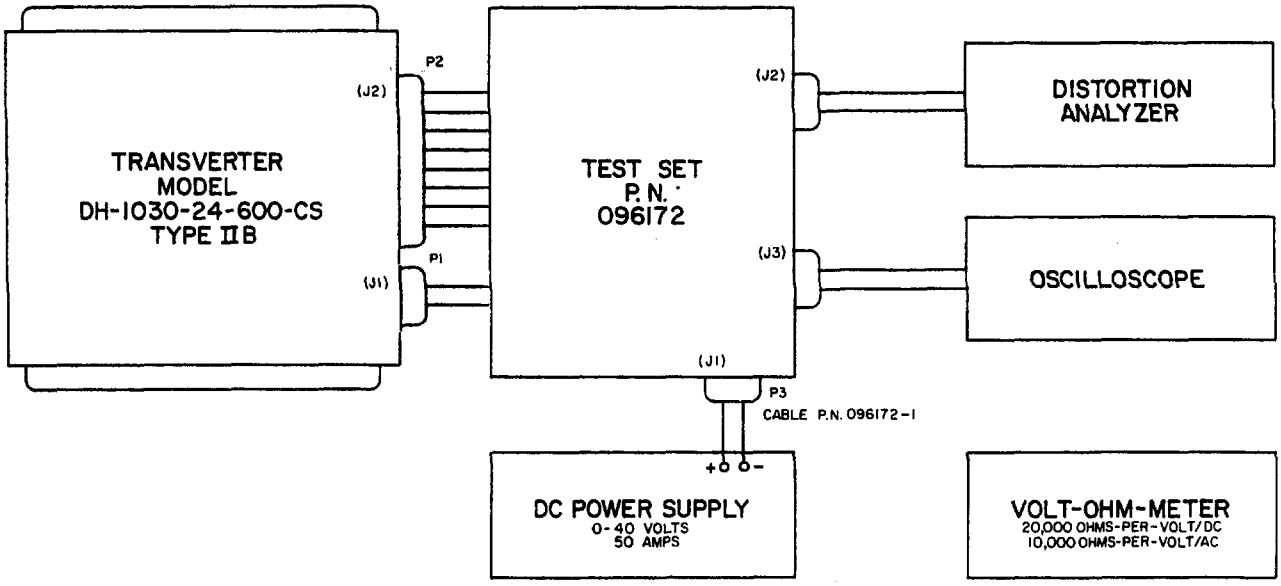
(k) Repeat procedures of paragraph (b) connecting HIGH VOLTAGE clip lead to pin H of connector J2. Isolation of pin H of connector J2, SPARE, to chassis ground must measure 5,000 megohms, minimum.

(l) Place POWER switch on the Insulation Tester in the OFF position and disconnect Insulation Resistance Tester before proceding with subsequent performance testing..

(2) Complete the following steps to prepare Transverter for performance testing. Refer to Fig. 701 for equipment and interconnection.

(a) Place ON/OFF switch on the DC Power Supply in the OFF position.

(b) Identify DC Power Cable P.N. 096172-1 and connect positive lead to the positive terminal on the DC Power Supply and the negative lead to the negative terminal of the DC Power Supply. Connect the Pendant connector plug P3 to receptacle J1 on the Inverter Test Set.



(c) Refer to Table 701 and proceed with performance tests noting carefully the interconnection of additional test equipment as required to complete the performance tests.

D. Performance Test.

NOTE

REMOVE COVER TO PERFORM ADJUSTMENTS AS INDICATED IN THE TEST PROCEDURES.

The procedures of the performance test listed in numbered steps in Table 701 should be accomplished in the sequence presented. In the event the required result is not obtained, the troubleshooting section should be consulted and the malfunction corrected before proceeding to the next step.

Test Set-up, PAI P.N. DH-1030-24-600-CS, Type IIB, Solid-State Static Inverter (Transverter)
Figure 701

STEP	SET-UP	PROCEDURE	RESULT
1.	Interconnect per Fig. 701 and par. 2.c. Test Button A, OFF,on Inverter Test Set, depressed. Button is illuminated by lamp DS1, S1A.	(a) Apply power to all measuring equipment for warm-up. (b) Check polarity of DC Power Supply and connect to Test Set.	
2.	OFF Button A on Inverter Test Set depressed, Button is illuminated by lamp DS1, S1A.	Apply power to DC Power Supply and increase voltage to 28.0 volts DC as indicated on DC VOLTS Meter M3 on Inverter Test Set.	Input current as indicated by DC AMPERES Meter M4 on Inverter Test Set should not exceed1.0 Ampere. OSCILLATOR/EQUALIZATION Meter M6 on Inverter Test Set should indicate 110 microamperes ± 15 microamperes.
3.	NO LOAD Button B on Inverter Test Set depressed, Button is illuminated by lamp DS2, S1B.	(a) Input voltage set at 28.0 volts DC. (b) Adjust Transverter resistor R324 as required for a reading of 115 volts AC. (c) Adjust frequency by selection of capacitor C302 and/or C303 in oscillator circuit of Transverter	Input current as indicated by DC AMPERES Meter M4 on Inverter Test Set should not exceed 3.0 Amperes. Output voltage as indicated by AC VOLTS Meter M2 on Inverter Test Set should be 115 volts. FREQUENCY Meter M5 should read 400 Hertz, ± 4 Hertz. OSCILLATOR/EQUALIZATION Meter M6 indicates 110 microamperes ± 15 micro-amperes.
4.	400 VA UNITY Button D on Inverter Test Set depressed, Button is illuminated by lamp DS4, S1d. Distortion Analyzer con-nected to J3, DISTORTION ANALYZER Output on Inverter Test Set.	(a) Input voltage set at 28.0 volts DC. (b) Adjust Transverter resistor R324 as required for a reading of 115 volts AC. (c) Adjust balance resistor R307 for minimum harmonic distortion. (d) Adjust load equalizer resistor R103 as required.	Input current as indicated by DC AMPERES Meter M4 on Inverter Test Set should not exceed 20 Amperes Output current as indicated by AC AMPERES Meter M1 on Inverter Test Set should be approximately 3.5 Amperes. Output voltage as indicated by AC VOLTS Meter M2 on Inverter Test Set should be 115 volts. Distortion Analyzer should read less that 5% distortion, typical reading 2.5 to 3.5%. OSCILLATOR/EQUALIZATION Meter M6 should indicate 150 microamperes.
5.	NO LOAD Button B on Inverter Test Set depressed, Button is illuminated by lamp DS2, S1B. Distortion Analyzer connected as in preceding Step 4.	Input voltage set at 28.0 volts DC.	Input current as indicated by DC AMPERES Meter M4 on Inverter Test Set should not exceed 3.0 Amperes. Output voltage as indicated by AC VOLTS Meter M2 on Inverter Test Set should be 115 volts. FREQUENCY Meter M5 should indicate 400 Hertz, ± 4 Hertz.

Performance Test Procedure
Table 701 (sheet 1 of 3)

STEP	SET-UP	PROCEDURE	RESULT
5. (Cont)			Distortion Analyzer should read less that 7% distortion, typical reading 4.6 to 6.0%.
6.	200 VA UNITY Button C on Inverter Test Set depressed, Button is illuminated by lamp DS3, S1C. Distortion Analyzer connected as in preceding Step 4.	(a) Reduce input voltage to 16.0 volts DC.	Output voltage as indicated by AC VOLTS Meter M2 on Inverter Test Set should indicate 100 volts AC,minimum.
		(b) Increase input voltage towards 40 volts DC.	Inverter should shut down as indicated by AC VOLTS Meter M2 indicating 0 volts at input voltage of 39 volts DC ± 2 volts.
		(c) Reduce input voltage to 28.0 volts DC.	
7.	400 VA UNITY Button D on Inverter Test Set depressed, Button is illuminated by lamp DS4, S1D. Distortion Analyzer connected as in preceding Step 4.	(a) Input voltage set at 28.0 volts DC.	Input current as indicated by DC AMPERES Meter M4 on Inverter Test Set should not exceed 20.0 Amperes Output voltage as indicated by AC VOLTS Meter M2 on Inverter Test Set should indicate 115 volts AC ± 5 volts. FREQUENCY Meter M5 should indicate 400 Hertz, ± 4. Distortion Analyzer should read less that 5% distortion, typical reading 2.5 to 3.5%.
		(b) Vary input voltage from 18-36 volts DC, taking readings at 2 volt intervals from 18-30 volts and at 36 volts.	Distortion Analyzer should read less than 5% from 18-30 volts DC (over 30 volts distortion will normally exceed 5%).
8.	600 VA UNITY Button E on Inverter Test Set depressed, Button is illuminated by lamp DS5, S1E. Distortion Analyzer connected as in preceding Step 4.	Input voltage set at 28.0 volts DC.	Input current as indicated by DC AMPERES Meter M4 on Inverter Test Set should not exceed 30.0 Amperes Output voltage as indicated by AC VOLTS Meter M2 on Inverter Test Set should read 115 volts AC ± 5 volts. FREQUENCY Meter M5 should indicate 400 Hertz, ± 4 Hertz Distortion Analyzer should read less that 5% distortion, typical reading 3.0 to 4.0%.
9.	400 VA .80 LAG Button F on Inverter Test Set depressed, Button is illuminated by lamp DS6, S1F. Distortion Analyzer and Frequency Meter connected as in preceding Step 3.	Input voltage set at 28.0 volts DC.	Input current as indicated by DC AMPERES Meter M4 on Inverter Test Set should not exceed 17.0 Amperes Output voltage as indicated by AC VOLTS Meter M2 on Inverter Test Set should indicate 115 volts AC ± 5 volts. FREQUENCY Meter M5 should indicate 400 Hertz, ± 4 Hertz Distortion Analyzer should read less that 5% distortion, typical reading 3.0 to 4.0%.

Performance Test Procedure
Table 701 (Sheet 2 of 3)

STEP	SET-UP	PROCEDURE	RESULT
10.	400 VA .95 LEAD Button G on Inverter Test Set depressed, Button is illuminated by lamp DS7, S1G. Distortion Analyzer connected as in preceding Step 4.	(a) Input voltage set at 28.0 volts DC. (b) Adjust balance resistor R307, if necessary, to obtain minimum distortion.	Input current as indicated by DC AMPERES Meter M4 on Inverter Test Set should not exceed 20.0 Amperes Output voltage as indicated by AC VOLTS Meter M2 on Inverter Test Set should read 115 volts AC ± 5 volts. Frequency Meter M5 should indicate 400 Hertz, ± 4.
11.	SHORT Button H on Inverter Test Set is depressed, starting automatic 5 second, timed short circuit of AC output of Transverter, Button is illuminated by lamp DS8, S1H.	Input voltage set at 28.0 volts DC.	Input current as indicated by DC AMPERES Meter M4 on Inverter Test Set should not exceed 35.0 to 50.0 Amperes Output current as indicated by AC AMPERES Meter M1 on Inverter Test Set should be 7.0 Amperes, (min), typical reading 8.0 - 9.0 Amperes
12.	400 VA UNITY Button D on Inverter Test Set depressed, Button is illuminated by lamp DS4, S1D. Distortion Analyzer connected as in preceding Step 4.	(a) Input voltage set at 28.0 volts DC. (b) Final check of output voltage, frequency, equalization, and distortion. (c) Check parallel phasing by observing phasing indicator.	Input current as indicated by DC AMPERES Meter M4 on Inverter Test Set should not exceed 20.0 Amperes Output voltage as indicated by AC VOLTS Meter M2 on Inverter Test Set should indicate 115 volts AC ± 2 volts. FREQUENCY Meter M5 should indicate 400 Hertz, ± 4. Distortion Analyzer should read less that 5% distortion, typical reading 2.5 to 3.5%. OSCILLATOR/EQUALIZATION Meter M6 should indicate 150 microamperes. Phasing indicator DS10, green.
13.	OFF Button A on Inverter Test Set depressed, Button is illuminated by lamp DS1, S1A. Test procedures are completed.	(a) Input voltage from external DC Power Supply returned to zero. ON/OFF switch on DC Power Supply in the OFF position. (b) Disconnect DC Power Supply from Inverter Test Set. (c) Disconnect Transverter from Inverter Test Set and replace cover per applicable assembly instructions.	

Performance Test Procedure
Table 701 (Sheet 3 of 3)

TROUBLESHOOTING

1. GENERAL.

This section outlines in tabular form information for use in localization and isolation of trouble in the PAI P.N. DH-1030-24-600-CS, Type IIB, Solid-State Static Inverter (Transverter). The troubleshooting procedures, Table 801, together with the information given in preceding section on Testing will in most cases localize and isolate the trouble. Reference to the schematic diagram, Fig. 1201, and the section on Detailed Theory will be necessary and helpful. The voltage measurements of Table 802 in conjunction with the waveforms illustrated in Fig. 801 will aid in isolation of trouble.

2. TROUBLESHOOTING.

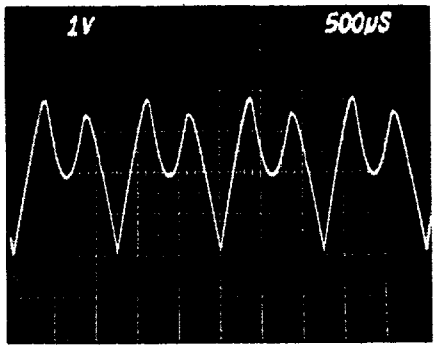
A. Localization.

The troubleshooting table, Table 801, provides a means of localizing malfunctions to a replaceable component or sub-assembly. The table is arranged in the same order of precedence as the performance tests, Table 701, in the preceding section. The applicable step of the performance test is shown in parentheses next to the trouble shooting step in the STEP column, in Table 801.

B. Isolation.

The voltage measurements of Table 802 are made using the volt-ohmmeter described in the Special Tools Section of this manual. Reference to the schematic diagram while making voltage measurements will aid in isolation of trouble within the unit.

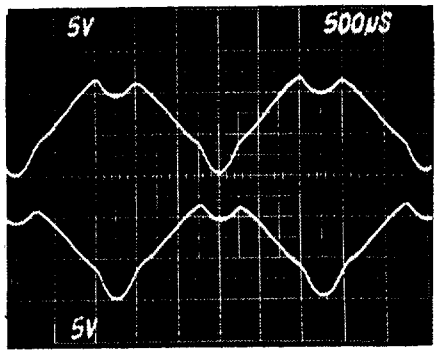
C. Analysis.



The waveforms pictured in Fig. 801 were made using the oscilloscope described in the Special Tools Section of this manual, and will aid in analyzing the equipment performance when troubleshooting procedures are being performed.

STEP	SYMPTOM	PROBABLE CAUSE	CHECK	REMEDY
1(2)	No current drain.	Transistor Q301 or Q302 inoperative.	Check voltage at base, collector, and emitter of Transistors Q301 and Q302 for proper voltage.	Replace defective transistor/s.
		Input polarity reversed.	Check connection of DC Power Supply and polarity of output.	Reverse output connection.
		Polarity protect Diode CR9 open.	Check continuity of circuit through Diode CR9 and Reactor L2.	Replace defective diode.
2(2)	High current drain.	Transistors Q401 and Q402 defective, shorted.	Check voltages at base, collector, and emitter of Transistors Q401 and Q402 for proper voltage.	Replace defective transistor.
		Transistor Q403 thru Q410 defective.	Check base drive resistors and transistor voltages.	Replace defective component
		Capacitor C206 shorted.	Check Capacitor C206 for short.	Replace defective capacitor.
3(3)	AC output voltage high or low, no load.	Resistor R324 not adjusted.	Check operation of Resistor R324 by adjustment noting change in output voltage.	Adjust Resistor R324 to obtain proper output voltage.
		Transistor Q308 or Q309 defective.	Check voltages at base, collector, and emitter of Transistors Q308 and Q309 for proper voltage.	Replace defective transistor.
		Zener Diode VR302 defective.	Check voltages at Zener Diode VR302.	Replace defective Zener diode.
		Diodes CR205 or CR206 defective.	Check for presence of negative voltage at junction of diodes CR205 and CR206, and Resistor R229.	Replace defective diode.
4(3)	Frequency high or low.	Capacitor C301, C302, or C303 defective or of improperly selected value.	Check value and test by substitution for proper value	Replace defective capacitor.
5(4)	Distortion above 5%	Zener Diode VR401, or Capacitors C201, C202, or C203 defective	Check VR401 voltage at junction of Zener diode VR401 and resistor R201, for proper value, -15 volts ± 5%,	Replace defective Zener diode.
			Check Capacitors for excess leakage or open condition.	Replace defective capacitor.
6(4)	AC output voltage high or low, with 400 VA 1.0 UNITY P,F. Load.	Repeat preceding step 3(3).	Repeat preceding step 3(3).	Repeat preceding step 3(3).
7(4)	AC output voltage cannot be increased to 115 volts AC.	Defect in control circuit, Transistor Q309, resistor R324, or Zener diode VR301.	Short emitter of Q303 and Q304 to negative bus at -27.5 volt DC point, voltage will increase to approximately 135 volts AC.	Replace defective component in control circuit

Trouble Shooting Chart
Table 801 (Sheet 1 of 2)



STEP	SYMPTOM	PROBABLE CAUSE	CHECK	REMEDY
8(4)	Transistors Q401 and /or Q402 operate with high heat rise.	Transistors Q305 and/or Q306 low output or inoperative.	Check voltages and waveforms at transistor base,colloector and emitter.	Replace defective transistor or pair of transistors.
9(4)	Transverter output drops off when input voltage exceeds 26 to 28 volts DC.	Zener Diode VR301 breaking down.	Check voltages at Zener diode VR301 and resistor R313.	Replace defective Zener diode.
10	Transverter operates on preinstallation check, will not operate in aircraft.	Defect in aircraft wiring.	Check for voltage at breakers and primary power source in aircraft.	Correct wiring defect.
			Check for shorted load by opening breaker to AC load in aircraft while power is applied to input of Transverter.	Correct short in line or load.

Trouble Shooting Chart

Junction of resistors R102 and R103, paralleling control circuit board, hole A and pin C of connector J2.	10.10V
Terminal E203, cathode of VR401, junction of resistors R326, R318, R322, R303, R310, R311, R312, and cathode of diode CR302.	15.12V
Junction of diodes CR305, CR306, and Resistor R328.	-15.52V
Junction of terminal E207 and cathode of diode CR9 (E3)	26.61V

NOTES:
Phoenix Aerospace Inc. Inverter Test Set P.N. 096172 connected to Transverter.
Test Button D 400 VA UNITY pressed..
Input from DC Power Supply
Voltage 28.0 Volts DC
Current 18.0 Amperes ± 2.0 A.
Voltage measurements between reference point and (–) negative side of primary power.
All voltages are DC.
Measured with digital Volt-ohmmeter, Fluke Model 8040A, or equivalent.

Voltage Measurements, PAI P.N. DH-1030-24-600-CS, Type IIB, Solid-State Static Inverter (Transverter) Table 802

STORAGE INSTRUCTIONS

1. GENERAL.

This section provides information preparing the PAI P.N. DH-1030-24-600-CS, Type IIB, Solid-State Static Inverter (Transverter) for use from a shipped or stored condition and for packing the unit for storage or shipment.

2. PREPARATION FOR USE.

The Transverter, when shipped from the factory, is mounted on a wood composition board, secured with 1/4-20 hardware, surrounded by 2 inch high density foam inserts, and enclosed in a corrugated shipping carton, PPP-B-636. To unpack the unit, cut sealing tape and open top of carton by lifting flaps to break adhesive. Remove foam inserts and remove unit from carton, and remove hardware securing unit to wood composition board. Visually examine the unit for damage which might have occurred during shipment or storage.

3. PREPARATION FOR STORAGE OR SHIPMENT.

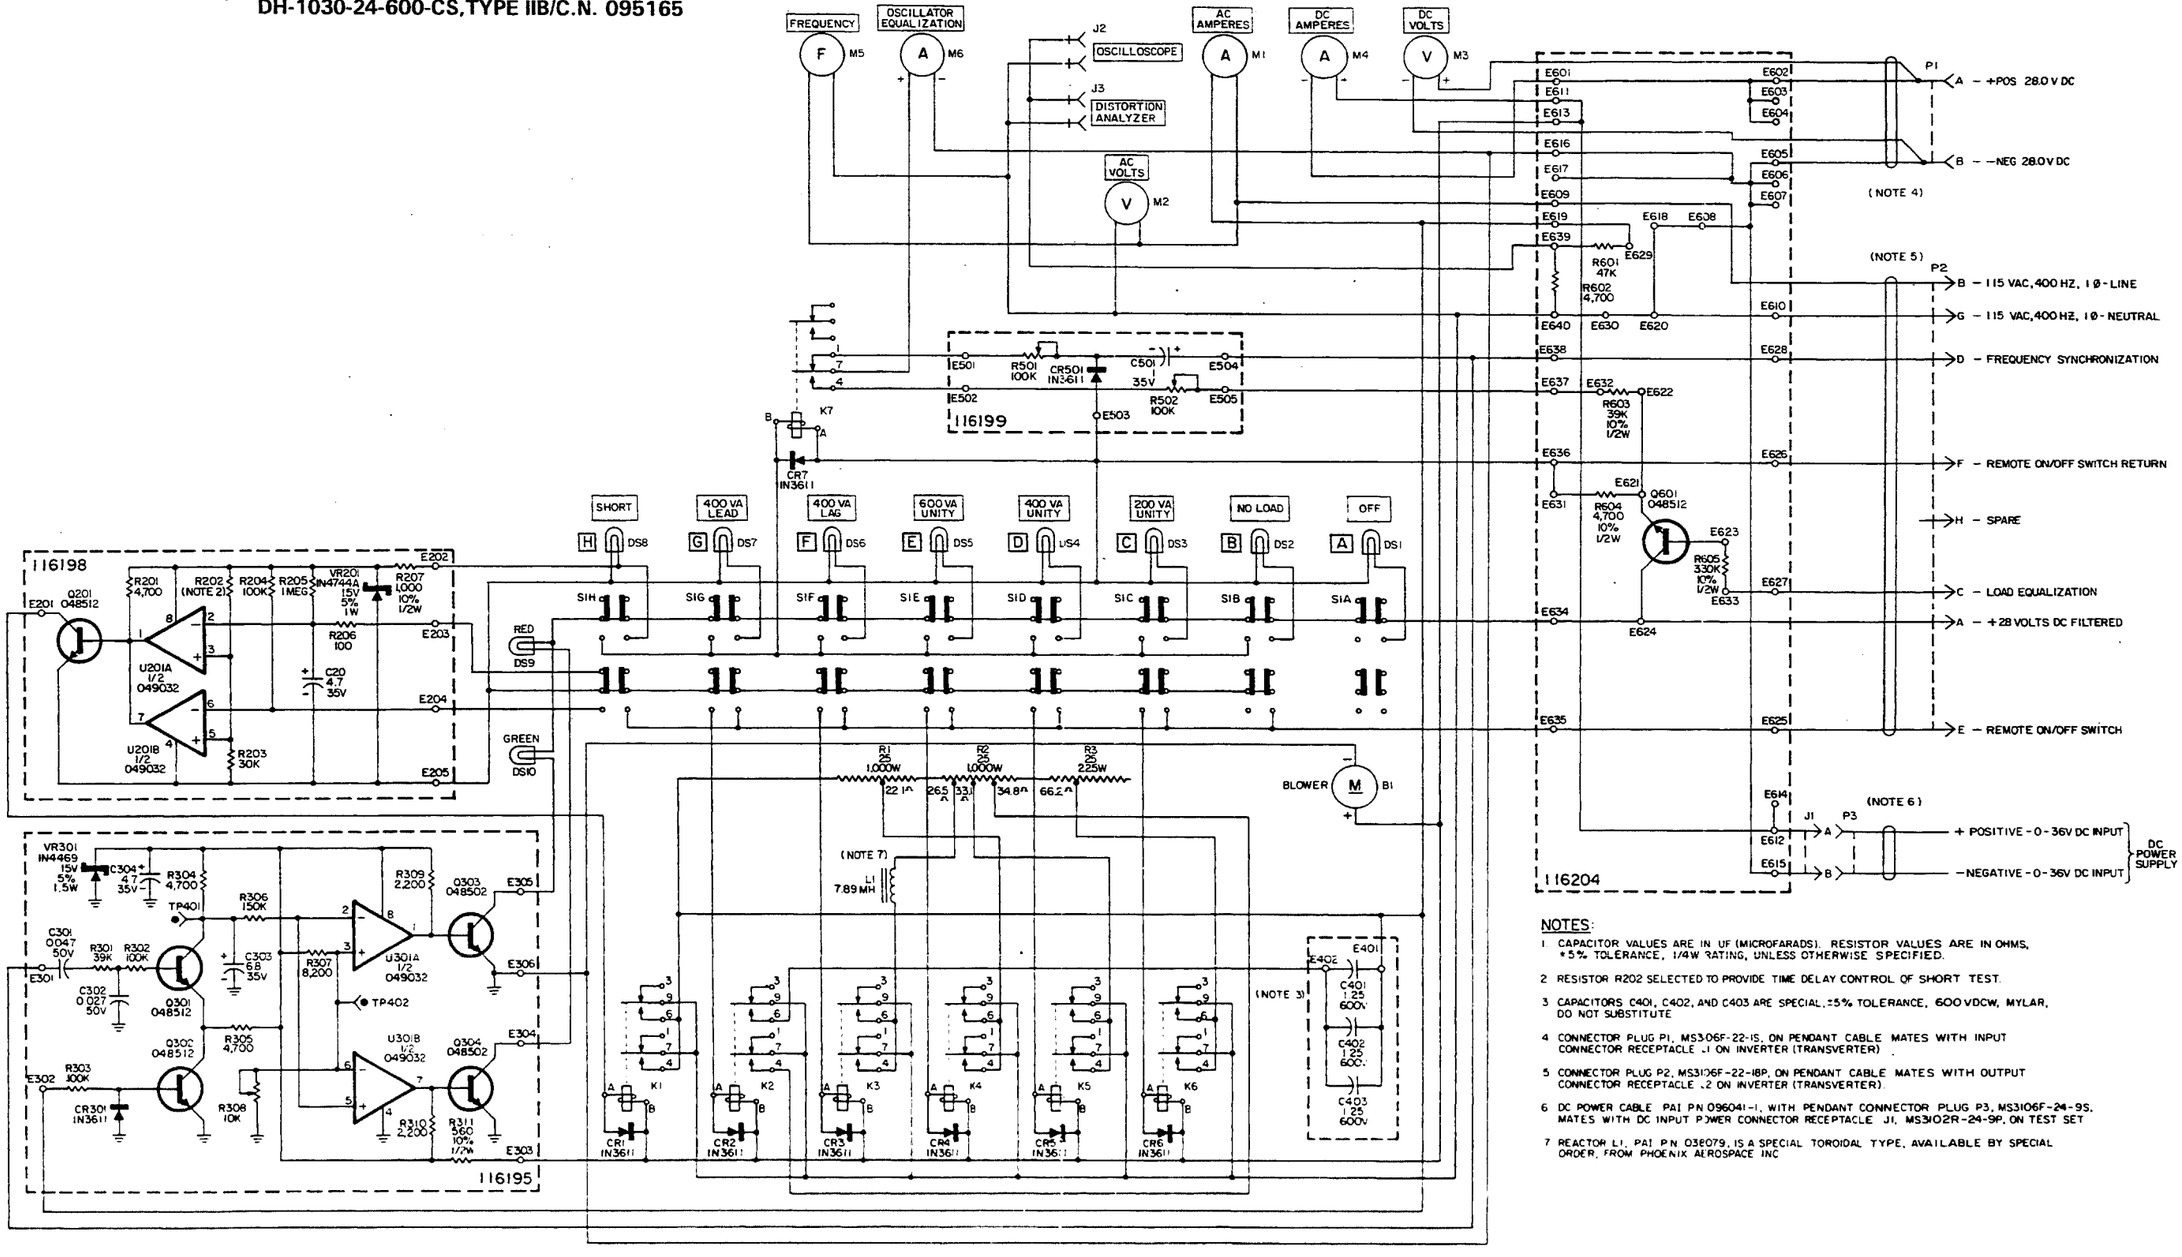
The Transverter may be stored for short periods of time without packing. If the unit is to be stored for extended periods or is to be shipped, it is recommended that the unit be returned to the original shipping carton.. The carton should then be sealed and labeled for storage.

SPECIAL TOOLS, FIXTURES, AND EQUIPMENT

1. GENERAL.

This section provides information on the special tools and test equipment required for overhaul of the PAI P.N. DH-1030-24-600-CS, Type IIB, Solid-State Static Inverter (Transverter).

2. STANDARD TEST EQUIPMENT.



Listed in Table 1001 are the items of standard test equipment required for overhaul of the Transverter. The listed item or suitable equivalent may be used if procedures are modified when references to test equipment are made.

EQUIPMENT	MANUFACTURER	MODEL NUMBER
OSCILLOSCOPE	HEWLETT-PACKARD	MODEL 132A
DISTORTION ANALYZER	HEWLETT-PACKARD	MODEL 333A
FREQUENCY COUNTER	HEWLETT-PACKARD	MODEL 5512A
DIGITAL VOLT-OHMMETER	JOHN F. FLUKE	MODEL 8040A
DC POWER SUPPLY	0-40 VOLTS DC 0-100 AMPERES	
INSULATION RESISTANCE TESTER	ASSOCIATED RESEARCH	MODEL 2956

Standard Test Equipment
Table 1001

3. SPECIAL TEST EQUIPMENT:

The special test equipment consists of only one item. This is a Test Set available either from Phoenix Aerospace, Inc. or readily fabricated locally. The toroidal reactor is available separately from Phoenix Aerospace, Inc. when the user desires to fabricate the Test Set. The schematic diagram is shown in Fig. 1001. All parts are listed with values and ratings to aid in local procurement for fabrication.

NOTES:

1. CAPACITOR VALUES ARE IN UF (MICROFARADS). RESISTOR VALUES ARE IN OHMS, ±5% TOLERANCE, 1/4W RATING, UNLESS OTHERWISE SPECIFIED.
2. RESISTOR R202 SELECTED TO PROVIDE TIME DELAY CONTROL OF SHORT TEST.
3. CAPACITORS C401, C402, AND C403 ARE SPECIAL, ±5% TOLERANCE, 600 VDCW, MYLAR, DO NOT SUBSTITUTE
4. CONNECTOR PLUG P1, MS3106F-22-1S, ON PENDANT CABLE MATES WITH INPUT CONNECTOR RECEPTACLE J1 ON INVERTER (TRANSVERTER)
5. CONNECTOR PLUG P2, MS3106F-22-18P, ON PENDANT CABLE MATES WITH OUTPUT CONNECTOR RECEPTACLE J2 ON INVERTER (TRANSVERTER).
6. DC POWER CABLE PAI P/N 096041-1, WITH PENDANT CONNECTOR PLUG P3, MS3106F-24-9S, MATES WITH DC INPUT POWER CONNECTOR RECEPTACLE J1, MS3102R-24-9P, ON TEST SET
7. REACTOR L1, PAI P/N 036079, IS A SPECIAL TOROIDAL TYPE, AVAILABLE BY SPECIAL ORDER, FROM PHOENIX AEROSPACE INC

Solid-State Static Inverter (Transverter)
Figure 1001

ILLUSTRATED PARTS CATALOG SECTION

1. INTRODUCTION.

This section of the Overhaul Manual provides a complete listing of parts for the PAI P.N. DH-1030-24-600-CS/Type IIB Solid-State Static Inverter (Transverter) as manufactured by Phoenix Aerospace Inc.

2. PURPOSE.

The information contained in this section is supplied to aid in provisioning, requisitioning, storing, and issuing of the replaceable parts, and to aid in identification of new and reclaimed parts.

3. APPLICATION.

The Illustrated Parts Catalog Section contains three separate listings: Numerical Index, Symbol Index, and Detailed Parts List. The subsequent paragraphs define the content and application of each listing.

A. Numerical Index.

The Numerical Index provides an alphanumerical listing of the parts listed in the Detailed Parts List. The prime function being to aid in rapid location using the information contained in the various columns.

(1) The PAI PART NUMBER column lists part numbers of procurable parts and assemblies as listed in the Detailed Parts List. Parts are listed in - alphanumerical order of precedence starting at the first letter extreme left and reading to the right as follows:

Letters A through Z
Numerals 0 through 9
(Alphabetical O's are considered as numerical zeros).

Second and succeeding positions of the part number appear in the order of precedence as follows:

Space (Blank column)
Diagonal (Slant) /
Point (Period)
Dash (-)
Letters A through Z
Numerical 0 through 9
(Alphabetical O's are considered as numerical zeros).

(2) Vendor Part Number Column.

The VENDOR PART NO. column lists the actual part number of the manufacturer supplying the part to Phoenix Aerospace Inc.

(3) Chapter-Section-Unit-Figure-Item Column.

The CH-SECT-UNIT-FIG.-ITEM column contains the specific location data where the listed part first appears in the Detailed Parts List and other pertinent data. Example: 24-20-00-1101-18 is indicative of the following:

24 is significant of the Chapter (derived from system identification numbers).
20 is significant of the Section (derived from sub-system identification numbers).
00 is significant of the Unit (derived from the application of particular unit).
1101 is significant of the Figure number.
18 is significant of the Item number

(4) Total Required Column.

The TTL REQ. column is the total of each item required in the unit whether it be piece part or sub-assembly.

B. Symbol Index.

The Symbol Index enables the location of component parts referenced from the schematic diagram by the reference symbol to a specific Figure and Item Number.

(1) Symbol Column.

The SYMBOL column contains an alpha-numerical listing of every component part which carries a reference symbol on the schematic diagram.

(2) PAI Part Number Column.

The PAI PART NUMBER column lists the vendor part number of the symbolized item.

(3) Chapter-Section-Unit-Figure-Item Column.

The CH-SECT-UNIT-FIG.-ITEM column contains the specific location data where the listed part appears in the Detailed Parts List and other pertinent data. (See preceding para. 3.A.(3) for example of information.

C. Detailed Parts List.

The Detailed Parts List is a breakdown of the complete unit into sub-assemblies and detailed parts. Each sub-assembly is listed in its order of disassembly and is followed immediately by its component parts properly indented to show its relationship to the assembly.

(1) Figure Item Column.

The FIG. ITEM column entries, key the parts breakdown to the applicable illustration. Items numbered on the Detailed Parts List preceded by a dash (Example: -1) do not appear on the illustration.

(2) PAI Part Number Column.

The PAI PART NUMBER column lists the applicable Phoenix Aerospace Inc part number.

(3) Nomenclature Column.

The NOMENCLATURE column describes the assembly, sub-assembly, or component part in a short form description, with the identifying Noun as the first word, followed by the modifiers as required. The indentions denote parts relation to the next higher assembly (NHA) or sub-assembly, applicable. The ATTACHING PARTS entries are listed immediately following the component which they attach.

(4) Vendor Part Number Column.

If a part is purchased by Phoenix Aerospace Inc from a vendor the part number appears in the VENDOR PART NUMBER column.

(5) Cage Code Column.

The CAGE CODE (Commercial and Government Entity Code) column lists the Manufacturer's Code (formerly referred to as the FSC No.), a five-digit number. Parts having part numbers assigned under MIL Standards, NAS, etc., will not have a code number in this column. Traceability is provided by Phoenix Aerospace Inc upon request.

(6) Units Per Assembly Column.

The UNITS PER ASSY column lists the quantity of sub-assemblies or parts required in the next higher assembly (NHA). The quantities specified, therefore, are not necessarily the total used per equipment. The letters RF denote that the item listed appears on another list and illustration and is referenced for aid in identification only.

4. VENDOR CAGE CODE AND NAME INDEX.

The following list is derived by extraction from the Federal Supply Catalog Handbook H4-1. The information is supplied to aid in procurement and identification of the various vendors.

CAGE CODE	VENDOR'S NAME AND ADDRESS
00853	Sangamo Capacitor Division Cornell-Dubilier Corporation Sangamo Road, P.O. Box 128 Pickens, SC 29671-9716
01019	Stoffel Seals Corporation 400 High Avenue Nyack, NY 10707
01121	Allen Bradley Company 1414 Allen Bradley Drive El Paso, TX 79936
04713	Motorola, Incorporated Semiconductor Product Sector 5005 McDowell Road Phoenix, AZ 85008-4229
08530	Reliance Mica Company, Inc. 342-351 39th Street Brooklyn, NY 11232
11502	International Resistive Company, Inc. Greenway Road P.O. Box 1860 Boone, NC 28607-1860
14552	Micro Semi Corporation 2830 S. Fairview Street Santa Ana, CA 92704-5948
16428	Belden Wire and Cable Div of Cooper Industries 350 NW N Street Richmond, IN 47374
19724	Teledyne-Ansonia Solderless Connector Divison 1 Riverside Drive Ansonia, CT 06401
24444	General Semiconductor Inc. 2001 W. 10th Place Tempe, AZ 85281
27014	National Semiconductor Corporation 2900 Semiconductor Drive Santa Clara, CA 95051-0606
27556	IMB Electronic Products, Inc. 15401 Carmenita Road Santa Fe Springs, CA 90670-5607
28520	Heyco Molded Products 750 Boulevard P.O. Box 160 Kenilworth, NJ 07033-1721
29632	Phoenix Aerospace Inc 220 W. 80th Terrace P.O. Box 8744 Kansas City, MO 64114-8744
32953	Powertech, Inc. 0 - 02 Fairlawn Ave Fairlawn, NJ 07410-1225
32997	Bourns, Incorporated Trimpot Division 1200 Columbia Avenue Riverside, CA 92507-2114

4. VENDOR CAGE CODE AND NAME INDEX (Cont).

CAGE CODE	VENDOR'S NAME AND ADDRESS
34371	Harris Corp Semiconductor Sector Military and Aerospace Div 200 Palm Bay Blvd, P.O.Box 883 Melbourne, FL 32902-0883

SCHEMATIC DIAGRAM - REVISION REFERENCE SHEET

REV	REVISION	EFFECTIVITY
A	DIODES: CR6/CR1 THRU CR15/CR8 CHANGED TO SEMICONDUCTOR,DIODE,SILICON, TYPE 1N5624,PAI P.N. 046015,FROM TYPE 1N5402,PAI P.N.046010.	22 SEP 71
B	CAPACITOR: C16/C206 CHANGED TO CAPACITOR,FIXED,POLYESTER, 1.25UF 3%,600VDCW, PAI P.N. 019017, FROM CAPACITOR,FIXED,POLYESTER, 1.0UF 3%, 400VDCW, PAI P.N. 019023. ADDED NOTE 4 TO SCHEMATIC DIAGRAM. SEMICONDUCTOR,DIODE,SILICON,PWR CR2/CR302, 1N3611, RELOCATED FROM BASE OF TRANSISTOR Q5 TO 15 VOLT BUS, TO JUNCTION OF CR3/CR303, CR4/CR304,AND ZR3/VR301 AND 15 VOLT BUS. DELETED CR5, SEMICONDUCTOR,DIODE,SILICON,PWR, 1N3611, PAI P.N. 046011.	18 DEC 71
C	TRANSISTORS: CHANGED-Q7/Q401,Q8/Q402,Q11/Q403 THRU Q18/Q410, SEMICONDUCTOR, TRANSISTOR, SILICON,POWER,NPN RCA TYPE 64497, PAI P.N. 048505,REV A, FROM RCA TYPE 60234, PAI P.N. 048505. DELETED CAPACITOR C11 0.1UF 10%,50VDCW, PAI P.N.019008. CHANGED-C14/C204 AND C15/C205, CAPACITOR,FIXED,POLYCARBONATE, 6UF 3%,115VAC,400 HZ, PAI P.N. 019015 REV A. ADDED NOTE REGARDING CAPACITOR VOLTAGE CHANGE.	22 JUN 73
D	DELETED CAPACITORS: C10-CAPACITOR,ELECTROLYTIC,TANTALUM, 1.0UF 10%, 35VDCW, PAI P.N. 021501; C19-CAPACITOR,ELECTROYTIC,ALUM., 1,400UF 40VDCW, PAI P.N. 021005. CHANGED CAPACITORS C17/C201 AND C18/C202 - CAPACITOR,ELECTROLYTIC,ALUM., 2,200UF, 40VDCW, PAI P.N. 021003, FROM CAPACITOR,ELECTROLYTIC,ALUM., 1,400, 40VDCW, PAI P.N. 021005. ADDED CAPACITOR C1A/C302-CAPACITOR,FIXED,POLYESTER, VALUE SELECTED TO TRIM OSCILLATOR, VALUE FROM 0.01UF TO 0.047UF, ADDED NOTE 7 TO SCHEMATIC DIAGRAM.	12 OCT 73
E	ADDED CAPACITOR C19/C203-CAPACITOR,ELECTROLYTIC,ALUM., 1,400UF,40VDCW, PAI P.N.021005. CHANGED CAPACITORS: C17/C201 AND C18/C202-CAPACITOR, ELECTROLYTIC,ALUM., 1,400UF,40VDCW, PAI P.N.021005 FROM CAPACITOR,ELECTROLYTIC,ALUM.,2,200UF 40VDCW,PAI P.N. 21003.	30 JAN 74
F	ADDED RESISTOR: R54/R307-RESISTOR,VAR,CERMET, 500 OHM,1/4W, PAI P.N. 054003, AND RELOCATE RESISTORS, R4/R305 AND R5/R306-RESISTOR,FIXED, COMP, 2,200 OHMS 5%,1/2W, PAI P.M. 050091 FROM 15 V BUS TO SERIES CONNECT WITH RESISTOR R54/R307, ARM/WIPER CONNECTS TO 15 V BUS.	30 JAN 75
G	CHANGED TRANSISTORS: Q1/Q301 AND Q2/Q302-SEMICONDUCTOR,TRANSISTOR, SILICON,NPN, CHANGED TO TYPE 2N2484, PAI P.N. 048513, FROM TYPE 2N2222, PAI P.N. 048506; Q3/Q303 AND Q4/Q304- SEMICONDUCTOR, TRANSISTOR,SILICON,NPN, CHANGED TO TYPE 2N2222A, PAI P.N. 048512, FROM TYPE 2N2222, PAI P.N.048506; Q7/Q401,Q8/Q402,Q11/0403 THRU Q18/Q410, SEMICONDUCTOR,TRANSISTOR SILICON,PWR,NPN, CHANGED TO TYPE 66090 RCA, PAI P.N. 048505, REV B, FROM TYPE 64497 RCA, PAI P.N. 048505, REV A; Q9/Q308-SEMICONDUCTOR,TRANSISTOR,SILICON,NPN, CHANGED TO TYPE 2N3117, PAI P.N. 048514, FROM TYPE 2N2222, PAI P.N. 048506; Q10/Q306-SEMICONDUCTOR,TRANSISTOR,SILICON,PNP, CHANGED TO TYPE 2N3505, PAI P.N. 048515, FROM TYPE 2N4036, PAI P.N. 048507.	5 FEB 75
H	CHANGED R51/R102-RESISTOR,FIXED,COMP, 4,300 OHMS 5%,1/2W, PAI P.N. 050090, FROM RESISTOR,FIXED COMP, 4,700 OHMS 10%,1/2W, PAI P.N. 050039	21 NOV 75
I	ADDED CAPACITORS: C21/C313 AND C22/C314-CAPACITOR,FIXED,POLYESTER, 0.1UF 10%,50VDCW,PAI P.N.019008; C23/C315-CAPACITOR,FIXED,POLYESTER, (SELECTED VALUE FROM 0.027 TO 0.047UF. ADDED NOTE 8 TO SCHEMATIC DIAGRAM.CHANGED CAPACITORS: C8/C309-CAPACITOR,ELECTROLYTIC,TANTALUM, 47UF 10%,20VDCW, PAI P.N. 021506, FROM CAPACITOR,ELECTROLYTIC, TANTALUM, 22UF 10%,15VDCW, PAI P.N. 021503; C9/C311-CAPACITOR,ELECTROLYTIC,TANTALUM, 4.7UF 10%,35VDCW, PAI P.N. 021504, FROM CAPACITOR, ELECTROLYTIC, 22UF 10%,15VDCW, PAI P.N. 021503; C7/C310-CAPACITOR, ELECTROLYTIC, 4.7UF 10%,35VDCW, PAI P.N. 021504, FROM CAPACITOR, ELECTROLYTIC, 22UF 10%,15VDCW, PAI P.N. 021503. ADDED RESISTORS: R55/R320-RESISTOR,FIXED,COMP, 2,200 OHMS 10%,1/2W, PAI P.N. 050035;	2 JUL 76

Schematic Diagram - Revision Reference Sheet,

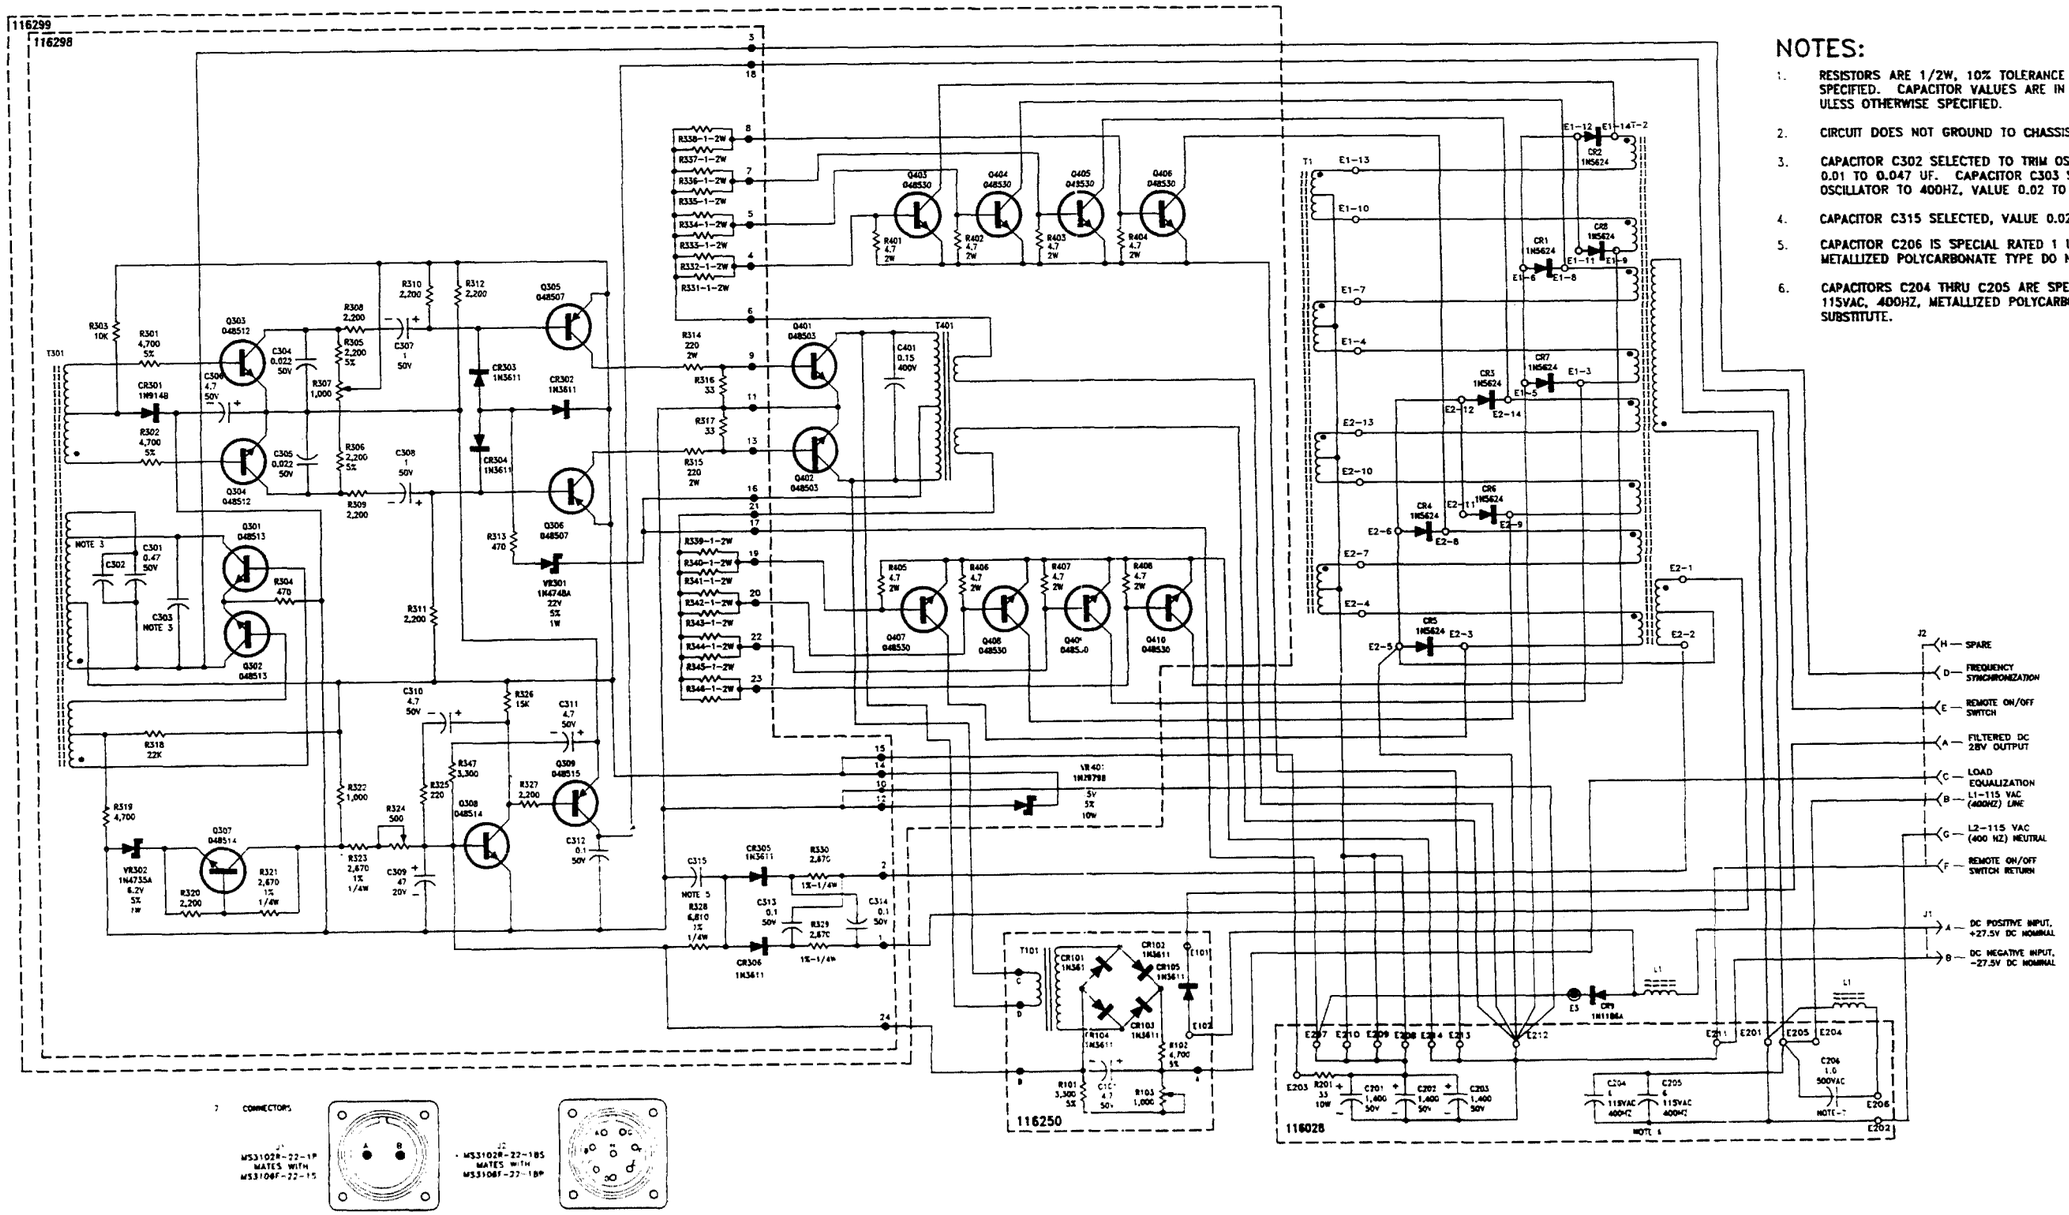
SCHEMATIC DIAGRAM - REVISION REFERENCE SHEET

REV	REVISION	EFFECTIVITY
I (Cont)	R56/R321,R57/R329, AND R59/R330-RESISTOR,FIXED,COMP, 2,700 OHMS 10%, 1/2W, PAI P.N. 050036. CHANGED R26/R328-RESISTOR,FIXED,FILM,PREC., 6,810 OHMS 1%,1/8W, PAI P.N. 050508, FROM RESISTOR,FIXED,COMP, 10K OHMS 10%,1/2W, PAI P.N. 050045. ADDED Q19/Q307-SEMICONDUCTOR,TRANSISTOR,NPN, TYPE 2N3117,PAI P.N.048514. DELETED DIODES: CR6 AND CR7 - SEMICONDUCTOR,DIODE, SILICON, TYPE 1N914B, PAI P.N. 046006.	2 JUL 76
J	CHANGED SEMICONDUCTOR,TRANSISTORS AS FOLLOWS: IDENTIFICATION FROM JEDEC NUMBER TO PHOENIX AEROSPACE INC PART NUMBER AS FOLLOWS: Q1/0301 AND Q2/Q302 TO PAI P.N. 048513 FROM TYPE 2N2484; Q3/Q303 AND Q4/Q304 TO PAI P.N. 048514 FROM TYPE 2N2222A; Q5/Q305 AND Q6/Q306 TO PAI P.N. 048507 FROM TYPE 2N4036; Q7/Q401, Q8/Q402, Q11/Q403 THRU Q18/Q410 TO PAI P.N. 048505 REV B, FROM TYPE 66090, RCA; Q9/0308 AND Q19/Q307 TO PAI P.N. 048514 FROM TYPE 2N3117; Q10/Q309 TO PAI P.N. 048515 FROM TYPE 2N3505.	14 SEP 76
K	CHANGED CAPACITORS: C17/C201, C18/C202, AND C19/C203-CAPACITOR,ELECTROLYTIC,ALUM., 1,400UF 50VDCW, PAI P.N.021011, FROM CAPACITOR,ELECTROLYTIC,ALUM., 1,400UF 40VDCW, PAI P.N.021005.	15 JUN 77
L	CHANGE CAPACITOR: C7/C310-CAPACITOR,ELECTROLYTIC,TANTALUM, 22UF 10%, 15VDCW PAI P.N. 021503 FROM CAPACITOR,ELECTROLYTIC,TANTALUM, 4.7UF 10%,35VDCW, PAI P.N. 021504	30 OCT 77
M	CHANGE RESISTOR: R51/R102-RESISTOR,FIXED,COMP, 4,700 OHMS 5%,1/2W, PAI P.N. 050092 FROM RESISTOR,FIXED,COMP, 4,300 OHMS 5%,1/2W, PAI P.N. 050090.	23 MAR 78
N	CHANGED RESISTORS: R21/R323-RESISTOR,FIXED,FILM,PREC., 3,010 OHMS 1%, 1/8W, PAI P.N. 050511 FROM RESISTOR,FIXED,COMP, 2,200 OHMS 10%,1/2W, PAI P.N. 050035; R22/R324-RESISTOR,VAR,COMP, 1,000 OHMS,1/2W, PAI P.N. 054002 FROM RESISTOR,VAR,COMP, 500 OHMS,1/4W, PAI P.N.054003.	22 APR 80
0	CHANGED RESISTORS: R57/R329 AND R58/R330-RESISTOR,FIXED,FILM,PREC 2,670 OHMS 1%,1/8W, PAI P.N.050548, FROM RESISTOR,FIXED,COMP, 2,700 OHMS 10%,1/2W, PAI P.N.050036.	29 OCT 80
P	. CHANGED RESISTOR: R21/R323-RESISTOR,FIXED,FILM,PREC., 3,010 OHMS 1%, 1/8W, PAI P.N. 050511, FROM RESISTOR,FIXED,COMP, 3,000 OHMS 5%,1/2W,PAI P.N. 050097.	10 DEC 80
Q	CHANGED RESISTORS: R21/R323-RESISTOR,FIXED,FILM,PREC,2,670 OHMS,1%, 1/8W, PAI P.N.050548, FROM RESISTOR,FIXED,FILM,PREC., 3,010 OHMS 1%, 1/BW, PAI P.N. 050511; R61/R321-RESISTOR. FIXED, FILM,PREC., 2,670 OHMS 1%,1/8W, PAI P.N. 050548, FROM RESISTOR,FIXED,COMP, 2,700 OHMS 10% 1/2W, PAI P.N.050036.	12 FEB 81
R	CHANGED CAPACITORS: C3/C304 AND C4/C305-CAPACITOR,FIXED,POLYESTER, 0.022UF,50VDCW, PAI P.N.019018, FROM CAPACITOR,FIXED,POLYESTER, 0.01UF 10%,50VDCW, PAI P.N. 019003. CHANGED, Q11/0403 THRU Q18/Q410 SEMICONDUCTOR,TRANSISTOR,SILICON,POWER,NPN, PAI P.N. 048530, FROM SEMICONDUCTOR,TRANSISTOR,SILICON,POWER,NPN. PAI P.N. 048505 REV B.	7 JAN 83
S	REDRAWN - REFERENCE SYMBOLS CHANGED TO DENOTE LOCATION OF COMPONENTS ON APPROPRIATE CIRCUIT BOARD OR MODULE. NOTES REVISED AND RENUMBERED -PREVIOUS REVISION NOTES REVISED TO CORRECT VARIATION IN REFERENCE SYMBOLS. ADDED CIRCUIT MODULE OR CIRCUIT BOARD SUB-ASSY P.N. TO SCHEMATIC.	12 AUG 83
T	CHANGED RESISTORS: R331 THRU R346- RESISTOR,FIXED,WW, 1 OHM 10%, 2W, PAI P.M.050321 (BWF 1), FROM PAI P.N.050301 (BWH 1); R401 THRU R408 RESISTOR,FIXED,WW, 4.7 OHMS 10%,2W PAI P.N .050324 (BWF 4.7), FROM PAI P.N. 050304 (BWH 4.7); R326-RESISTOR,FIXED,COMP, 4,700 OHMS 10%, 1/2W, PAI P.N.050039, FROM RESISTOR,FIXED,COMP, 15K OHMS 10%,1/2W, PAI P.N.050045. ADDED CAPACITOR: C316-CAPACITOR,ELECTROLYTIC,TANTALUM, 1.0UF 10%,35VDCW, PAI P.N.021501.	23 DEC 83



Schematic Diagram - Revision Reference Sheet,

SCHEMATIC DIAGRAM

NOTES:

1. RESISTORS ARE 1/2W, 10% TOLERANCE UNLESS OTHERWISE SPECIFIED. CAPACITOR VALUES ARE IN UF (MICROFARADS) ULESS OTHERWISE SPECIFIED.
2. CIRCUIT DOES NOT GROUND TO CHASSIS.
3. CAPACITOR C302 SELECTED TO TRIM OSCILLATOR, VALUE 0.01 TO 0.047 UF. CAPACITOR C303 SELECTED TO TUNE OSCILLATOR TO 400HZ, VALUE 0.02 TO 0.047 UF.
4. CAPACITOR C315 SELECTED, VALUE 0.027 TO 0.047.
5. CAPACITOR C206 IS SPECIAL RATED 1 UF ?5%, 500VAC, METALLIZED POLYCARBONATE TYPE DO NOT SUBSTITUTE.
6. CAPACITORS C204 THRU C205 ARE SPECIAL RATED 6UF ?3% 115VAC, 400HZ, METALLIZED POLYCARBONATE TYPE, NO NOT SUBSTITUTE.

INTRODUCTION

1. General

This equipment maintenance manual has been prepared in compliance with ATA specification No.100 by the (AIR TRANSPORT ASSOCIATION OF AMERICA). Its purpose is to describe the procedures, applied in the manufacturer's shops to enable a mechanic, unfamiliar with the equipment, to set it back to operating condition or overhaul it.

The operations described must be carried out in maintenance shops using special tools and test benches.

This manual does not cover standard techniques, maintenance intervals nor details which are likely to vary depending on the shop facilities available.

2. Format

A. The page numbering system of the manual consists in using a page number block for each section as follows. As concerns small basic items of equipment, more than one section can be covered on the same page.

1-100	DESCRIPTION AND OPERATION
101-200	TESTING AND TROUBLESHOOTING
201-300	(NOT ASSIGNED)
301-400	DISASSEMBLY
401-500	CLEANING
501-600	INSPECTION
601-700	REPAIR
701-800	ASSEMBLY AND STORAGE
801-900	FITS AND CLEARANCES
901-1000	TOOLS AND SPECIAL EQUIPMENT
1001-1100	ILLUSTRATED PARTS LIST

B. In general, all values are expressed in units of International System (meter, kilogram, second) or multiples and sub-multiples of same.

In some particular cases more appropriate units are employed.

3. Revision

With each revision issued for the manual, detailed instructions are supplied cross-referring to the page numbers concerned for insertion and deletion. The revised, added or deleted material is indicated by the letter R printed in the margin.

LIST OF PRODUCTS

NOTE : Equivalent products may be used in place of those listed.

DESCRIPTION AND OPERATION

1. Description

A. General

The electrical storage battery supplies the aircraft with 24 V D.C. until the generators operate or in case of generator output drop.

It also enables direct or indirect starting of the propulsion engine(s).

The battery comprises 20 cadmium-nickel series-mounted storage cells contained in a metallic box which accommodates a connector receptacle.

The box of battery P/N 4076-1 accommodates an additional connector receptacle which is connected to the thermostat.

B. Characteristics

(1) Dimensions and weight

	OVERALL DIMENSIONS IN mm (in.)			WEIGHT IN kg (lb)
	LENGTH	WIDTH	HEIGHT	
Box assembly	301.5 (11.87)	267.4 (10.53)	260.4 (10.25)	5 (11.02)
Storage cell VP 400 KH	79 (3.11)	34.7 (1.37)	236 (9.29)	1.525 (3.36)

Weight of the complete battery, ready for use : 37 kg (81.55 lb) ± 2%.

(2) Technical features

- Alkaline, spill-proof, cadmium-nickel battery, 24 V D.C., 36 Ah.

PRINTED IN FRANCE

- Connector receptacle complying with MS18093 and NFL56205 specifications.

- Very thin, sintered, cadmium-hydrate impregnated negative plates, and nickel-hydrate impregnated positive plates.

- Composite separator made of synthetic fibre. Alkaline electrolyte (chemically pure potassium hydroxide aqueous solution. Specific gravity 1.30).

- Polyamid boxes and covers assembled by thermowelding.

R - Nickel-plated cuprochromium output terminals.
R Sealing around the therminals is provided by packing
R glands fitted with preformed packings.

- Polyamid safety valve screwed in a housing located in the center of the cover.

- Dimensional specification : NFL56135 with connector receptacle NFL56205.

DISCHARGE RATE	36A (+25°C) (+77°F)	360A (+25°C) (+77°F)	540A (+25°C) (+77°F)	180A (-15°C) (+5°F)	360A (-15°C) (+5°F)
Discharge duration	1 hr.	5 min.	3 min.	10 min. 40 sec.	4 min. 40 sec.
End-of-discharge voltage	21 V D.C.	18 V D.C.	16 V D.C.	18 V D.C.	15 V D.C.
Capacity	36 Ah	30 Ah	27 Ah	32 Ah	28 Ah

R - Nominal capacity C1 = 36 Ah (at discharge rate for 1 hour).

- Maximum instantaneous power (at + 25°C (+ 77°F)) : 18 kW (1380 A - 13 V).

- Service life : minimum of 100 cycles as per regulation AIR 8421.

- Charging in flight at 28.5 V D.C. or in a workshop (see "Testing and Troubleshooting", para. 1. B.).

R Special characteristics applicable to battery P/N 4076-1.

- Thermostat fitted to a special link and connected to a connector receptacle located under the main connector receptacle.

R - Operating temperature (closing) : 71 + 3°C (160
R + 5°F) increasing temperature).

- Thermostat connector receptacle : complying with MIL-C26482 specifications (CANNON : KPTM07-E-10-6-P).

C. Detailed description (See Fig. 1)

(1) Complete box

This comprises :

- a box assembly (10),

- a complete cover (20) with an insulating gasket (30) made of silicone elastomer bonded to the inner face.

(a) Box

The box is laterally provided with two vent pipes and four spring fasteners.

An identification plate (310), a filling instruction plate (300) and a modification plate (320) are affixed onto the front face which supports the connector receptacle base plate.

The front face of battery P/N 4076-1 also supports the base plate of the connector receptacle connected to the thermostat.

(b) Cover

The cover is laterally provided with four catches intended for attachment to the box, and with a bar notched at both ends and intended for battery attachment through tie-rods secured to a rack.

An instruction plate (300) is also affixed onto the cover.

(2) Storage cells

The twenty electrical storage cells (40) are arranged in two rows of seven and one row of six.

PRINTED IN FRANCE

Each storage cell is equipped with a safety valve (120) fitted with a preformed packing (130).

The storage cell terminals are made up of two threaded rods. Each rod is fitted with :

- a preformed packing (50),

- a flat washer (60),

- a spring washer (70),

- a spacer ring indicating polarity (-) (80) or (+) (90),

- a terminal lower nut (100),

- a spring washer (110),

- a terminal nut (100).

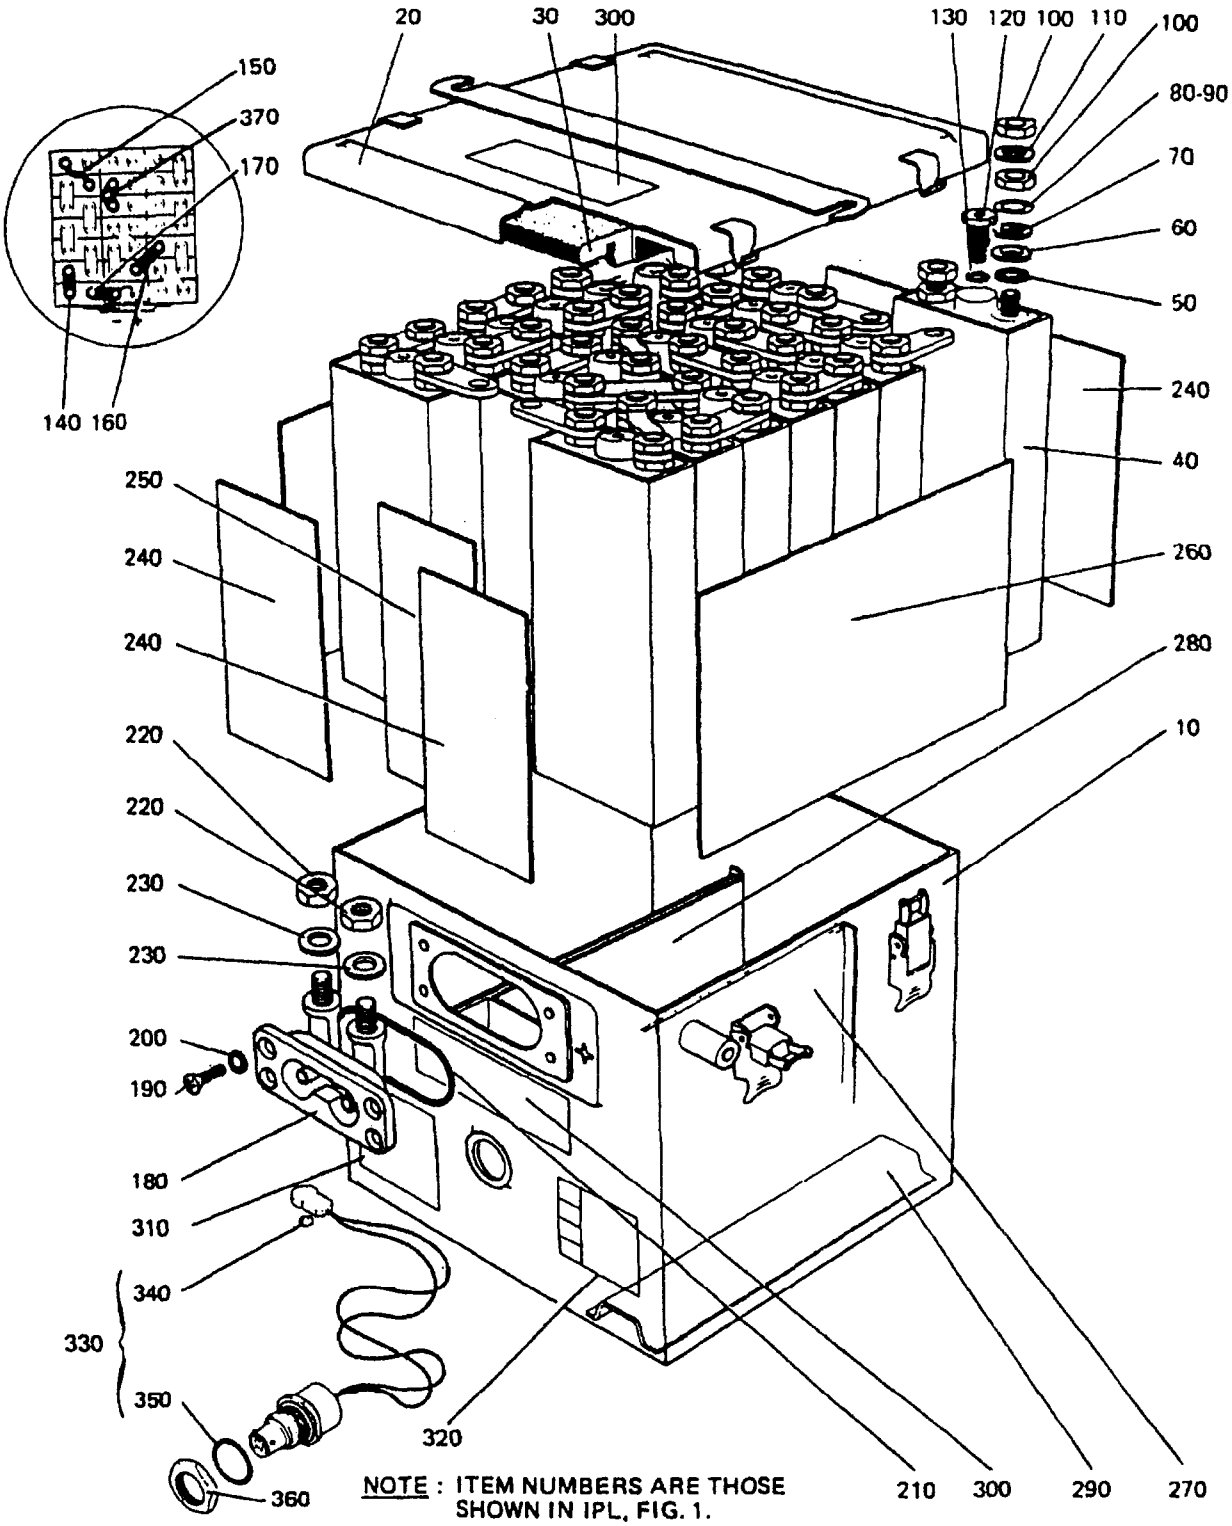
(3) Accessories

The accessories are used to secure the storage cells. There are :

- six endplates (240 and 250),

- two notched sideplates (260),

- four intermediate insulator plates (270 and 280) inserted between the three rows of storage cells,



- twenty-one links (140, 150, 160 and 170) ensuring series-connection of storage cells and connection to the connector receptacle.

Battery P/N 4071-1 is provided with a special link (370) (to which the thermostat is secured) instead of a link (140).

(4) Connector receptacle

Main connector receptacle (180) is secured to the box by four screws (190) and washers (200).

On battery P/N 4071-1, the thermostat connector receptacle is secured to the box by a preformed packing (350) and locking nut (360).

NOTE : ITEM NUMBERS ARE THOSE SHOWN IN IPL, FIG. 1.

DESCRIPTION
FIGURE 1

PRINTED IN FRANCE

2. Operation

A. Principle of operation

The battery plates store electrical power supplied by a charging source, and supply power when the battery is connected to a load circuit, i.e. when it discharges.

During charge, nickel hydroxide Ni $(OH)_2$ of the positive plates is oxidized and is transformed into superior hydroxide Ni O OH ; cadmium hydroxide Cd $(OH)_2$ of the negative plates is reduced and is transformed into cadmium metal (Cd). Reverse reactions take place during discharge and active materials return to their initial state. The electrolyte (potassium solution) does not undergo any chemical change.

For a battery with a given volume, the nominal capacity of the battery discharged in 1 hour is determined by the quantity of electricity (Ah) the battery can supply.

The efficiency of the battery, in terms of quantity of electricity, is 71.5%. This means that, in order for a 36 Ah battery to supply 100% of its capacity, it must store a quantity of electricity of 50 Ah, i.e. 140% of Cl (case of recycling, see "Testing and Troubleshooting", para. 1. B.).

It is only on this condition that complete chemical transformation of the active materials will take place.

B. Operation in normal use

(1) Charging

Charging the battery on an aircraft is ensured by connecting it in parallel, at 28.5 ± 0.5 V D.C., with the aircraft generator(s), or with one (or several) transformer-rectifier(s) supplied by one (or several) A.C. generator(s).

In the case where the charging sources are not accurately regulated, it is advisable to particularly check the water consumption in the storage cells, at least at the beginning of the operating period. Moreover, it is advisable to regularly check that the charging voltage supplied by the different systems does not exceed 28.5 ± 0.5 V D.C. at a constant rate (for a temperature of 20 ± 5°C (68 ± 9°F)). R

NOTE : - When a battery, in which the active materials have been fully transformed, is subjected to an extended charging operation, the battery becomes overcharged and the current which passes through it can only give rise to the decomposition of the electrolyte water content into its two elements : oxygen and hydrogen (the rate of decomposition is 1 cm^3 (0.061 cu.in.) of water for an overcharge of 3 Ah). Water consumption in overcharging conditions is proportional to the value of the overcharging current.

- When a battery is charged from a constant voltage supply, the value of the end-of-charge current depends only on the voltage of this supply and the temperature of the battery.

Without exceeding the limits laid down in AIR 2021 specifications, the charging network voltage should be dropped when the internal temperature of the cells frequently remains high for long periods.

The rule to be followed consists in dropping the charging voltage by 1 V D.C. each time the stabilized temperature of the twenty storage cells increases by 15°C (27°F) (from + 25°C (+ 77°F)).

R

- The battery is designed to withstand, for short periods of time, large accidental fluctuations of the overcharge current, providing the electrolyte levels within the cells are correct.

(2) Discharging

The nominal capacity C1 of the battery corresponds to a 1 hr rate of charge ; that is, the battery can supply a 36-amp current for 1 hour, when it is 100% charged.

However, the battery can, without danger, supply currents greatly exceeding the nominal discharge current. For instance, a battery with a 36 Ah nominal capacity can supply, in peak conditions, currents about twenty times its nominal rating, i.e. 720 A under 19.5 ± 0.5 V D.C. at + 25°C (+ 77°F).

PRINTED IN FRANCE

The battery is designed to withstand complete discharge (for instance, as much as 3 Cl, at an emergency rate). However, at the end of discharge, the current supported by the least charged cells can reverse their polarities (unbalance) (see "Testing and Troubleshooting", para. 1. B. (2) (b)).

TESTING AND TROUBLESHOOTING

NOTE : Tools and special equipment to be used are listed under "Tools and Special Equipment".

1. Testing

A. Setting into service

(1) Ground maintenance

(a) Operating voltage

The nominal charging voltage for 20-cell batteries is 28.5 V D.C. at 20°C (68°F). An end-of-charge current matching the water consumption is obtained.

In case the water consumption is excessive, i.e. more than 25 cm^3 (1.53 cu.in.) per cell (see para. B. (3) (b)), check the voltage above, or the usual temperature of the batteries in service (see aircraft Maintenance Manual).

(b) Insulation

Electrolyte condensation or overflowing may reduce the value of the insulation between the battery electrical circuit (connector receptacle disconnected) and the box.

The value of the insulation under 45 V D.C. should be greater than 10 megohms.

(c) Charge condition

The battery can be charged in flight up to 90%. When this state is reached, the open-circuit voltage is about 26 V D.C.

When the off-load voltage of the battery after an idle period is greater than 25.5 V D.C., it can be deemed at least 50% charged. If required (see aircraft maintenance manual), perform fast-charging (see para. (2) (c)).

PRINTED IN FRANCE

(d) Maintenance periods

Maintenance on the aircraft is defined by the corresponding specifications. The workshop maintenance periods and removal conditions are covered in the aircraft manuals and determined by the users, taking account of the operating conditions.

The maintenance operations can be broken down as follows :

- the complementary fast-charging operations above,

R - charging and topping up of the electrolyte
R level including :
R - residual discharge (see para. B. (2) (a)),
R - fast charging as per the procedure mentioned
R in paragraph A. (2) (c) 1st method,
R - topping up of the electrolyte level and valve
R cleaning (see para. B. (3) (b)),
R - visual inspection of the thermostat (see "Inspection"),

- recycling, including :
  - residual discharge,
  - balancing as required,
  - complete charging and topping up of the electrolyte levels,
  - valve cleaning,
R - checking the thermostat for operation,
  - checking the capacity (discharge and complementary checks as required),
  - final charging after checking the insulation,

- reconditioning, including :
  - disassembling the battery,
  - cleaning,
  - inspection,
  - assembling the battery.

This operation is to be performed during recycling, after the capacity check and before the final charging.

It is either scheduled or to be performed when cells are to be replaced.

(2) Charging in workshop

(a) General conditions

Equipment required :

- battery charger,

- valve wrench.

CAUTION : - CHARGING SHOULD BE PERFORMED ONLY IN CLEAN AND VENTILATED PREMISES WHICH ARE NOT USED FOR LEAD BATTERIES (ACID ATMOSPHERE).

- REMOVE THE COVER OF THE BATTERY AND UNSCREW, BUT DO NOT REMOVE, THE VALVES (USING THE VALVE WRENCH), IN ORDER TO ALLOW THE GASES PRODUCED BY THE ELECTROLYTE TO BE EVACUATED WITHOUT PLACING THE ELECTROLYTE IN CONTACT WITH THE AMBIANT AIR (RISKS OF CARBONATION).

NOTE : - After charging a discharged battery for 5 min., add 10 to 15 cm^3 (0.61 to 0.92 cu.in.) of distilled water to very dry cells if their voltage is greater than 1.5 V D.C. (see para. B. (3)).

When this can be foreseen, it is advisable to check the voltages of each cell at the beginning of the charging operation.

- During charge, and particularly near the end of the charging period, a production of foam may occur. This phenomenon is generally due to :
  - the presence of greasy matter inside the cell (for instance, grease or oil which could have accidentally ingressed through the valve clearing hole),
  - excessive reduction of the specific gravity of the free electrolyte above the plates. This can happen particularly when distilled water is added to a cell having consumed all (or even more than) its content of free electrolyte.

R
R

PRINTED IN FRANCE

In this case, it is necessary to add a large volume of distilled water, which does not immediately mix with the concentrated electrolyte remaining in the cell.

To stop this phenomenon, it is generally sufficient to interrupt the charging operation and to perform a discharge allowing the electrolyte to mix. The next charging operation will further improve electrolyte homogeneisation, and the phenomenon should then disappear.

In the case where the foam is formed by the contact with greasy matter inside the cell, practically nothing can be done except preventing the foam from spreading over the covers and flowing between the cells. This can easily be performed by fitting a water-absorbent cotton pad in place of the valve.

(b) Slow-rate low-current charging

On the first time the battery is set into service (new battery), after important balancing operations and after removing the discharged batteries from storage, this type of charging is advisable to ensure homogeneous charging of all cells.

Charge the battery at 3.6 A constant current up to 30 V D.C. as measured across the terminals, then continue with the same rate of 3.6 A for 4 hr.

Charging can be performed in two periods provided that the first period lasts at least 8 hr.

Do not interrupt the charging operation for the last 5 hr. (to ensure normal topping up of the electrolyte levels).

(c) Fast-rate charging (discharged battery)

This charging operation is performed at two successive regulated current rates :

- First method

R First charge at 18 A up to 31 V D.C. (2 hr. 40 min. maximum depending on the actual capacity of the battery), then charge at 3.6 A for 4 hr. (the voltage is then about 32 V D.C.).

- Second method

First charge at 36 A up to 31.4 V D.C. (1 hr. 15 min. max. depending on the actual capacity of the battery), then charge at 3.6 A for 4 hr. (the voltage is then about 32 V D.C.).

NOTE : The high current phase is limited by the voltage, in order not to overload (or underload) batteries with excessively different capacities and to completely charge the battery in about 6 hr.

(d) Charging a battery whose charge is unknown

Applicable when a complement of charge is needed, or if the battery has not been used for a period of less than 2 months, if it is not possible to perform complete recycling :

- charge at 3.6 A until the voltage reaches 29 to 30 V D.C.,

- or charge at 18 A until the voltage reaches 30 to 31 V D.C.,

- or charge at 36 A until the voltage reaches 31 to 31.4 V D.C.

B. Recycling

(1) Equipment and product required

(a) Equipment

- Battery charger.

- D.C. voltmeter, 0 to 3 V/0 to 35 V, class 0.5.

- Stopwatch.

- 20 resistors (1 ohm approx. - 1 W min. each) fitted at both ends with "crocodile" clips.

PRINTED IN FRANCE

- Plastic syringe fitted with a cylindrical adaptor and a stop.

- Valve wrench.

(b) Product

- Distilled water.

R (2) Residual discharge and rebalancing
R
R (a) Residual discharge

After removing the battery for normal charging operation in flight (scheduled removal) or after detecting a fault, make sure that the discharge value is practically nil after removal.

Discharge 85% of C1 at a constant current, i.e. 30 A, and note the time necessary to obtain a voltage of 20 V D.C. across the battery terminals. The current should automatically or manually be regulated.

When the voltage across the terminals passes between 22 and 21 V D.C. (in other words, if sudden voltage drops occur), measure the voltage of each cell in order to detect and localize unbalance. If the unbalance is practically nil (normal battery), let the battery cool down before performing a new charging operation and topping up of levels (see para. (3)).

(b) Rebalancing

As soon as the voltage of one or several cell(s) drops below 1 V D.C. or, as a limit, when the voltage across the terminals of the battery reaches 20 V D.C., stop discharging (and note the discharge duration). Use a 1-ohm resistor to shunt each cell and keep the resistors in place for 16 to 24 hr. (for instance, one night).

In these conditions, each cell will discharge at a slow rate through its individual resistor without danger of reversing the polarities.

NOTE : The complementary checks covered in paragraph (4) (b) provide a means of classifying the cells after their capacity ; this is not covered at this stage.

R (3) Complete charging and topping up of the electrolyte level

(a) Charging

Charge the battery as per paragraph A. (2) (b) or A. (2) (c) to ensure complete charging to 100% of the available capacity.

This charging provides a quantity of electricity equal to 140% of the capacity of the battery. During the final stage, a certain quantity of water from the electrolyte is decomposed and will have to be replaced as per the following operation.

At the end of the charge, the electrolyte is at its maximum level (presence of H_2 and O bubbles on and between the plates) and the voltage of the battery is 31.5 to 32 V D.C. (between 15 and 25°C (59 and 77°F)). The individual voltages of the cells should be homogeneous and about 1.6 V D.C.

R (b) Topping up the electrolyte level

During the last charging hour, as close as possible to the end of charge, and keeping the charge at 3.6 A, add distilled water to top up the level of the liquid in each cell.

NOTE : In the case of simultaneous recharging of several batteries, take account of the R time required to top up their levels. If necessary, extend the charging time by a few minutes so as to complete this operation.

R Checking the level as described below is valid only if it is performed at the end of charging, while the current flows.

CAUTION : IF THIS ADJUSTMENT IS NOT PERFORMED AS PER THESE SPECIFICATIONS, THE CELLS WILL OVERFLOW.

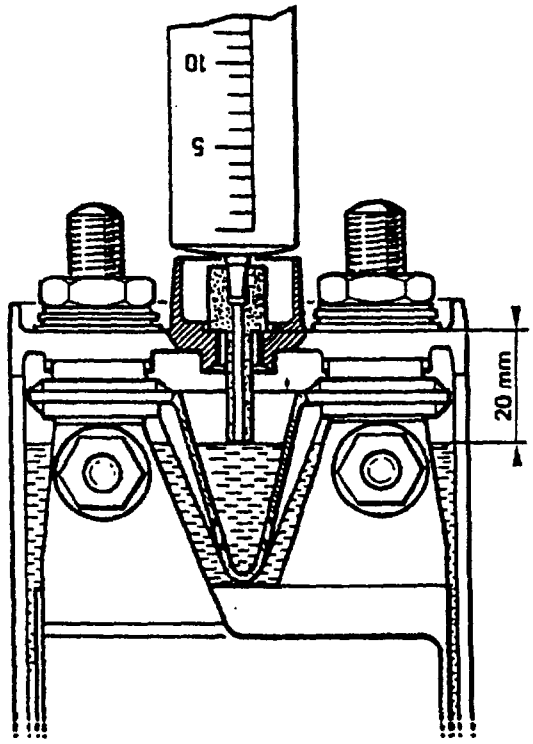
The level of the electrolyte should be at 20 mm (0.79 in.) below the valve seat (the valve and valve seal should be removed).

PRINTED IN FRANCE

To adjust the level, after removing each valve (see "Disassembly"), use a plastic syringe whose adaptor is provided with a tube and a stop ; the end of the syringe should be at 20 mm (0.79 in.) below the valve seat (see Fig. 101).

By maintaining the stop shoulder in contact with the valve seat, and by pulling the syringe piston, checking for correct topping up is immediate.

- if the level is too low, the syringe piston will come up "dry",



- any excess fluid will be sucked into the syringe until the level coincides with the tip of the tube.

If the volume of water added to any cell is greater than 25 cm^3 (1.53 cu.in.), check the conditions of use (see para. A. (1) (a)). For new batteries with a normally correct level, the volume of added water should not exceed 10 cm^3 (0.61 cu.in.).

NOTE : Clean the valves (see "Cleaning", para. 1) while the levels are being adjusted. Leave the cells unplugged for as short a time as possible.

CAUTION : NEVER USE ACID OR A SOLUTION OF ACID AND WATER TO ADJUST CELL LEVELS IN NICKEL-CADMIUM BATTERIES. ANY TRACE OF ACID, HOWEVER SMALL, WILL IRREMEDIABLY DAMAGE THE BATTERY. ONLY USE EQUIPMENT WHICH HAS NEVER BEEN USED FOR LEAD BATTERIES. AVOID USING CHEMICALLY PURIFIED WATER WHICH CONTAINS ACID OR CHLORINATED ELEMENTS.

R (4) Checking the thermostat for operation (see
R "Inspection").

TOPPING UP WITH A SYRINGE FITTED WITH A CALIBRATED ADAPTOR
FIGURE 101

PRINTED IN FRANCE

R (5) Capacity check

(a) Discharge

R Within 24 hours after charging and topping up the level, discharge the battery down to 30 A (see para. (2) (a)). Note the discharge duration and the time when some cells drop below 1 V D.C. Stop discharging when reaching 20 V D.C. across the battery terminals.

Conclusions to be drawn from the above test :

- the battery is correct if the duration of the first discharge of the battery (see para. (2) (a)). is greater than 30 min., and the duration the second discharge is at least equal to 1 hr. (84% charge),

- if the duration of the first discharge is less than 30 min., and the duration of the second discharge is correct (1 hr. minimum), the condition of the battery is correct, but it is not completely charged (less than 15 Ah) and the operating conditions should be checked,

- if some cells remain shorted during discharge, discard them (see para. (c)),

R - if the duration of the second discharge is less than 1 hr., or if the voltage of some cells is less than 1 V D.C. within 1 hour of discharge, the battery should undergo a more complete overhaul. Perform the complementary checks (see para. (b)).

(b) Complementary checks

The capacity supplied by the battery is :

$$35 \text{ A} \times \frac{\text{number of minutes before 20 V D.C.}}{60}$$

= Number of Ampere-hours (Ah)

If the capacity is not greater than 30 Ah, or if the voltage of each cell rises too quickly during charging, drops, or is excessively low at the end of charge, some cells may have been insufficiently balanced, the volume of added water is insufficient, or the cell separators are damaged.

- Repeat the balancing operations more accurately by discharging at 10 A.

Meanwhile, regularly measure and note the voltage of each cell, observing the sequence of measurement. Locate and shunt the cells whose voltage drops below 1 to 0.9 V D.C. using a 1-ohm (1 W) resistor.

Stop discharging at the latest when the voltage reaches 10 V across the battery terminals. Keep the shunts in place as described in paragraph (2) (b).

Repeat the remaining operations : slow-rate charging (see para. A. (2) (b)), checking the levels (see para. (3) (b)) and a new test discharge (see para. (a)).

Regularly check the voltage of each cell during the first and last hour of charging.

At the end of this test, discard the following cells whose operation is defective :

- cells not reaching 1.2 V D.C. after 5 min. charging,

- cells whose voltage is less than 1.5 V D.C. at the end of 3.6 A charging,

- cells whose voltage is greater than 1.7 V D.C. at the end of charging (at 20°C (68°F)),

- cells whose voltage still falls below 1 V D.C. before 1 hr's. discharge, when the last test discharge is performed.

NOTE : A more accurate procedure intended to discard the defective cells consists in extending the end of charge described in paragraph A. (2) (b) for 4 to 5 hr. under 3.6 A and localizing the cells whose voltage falls after reaching 1.6 V D.C.

PRINTED IN FRANCE

(c) Replacing cells

Replacing cells requires disassembly and reconditioning of the battery. After replacing the cells, perform a fast-rate charging (see para. A. (2) (c)).

The capacity of the replacement cells and remaining cells should be approximately the same, to avoid creating new unbalance. Only a small number of new cells can be installed in a battery comprised of average cells. It is advisable to series-connect average cells to obtain homogeneous batteries.

The tests as described in paragraph (b), together with an accurate control of the voltage rise of the cells during charging, allow for qualitative classification and thus economical use of the cells.

R (6) Final charging

Check for insulation (see para. A. (1) (b)) before performing this charging operation prior to setting into service. Perform a fast-rage charging (see para. A. (2) (a) and A. (2) (c)).

NOTE : For batteries actually in use, it is not necessary to perform the last phase of 4 hr. at 3.6 A, as electrolyte is being consumed at this stage.

DISASSEMBLY

NOTE : - See "Testing and Troubleshooting" to determine the condition of the unit or the most likely cause of faulty operation.

- Tools and special equipment to be used are listed under "Tools and Special Equipment".

1. Disassembly (See IPL, Fig. 1)

- Remove cover (20).

CAUTION : MAKE SURE THAT THE BATTERY IS COMPLETELY DISCHARGED BEFORE PERFORMING THE FOLLOWING OPERATIONS.

- Remove terminal nuts (100), spring washers (110), washers (220), washers (230) and rigid links (140, 150, 160 and 170) interconnecting cells (40).

NOTE : For battery P/N 4076-1, clear link (370), to which the thermostat is secured, without exerting any tractive force on the leads connecting the link to the thermostat connector receptacle.

- Extract each cell using wrench 13169.

- Remove the two sideplates (260), intermediate insulator plates (270 and 280) and endplates (240 and 250).

- Unscrew the four attaching screws (190), fitted with washers (200), and remove connector receptacle (180) ; recover preformed packing (210).

- Remove cell valves (120) using wrench 15528 (use the two lugs provided to facilitate unlocking) ; recover preformed packing (130).

- Remove thermostat (330) (battery P/N 4076-1) :
  - unscrew self-locking nut (340) securing the thermostat to link (370),
  - unscrew connector receptacle holding nut (360), recover preformed packing (350) and take out the assembly.

CLEANING

1. Cleaning the valves

CAUTION : THE USE OF GASOLINE, CHLORINATED SOLVENT OR ANY OTHER SOLVENT IS STRICTLY PROHIBITED.

Remove the valves and dip them for several hours (one night, for instance) in a container filled with distilled water or, if not available, with very clean and non-acid water.

The purpose of this dipping operation is to dissolve the salts likely to accumulate within the valve clearing ports.

While the valves are immersed, take all appropriate precautions to prevent foreign matter from falling inside the cells, and to avoid the reaction of the electrolyte in contact with the ambient air.

Before fitting back the valves on the cells, check them for operation (see "Inspection").

2. Cleaning the cells

Two cleaning procedures can be used :

- cleaning with well-filtered compressed air,

- cleaning by washing.

A. Cleaning with compressed air

NOTE : To avoid any short-circuit, blow with a rubber hose or a pipe fitted with an insulating adaptor.

Thoroughly blow on the cell covers, in order to expel outside the box the dust and the salts likely to have accumulated on the covers.

B. Cleaning by washing (cells removed)

- This procedure is more rational and consists in washing the terminals, covers and cell walls with warm water and a smooth non-metallic brush, in order to remove any trace of potassium or salts.

- Beforehand make sure that the cell valves are installed.
- Never immerse the cells in water.
- Wipe each cell, then let in dry in ambient air.

3. Cleaning the box

Wash with water and let dry in the ambient air after wiping.

4. Cleaning the nuts, links, spring washers, endplates and sideplates

- Clean with warm water and a brush, and let dry in ambient air.
- Discard any corroded or mechanically defective part.

INSPECTION

NOTE : Tools and special equipment to be used are listed under "Tools and Special Equipment".

1. Visual inspection

- Inspect the box on the outside and make sure that it does not show any trace of impact.

- Check the cells for condition, in order to detect any electrolyte seepage around the terminals, traces of shorting, corrosion by potassium, cover lifting, cracked cells, etc.

- Localize the corroded or damaged parts, if any.

2. Checking a valve

- Remove the valve.

- Screw the valve fitted with its seal on a metallic tube fitted with an appropriate adaptor.

- Connect this tube to an adjustable pressure reducing valve and then to a compressed air line or a compressed air cylinder.

- Adjust the pressure to 0.5 bar (7.25 psi) and dip the valve in a container filled with water. If the valve is in good condition, air bubbles should come off.

- If there are no bubbles, increase pressure until the air escapes, then gradually decrease pressure to 0.5 bar (7.25 psi) and note the value for which the air stops escaping.

- Discard any valve whose operating pressure is greater than 0.7 bar (10 psi) after this "lifting" operation is performed, and replace the valve by a duly tested spare valve. Also discard any valve whose operating pressure is less than 0.14 bar (2 psi).

- Install the valve using only the knurled upper part of the valve wrench.

- Check the packing for condition.

3. Checking the nuts for tightness

Check that all nuts are correctly tightened :

R - terminal lower nuts ; torque : 0.5 ± 0.1 daN.m (3.69 ± 0.738 ft.lb),

R - terminal nuts ; torque after assembly : 1.3 ± 0.1 daN.m (9.594 ± 0.738 ft.lb).

4. Checking the connector receptacle

Check the connector receptacle pins for condition ; replace the connector receptacle if the pins show any trace of arcing or excessive oxidization.

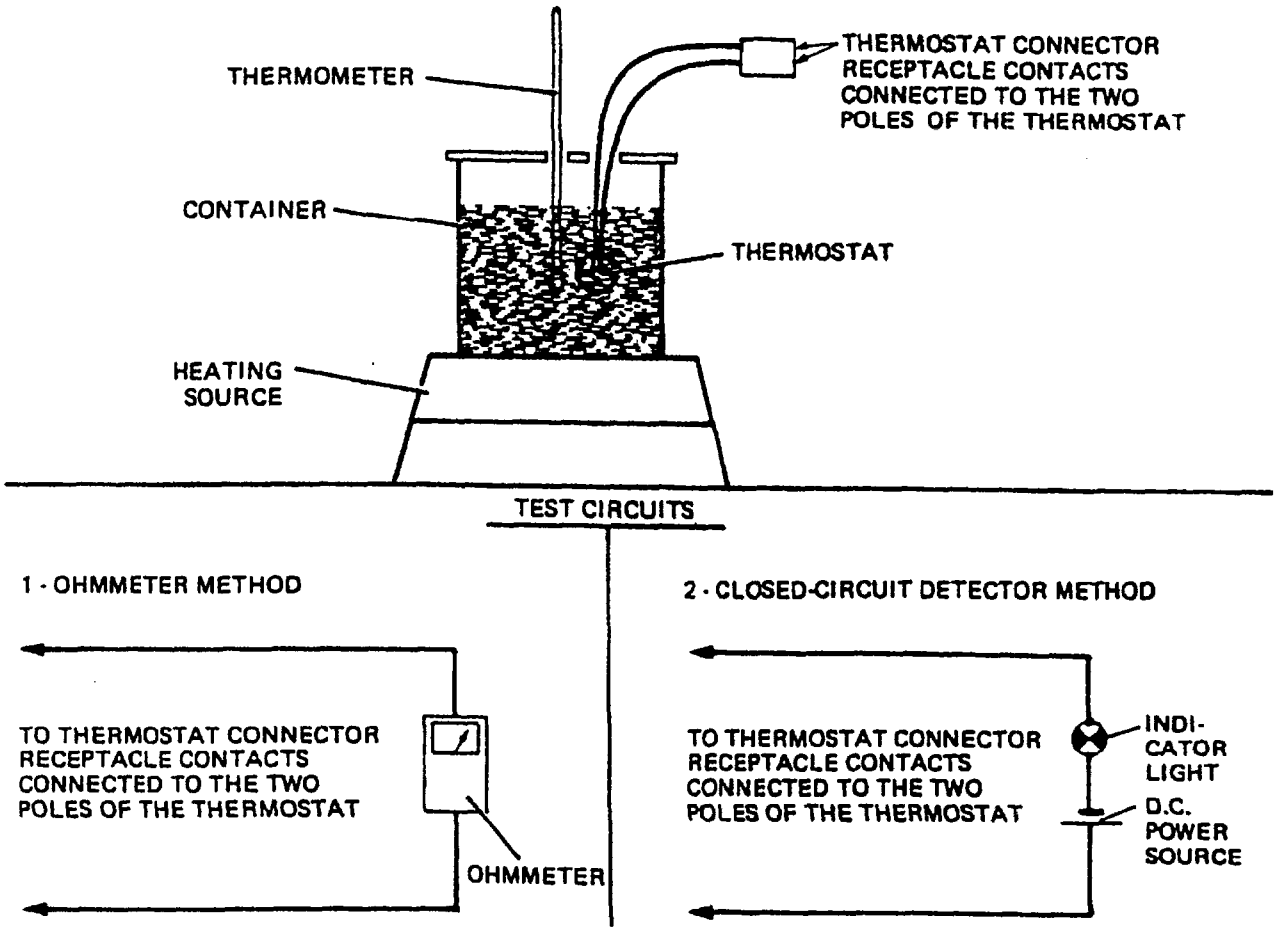
R 5. Visual inspection of the thermostat (battery P/N 4076-1)

R Visually check the thermostat and the thermostat connector receptacle for condition.

R Check in particular that :

R - the thermostat is secured to the battery link,

R - the connecting leads or cable between the connector receptacle and the thermostat are not damaged.



R 6. Checking the thermostat (battery P/N 4076-1)

CAUTION : MAKE SURE THAT THE BATTERY IS COMPLETELY DISCHARGED BEFORE PERFORMING THESE CHECKS.

A. Functional check (See Fig. 501)

- Dip the thermostat in a 0.5 l (0.109 Imp. Gal. ; 0.132 US Gal.) container, three-quarters filled with water. Make sure that the thermostat is not in contact with the container walls.

- Dip a thermometer in the container, being careful to place the bulb of the thermometer in the immediate vicinity of the thermostat.

CHECKING THE THERMOSTAT
FIGURE 501

PRINTED IN FRANCE

- Connect the test circuit (ohmmeter or closed-circuit detector) to the two connector receptacle contacts C and D of the thermostat assembly.

- Gradually heat the container water, being careful to maintain the water at a temperature close to 60°C (140°F) for about 10 min. This is necessary to bring all thermostat components to the same temperature as the water.

- Continue to heat the water gradually and note on the thermometer the temperature at which the thermostat operates (rising temperature).

Thermostat closing is indicated by the ohmmeter pointer moving from the "infinite" position to the zero position, or by the illumination of the closed-circuit detector indicator light.

Thermostat operation is correct if the temperature noted is within 68 to 74°C (154.4 to 165.2°F).

- As soon as thermostat closing is noted, stop heating the water and place the 0.5 l (0.109 Imp. Gal. ; 0.132 US Gal.) container in a 1 l (0.219 Imp. Gal. ; 0.264 US Gal.) container.

Pour cold water into the larger container until the water level is the same in the two containers.

- Note the temperature at which the thermostat contacts will open (falling temperature). When the contacts open, the ohmmeter pointer resumes the "infinite" position or the closed-circuit detector indicator light goes out.

Thermostat operation is correct if the difference between closing and opening temperatures is between 4 and 10°C
R (7.2 and 18°F).

- In the case where the operating temperatures recorded are not within tolerance limits, perform the above tests again.

- Remove the thermostat and link assembly from the container and dry thoroughly.

TO BE DELETED UPON ISSUE OF A FORMAL REVISION

B. Insulation test

- Using an ohmmeter, measure the insulation of each pole of the thermostat with respect to its metallic box.

- The insulation value obtained should be greater than or
R equal to 30 Mohm under 45 V D.C.

PRINTED IN FRANCE

REPAIR

1. Box

Straighten out the sides of the box and remove any dents which have been produced following impact.

2. Cells

Repair essentially consists in the replacement of cells acknowledged defective (see "Testing and Troubleshooting", para. 1. B. (4) (c)). New cells must first be discharged (see "Testing and Troubleshooting", para. 1. B. (2) (a)).

ASSEMBLY AND STORAGE

NOTE : - The products to be used are listed under "List of Products".

- Tools and special equipment to be used are listed under "Tools and Special Equipment".

1. Assembly (See IPL, Fig. 1)

NOTE : In case cells must be replaced, see "Testing and Troubleshooting", paragraph 1. B. (4) (c).

- Install connector receptacle (180), fitted with its preformed packing (210), and secure it with four screws (190) and washers (200).

- Install the thermostat connector receptacle from the inside of the box and secure it with nut (360) fitted with preformed packing (350). Place the thermostat outside the box (battery P/N 4076-1).

- Install cells (40), stricIty complying with polarities (see Fig. 701) and inserting :
  - the two sideplates (260) and intermediate insulator plates (270 and 280) between the three rows of cells,
  - endplates (240 and 250).

- Secure the thermostat to link (370) with nut (340), and install link (370) (battery P/N 4076-1).

- Install links (140, 150, 160 and 170).

- Secure the links with nuts (100), washers (110), nuts (220) and washers (230).

- Tighten the nuts using a torque wrench (torque : 1.3 ± 0.1 mdaN (9.595 ± 0.738 ft.lb)).

- Lightly smear the terminals, nuts and rigid links with petrolatum or neutral light machine oil (non acid).

- Measure the insulation resistance value (see "Testing and Troubleshooting", para. 1. A. (1) (b)).

- Charge the battery (see "Testing and Troubleshooting", para. 1. B. (5)).

2. Storage

A. Preparing the battery for storage

- After topping up the levels (see "Testing and Troubleshooting", para. 1. B. (3)), discharge the battery with a constant current of 18 A until the voltage across the terminals falls to 20 V D.C.

- Using petrolatum or neutral light machine oil, lightly smear the terminals, nuts, links, connector receptacle contacts, and the metal parts which are likely to be damaged by atmospheric agents.

- Install the cover and place the battery in its normal vertical position.

B. Storage premises

Store the equipment is dust-free and dry premises.

C. Temperature requirements

The battery can be stored between - 60 and + 60°C (- 76 and + 140°F).

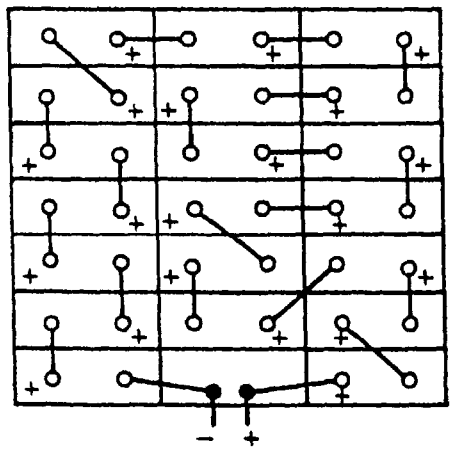
However, the optimum storage temperature range is between 0 and + 30°C (+ 32 and + 86°F).

D. Storage life

Unlimited.

E. Packing

The battery is usually wrapped in waxed paper and placed in a wooden case.



For long-term storage or overseas transportation, it is advisable to enclose the equipment in a plastic sealed or "cocooned" envelope.

F. Transportation

It is important that all required precautions should be taken to transport the battery in its normal position. To this effect, the wrapping should bear the inscriptions "TOP" and "BOTTOM".

G. Removal from storage

Charge the battery at a slow or fast rate, as required (see "Testing and Troubleshooting").

ILLUSTRATED PARTS LIST

INTRODUCTION

1. General

The Illustrated Parts List (IPL) is prepared in compliance with ATA 100. The IPL is intended to identify all the components of the unit.

The Illustrated Parts List contains the following sections :

- Introduction
- Vendors Code List
- List of Circuit Symbols (if applicable)
- Alphanumeric Index of Manufacturer's Part Numbers
- Detailed Parts List

2. How to use Detailed Parts List

The Detailed Parts List includes the nomenclature and illustrations of the unit components.

The Detailed Parts List columns are arranged as follows :

- 1st column : Fig. Item - Figure and Item number.
- 2nd column : Part Number - Manufacturer's part number.
- 3rd column : Nomenclature.
- 4th column : Usage code - Effectivity.
- 5th column : Units per Assy. - Quantity per next higher assembly.

A. Figure and Item numbers

The figure number, covering items listed, is indicated on the first line at the top of each page.

Each part-numbered assembly, sub-assembly or item listed in the parts list is assigned an item number followed by a letter identifying the variant. The basic variant is lettered A.

Assemblies, sub-assemblies and parts listed, but not illustrated, are identified by a dash (-) preceding the corresponding item numbers.

A "lettered index" appearing before the item number is a cross reference to the illustration of the variant called out from the corresponding main figure.

B. Manufacturer's part number

Each of the assemblies, sub-assemblies and detail parts, illustrated or not, is assigned a manufacturer's part number.

When the manufacturer's actual part number exceeds 15 characters, an equivalent assigned part number is listed in the "Part Number" column preceded by the following annotation :

ORDER OVERLGTH... MADE BY V...

Both part numbers are listed in the Alphanumeric Index in their logical order ; the actual overlength part number is cross-referenced to the assigned part number preceded by the annotation, "SEE...".

C. Nomenclature

The nomenclature is indented to show the relationship between the parts listed, as follows :

1 2 3 4 5 6 7

Assembly
. Detail parts for assembly
. Sub-assembly
. Attaching parts and/or storage parts for sub-assembly
+ + +
. . Detail parts for sub-assembly
. . Sub-sub-assembly
. . Attaching parts and/or storage parts for sub-sub-assembly
+ + +
. . . Detail parts for sub-sub-assembly
etc.

A vendor code is indicated for all items or articles not made by the prime manufacturer of the assembly.

This vendor code or the abbreviation "NP" (nonprocurable) is placed at the extreme right-hand side of the 1st line of the nomenclature.

D. Effectivity (Usage code)

An alphanumeric usage code indicates the applicability of sub-assemblies and detail parts to the next higher assembly(ies) or sub-assembly(ies).

When the applicability is general, the usage code column is left blank.

The usage code corresponds to the figure/item number of the next higher assembly(ies) or sub-assembly(ies). e.g., effectivity 1A, 1B, 1C is written 1ABC.

E. Units per assembly

The Units per Assy column shows the number of units required for the next higher assembly.
In some cases this information is replaced by the letters REF (reference) or AR (as required).

3. Terms and abbreviations used

- AR : As required
- ATTACHING PARTS
- DELETED
- DET : Detail
- LH and RH : Left and right
- MADE BY
- MADE FROM
- MATCHED PART
- MODIFIED FROM
- NHA : Next higher assembly
- NP : Nonprocurable
- OPT TO : Optional parts
- ORDER OVERLGTH MPN : Actual part number exceeding 15 characters

- OVERSIZE : Oversize repair parts
- POST SB : After applying Service Bulletin instructions
- R : Modified
- REF : For reference
- SEE
- SEL FROM : Select from parts
- STORAGE PARTS
- SUPSD BY : Superseded by
- SUPSDS : Supersedes
- UNDERSIZE : Undersize repair parts

4. Updating

When an item is revised, added or deleted, the letter "R" is shown in the RH margin (the page date of issue changes).

The letter "R" appears in the RH margin opposite the page number when all the item numbers are changed.

INTRODUCTION

This manual has been prepared to acquaint you with the fundamental operating characteristics of SONOTONE® sintered-plate, nickel-cadmium batteries and to assist you in obtaining maximum performance with minimum maintenance and servicing.

Over a period of years, literally thousands of SONO-CAD™ battery units have been operating in aircraft, missiles, satellites, ground vehicles, communication equipment, marine installations, ground power standby equipment and hundreds of other applications where rechargeability, flexible voltag and reliable power are essential.

Your Sonotone battery is manufactured to th highest precision standards. Care has been taken i every step of the manufacture to assure a produ of the very highest quality. Your battery has bee carefully tested at factory laboratories before bein shipped. Proper care and maintenance, as outline in this manual, will aid you in keeping your batter at peak performance and prolong its useful life.

PART I–PRINCIPLES OF OPERATION

1.0 Electro-Chemical Principles of the Sonotone Battery

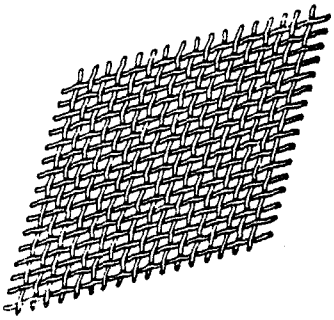
1.1 DURING CHARGE

The active material of the negative plate is cadmium-oxide. When the charging current is applied, this material gradually loses its oxygen and becomes metallic cadmium. The active material of the positive plate is nickel-oxide. This is brought to a higher state of oxidation by the charging current. As long as this current continues, changes take place until both materials are completely converted.

Toward the end of this charging process, and during overcharge, Sonotone cells will gas. This is a result of electrolysis of the water component of the electrolyte. The gas created at the negative plates is hydrogen and that at the positive plates is oxygen. The amount of gas created is dependent upon the temperature and the amount of charging current.

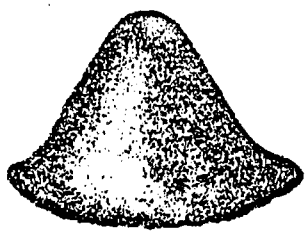
The cells will accept charge at temperatures ranging from —65° to +165°F. The electrolyte does not enter into any chemical reaction with either the negative or positive plates, but acts merely as a conductor of current between them. There is no significant change in the specific gravity, since the electrolyte acts only as a conductor.

1.2 DURING DISCHARGE



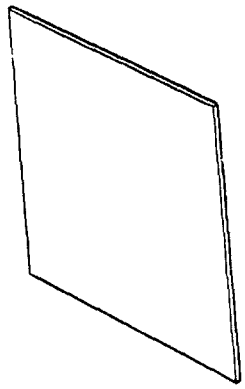
A chemical action in reverse of that which occu during charge is immediately initiated when ele trical energy is withdrawn from the cell. The neg tive plate gradually gains back oxygen and th positive plate gradually loses oxygen. There is n gassing on normal discharge due to this interchan of oxygen.

This process results in the conversion of th chemical energy of the plates into electrical energ The rate of which this conversion takes place is pr marily determined by the external resistance im posed by the electrical circuit to which the cell connected. Due to the type of cell construction, the is extremely low internal resistance within the cel The chemical nature of the electrolyte and its sp cific gravity remain unchanged during discharg The relative constancy of the cell voltage durin discharge is due mainly to these factors.

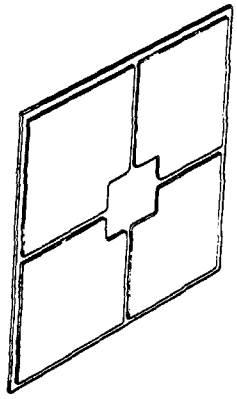


2.0 Construction of the Sonotone Battery

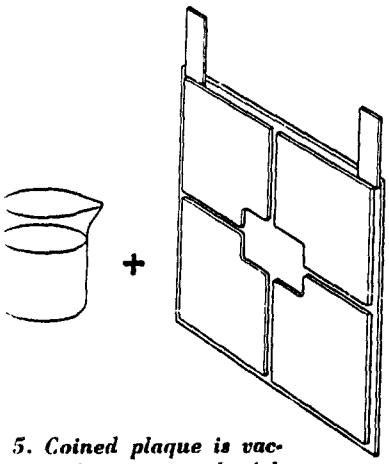
2.1 PLAQUES AND PLATES



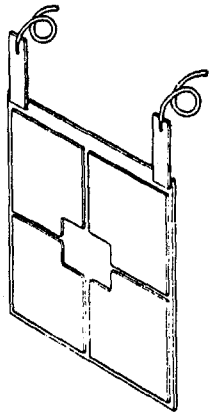
The basic feature of the Sonotone battery is its sintered plate, as shown in the series of diagrams below.



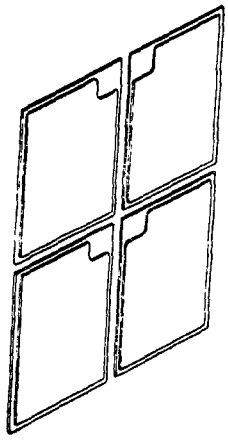
1. Here's how a Sonotone battery is made. We start with a nickel screen.



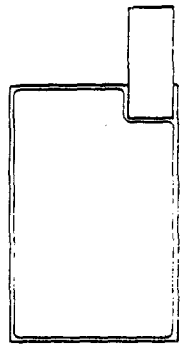
2. Then nickel powder is sintered about screen.



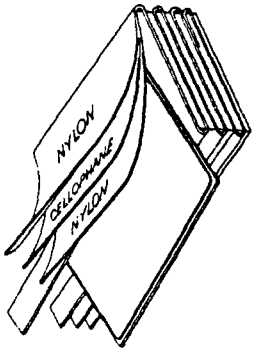
3. This forms a plaque approximately 80% porous at this stage.



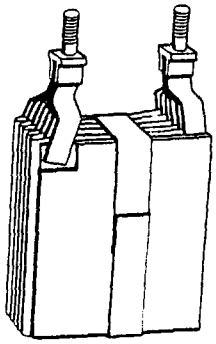
4. Plaque is coined with a plate die.



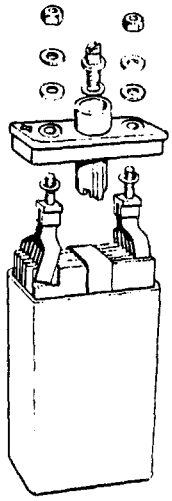
5. Coined plaque is vacuum impregnated with nickel or cadmium salts, electrochemically deposited within pores.



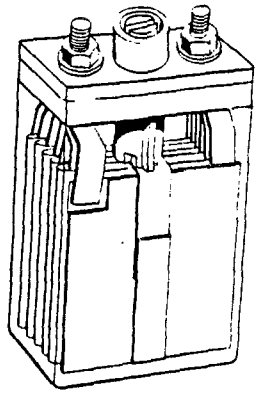
6. Current is passed through plaque in presence of electrolyte, to convert nickel or cadmium salts to final form.



7. After washing and drying, finished plaque is cut into plates.



8. A nickel tab is spot welded to plate.



9. "Stackup" is prepared by folding separator material between alternate positive and negative plates.

10. Nickel terminals are welded to completed "stackup," which with its cellophane binder forms the complete assembly of the core.

11. Cover and vent assemblies are attached and sealed to "stackup."

12. Entire unit is inserted in cell case and sealed.

2.2 SINTERED-PLATE CONSTRUCTION METHODS

Sintering is that process by which micro-fine powder is fused together at high temperatures to form a porous plaque structure. The porous structure of the Sonotone plaque is obtained by sintering nickel powder to a fine-mesh wire screen. The active material which distinguishes between the negative and positive plates is then electrochemically deposited within the pores of the plaque. Positive plaques are made by depositing nickel-hydroxide, negative plaques by depositing cadmium-hydroxide.

The plaques are then formed, washed, dried and cut into the desired plate size. Nickel connecting tabs are welded to one corner of each plate. Positive and negative plates are then grouped into a core assembly. The connecting tabs of all plates project upward toward the proper terminals, to which they are welded.

The sintered plates are positioned very closely together and are kept from actual physical contact by a thin multi-layer laminate, known as a separator.

While the surface of a sintered plate appears to be relatively smooth, it is actually a maze of tiny hills and valleys *(see Figure 1)*. This physical property multiplies the apparent surface area several hundred times and permits the utilization of a tremendous area of active material. The porosity of the plate permits the absorption of electrolyte. This further increases the volume of active material in direct contact with the electrolyte.

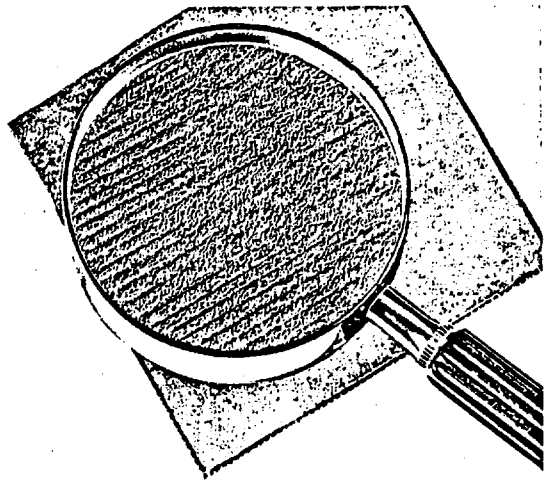


FIGURE 1

The porosity of Sonotone plates is created by a partial sintering of the nickel powder. This powder has been carefully selected for particle size and shape. After sintering, the total active surface area of one Sonotone nickel-cadmium plate is equal to that of several hundred solid plates of the same size.

2.3 SEPARATORS

A continuous strip of highly specialized fabric and pliable plastic composes the separator. This continuous separator is interposed between the plates as each successive plate is added to the "stackup" in preparing the core assembly. Thus the plates within the core are separated by a porous insulating barrier. This design provides the needed physical strength with minimum bulk and excellent electrical insulation, as well as efficient electrolytic conduction when immersed in the electrolyte. To insure complete insulation, the separator is slightly wider than the dimensions of the plate.

2.4 CELLS

The core assembly in a Sonotone battery is firmly affixed to a plastic or metal cover. This integral unit is then fitted snugly within a transparent plastic or metal case and the cover is cemented or welded in position. The cell thus becomes a compact, enclosed unit. The plates extend to the bottom of the cell, since no active material will flake or shed from them. This contributes to the solidity of the cell and gives it the ability to withstand extreme conditions of shock and vibration.

2.5 VENTS

Each cell is provided with a vent plug. This plug consists of a metal or plastic core and an outer collar of rubber. It can be removed for the addition of distilled water or adjustment of the electrolyte. When in place, the rubber expansion collar permits the gas created on charge to escape. Since there is no gassing on discharge, the vent automatically seals the cell, preventing leakage of electrolyte and also preventing entrance of foreign substances into the cell.

2.6 BATTERY ASSEMBLIES

To provide the voltage for a given application, cells are assembled into batteries and are housed in a steel battery case. An individual cell may be replaced in the event of damage, thus eliminating loss of the entire battery.

2.7 ELECTROLYTE

A 30%-by-weight solution of potassium hydroxide (KOH) in distilled or demineralized water is used as the electrolyte in the Sonotone battery.

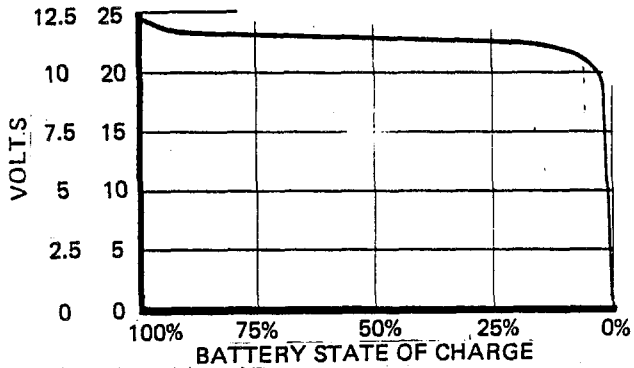
No overall chemical change occurs in the electrolyte during charge or discharge. As a result, no appreciable changes in the specific gravity are observed. The specific gravity of the electrolyte at room temperature remains between 1.24 and 1.32. The electrolyte level, observed through the windows in the side walls of the battery case or by looking into the vent wells, should be at the top of the plate portion of the core assembly. Sonotone batteries are normally shipped wet from the factory, since shelf life is not affected.

3.0 Discharge Characteristics of Three Basic Sonotone Battery Types

3.1 PLATE THICKNESSES

Sonotone batteries of the sintered-plate, nickel-cadmium type are divided into three classes, in accordance with the following discharge requirements:

a. H-TYPE BATTERIES—Contain thin plates and are intended for very high current service such as required in turbine engine-starting applications, particularly during cold-temperature operation.



b. M-TYPE BATTERIES—Contain medium thick plates and are intended for medium rate current requirements, such as reciprocating engine starting applications. They will perform satisfactorily at all temperature ranges—from sub-zero Antarctic conditions to the blistering tropics.

c. L-TYPE BATTERIES—Contain thick plates and are intended for low current drains where great capacity at a low rate is required, such as transistorized power supplies. They will perform satisfactorily at low temperatures at very low current drains.

3.2 TYPICAL DISCHARGE CHARACTERISTICS

All Sonotone batteries offer a constant voltage throughout their discharge. Figure 2 illustrates a typical discharge voltage curve under moderate load.

FIGURE 2

TYPICAL DISCHARGE VOLTAGE CURVE UNDER MODERATE LOAD

PART II-INSTALLATION

4.0 Unpacking and Inspection of New Batteries and Cells

4.1 INSPECTION PRIOR TO INSTALLATION

When the battery is unpacked, a thorough inspection should be made to insure that no damage occurred during shipment. Inspect the shipping container, as well as the battery, to make certain that the cells have not been damaged. Before putting your battery in service, follow these points carefully:

4.2 CHECK LIST

a. *CHECK FOR DAMAGE*—See if any liquid has spilled into the shipping container. This may be a sign of a damaged cell.

b. *CHECK ELECTRICAL CONNECTION*—Check all electrical connections for tightness. Test all screws and nuts on all terminals to insure tightness. Poor electrical contact may result in damage to your battery.

c. *CHECK LIQUID LEVEL*—CAUTION: Sonotone batteries are shipped with the proper amount of liquid. Do not add liquid until you have first attempted to charge your battery. When a battery has been discharged or allowed to stand unused for a long period of time. the electrolyte becomes absorbed into the plates. Your battery has been shipped discharged, which is the chief reason why the liquid level is low. Charging the battery will cause the liquid level to rise to a point just above the tops of the plates.

d. *CHECK VENTS*—Your battery is equipped with special type vents which permit the gases to escape from the cells. Do not obstruct these vents in any manner which will interfere with their operation. Some batteries are shipped with solid vent plugs which are used as shipping plugs. If these have been used on your battery, the battery will be marked with a tag, "Remove Shipping Plugs." The vent plugs are then inside a small cloth bag tied to the battery. Replace shipping plugs with the vent plugs before charging the battery.

e. *INDIVIDUAL CELLS*—When individual cells have been ordered, care must be exercised in charging. Do not charge individual cells unless the plastic cell case is supported externally in some manner. Gas pressure during charge on unprotected cells may crack the cell case. If no clamping device is available, remove the filler caps or vent screws to prevent a buildup of gas pressure inside the cell during charge *(consult Operation and Maintenance, 5.0)*.

4.3 INSTALLATION OF THE BATTERY

4.3.1 CLEANING COMPARTMENTS

Prior to installation, compartments or battery boxes which have previously housed lead-acid batteries must be washed out, neutralized with ammonia or washing soda solution, allowed to dry thoroughly and then painted with alkaline-resistant paint.

4.3.2 CHARGING NEW BATTERY

Your battery has been discharged prior to shipment. It will therefore need charging before installation *(see Table I)*. If by special order your battery is shipped in a charged state, it is advisable to give it a freshening charge *(consult Charging Methods 5.3)*.

4.3.3 SECURING BATTERY IN POSITION

When installing the battery in its permanent location, care should be taken to see that all post nuts are drawn down tight and that all electrical connections are made secure. Leads to the battery should be of sufficient size to carry the maximum current encountered without excessive voltage drop. If the battery is in mobile service, such as on an aircraft or other vehicle, it must be secured by holddowns. It is desirable to arrange the compartment so that the battery is either accessible or can be readily removed for servicing.

4.3.4 PROPER AIR CIRCULATION

Stationary batteries consisting of several tray groups should be installed with trays separated from each other to permit some circulation of air. This air space around the trays also serves to break up possible current leakage paths. Tray-to-tray connectors are of proper length to allow a minimum of ½" between trays.

4.3.5 VENTING OF GASES

Where the batteries are installed in a confined location, it must be realized that some hydrogen and oxygen gases are evolved during the charging cycle. It is therefore necessary to provide some means of ventilation to remove these gases from this confined area, avoiding accidental ignition of the hydrogen.

There are two types of venting systems to be considered. The first is a battery case containing vent nozzles and the second the battery case containing viewports or cover containing louvers. If the battery case contains vent nozzles, these must be used to vent gases either overboard or into a compartment that will meet the air flow requirements outlined below. If the battery case contains viewports or cover has louvers, the air flow must be of sufficient volume to keep the mixture of air and hydrogen below 5%. In both cases mentioned above, the air flow should be a minimum of 5 cubic feet per minute.

4.3.6 CHECKING POLARITY

Check the polarity of each cell or group of cells to be sure that they are connected in proper series. The polarity of each cell is indicated by a plus sign molded into the cell cover adjacent to the appropriate cell post.

4.3.7 INSULATING BATTERY

Sonotone has recently developed a new epoxy coating for its line of aircraft batteries. This epoxy coating is designed to improve the insulation between the cells and the battery container. It will eliminate the small discharge current formerly produced when spillage or spewage of electrolyte was encountered. This is a standard item on certain batteries produced at this time and will be a standard item on most units produced in the future.

Batteries in the field that are not now epoxy coated may have this done by returning the battery to Customer Return Department, Battery Division, Sonotone Corporation, Cold Spring, N. Y. 10516. The cost is determined by the battery type. Where batteries are mounted in groups, it may be necessary to provide insulation from each other and from the trays in which they are mounted *(consult Trouble Shooting, 7.0)*.

4.3.8 VOLTAGE REGULATION

Where the battery is being used in a mobile application, such as aircraft or ground vehicles, it will be necessary to make certain that the voltage regulating device is set to the proper limits, *as indicated in Table I.* This is an extremely important phase of your installation, as an improper voltage regulator setting can destroy a Sonotone sintered-plate, nickel-cadmium battery in a relatively short period of operation.

4.3.9 QUICK DISCONNECT DEVICES

Should the battery be installed using a multipin quick-disconnect type of plug, it is important to be certain that the connecting half of the plug, which is normally attached to the vehicle or aircraft, is wired correctly with respect to the terminal pins on the battery. A battery installed in an electrical circuit with the polarity reversed will not perform and may become seriously damaged.

4.3.10 SAFETY WIRING

In installations where safety wiring is to be used, be extremely cautious about the use of this wire near or on battery and cell terminals. It is in some instances, possible to completely isolate the metal battery case from the electrical system into which it has been installed and then establish a direct short to ground through the improper use of safety wire.

When installation is completed, be sure that no loose objects, such as screws or tools, have been accidentally left in the battery compartment or inside the battery.

PART III-
OPERATION, MAINTENANCE AND TROUBLE SHOOTING

5.0 Operation and Maintenance

5.1 GENERAL CARE

To obtain continued peak performance, a Sonotone battery should be kept in a clean, dry state. Batteries that are subjected to deposits of metallic dust on the cells, such as those in locomotive or steel plant stations, should be covered. The buildup of metallic dust or any other conductive substance will self-discharge the cells more rapidly by providing a conductive path.

Keep open flame and metal objects, such as tools, etc., away from the exposed parts of the battery. If objects are accidentally dropped across the terminals, these might cause a short circuit that could damage a cell or cells.

Should the batteries accumulate dust or a white deposit which sometimes forms around the tops of the cells, it is advisable to flush the tops of the batteries with ordinary tap water.

CAUTION: Do not attempt to clean the battery tops with solvents, acids or any chemical solution. Sonotone batteries are primarily constructed with plastic or nylon cells. The plastic may be injured by introducing solvents, etc. While flushing the batteries with tap water—if necessary—it is permissible to use a bristle brush to clean any stubborn dirt particles.

CAUTION: Do not use wire brushes. After cleaning, any excess liquid should be drained and the batteries should be permitted to dry. Where possible, this drying may be accelerated by the use of compressed air.

5.2 CHARGING CHARACTERISTICS

A Sonotone nickel-cadmium battery will accept a charge at a much faster rate than a lead acid battery and may be charged at temperatures below −20°F. Charging is more efficient at battery temperatures between +40° and +80°F.

5.3 CHARGING METHODS

As mentioned earlier in the section entitled *Installation*, it will be necessary to charge your battery prior to putting it into service. While in service in many installations, the battery will be charged by the equipment in which it is installed. During particular maintenance and inspection removals, however, it may be necessary to charge the battery in the shop. *IMPORTANT— BATTERIES MUST BE CHARGED IN AN UPRIGHT POSITION.* The construction of the Sonotone sintered-plate cell is such that it is readily adaptable to standard charging systems. These include constant voltage, constant current, stepped constant current charge or float charging. Most efficient performance from a constant current will result when the charging rate is such that 140% of the rated capacity of the cell is returned at the rates *indicated in Table I.*

The following material is devoted to various charging methods:

5.3.1 CONSTANT CURRENT CHARGING

The length of time required to charge a battery by the constant current method depends on the size or capacity of the battery, the state of charge of the battery and the magnitude of the charge current. In order to maintain a constant current, it should be noted that the voltage of the system will run from 1.4 volts per cell at the beginning of charge to a maximum of 1.75 volts per cell at the end of charge. In *Table I*, we recommend a constant current rate which is arrived at in the following manner: Take the current output at the 5-hour rate and charge at that current for 7 hours. *Example—the recommended constant current charge for a 40-ampere-hour battery would be computed as follows: 40 ampere hours divided by 5 hours equals 8 amperes.* You would therefore charge this battery at 8 amperes for 7 hours. A typical constant current charging curve *is shown in Figure 3.*

Constant current charging can be accomplished manually by monitoring the charging apparatus and adjusting the voltage periodically to maintain a constant charge rate. Chargers of the self-regulating rectifier type are available to provide constant current without the attention of an operator. Sonotone Corporation manufactures a Battery Charger/Ana

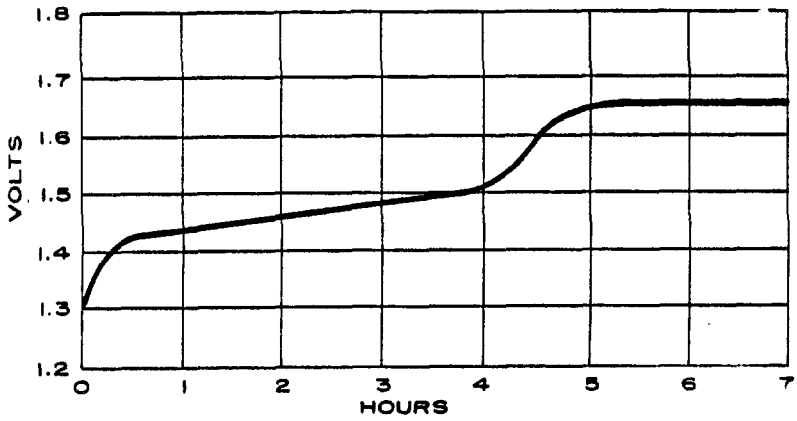


FIGURE 3

TYPICAL VOLTAGE VARIATION DURING CONSTANT CURRENT CHARGE

lyzer designed for this purpose. A complete brochure may be obtained from the Field Service Manager, Battery Division, Sonotone Corporation, Elmsford, N. Y. 10523. *Request Data Sheet BA-166.*

If a battery is partially discharged, the charge rate *shown in Table I* will still apply. It may not be necessary, however, to charge the battery for the full length of time indicated. To determine whether the battery has reached the full charge state, monitor the battery and note the time that the voltage takes the sharp rise *indicated in Figure 3.* After the sharp voltage rise, it is then necessary to permit the battery to charge for an additional 2 hours at the rate *shown in Table I.* During this 2-hour portion of charge, it is possible to check the cell voltages and determine whether all cells are rising evenly. Should some cells indicate a voltage lower than 1.55 volts, it is advisable to leave the battery on charge until these cells come up to a minimum of 1.55 volts.

Note: During the greater portion of charge, the cell voltages will remain between 1.4 and 1.45 volts. On a conditioned battery, when it has been charged for approximately 70% of the time necessary to charge it fully, the voltage will take the sharp rise mentioned above. Should the individual cell voltage fail to rise to 1.55 volts or more, it may be necessary to replace these cells *(consult Trouble Shooting, 7.0).*

5.3.2 STEPPED CONSTANT CURRENT CHARGING

If it is necessary to obtain a rapid charge, the principles of the previous paragraph still apply—the battery may be permitted to charge at a current equal to its capacity. *Example—a 40-ampere-hour battery at a charging rate of 40 amperes.* At this high rate, the battery should be monitored and when the total battery voltage averages 1.50 volts per cell, the rate should then be reduced to the rate shown on Table I. At the time of reduction, a conditioned battery will have completed approximately 70% of the charge cycle if it was completely discharged to begin with. This method of charging must be monitored, as the high rate will eventually use all the water in the battery if permitted to continue past the gassing point. This loss of water will cause higher concentration of the electrolyte and possible overheating which will damage the cell.

5.3.3 FLOAT CHARGING

Fully charged batteries may be floated across a line voltage of approximately 1.42 volts per cell. Example—a 24-volt aircraft battery which contains 19 cells may be trickle charged at 27.0 volts. A battery floated in this manner will draw about .003 amperes per ampere hour of capacity. *Example—a 40-ampere-hour battery will float at approximately .120 amperes.* This voltage setting will vary slightly with ambient temperature of operation.

5.3.4 CONSTANT VOLTAGE CHARGING

In most applications where Sonotone sintered-plate, nickel-cadmium batteries are used, the constant voltage charging method is employed. Aircraft, automobiles, boats, factory equipment and all mobile applications use the voltage-regulated genera-

NOTE: Additional constant current charging instructions when using Sonotone Battery BB-449/U at low temperatures—current of 2.8 amperes should be used for a period of 7 hours. Although this method may be used at temperatures below −20°F, it is usually not recommended.

tor charging circuit. The graph *shown in Figure 4 (Page 22)* indicates what happens essentially during this type of charge.

A voltage produced by the generator permits current to flow to the battery. In a discharged battery, the maximum surge of current will be approximately 10 times the rated capacity. The high surge currents are due to the low internal resistance of the battery. Make certain that the charging source is protected against overload in the event of a marginal power supply. As the battery approaches a charged state, the current falls off rapidly and the voltage rises. The recommended voltage setting for the regulator, *shown in Table I*, is computed by multiplying the number of cells in the battery by a factor of 1.5 to 1.55. *Example—a 12-volt automotive battery which contains 10 cells should have the regulator set to cut out between 15.0 and 15.5 volts.*

It should be noted that this type of charging, particularly in applications where the battery is excessively discharged, may produce an unbalance in cell capacity *(consult Trouble Shooting—Apparent Loss of Capacity, 7.1)*. If the battery requires equalization and a constant current charging source is not available, it may be equalized by the method *shown in Reconditioning Service Procedures, 9.3.*

5.4 DISCHARGING THE BATTERY

You will note, in the section entitled *Replacement of Damaged Cells, 6.1*, that you are instructed to discharge the battery. The following information is designed to help you in this operation.

5.4.1 USING EQUIPMENT AS A LOAD

A battery may be discharged by merely permitting it to operate the equipment in which it is installed without permitting the generator or other charging source to replenish it.

When the battery fails to operate the equipme it is in a state of partial discharge. It should th be removed from the equipment and discharg through a resistance high enough to permit the c rent to flow at approximately the 2-hour rate. *I ample—a 40-ampere hour battery may be permit to discharge at 20 amperes or less.* When the volt has dropped to a sufficiently low point that the c rent has apparently ceased to flow, the battery then be considered discharged. Where cells are be individually shorted *(see Figure 5)*, it is imp tant that the shorting wires or bars be placed position on the cells while the resistance is still c nected to the battery.

Should the battery be permitted to stand after resistance has been removed, it will recover su ciently so that the application of the shorting devi will create severe arcing and intense heat. To termine when a battery has been sufficiently charged and ready for short circuit, the termi voltage of the entire battery must be less than 1(of the rated voltage. It is then safe to short circ *Example—a 12-volt battery having been dischar at a rate equal to or lower than the 2-hour rate n be short circuited when the terminal voltage of entire battery is 1.2 volts or less.* Where possi the shorting of individual cells is suggested.

5.4.2 USING A RESISTANCE LOAD BANK

A battery being discharged in the shop may discharged through a resistance which will per the current to flow at a rate no higher than its 1-h rate. Example—a 40-ampere hour battery may discharged at a rate of 40 amperes. When the batt appears to be discharged and current is no lon flowing, it is then advisable to continue to discha through a slightly higher resistance, permitting current to flow at the 2-hour rate or lower. *Exam*

(Continued on Page

NOTE: Additional constant voltage charging instructions when using Sonotone Battery BB-449/U—this method may be used at all temperatures. The recommended voltage settings are as follows:

Temperature	*Voltage*
90 to 110°F	*29 ± 1*
50 to 90°F	*30 ± 1*
0°F	*32 ± 1*
—20°F	*33 ± 1*
—40°F	*35 ± 1*

The maximum current delivered by the charger should be 30 to 100 amperes.

MA-11	—	—	—	—	90377-1	8565D
20-S102	—	—	—	—	17334-2	8565D

—a 40-ampere-hour battery may be permitted to discharge at 20 amperes.

IMPORTANT—Do not attempt to discharge a Sonotone sintered-plate, nickel-cadmium battery at an excessively high rate and then attempt to short circuit each cell at the end of this discharge. Batteries which have been discharged at high rates are not fully discharged. Application of shorting devices to the individual cells at the end of such a high discharge will produce severe arcing and intense heat. To determine when a battery has been sufficiently discharged and ready for short circuit, the terminal voltage of the entire battery must be less than 10% of the rated voltage. It is then safe to short circuit. *Example—a 12-volt battery having been discharged at a rate equal to or lower than the 2-hour rate may be short circuited when the terminal voltage of the entire battery is 1.2 volts or less (consult Description of Reconditioning Service, 9.4).*

5.5 LIQUID LEVEL ADJUSTMENT

During the normal operation of the Sonotone sintered-plate, nickel-cadmium battery, it is necessary occasionally to add liquid. The amount of water used is relatively small when compared to the amount used in a lead acid battery. Usage rate will depend upon the application, charging voltage, ambient temperature and several other factors. For this reason, it is advisable to maintain accurate records on particular applications so a realistic water replacement schedule can be established. Use only distilled or demineralized water. Storage batteries are easily contaminated through the use of tap water which contains minerals, chlorines, softening agents and other foreign materials. Water additions to adjust the liquid level should be made immediately after charging or after the battery has been permitted to remain in a state of rest for a minimum of three hours. Never adjust the electrolyte level after discharge unless abnormal high voltage readings (greater than 1.5 volts) are encountered immediately after placing a discharged battery on charge.

WARNING: Do not use acid. Injury may result and equipment damage can occur. Never use tools which have any acid deposit on them.

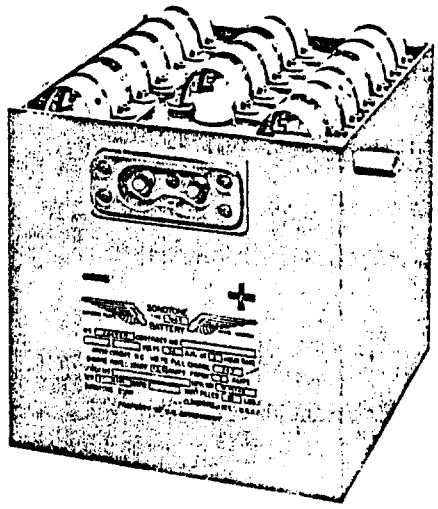

FIGURE 5

5.5.1 PROPER LIQUID LEVEL

The proper liquid level of all Sonotone sintered-plate, nickel-cadmium batteries is just above the tops of the plates or plastic insert (¼" immediately after charge or ⅛" after 3-hour stand). In some Sonotone batteries, it is possible to see the liquid level through the ports in the side of the battery can. In Sonotone batteries where these ports are not provided, such as certain aircraft types, it is necessary to determine this liquid level by looking down into the vent well after the filler cap has been removed.

If it is not possible to determine the liquid level in this manner, we recommend the use of a polystyrene tube, open on both ends and having approximately ⅛-inch inside diameter about six inches long *(see Figure 6).*

This tube is inserted into the filler opening deep enough to touch the top of the plates or plastic insert. Grasping the tube between the thumb and the middle finger of the right hand, place the index finger over the top open end of the tube and remove the tube from the filler well. If the level in the lower

NOTE: Additional instructions on the liquid level adjustment when using Sonotone Battery BB-449/U—the proper electrolyte level is ⅝" above the tops of the plates measured from 3 to 6 hours after charge. An open end glass or preferably a transparent plastic tube ⅛" to ¼" in diameter should be used for this, as described above.

end of the tube is as stated above, the liquid level is adjusted properly. If no liquid is withdrawn, add distilled or demineralized water until the proper level is reached in the polystyrene tube, using the method described above. Adjustments in liquid level may be made by a syringe of the type *pictured in Figure 7.*

5.6 ELECTROLYTE SPECIFIC GRAVITY

The electrolyte is a solution consisting of 70% distilled water and 30% potassium hydroxide, resulting in a specific gravity of 1.3. Cells which have lost electrolyte by accidental overfilling may have a lower specific gravity. Specific gravities after use may range between 1.240 and 1.320 without an appreciable effect on battery operation at normal ambient temperatures. We *do not* recommend that the user attempt to readjust this specific gravity unless it is extremely impractical to remove the battery from service long enough to have it properly adjusted at the factory. Should you find it necessary to make this adjustment, a supply of electrolyte may be purchased from your local Sonotone aircraft battery distributor or the Field Service Manager, Battery Division, Sonotone Corporation, Elmsford, N. Y. 10523.

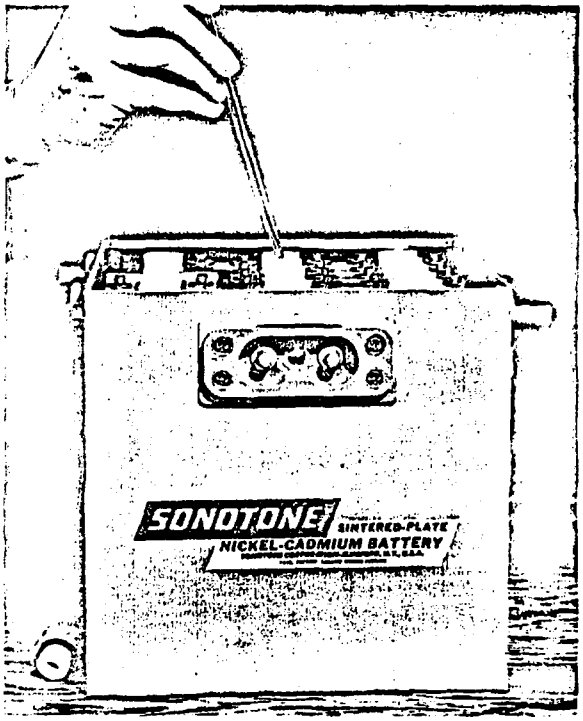

FIGURE 6

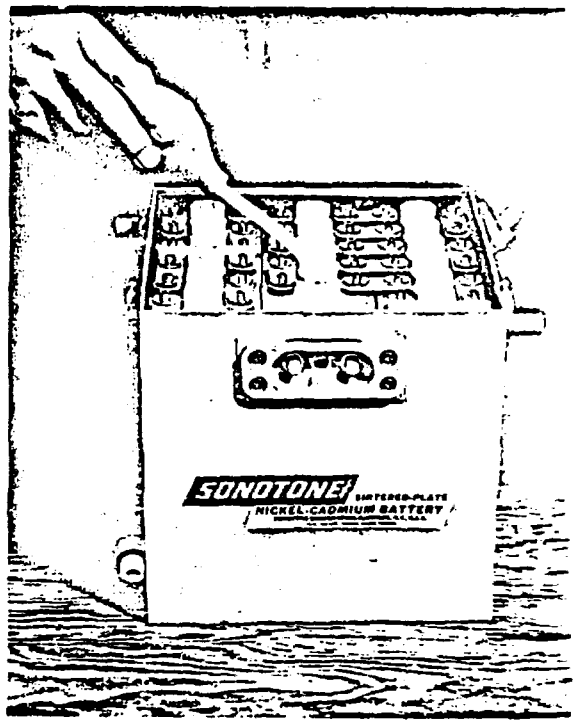

FIGURE 7

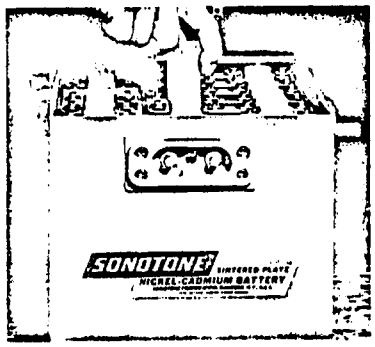
NOTE: Additional instructions on the electrolyte specific gravity when using Sonotone Battery BB-449/U—for low temperature operation at −40°F, the specific gravity should be 1.280 to 1.320.

6.0 Repair and Replacement



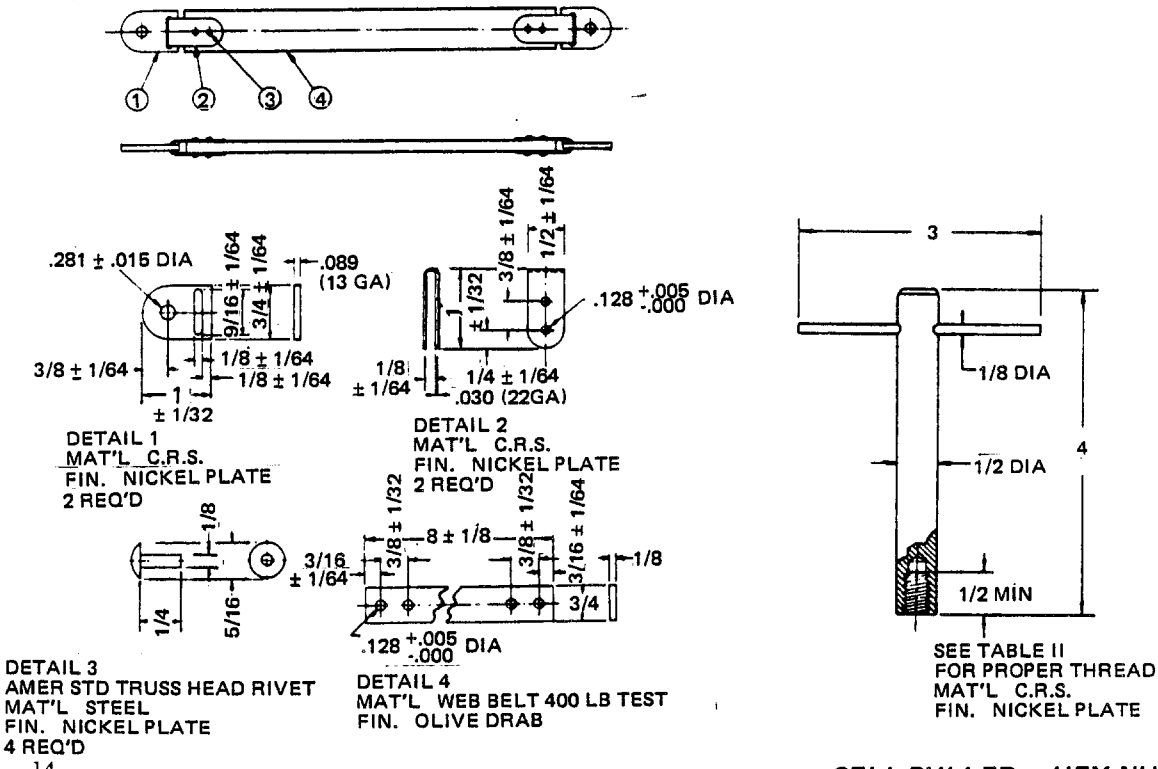


FIGURE 8

6.1 REPLACEMENT OF DAMAGED CELLS

If a cell becomes contaminated or physically damaged and the cell must be replaced, the procedure is as follows:

a. Clean battery *(consult General Care, 5.1).*
b. Remove end terminal connections. Save all the hardware.
c. Remove all vent plugs, using vent wrench *shown in Figure 8.*
d. Remove enough cell connections to permit the cell to be withdrawn from the battery case.
e. Do not withdraw cell from battery unless replacement cell is available immediately.
f. Withdraw cell, using one of the tools *shown in Figure 9. Also see Figure 10.*
g. Replace with new cell, making certain to insert the cell with the polarity symbols in the right direction. Cells are connected plus to minus. If the cell is difficult to insert, apply a light coat of petroleum jelly or silicone grease to the sides of the cell case before reassembly.
h. Replace connectors, assembling hardware finger tight. CAUTION: Do not use "homemade" hardware, as many of these parts are specifically designed to produce an adequate electrical connection. Spare or replacement hardware may be obtained from your local Sonotone Aircraft Battery Distributor or Field Service Manager, Battery Division, Sonotone Corporation, Elmsford, N. Y. 10523.
i. Torque terminal connections to the values *indicated in Table II,* using calibrated torque

The tools shown in Figure 9 are not available from Sonotone. They are of simple construction and can be made in any machine shop.

CELL PULLER – CAP SCREW TYPE

CELL PULLER – HEX NUT TYPE

FIGURE 9

wrench. A typical torque wrench *is shown in Figure 11.*

j. Discharge entire battery *(consult Discharging a Battery, 5.4)*. Monitor each cell to determine that all cells are completely discharged. Should some cells reverse and others retain a portion of their charge, it will be necessary to short the cells individually until each cell is completely at zero *(see Figure 5)*.

k. Charge battery by constant current method *(consult Charging Methods, 5.3)*.

l. Adjust liquid level *(consult Liquid Level Adjustment, 5.5)*. The battery is then ready to be put into service.

m. Return damaged cells for analysis and possible repair to Customer Return Department, Battery Division, Sonotone Corporation, Cold Spring, N. Y. 10516.

6.2 REPLACEMENT OF DAMAGED END CONNECTORS

In some battery types, primarily those used in aircraft, the battery is provided with a special quick disconnect receptacle such as a type manufactured by Elcon or Cannon or any of a number of MS type receptacles. Should one of these connectors become damaged, it will be necessary to replace it with a replacement part obtained from your local Sonotone aircraft battery distributor or the Field Service Manager, Battery Division, Sonotone Corporation, Elmsford, N. Y. 10523. Care should be taken in the removal of this connector to preserve all the hardware and gasketing, if possible, so that the new part may be installed properly.

To remove the connector, first remove those connections which go to the end cells in the battery, thus reducing the possibility of a short circuit when the connector body is removed from the battery case *(see Figure 12)*. All Sonotone batteries have the same hardware arrangement, attaching the end connector to the battery, as is used on the intercell connectors. When installing the replacement part, it is necessary to *consult Table II* for torque values.

CAUTION: Do not substitute "home-made" hardware. Care must be taken that the polarity of the end connector is carefully observed so that, when the battery is installed in the equipment, the system will function properly.

6.3 MAINTENANCE RECORD KEEPING

In order to provide an accurate source of information on each battery in service, it is advisable to keep

(Continued on Page 17)

a maintenance log on each. Should a battery malfunction, you will then be able to give the complete history of this specific unit to the Field Service Manager, Battery Division, Sonotone Corporation, Elmsford, N. Y. 10523, and assist us in the determination of the problem. *A typical battery log is illustrated in Figure 13, inside back cover.*

Following is a list of typical malfunctions encountered in the maintenance and operation of sintered plate, nickel-cadmium batteries. This list will serve as an index to the preceding information.

7.0 Trouble Shooting

7.1 APPARENT LOSS OF CAPACITY

A characteristic observed in nickel-cadmium batteries is apparent loss or temporary loss of capacity. When this temporary loss occurs, the battery capacity will be lower than the rated capacity. This effect is more common when recharging across a constant potential bus, such as in aircraft, than when recharging by the constant current method. The loss of capacity is normally an indication of imbalance between cells because of differences in temperature, charge efficiency, self discharge rate, etc., in the cells. In applications where lead acid batteries have been used, the serviceman is likely to treat this loss of capacity as a natural aging quality of the battery. Nickel-cadmium battery capacity does not decrease appreciably with age. A loss of capacity is a warning and should not be treated lightly. Periodic deep cycling will be an invaluable aid in alleviating this condition *(consult Reconditioning Service Procedures, 9.3).*

7.2 COMPLETE FAILURE TO OPERATE

Where a battery fails to operate at all, the trouble can usually be traced to an electrical connection. In some instances, the defective connection will be in the circuitry of the equipment in which the battery is installed. This would show up as a broken lead, a relay which fails to operate, improper plug or receptacle installation or similar difficulties. Failure in the battery itself can be caused by an end terminal connector becoming loose or disengaged or perhaps because the charge cycle failed to operate. Should the failure be due to poor intercell connection within the battery, clean and retighten hardware using the proper torque values *(consult Table II).*

7.3 EXCESSIVE SPEWAGE

A battery which has spewed excessively will usually display large crystalline deposits on the tops of the cells. In some cases, a considerable amount of liquid will collect in the bottom of the battery container. A battery in this condition has been subjected to high charge voltages or high ambient temperatures during charging or a combination of the two. The liquid level may also have been improperly adjusted. To correct this condition, clean the battery *(consult General Care, 5.1).* Then charge the battery as required and adjust the electrolyte level *(consult Liquid Level Adjustment, 5.5).* Place battery back into service.

7.4 DISTORTION OF CELL CASES

When a battery has one or more cells with distorted plastic cases, the battery may have been overcharged as described in *Excessive Spewage, 7.3.* This battery must be removed from service and either returned to the factory or sent into the maintenance shop for cell replacement *(consult Replacement of Damaged Cells, 6.1).*

7.5 FAILURE OF ONE OR MORE CELLS TO BALANCE WITH OTHERS

During the charging procedure *(consult Constant Voltage Charging, 5.3.4),* it is sometimes noted that one or more cells fail to rise to the required 1.5 to 1.55 volts at the end of charge. The battery should be treated *as described in Constant Current Charging, 5.3.1.* If these cells still fail to rise to the required voltage they should be removed and replaced according to the procedure *outlined in Replacement of Damaged Cells, 6.1.*

7.6 FOREIGN MATERIAL WITHIN THE CELL CASES

Cells which have been removed because of failure to respond to the normal charging procedures *see preceding paragraph,* may display some evidence of foreign substances within them. This material may be gray, black or brown in color. Such foreign substances are most commonly introduced into the cell through the addition of impure water or water contaminated with acid. Other causes for this dissolution

can be heat generated by extremely high rate charging, charging without sufficient electrolyte in the cell, too high a concentration of electrolyte or a combination of two or more of these conditions.

For instance, a battery has been serviced and electrolyte (potassium hydroxide) has been added to raise the specific gravity. The battery is then permitted to charge at a sufficiently high rate and drive off water. This produces a high concentration of electrolyte, which in turn generates some heat. This set of circumstances will damage the materials in the cell plates and will be indicated by the appearance of black or gray particles in the cell. These cells will usually show up as unbalanced *(consult Apparent Loss of Capacity, 7.1)* and must be removed from service.

7.7 FREQUENT ADDITION OF WATER

If one or more cells require more water than the others, they may be out of balance *(consult Apparent Loss of Capacity, 7.1)*. Discharged cells will always appear low in liquid *(consult Liquid Level Adjustment, 5.5)*.

7.8 CORROSION OF TOP HARDWARE

Excessive rust appearing on the top hardware of a battery may be caused by the presence of acid fumes in the area. This condition will be prevalent where batteries are installed in chemical plants or other places where they are subjected to corrosive fumes, spray or chemical moisture. The battery should be kept clean *(consult General Care, 5.1)* and installed in a compartment which has been cleaned *as per the instructions in Installation of Battery, 4.3.*

7.9 APPEARANCE OF BURN MARKS ON CONNECTORS

When an intercell connector or an end connector shows indication of burning, this usually denotes that the connectors involved have not been properly tightened. For proper torque values, *see Table II.* Burned outer connecting plugs is an indication of plug failure. The battery plug or the mating half should be replaced if necessary *(consult Replacement of Damaged End Connectors, 6.2)*.

7.10 OVERHEATING OF INTERCELL CONNECTORS

If intercell connectors become hot or show signs of overheating, disassemble, clean and reassemble. Torque the connections properly *as specified in Table II.*

7.11 BATTERY CASE LEAKAGE TO GROUND

When a battery has been in an aircraft for a considerable period of time, a voltage can sometimes be detected between either terminal pin or the metal battery case. This voltage is most usually caused by a collection of electrolyte around the cells, usually as a result of spewing from the cell vent caps. The electrolyte is conductive. It is for this reason that voltage can be read. Voltage is merely potential and of itself can do no harm.

The measure of whether or not this potential is affecting battery performance is the amount of current that this leakage path will support. If, for instance, the leakage path will support .050 amperes, this would be the equivalent of a battery self-discharging completely in 500 hours (CA-20 or CA-4). Usually, we consider .050 amperes or less a safe leakage path. Beyond that value, it is advisable to flush the battery vigorously with tap water and permit it to dry in the sun, if possible, or by applying forced warm air. When the battery is completely dried out, this leakage path should no longer be apparent.

The leakage may also be caused by a damaged case-to-cover seal on an individual cell. To determine which cell is damaged, the following method should be applied.

a. Place one probe of the voltmeter on either the positive or negative terminal post and the other against the battery case.
b. Observe the voltage.
c. Leaving the probe on the metal battery case, move the other probe from cell terminal to cell terminal.
d. The indicated voltage should decrease and finally go negative. At this changeover point, you will find the leaking cell.
e. This cell should be removed from service and returned for repair to the Customer Return Department, Battery Division, Sonotone Corporation, Cold Spring, N. Y. 10516.
f. Inspect surrounding cells and hardware for damage.
g. A new cell should be added *in accordance with Repair and Replacement, 6.0.*

7.12 HEATED BATTERIES

In some special applications, Sonotone has provided a specially designed battery which incorporates the use of an internal heater blanket and the

accompanying thermostats and input plug necessary to energize the heater. Batteries of this nature are composed of the same type of cells previously discussed in the various sections of this manual and, therefore, these difficulties encountered in cell performance can be handled exactly as though the battery were not equipped with a heater. The heater itself is usually an insulating blanket containing a wire filament. Failure of the blanket to operate can be caused by a break in this filament and is easily detected through the use of a continuity meter. Another cause of heater failure is sometimes centered in the operation of the thermostat. Thermostats can be checked by submitting them to sizeable temperature differences and checking their operation with a continuity meter.

Heater blankets and thermostats cannot be repaired in the field and, should a breakdown be experienced, the material must be returned for replacement to the Customer Return Department, Battery Division, Sonotone Corporation, Cold Spring, N. Y. 10516. Because of the large number of possible variations in heated battery design, it is not possible in this manual to become any more specific on this subject. In applications where heated batteries are used, if other troubles are encountered, contact Field Service Manager, Battery Division, Sonotone Corporation, Elmsford, N. Y. 10523.

8.0 Storage

8.1 CHARGE RETENTION

Sonotone sintered-plate, nickel-cadmium batteries may be stored for long periods of time in any state of charge. The charge retention will depend largely on the ambient temperature of the storage area. A battery stored at 80°F will retain approximately 60% of its rated capacity over a period of one year. A battery stored in an ambient temperature of 0°F will retain approximately 90% of its capacity for a period of one year.

8.2 STORAGE MAINTENANCE

The active materials of the plates are insoluble in the electrolyte and therefore cannot react in any way with the electrolyte when the battery is stored on open circuit. Before placing a battery in storage, the battery should be cleaned *(consult General Care, 5.1)*. If long periods of storage are expected, it is advisable to coat the intercell connectors with a light coat of silicon grease to prevent any corrosion from forming. A battery being placed into service after storage should be given a freshening charge prior to installing it into the equipment *(consult Charging Methods, 5.3)*.

PART IV-SHOP PROCEDURE

9.0 Recommended Shop Procedure to Determine Condition of Aircraft Battery

The information in this part is a condensation of some of the procedures outlined in this manual, plus special information on aircraft batteries.

9.1 SEPARATION OF NICKEL-CADMIUM AND LEAD ACID BATTERY FACILITIES

Nickel-cadmium batteries use potassium hydroxide and distilled water as an electrolyte. Chemically, this electrolyte is an exact opposite of an acid electrolyte.

Anything associated with the lead acid battery (acid fumes included) should never come in contact with the nickel-cadmium battery or its electrolyte. Even traces of sulphuric acid from a lead acid battery entering the electrolyte of a nickel-cadmium battery will result in damage. Also, acid fumes can damage the hardware of the nickel-cadmium battery.

Separate shops are recommended for the two types of batteries. If separate shops are not possible, separate bench facilities shall be provided at opposite ends of the service area. Indicate each area clearly and keep all tools and materials separate and clearly marked.

9.2 VISUAL INSPECTION

A visual inspection of the battery in the aircraft should be made at least once every 50 flight hours on non-epoxy coated batteries and once every 100 hours on epoxy batteries. The battery connector, receptacle and vent lines should be checked for contact failure or damage and the allenhead screws or nuts should be torqued, *as per Table II.*

The cover should be removed to inspect for excess spewage and discoloration or deterioration of intercell hardware. Some slight deposits of potassium carbonates (white in color) may be encountered. If it is excessive, the battery should be removed and cleaned *(see below).* Further inspection and replacement of parts is described in this manual.

9.3 RECONDITIONING SERVICE PROCEDURES

Flight hours are the main factor determining the frequency of reconditioning service procedure, depending on these four variables:

a. Type of starting service.

b. Duty cycle for battery.

c. Ambient operating temperatures.

d. Generator voltage regulator setting.

Therefore, we can only suggest an average time between reconditioning cycles *(Table III)* because of the widely varied flight profiles seen by individual aircraft. The user will eventually apply his experiences and the information gained during the reconditioning service in determining the maximum time. At no time should a battery be allowed to deteriorate to a point where the operation of the battery affects the mission or operation of the aircraft.

TABLE III

Aircraft Type	Approximate Flight Hours Between Reconditioning Cycles
Lear Jet Model 23	100
Jet Commander	100
Grumman Gulfstream I	500
Fairchild F-27	200
Boeing 727	400
Grand Commander	500
North American Sabreliner	200
Lockheed JetStar	150
Turbo Commander	200
MU-2	200

The use of a service log for each battery and aircraft is especially helpful to the user in determining the optimum period between reconditioning. A sample log and check list will be found on the inside back cover of this manual *(Figure 13).*

9.4 DESCRIPTION OF RECONDITIONING SERVICE

The procedure for removing a battery for a reconditioning cycle should start with a visual inspection in the aircraft *(consult Visual Inspection, 9.2).* If the battery needs cleaning, it can be performed in the maintenance area. If the spewage is minor, it can be removed with a nylon bristle brush and the battery flushed with water as follows:

9.4.1 *FLUSHING OF BATTERY*

a. Prior to flushing the battery with water, check the tightness of the vent plugs.

b. Tip battery on side away from battery receptacle.

c. The top of the cells should then be flushed with tap water.

d. Air hose away excess water.

NOTE: If any of the rubber insulation has deteriorated or pulled away from the can, the battery should be disassembled and the rubber recemented.

Use rubber-to-metal cement type 35-2 by G. C. Electronics or equivalent. Replacement can also be made by using neoprene rubber of a 40-60 dryrometer by Minor Rubber Company or equivalent. The rubber thickness is 1/16" to 1/32", depending upon the type of battery.

9.4.2 *CHECKING CURRENT FLOW*

After flushing and air hose drying, check the current flow between the positive terminal and the case, then the negative terminal and case.

a. First select a meter, such as Simpson 261 or 263, which contains an amperage scale of a minimum of 500 milliamperes. Select the highest current setting on the meter.

b. Take the positive lead of the meter and place on the positive terminal of the battery receptacle and the negative lead on the battery can.

c. Decrease the current setting until a scale is reached where, if any current flow exists, it is readable. Record the current.

d. Move the selector switch on the meter to the highest current setting. Place the negative lead of the meter on the negative terminal of the battery receptacle and the positive lead on the battery can. Proceed as outlined above.

e. If the current flow is more than 50 milliamperes, the unit should be disassembled and cleaned.

NOTE: Do not use the voltage reading between the terminals and the battery can as a criteria for rejection, since current flow is the determining factor.

9.4.3 EPOXY-COATED BATTERIES

Some Sonotone nickel-cadmium batteries are now supplied with the battery container and cover epoxy-coated. In this instance, the current flow may be measured by reading from the battery terminals of the receptacle to the snaps that restrain the cover. This is mainly a safety precaution, since in epoxy-coated cans the cells should be completely insulated from the battery case.

9.4.4 CHARGING

The battery should then be charged on a charger/analyzer *(Sonotone Model PCA-131—see later reference)* on a constant current source at a 5-hour charge rate or on a constant potential source at 28.5 volts for a 24-volt battery. *(For aircraft batteries of other voltages, use 1.5 volts by the number of cells = constant potential charge volts.)* If the constant current charge is used, continue until the total battery voltage reaches 30 volts *(average 1.58 volts/cell).*

9.4.5 USING CONSTANT POTENTIAL

If a constant potential charge is used, continue charge only until the current tapers off and stabilizes.

9.4.6 ADJUSTING ELECTROLYTE

At this time the electrolyte level may be adjusted to ¼" above the top of the plates or visible insert. If the battery is allowed to stand 2 to 4 hours after charge, then the level should be adjusted to ⅛" above the plates or visible insert.

NOTE: Make adjustments with distilled, deionized or demineralized water. We do not recommend the addition of potassium hydroxide, as water only is normally lost due to electrolysis. Potassium hydroxide can be added only on specific instructions from the Field Service Manager, Battery Division, Sonotone Corporation, Elmsford, N. Y. 10523.

9.4.7 DETERMINING STATE OF CHARGE

Unlike a lead acid battery, the electrolyte in a nickel-cadmium battery acts only as a conductor. Therefore, it is impossible to determine the state of charge from the specific gravity or from open circuit voltage readings. **The only way to tell the state of charge is by a measured discharge.**

9.4.8 DISCHARGE

At this time, the battery is ready for discharge. Select a discharge rate of either the 1 or 2-hour rate *(see Table IV).*

a. The total battery voltage should be monitored until an average of 1.0 volt/cell is reached.
b. At this point, the time should be recorded.
c. If the discharge time is less than 70% of that specified *(see Table IV)*, then a supplemental discharge (deep cycle) should be performed.

TABLE IV

Battery Type	*Rate 1-Hour*	*2-Hour*	*Battery Type*	*Rate 1-Hour*	*2-Hour*
CA-4	20	11	CA-40	38	20
CA-5	34	17	CA-44	38	20
CA-6	20	11	CA-51	5.0	2.5
CA-7	10	5.5	CA-52	5.0	2.5
CA-9	20	11	CA-53	5.0	2.5
CA-10	10	5.0	CA-88	55	30
CA-15	10	5.5	CA-101	10	5.0
CA-20	20	11	CA-102	10	5.0
CA-20H	20	11	CA-121	10	5.5
CA-21	20	11	CA-727	20	11
CA-24	20	11			
CA-31	3.0	1.5			

Cutoff voltage of 1.0 volt/cell.

9.4.9 DEEP CYCLING

The deep cycle consists of continuing the discharge listed above.

a. As each individual cell reaches 0.6 volt, a metal shorting strap should be placed across the terminals while the load is still applied. It will be impossible to short out all cells within a battery since, during constant resistance discharge, the current decreases as the voltage decreases. Therefore, when approximately 75% of the cells are shorted with metal straps, a 1.0 ohm resistor of 1 or 2 watts should be placed across each of the remaining cells.
b. The battery should remain shorted as above for a period of 3 or more hours.
c. If the discharge time is 70% or greater than that specified *(see Table II)*, the supplemental discharge (deep cycle) can be eliminated.

TABLE V

Battery Type	*Time*	*Current*	*Battery Type*	*Time*	*Current*
CA-4	7-hour	5-amp	CA-40	7-hour	8-amp
CA-5	"	8-amp	CA-44	"	8-amp
CA-6	"	5-amp	CA-51	"	1.0-amp

CA-20	"	5-amp	CA-102	"	3-amp
CA-20H	"	5-amp	CA-121	"	3-amp
CA-21	"	5-amp	CA-727-3	"	5-amp
CA-24	"	5-amp			
CA-31	"	0.8-amp			

9.4.10 FINAL CHARGE

The battery is now ready for charge. Charge battery by the constant current method only.

a. Place the battery on charge at the 5-hour rate for 7 hours *(Table V)*. Care should be taken to see that the total ampere-hour charge equals that outlined in Table V. If the charge current decreases during charge, manually adjust current to maintain the proper value.

b. During the final 5 minutes of charge (for automatic chargers that have terminated, reset the charge for 10 additional minutes), the voltage of each individual cell should be read.

c. The minimum voltage should be 1.55 volts/cell and the maximum 1.75 volts/cell at room temperature (70-80°F). If any cell fails to rise to at least 1.55 volts, the constant current charge should be continued for an additional hour. At this time, monitor the cell voltage again.

d. Any cell that fails to rise above 1.55 volts or exceeds 1.75 volts should be removed from service and may be returned for rebuilding or overhaul to Customer Return Department, Battery Division, Sonotone Corporation, Cold Spring, N. Y. 10516.

NOTE: Any battery having a discharge time less than 70% of that specified in Table IV SHOULD be given another discharge and recharge *(per Discharge, 9.4.8, and Deep Cycling, 9.4.10)*.

CAUTION: Any battery having a discharge time less than 30% of that specified in Table IV MUST be given another discharge and recharge *(per Discharge, 9.4.8, and Deep Cycling, 9.4.10)*.

9.4.11 COMPLETION OF CHARGE

Following completion of the charge, the electrolyte level should again be checked, using the levels outlined earlier *(consult Adjusting Electrolyte, 9.4.6)*. Torque the nuts or allenhead screws, attached to the intercell connectors *(see Table II for correct torque values)*.

9.4.12 CHECKING CURRENT PATH

The final step now is to recheck the current path between the cell and battery case, using the maximum current outlined previously *(consult Checking Current Flow, 9.4.2)*.

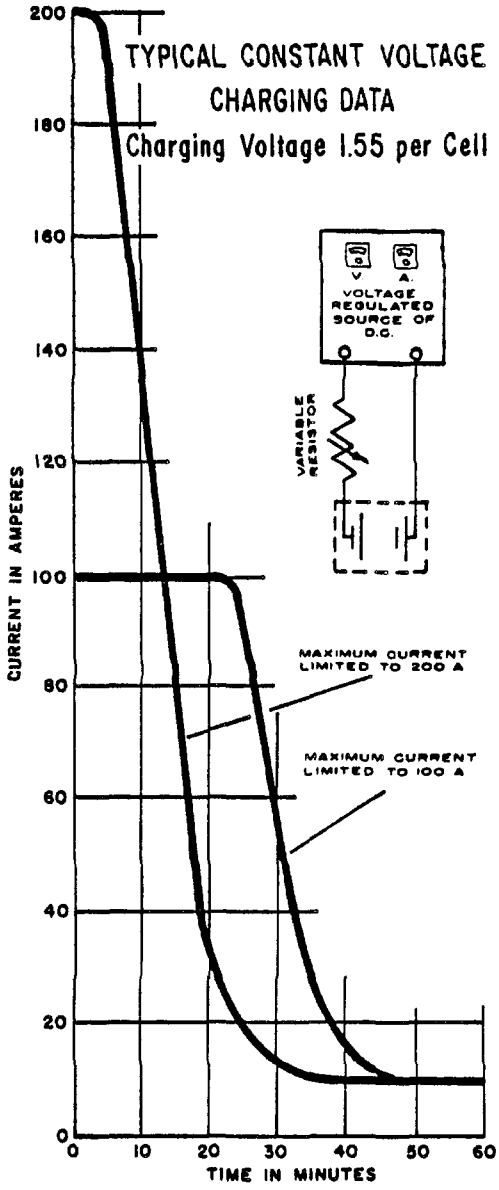

FIGURE 4

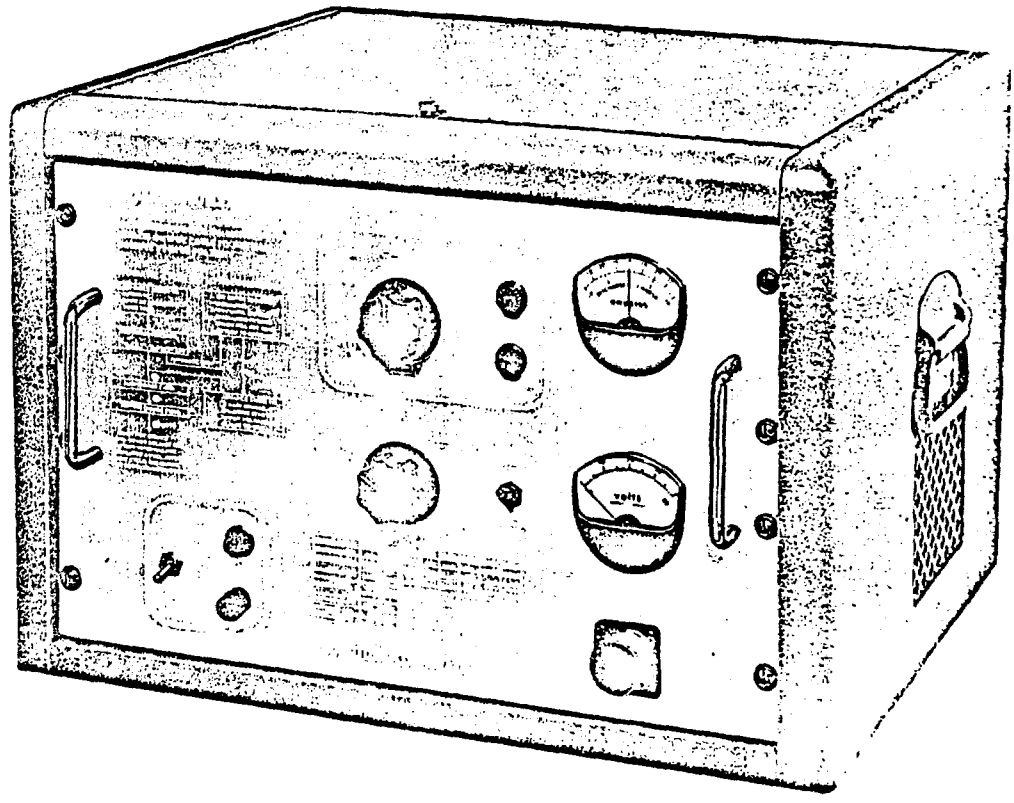
10.0 Sonotone Battery Charger/Analyzer PCA-131

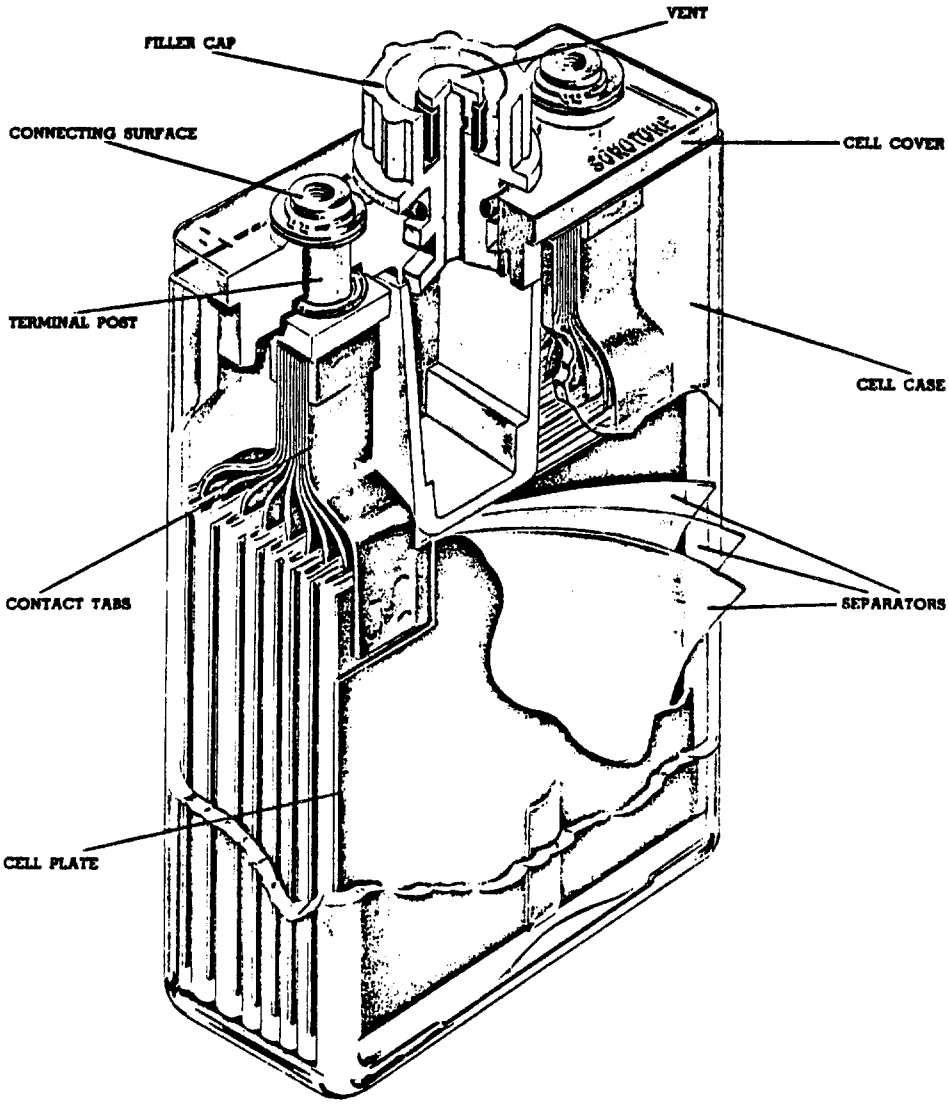
10.1 IMPORTANCE OF RECONDITIONING



The data obtained in performing the reconditioning cycle is invaluable for determining the maximum flight hours between reconditioning service. More frequent reconditioning is recommended whenever possible, however.

In aircraft where more than one battery is used, either in series or parallel starting, care should be taken that the batteries are not allowed to become unbalanced. Perform the reconditioning service on both batteries during the same inspection period.

The Sonotone Model PCA-131 Charger/Analyzer is designed to provide maximum service from nickel-cadmium aircraft batteries. It features a "Go, No-Go" indication of battery condition.



The correct charge and discharge current is preselected with the setting of the switch position. The battery can be left unattended during charge and automatically adjusts for changes in line voltage. It will automatically terminate the discharge if the average battery voltage falls below a preselected end voltage. You can then determine the actual discharge time from the running timer. The discharge percentages discussed also apply to the Sonotone Charger/Analyzer.

Complete information on Sonotone's solid state Charger/Analyzer, the Model PCA-131—such as operation instructions and charger/analyzer specifications—may be obtained from the Field Service Manager, Battery Division, Sonotone Corporation, Elmsford, N. Y. 10523 *(request Data Sheet BA-166)*.

SECTION 1

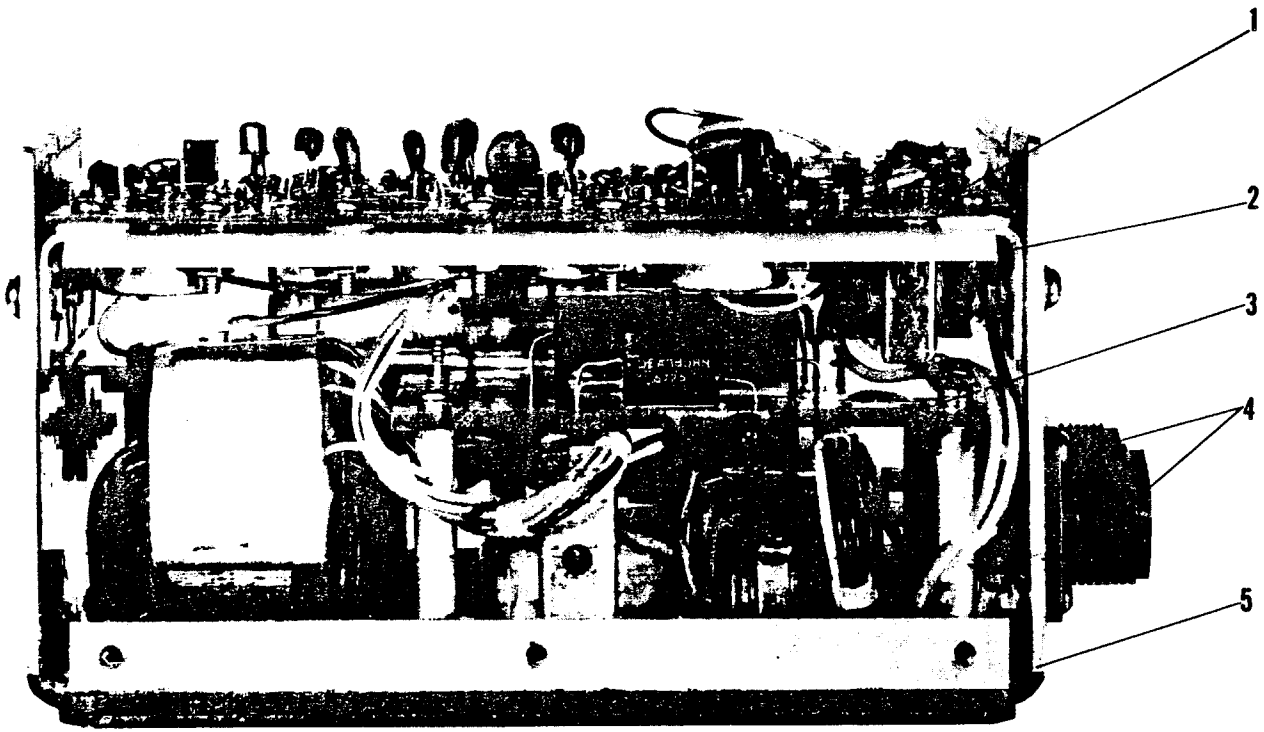
GENERAL DESCRIPTION

SCOPE OF PUBLICATION

1-1. This manual pertains to the static power inverter, Model No. SPS48, Part No. 5590F1-1, manufactured by Spar Aerospace Products Limited, Box 6022, Toronto International Airport, Ontario, Canada. The information is for the benefit of personnel responsible for operation and service of the equipment and includes operating theory, fault analysis, maintenance and a part listing of electronic components.

1-2. The information reflects a single configuration of the SPS48 inverter.

EQUIPMENT DESCRIPTION



1-3. The SPS48 is a 65va, single phase inverter which operates from an input of 20 to 30 vdc and provides single phase outputs of either 26 or 115 vac at 400 Hz or a combination of both, at less than 5% total harmonic distortion. The equipment is used in airborne and ground application where a 400 Hz source of power is required.

1-4. The SPS48 is of solid state design with the components mounted on boards suspended across a U-shaped chassis. See figure 1-1. The chassis is enclosed by an inverted U-shaped cover secured by six screws and lock washers. A pair of flanges protrude from the base of the chassis to provide a rectangular mounting hole pattern.

1-5. The base of the chassis houses the large transformer, T3, and inductors, L1 through L3. An intermediate component board assembly, containing capacitors C12 through C16 is supported on tubular pillars. The top component assembly consists of a heat sink tray upon which is mount the logic component board. The heat sink tray incorporates five transistors Q1, Q10 thru Q13, the silicon rectifier CR28 and the two driver transformers T1 and T2.

1-6. The input and output power connectors, J1 and J2 respectively, are mounted externally on the forward vertical face of the chassis.

1-7. The unit can be installed in any desired orientation.

SECTION 2

THEORY OF OPERATION

INTRODUCTION

2-1. This section contains a functional description of the SPS48 circuitry. Refer to the overall schematic diagram, Figure 5-1.

CIRCUIT DESCRIPTION

2-2. The SPS48 operates from a d-c source of 20 to 30 volts applied across pins A and B of the input connector J1. The unit can accommodate a wide range of input voltages as specified in Figure 1-2, and provides a regulated output voltage by means of a pulse-width modulating technique.

INPUT PROTECTION

2-3. The input line incorporates an input filter comprising L1 and C12. CR28 and CR2 provides reverse polarity protection in the event that the input voltage is reversed accidentally. Zener CR1 and resistor R1 are incorporated to shut down the inverter to protect the equipment if an overload transient in excess of 40v is experienced.

REGULATED 15 VOLT SUPPLY

2-4. Following the input filter and transient protection is a series regulator circuit comprising CR7, R2, Q1 and C17. This circuit provides a regulated 15-volt input to the inverter logic circuitry. Resistor R2 supplies a current to keep zener diode CR7 turned on, maintaining the reference voltage. C17 provides additional filtering to ensure that noise is eliminated since the presence of ripple in the reference voltage would cause undesirable ripple at the output of Q1.

OSCILLATOR CIRCUIT

2-5. Q3, in conjunction with R7, R8, R10, R11 and C1 represent a unijunction oscillator which provides a stable 800 Hz output. The oscillator is capable of maintaining a 1% accuracy in frequency over the total operating temperature range. Trim potentiometer R10 permits accurate adjustment of the frequency to 800 Hz to compensate for variations in component values.

2-6. When Q3 fires, a positive pulse is coupled through C2 and turns transistor Q5 on. The pulse is coupled simultaneously to Q8 via R26 and CR12, in order to set the Schmitt trigger, Q6 and Q8.

RAMP AND CLAMP CIRCUIT

2-7. The circuit comprising Q5, CR11, C4 and the associated resistors form a ramp and clamp circuit. R20 and C4 form a simple RC circuit, connected across the regulated 15 volt supply. The capacitor charge builds up exponentially while Q5 is turned off. When Q5 is turned on, diode CR11, which is at a positive voltage established by the RC charging rate, is clamped to ground. The output, used as a reference point in the pulse-modulation circuit, is connected to the base of Q6 via R19.

2-8. There is, therefore, a simultaneous condition in which Q6 and Q8 are turned on, and the pulse occurring at R18 (collector of Q5) triggers the flip-flop, Q7 and Q9 from one state to the other. The flip-flop cycles at the output rate of 400 Hz.

FLIP-FLOP CIRCUIT

2-9. In the condition when Q9 is triggered on by the pulse from Q5, the output of Q7 is high, current cannot flow via R40 and CR17 to ground. A second path would be through CR23 and R41 to turn on Q11. However, the Schmitt trigger Q8 is on, therefore the current flows through R40, CR19, CR14 and the collector-emitter circuit of Q8 to ground. Hence, no base drive voltage is developed on Q11 and it remains off.

2-10. The ramp voltage across C4, is compared with the voltage at the emitter of Q4, via R19 and R17. If this voltage turns Q6 off, its collector is at ground potential. This removes the base drive via Q6 and R22 to Q8. Therefore Q8, deprived of its base drive, is turned off and the voltage at CR14 is raised to the d-c supply level. The current can now flow via R40, and diode CR23, thereby developing a voltage across R41 and turning Q11 on.

2-11. The time at which Q11 turns on, the left hand edge of the pulse, (i.e. the pulse-width modulated input to Q11) varies in time depending upon the regulation requirements of the inverter.

2-12. During this sequence Q7 is off and Q9 is on with its collector at ground potential. This completes a path for the current via R38, CR16 and through Q9 which ensures that during this half cycle, (1.25 milliseconds), Q10 is kept off.

2-13. On the next half cycle, Q7 is triggered on, thereby turning Q9 off. The sequence is now repeated for the alternate flip-flop state with Q11 being held off and Q10 supplied with a pulse-width controlled signal to its base. The right hand edge of the pulse is fixed in time, occurring when the flip-flop switches its state.

INVERTER OUTPUT

2-14. The pulse-width modulated waveform at the bases of Q10 and Q11 drives the transistors from off to on. These transistors provide drive signals to Q12 and Q13 via T1 and T2. Transistors Q12 and Q13 supply a variable pulse-width square wave to T3, the output transformer. In addition, inductor L3A and L3B, which is bifilar wound to reduce leakage inductance, is included in the collector circuits and forms part of the output filter. This inductor is effectively reflected into the secondary of T3 to create an LC filter comprising L3A, L3B, C15 and C14. Therefore, the basic configuration of the filter is a series inductance and a shunt capacitance across the output which attenuates the high frequency harmonics above 400 Hz. The inductor does not appear physically in the output but is reflected into the secondary winding, permitting the output winding, XY, which samples the output voltage, to be a secondary winding on the output transformer.

2-15. Capacitor C13 and inductor L2 are connected in series across the output. They provide a trap for the third harmonic voltages occurring in the output voltage.

SAMPLED OUTPUT

2-16. The a-c signal from the XY winding of transformer T3 represents a sample of the inverter output which is used as an input to the regulating circuitry. The output is fed back to a full-wave diode bridge comprising CR3, CR4, CR5 and CR6. The bridge feeds a voltage divider network comprising R3, R4, R5 and diodes CR8 and CR9. These diodes provide temperature compensation

for the bridge diodes. Potentiometer R4 allows adjustment over a limited range to set the inverter output voltage to 115 vac.

MILLER INTEGRATOR

2-17. The voltage across the divider network is applied to a high gain Miller integrator consisting of Q2, Q4 and the Miller capacitance C3. The integrator functions as a low-pass filter which converts the full-wave input into smooth d-c so that it can be compared with the ramp voltage. The voltage that appears at the potentiometer side of R6 is compared with the voltage across CR10. Diode CR10 is a temperature-compensated zener reference voltage which is fed a fixed, specified current from the d-c supply via resistor R12.

2-18. A filtered sample of the output voltage appears at the emitter of Q4. The emitter of Q4 is at a voltage which is proportional to the sample voltage which appears at XY. The emitter voltage increases and decreases as the voltage sample is compared with the voltage across CR10, which is the reference for the regulation system.

SCHMITT TRIGGER

2-19. There are two inputs to the Schmitt trigger; one from the Miller integrator via R17, the other from the ramp circuit, C4 and R20, via R19. Reference paragraph 2-6, Q6 is turned on by a pulse from the oscillator Q3, via R26 and CR12. This ensures that the Schmitt trigger is on and keeps the collector of Q8 at ground potential at the commencement of each half cycle, thereby permitting pulse-width modulation on the left hand edge of the pulse.

2-20. At this instant there is a positive voltage at the Q4 emitter end of R17, but its magnitude is not sufficient to turn Q6 off. However, the other input to the Schmitt trigger from the ramp, via R19 increases to a level which eventually turns Q6 off. When Q6 is turned off, Q8 is also turned off and CR14 returns to ground through a high impedance path via R30. This allows either Q10 or Q11 to turn on and provide a pulse to the output.

DRIVER CIRCUIT

2-21. VDR1 and VDR2 are voltage dependent resistors. They are used to clip the inductive voltage swings on T1 and T2 when Q10 and Q11 are turned off. The resistors absorb inductive voltage transients thus protecting the associated transistor.

2-22. Diodes CR29 and CR30 provide transient protection for Q12 and Q13. Resistors R42 and R43 provide base returns for Q12 and Q13.

OUTPUT CIRCUIT

2-23. The transformer T3 provides an output waveform of the required rms voltage which is sinusoidal with a maximum total harmonic distortion of 5%. The 115 vac, 400 Hz output is available at pin J2-C; 26 vac, 400 Hz at pin J2-B; with pin J2-A common.

2-25. The transformer ensures that the outputs are isolated electrically from the input and ground.

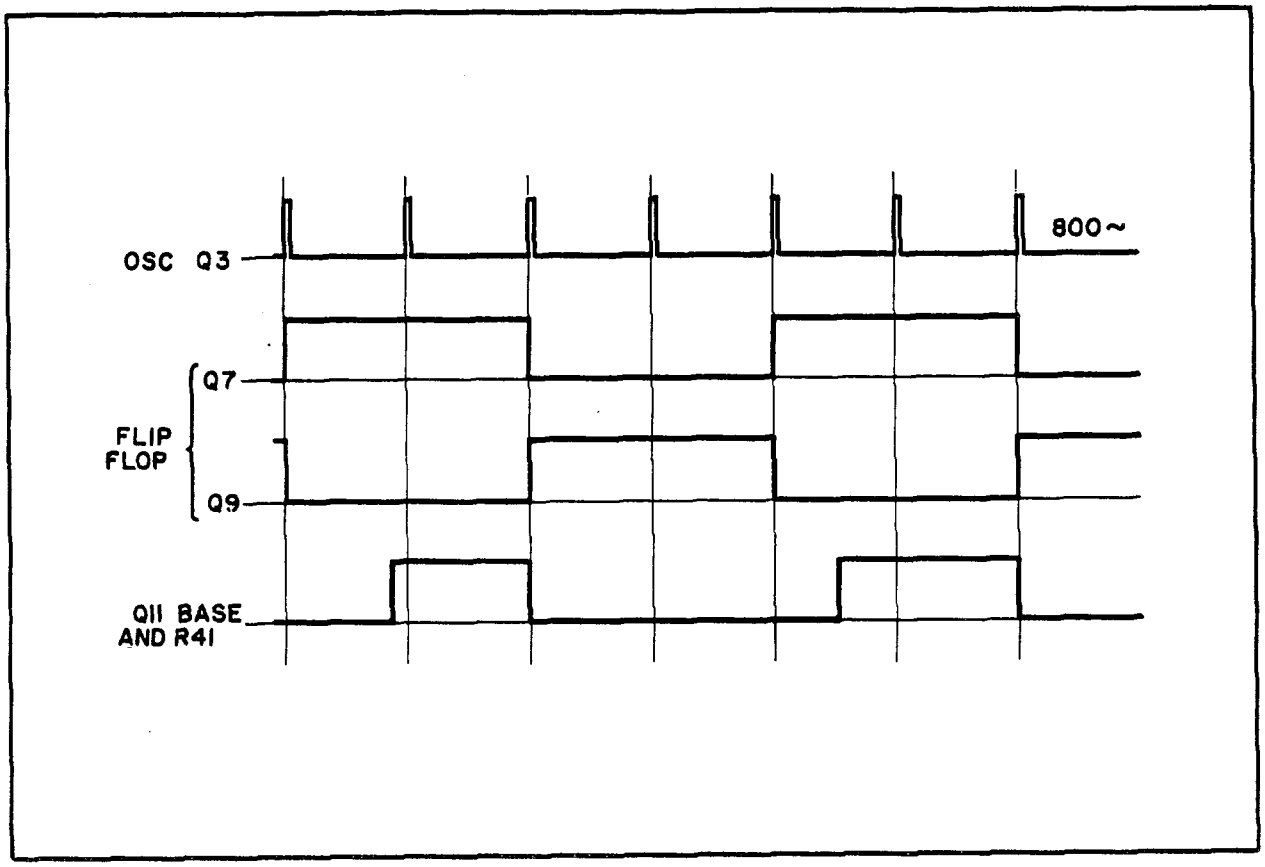

Figure 2-1. Circuit Waveforms

SECTION 3

MAINTENANCE

INTRODUCTION

3-1. This section describes briefly the scope of maintenance which is applicable to the SPS48 inverter. Maintenance is limited to a functional test procedure, and a descriptive analysis of possible malfunction conditions. The section also includes internal photographs of the unit identifying pertinent electronic components.

VISUAL EXAMINATION

3-2. Before the inverter is connected to any test equipment or power supply, remove the cover and carry out a visual examination paying particular attention to the following points:

(a) Ensure that there is no dirt, dust or other foreign matter inside the unit.

(b) Ensure that all securing and locking screws are tight.

(c) Ensure that all solder joints are visually good, without excess solder and are clear of flux.

(d) Check the wiring for any sign of damage.

(e) Check the electrical connectors for signs of damage.

(f) Check electrical components for signs of overheating.

(g) Check the cover assembly for signs of damage and chipped paint.

EQUIPMENT TEST

3-3. The following test procedure ensures that a unit is functioning satisfactorily within the specified performance tolerances. The test may also be used to isolate faults at the field maintenance level based on malfunction reports in operation.

TEST EQUIPMENT

3-4. The following test equipment is required:

(a) Load test panel, Spar Part No. V1695 or equivalent.

(b) Avometer, Model 8 or equivalent (Qty 3).

(c) Frequency counter, Hewlett Packard Model 5500C or equivalent.

(d) Distortion analyzer, Hewlett Packard Type HP331A.

(e) Power supply, variable 20 to 30 vdc, 5 amp capacity or better.

TEST PROCEDURE

3-5. Under steady state conditions, the nominal load of 65 va is equally divided between the 115v and 26v outputs. In the following test procedure all a-c voltmeter readings are rms values. Connect the inverter to be tested as shown in the test set-up, Figure 3-1.

3-6. No load performance. Proceed as follows:

(a) Set the load switch to the no-load position and the output selector switch to the 115v position.

(b) With the avometer (2) set to a suitable a-c volts range, adjust the input voltage to 25 vdc.

(c) Switch the test panel ON and check that the outputs fall within the following tolerances: voltage, 105 to 121 vac; frequency, 396 to 404 Hz; harmonic distortion, 5% or less. Record the readings.

NOTE

The output voltage can be varied over a limited range by adjusting trim potentiometer R4. The oscillator frequency is adjusted by means of variable resistor R10.

(d) Switch the output selector switch to the 26v position.

(e) Set the avometer (2) to a suitable a-c volts range.

(f) Check that the outputs fall within the following tolerances: voltage, 24.2 to 27.3 vac; frequency, 396 to 404 Hz; harmonic distortion, 5% or less. Record the readings.

(g) Repeat steps (a) through (e) with input voltages of 27.5 vdc and 29.5 vdc. Record the readings. Do not disconnect the test equipment.

3-7. Full Load Performance. Proceed as follows:

Set the load switch to the full load position and repeat the performance test specified in paragraph 3-6. Check that the output current falls within the following tolerances: 115 vac output, 0.263 to 0.303 amps; 26v output, 1.17 to 1.35 amps.

CLEANING

3-8. The following paragraphs describe the procedures for cleaning the interior and exterior of the inverter.

CLEANING MATERIALS

3-9. The SPS48 may be cleaned with a stream of filtered, compressed, dry air at a pressure of less than 30 psi. Remove any grease spots with a high quality cleaning fluid, used sparingly, and then dust with a lint-free cloth and cleaning brush. Water may be used for cleaning the metallic parts of the cover assembly. For general cleaning purposes, the following mixed solution is recommended: 70 percent dry cleaning solvent, 5 percent chlorethylene, and 25 percent methylene chloride.

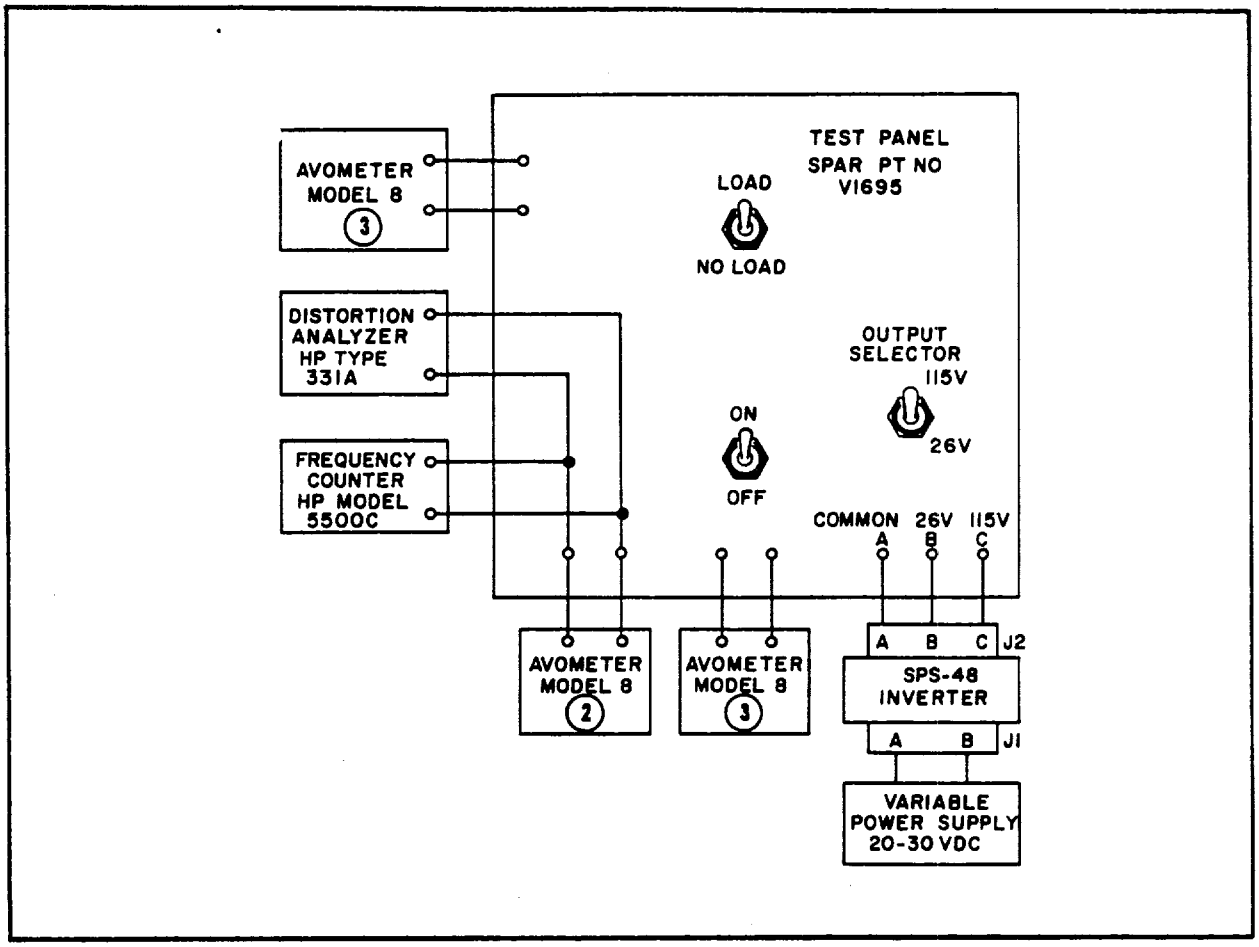

Figure 3-1. SPS48 Static Power Inverter - Test Set-up

WARNING

This mixture, although considerably less toxic than carbontetrachloride, must be used only in a well ventilated room.

CAPACITORS, RESISTORS, INDUCTORS AND TRANSFORMERS

3-10. Clean capacitors, resistors, inductors and transformers with a soft cloth moistened with the general cleaning solution, described in paragraph 3-9. Where possible, remove corrosion on metallic parts with crocus cloth. Remove any resulting particles with a fine brush and vacuum source. Refinish printed circuit boards with a clear epoxy coating, such as Fullers Resiweld No. 7200.

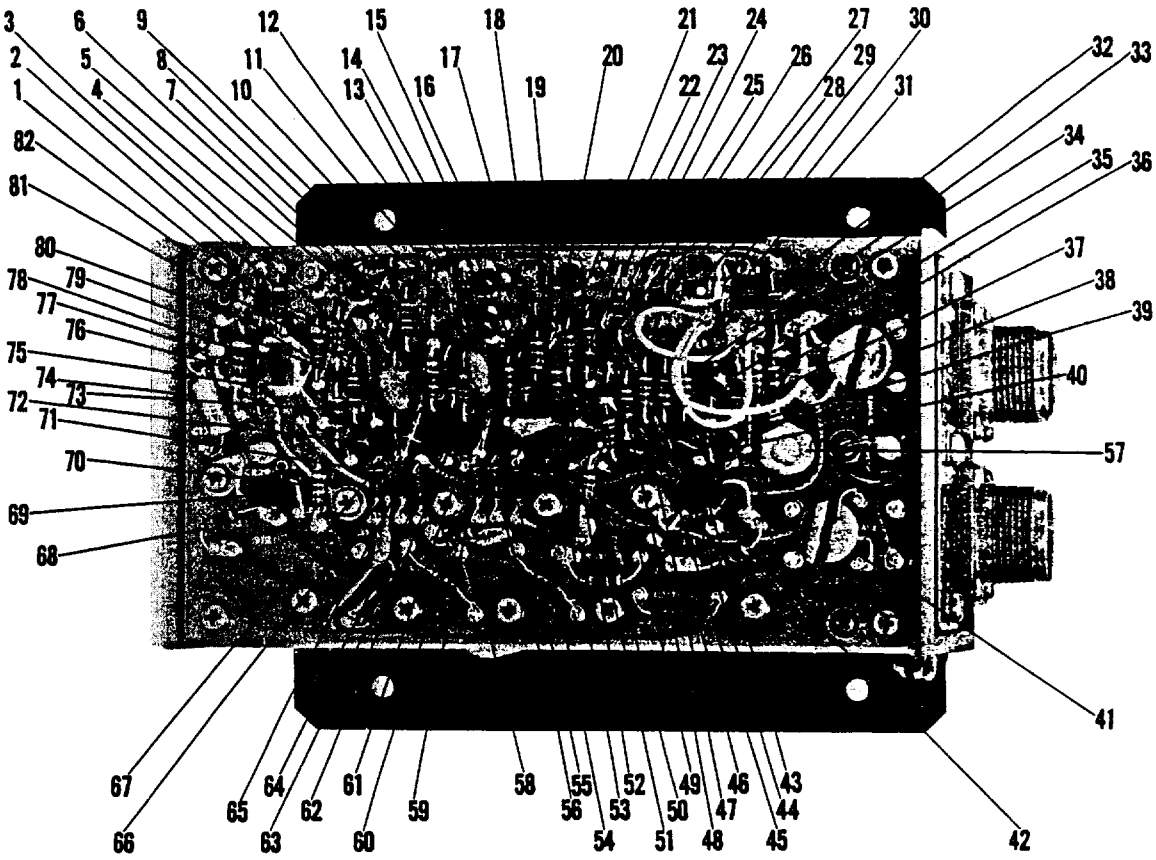
TERMINAL BOARDS

3-11. Clean terminal boards with a stiff brush and soft cloth moistened with the general cleaning solution described in paragraph 3-9. Carefully remove any corrosion with crocus cloth or No. 0000 sandpaper, afterwards cleaning with the general cleaning solution.

CABLE CONNECTORS

3-12. Clean dirty cable connectors with a fine brush or soft, lint-free cloth moistened with the general cleaning solution described in paragraph 3-9. Clean corroded contacts with crocus cloth or No. 0000 sandpaper.

FAULT ANALYSIS

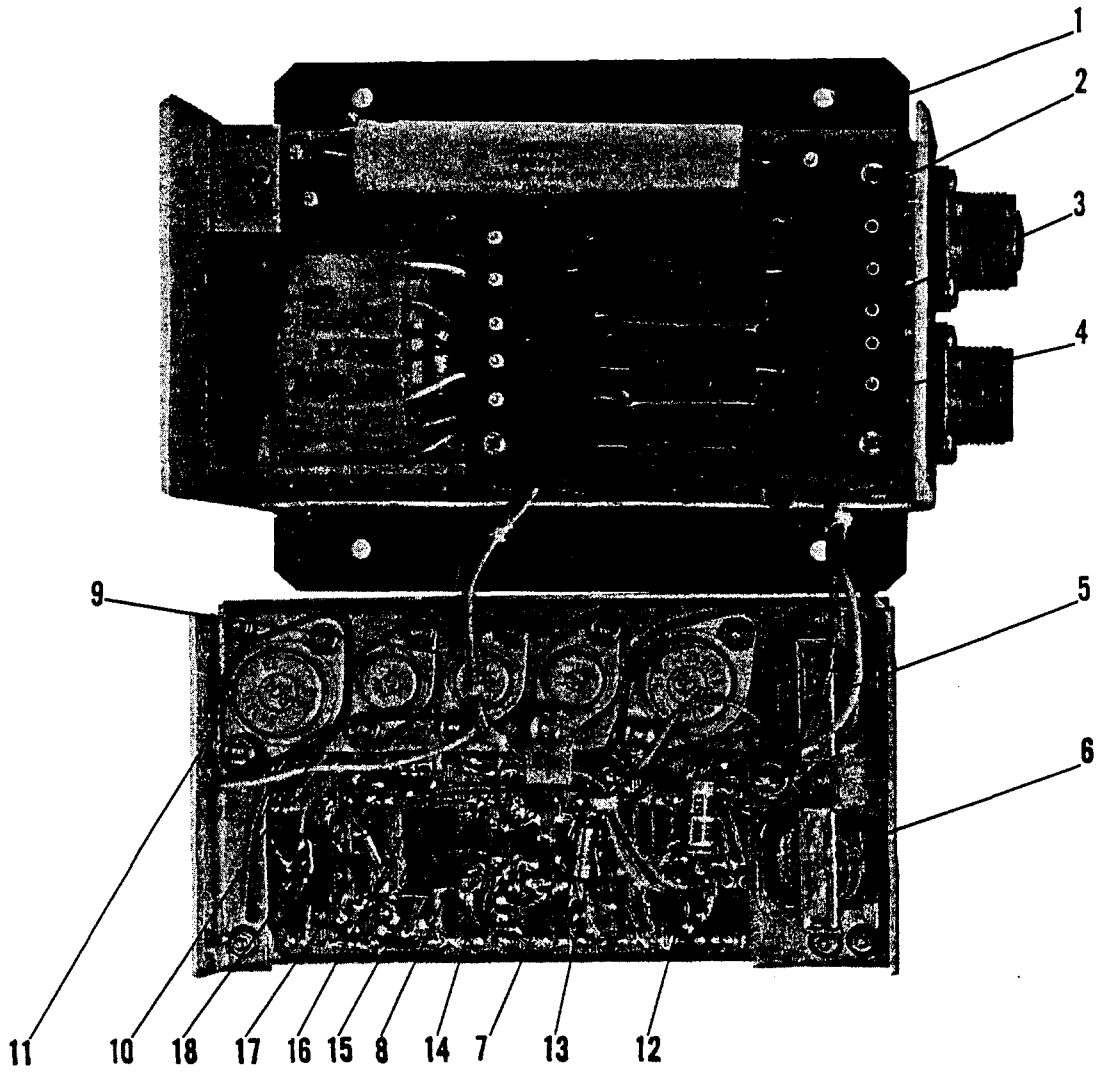


3-13. Symptoms of malfunctions will normally be detected by erroneous output conditions. The fault analysis is therefore confined to examinations of the output voltage, frequency and waveform.

3-14. FREQUENCY. If the frequency of the output is incorrect the unijunction oscillator, Q3, should be suspected. Limited adjustment of the frequency can be accomplished by means of potentiometer R10, located on the top panel remote from the connectors. If the output frequency is considerably out of tolerance, check the input voltage, the regulated supply potential and the regulator Q1, R2 and CR7 output. Ensure that all leads are connected properly.

3-15. OUTPUT VOLTAGE, HIGH OR LOW. Out-of-tolerance voltage output could be caused by a fault in any of the regulation circuit comprising the diode bridge, CR3 through CR6; the divider network, or the Miller integrator Q2 and Q4.

3-16. DISTORTED WAVEFORM. Distortion of the output waveform could indicate problems in the output filtering network. The primary filter comprises inductor L3A and L3B and capacitor C14 and C15. Improper drive to Q10, Q11 or Q12, Q13 resulting in an extremely narrow pulse would cause excessive distortion. There would be insufficient energy in the pulse to provide an acceptable sine wave even under no load conditions, due to losses in the transformer and filter.



3-17. NO OUTPUT. In the event of no output a complete signal trace would be required. Malfunctions or component breakdown in virtually any part of the circuit could result in a no output condition.

REPLACEMENT PART LIST

4-1. This section contains a replacement part list for the components within the static power inverter SPS 48. The electronic components are listed with their reference designators arranged in alpha-numeric (computer) sequence.

4-2. The locations of components are shown in Section 3. Parts manufactured by Spar Aerospac Products Limited or parts for which Spar retains specification control are identified by the Spar vendor code. Parts not manufactured by Spar Aerospace Products Limited are identified by the appropriate vendor code derived from the Federal Supply Code for Manufacturers, H4-1. A cross reference list of the vendor codes and the vendor's name and address is given below.

Code	Vendor's Name and Address
01884	Dearborn Electronics Inc., P.O. Box 530, Orlando, Fla. 32802
05397	Union Carbide Corp., Linde Division, Kemet Dept., Cleveland, Ohio.

EXCLUSIVE DISTRIBUTOR

The customer support organization at TRW Aeronautical Systems, Lucas Aerospace is complemented by the TRW Aeronautical Systems, Lucas Aerospace Equipment Services Division, the exclusive stocking distributor of TRW Aeronautical Systems, Lucas Aerospace parts and technical publications. The Equipment Services Division has major distribution and support facilities at three strategic worldwide locations as listed below. A multi-million dollar inventory is maintained by these facilities and parts dispatch can be accomplished throughout the world within hours.

REGION	ADDRESS	COMMUNICATIONS
AMERICAS:	TRW Aeronautical Systems, Lucas Aerospace ESA 30 Van Nostrand Avenue Englewood, NJ 07631-4396 USA	PHONE (1) 201 567 6400 AOG (1) 201 567 6411 FAX (1) 201 541 7610 (1) 201 894 1965 SITA/ARINCBDRLU7X
EUROPE/MIDEAST/ AFRICA:	TRW Aeronautical Systems, Lucas Aerospace ESE Stratford Road Solihull B90 4LA United Kingdom	PHONE 44 (0) 121 451 5999 AOG 44 (0) 121 451 5904 FAX 44 (0) 121 451 5881
ASIA/PACIFIC:	TRW Aeronautical Systems, Lucas Aerospace CSP 35 - 37 Loyang Way Singapore 1750	PHONE (65) 545 9975 AOG (65) 545 6253 FAX (65) 545 9965 SITA/ARINCSINLU7X

Parts and assemblies not authorized for repair in the field must be sent to the TRW Aeronautical Systems, Lucas Aerospace Repair and Overhaul (R&O) at the location below.

REGION	ADDRESS	COMMUNICATIONS
ALL:	TRW Aeronautical Systems, Lucas Aerospace 777 Lena Drive Aurora, OH 44202 USA	PHONE (1) 330 995 1000 FAX (1) 330 995 1117

CAUTION: Any use of parts, materials, or processes not authorized by TRW Aeronautical Systems, Lucas Aerospace for the maintenance or service of these units may affect their continued flightworthiness or invalidate certification.

INTRODUCTION

1. Purpose

This Component Maintenance Manual (CMM) provides detailed instructions for the servicing of TRW Aeronautical Systems, Lucas Aerospace 23048 Series of DC Starter-Generators. Servicing of a DC Starter-Generator is dependent upon the extent of disassembly and repair instructions listed herein:

(1) Replacement of non-reusable parts such as bearings and miscellaneous hardware.

(2) Cleaning of subassemblies.

(3) Detailed inspection of parts, electrical check of all electromagnetic parts (including; insulation integrity check), Non-Destructive Test (NDT) inspections, and complete acceptance testing.

(4) Reconditioning of housing finishes as required.

(5) Repair/rework of parts as required.

(6) Recertification including final assembly, records, and release tags.

Servicing or selected equipment repairs do not affect the Technical Standards Order (TSO) and the equipment is released on a continue time basis.

An illustrated parts list is included at the back of this CMM for component identification and ordering of approved replacement parts. The structure and content of this manual is in general accordance with the requirements established by the Air Transportation Association (ATA) for aircraft CMMs. This manual is formatted to conform to iSpec 2200 (ATA Specification 2200) Information Standards for Aircraft Maintenance.

Your are advised to become thoroughly familiar with the equipment and the contents of this CMM. Give careful attention to applicable warnings and cautions. Before performing any servicing procedure, become thoroughly familiar with the capabilities and limitations of the equipment. Make sure all necessary safety equipment, test equipment, repair materials, special tools, and fixtures are on hand.

If you find an error, omission, or other technical discrepancy, please fill out a copy of the Technical Publication Comment Form found at the back of this manual and send a copy to the Technical Publications Supervisor at TRW Aeronautical Systems, Lucas Aerospace in Aurora, Ohio.

2. User Qualification and Certification Requirements

The information contained in this manual is intended for use by persons properly trained and certified in the repair and service of aircraft electrical accessories. Eligibility and certification of service technicians shall be in accordance with guidelines established by the U.S. Federal Aviation Administration or an equivalent regulatory authority. Refer to U.S. Code of Federal Regulations 14 CFR, parts 65.101 through 65.103 and part 145.33.

© 2000 TRW Aeronautical Systems

Where special processes are included by reference to military or commercial standards, the qualifications and certification of personnel performing the process shall be as indicated in the cited standard. Strictly follow the detailed requirements of all cited military or commercial standards used in the repair of this equipment.

3. Quality Assurance Requirements

The repair station's quality assurance activity is responsible for the correct performance of all tests and inspections specified in this manual. The quality assurance activity shall also be responsible for maintaining all necessary test, inspection, and maintenance records for each unit received for service.

All instrumentation and inspection equipment used shall be calibrated and controlled in accordance with ISO 10012-1, with all standards traceable to the National Bureau of Standards or an equivalent standards regulatory authority.

The quality assurance activity shall be responsible for certifying that personnel, skills, and materials meet the requirements of the work to be performed. Components of the generator undergoing servicing that are recovered as products of disassembly shall be examined 100% to determine serviceability.

The quality assurance activity shall maintain documented evidence that specifications applicable to special processes such as soldering, non-destructive testing, plating, etc.; have been complied with during servicing and/or repair of the generator.

4. Safety Advisory

This manual describes physical and chemical processes that require the use of chemicals or other commercially available materials that require precautionary attention.

The user of this manual should obtain material safety data sheets and Occupational Safety and Health Act (OSHA) Form 20 or equivalent from the manufacturers or suppliers of materials to be used. The user must become completely familiar with and follow all manufacturer/supplier procedures, recommendations, warnings, and cautions for the safe use, handling, storage, and disposal of the materials. User of this manual are also advised to refer to applicable safety information contained in the "NIOSH Occupational Guideline for Chemical Hazards" published by the United States Department of Labor.

WARNING: **ALERT OPERATING AND MAINTENANCE PERSONNEL TO POTENTIAL HAZARDS THAT COULD RESULT IN PERSONAL INJURY; THEY DO NOT REPLACE THE MANUFACTURER'S RECOMMENDATIONS.**

CAUTION: Alert operating and maintenance personnel to conditions that could result in equipment damage.

5. Materials List

The materials listed in this paragraph are required for processes throughout this manual. Warnings and/or cautions will precede the use of the materials listed in Table 1.

© 2000 TRW Aeronautical Systems

WARNING: BEFORE HANDLING ANY OF THE FOLLOWING MATERIALS, BE AWARE OF ALL HANDLING, STORAGE, AND DISPOSAL PRECAUTIONS RECOMMENDED BY THE MANUFACTURER OR SUPPLIER. FAILURE TO COMPLY WITH MANUFACTURER OR SUPPLIER RECOMMENDATIONS CAN RESULT IN SERIOUS INJURY, PHYSICAL DISORDER, OR DEATH.

Material	Used in...
Chem film, chromate	REPAIR, ASSEMBLY
Cleaning solvent	CLEANING, ASSEMBLY
Isopropyl alcohol	CLEANING, CHECK, REPAIR, ASSEMBLY
Lubricating oil	ASSEMBLY
Thread locking compound	REPAIR, ASSEMBLY
Trichloroethane	CLEANING, ASSEMBLY
Zinc chromate primer	REPAIR, ASSEMBLY

Table i - Hazardous Materials

6. Non-TRW Aeronautical Systems, Lucas Aerospace Authorized Components and Processes Policy

TRW Aeronautical Systems, Lucas Aerospace authorizes the use of genuine TRW Aeronautical Systems, Lucas Aerospace spare parts which meet engineering design specifications and quality standards, and have traceability to having been procured and certified to these specifications by the TRW Aeronautical Systems, Lucas Aerospace, Aurora Quality Assurance incoming and inprocess inspection systems. The TRW Aeronautical Systems, Lucas Aerospace Equipment Service Centers are the only authorized distributors of genuine TRW Aeronautical Systems, Lucas Aerospace replacement parts and complete units.

It is the obligation of all repair and service facilities to provide the FAA, or any other in-country air authority, with proper traceability documentation indicating approval of all spare parts, materials, and processes to ensure configuration compliance and continued air worthiness.

The use of any non-TRW Aeronautical Systems, Lucas Aerospace parts, or any parts not having been submitted to TRW Aeronautical Systems, Lucas Aerospace Quality Assurance inspection systems will invalidate any and all factory warranties. All TRW Aeronautical Systems, Lucas Aerospace warranties are automatically voided on any TRW Aeronautical Systems, Lucas Aerospace designed unit that has been modified by the installation of any unauthorized parts, materials, or unapproved processes supplied by other outside services. The repair station's quality assurance activity shall assume produce liability for all units that have been modified in this fashion.

Damage resulting from the use of non-TRW Aeronautical Systems, Lucas Aerospace, replacement parts, materials, or processes is not covered by the warranty or service policy for any product or any application.

DESCRIPTION AND OPERATION

1. Equipment Description

The 23048 series of DC Starter-Generators are designed to provide torque for engine starting and to generate 30 volts DC electrical power. Refer to the ILLUSTRATED PARTS LIST section for an illustration and parts breakdown of the Starter-Generator.

The 23048 DC Starter-Generator is an air-cooled, self-excited, brush-type unit that consists of a stator and housing assembly incorporating four main poles and four interpoles, an armature assembly attached to a dampening type drive shaft, end bell bearing supports, brush assembly, fan assembly, and terminal block assembly.

The drive shaft is splined on both ends; at the drive end for engaging the engine gearbox, and at the anti-drive end for coupling to the armature shaft. The anti-drive end also contains a mounting surface and threaded end for attaching the fan assembly. The drive shaft is provided in either dry or wet spline styles depending on the starter-generator model; the wet spline style uses a preformed packing on the drive end spline. The drive shaft and attached armature assembly are supported by bearings mounted in the in the drive and anti-drive end bells. At the drive end of the drive shaft is a clutch-type dampener assembly that absorbs torsional vibration generated by changes in engine gearbox speed and electrical load conditions.

Electrical connection to the Starter-Generator is made at the terminal block assembly. Internally, electrical power passes through the armature and stators via a radio noise filter in the terminal block assembly and the commutator brush assemblies attached to the anti-drive end bell.

Unit cooling at all rated conditions is achieved by either of two methods: (1) by air blast with supplemental air provided by the fan assembly at the the anti-drive end, or (2) by self-cooling with the air provided by the fan assembly. The fan is protected by a screen cover on self-cooled models..

The Starter-Generator is mounted on the engine mounting pad by using an appropriate Quick Attach-Detach (QAD) kit, as specified in the ILLUSTRATED PARTS LIST. The QAD kit, which consists of a drive-end pad end-bell and a rim clenching clamp, is only supplied with certain models of the Starter-Generator. For all other models, the QAD kit must be ordered separately.

2. Operation

CAUTION: The starter function should not be activated for more than the few seconds needed for a normal engine start. Large start currents and long start times create excessive temperatures that can damage the Starter-Generator.

When used as an engine starter, the Starter-Generator can be energized either by batteries or by ground-power units. The Starter-Generator uses a series starting field that should only be be activated with the shunt field de-energized.

When operating as a generator, the Starter-Generator provides rated DC output at a rotational speeds within the rated speed range.

© 2000 TRW Aeronautical Systems

The generator will operate satisfactorily with either a carbon-pile or static type regulator conforming to BuWep Drawing E-1597-1 and MIL-R-6809. A reverse-current relay is normally used for automatically disconnecting the generator from the load bus, if generator voltage drops below a pre-determined minimum.

Electrical and mechanical characteristics of the 23048 series of DC Starter-Generators are provided in Tables 1 and 2.

Characteristics	Specification
Rated Power Output	6.0 kW (200 Amp models), 7.5 kW (250 Amp models)
Rated Voltage	30 VDC nominal; 26-30 VDC over speed range
Speed Range:	See Table 2.
Continuous Load in Speed Range	See Table 2.
Operating Altitude	35,000 ft. (10.668 km) maximum
Cooling	Blast air with fan supplement (all except self-cooled models) Self-cooled (23048-004, 23048-008, 23048-012, 23048-014, 23048-015, 23048-018 only)
Air Opening (Diameter)	3.0 in. (114.3 mm) - Blast air cooled models 5.2 in. (132.1 mm) - Self-cooled models
Direction of Rotation	Counterclockwise (viewing drive-end)
Weight (Less QAD kit)	See Table 2.
Overhung Moment	See Table 2.
Mounting Pad	AND 10261 XI-B, AND 10262 Type XII-A, or MS3331-1. See IPL for appropriate QAD mounting kit.
Drive Spline	12 Teeth; 0.600 in. pitch diameter (all except 23048-023) 16 Teeth; 0.800 in. pitch diameter (23048-023 only)
Terminal Designations: B + E – A + D C +	Positive Negative Positive field Equalizer Starting
External Start Power	28 VDC, 800 A max. - (All except 1000 Amp models) 28 VDC, 1000 A max. -(23048-018, 23048-021, 23048-023, 23048-027, 23048-028)
Overall Length (Less spline drive)	See Table 2.
Housing Diameter (over clamp)	6.22 in (157.98 mm).

Table 1 - Equipment Specifications

TESTING AND FAULT ISOLATION

1. Introduction

The procedures provided in this section are performance tests and are classified as either verification tests or acceptance tests. A verification test is conducted to assist in fault isolation or to confirm the cause for removal before the repair or overhaul of the DC Starter-Generator. An acceptance test is conducted after the repair or overhaul of the unit. Record all test results on a photocopy of the data sheet(s) provided at the end of this section.

Verification Testing: A starter-generator requiring confirmation of the cause for removal or qualification for continued service must be inspected as detailed in paragraph 3 of the CHECK section before testing can begin. A unit that passes initial inspections may be tested in accordance with this section to determine performance or to isolate a particular fault. When a fault is identified during testing, refer to the fault isolation tables in this section to determine the probable cause.

Acceptance Testing: A unit that has been overhauled or repaired and is ready to be returned to service must be tested in accordance with this section to verify minimum performance standards. Only when an acceptance test is fully completed, and in the order presented in this section, can zero operating hours time since overhaul (TSO) be assigned to an overhauled unit.

2. Test Conditions

Parameter	Operating Condition
Ambient Temperature	50° to 104°F (10° to 40°C)
Barometric Pressure	27 to 33 in. (690 to 840 mm) of mercury
Mounting	Drive shaft (rotational axis) horizontal
Forced Air Cooling is required for models: 23048-001, 23048-006, 23048-017, 23048-020, 23048-022, 23048-012*, 23048-014*, 23048-015*, 23048-016*, 23048-018*, 23048-021*, 23048-023*, 23048-027*, 23048-028*	Cooling air shall be supplied through a tube that is straight for a length of 3 ft. (0.9 m) and has an inner diameter of: 3.0 in. (76.2 mm) (models without asterisks) or 5.2 in. (132.1 mm) (models with asterisks).

Table 1001 - Performance Test Conditions

© 2000 TRW Aeronautical Systems

Parameter	Operating Condition
Models 23048-004/M/T/TM and 23048-008 are self-cooled	A static pressure of 6.0 in/H_2O, measured 12 in. (305 mm) upstream from the air inlet, is required for all models except models 23048-001 and 23048-006), which require 0.5 in/H_2O static pressure.
Brush Seating NOTE: Refer to REPAIR Section for brush seating procedures. Careful brush sanding ensures that all brushes are in proper contact with commutator, and makes prolonged running prior to test unnecessary	Before test measurements are made: For all models, brushes shall be seated 100% in the direction of rotation. For all models except 23048 -017, 23048-020, and 23048-022, brushes shall be seated at least 90% in the axial direction. For models 23048-017, 23048-020, and 23048-022, brushes shall be seated at least 75% in the axial direction..

Table 1001 - Performance Test Conditions (Continued)

WARNING: DURING GENERATOR OPERATION, THE STARTER- GENERATOR CAN PRODUCE A HIGH OUTPUT CURRENT THAT CAN CAUSE SEVERE SHOCK OR DEATH. MAKE SURE ALL POWER IS SHUT OFF TO THE STARTER-GENERATOR BEFORE REMOVING OR REPLACING TEST EQUIPMENT, INSTRUMENTS, OR ASSEMBLIES. TAKE EXTREME CARE WHEN PERFORMING "LIVE CIRCUIT" TESTS AND FAULT ISOLATION PROCEDURES.

3. Required Test Equipment

Use instruments with accuracy and calibration in compliance with ISO-10012-1.

Equipment Type (Quantity)	Range and Accuracy or Equipment Rating	Generator Test Wiring Diagram Reference
Ammeter, DC (1)	0-500A	DC Ammeter
Drive Test Stand	Capable of driving starter-generator 5500 to 14,000 rpm, and suitable metering to measure speed, voltage, current, and temperature	
HI-Pot Tester(1)	250 VAC rms, 50/60 Hz	
Load Bank, Variable	30 V, 0-160 A	Load Bank
Ohmmeter (1)		

Table 1002 - Test Equipment Requirements and Specifications

© 2000 TRW Aeronautical Systems

Equipment Type (Quantity)	Range and Accuracy or Equipment Rating	Generator Test Wiring Diagram Reference
Power Supply, DC, Variable (1)	0-30 VDC	Power Supply
QAD Mounting Kit	(See IPL for appropraite kit no.)	
Regulator		Regulator
Resistor	1.25 Ohm,	
Shunt , Precision (1)	100 V	
Starter Test Stand	Capable of measuring a locked rotor torque of 20 lb-ft and having a power supply capacity of not less than 500 amperes at 13 VDC.	
Voltmeter, DC (1)	0-3 V	DC Voltmeter, 0-3
Voltmeter, DC (1)	0-30 V	DC Voltmeter, 0-30
Commutation Viewing Adapter		Figure 9007

Table 1002 - Test Equipment Requirements and Specifications (Continued)

4. Test Preparation

Unless otherwise specified, numbers in parentheses () refer to item numbers given in Figure 10001 of the ILLUSTRATED PARTS LIST.

A. Perform an initial inspection.

Perform an initial inspection of the starter-generator in a brightly lit work area to determine its overall condition. Parameters for this initial inspection are given in the CHECK section.

B. Install the starter-generator onto the drive stand.

(1) Turn off all power to the drive stand.

(2) Install the appropriate QAD kit mounting adapter onto the drive stand. Refer to the ILLUSTRATED PARTS LIST for the kit number required.

(3) While supporting the anti-drive end of the starter-generator, align and install the drive end to the mounting adapter.

(4) Make sure that the drive stand and the starter-generator mating splines are correctly engaged.

(5) Install the rim clenching clamp and tighten the self-locking hex nut to 70 in. lbs. (7.9 Nm).

(6) Replace the brush cover IPL 10001 (50) with the Commutation Viewing Adapter, Figure 9007.

© 2000 TRW Aeronautical Systems

(7) Connect cooling equipment for all models requiring external cooling. See Table 1001.

(8) Connect the starter-generator to the test circuit as shown in Figure 1001.

(9) Figure 1002 shows, in schematic diagram form, the electrical connections to the starter-generator.

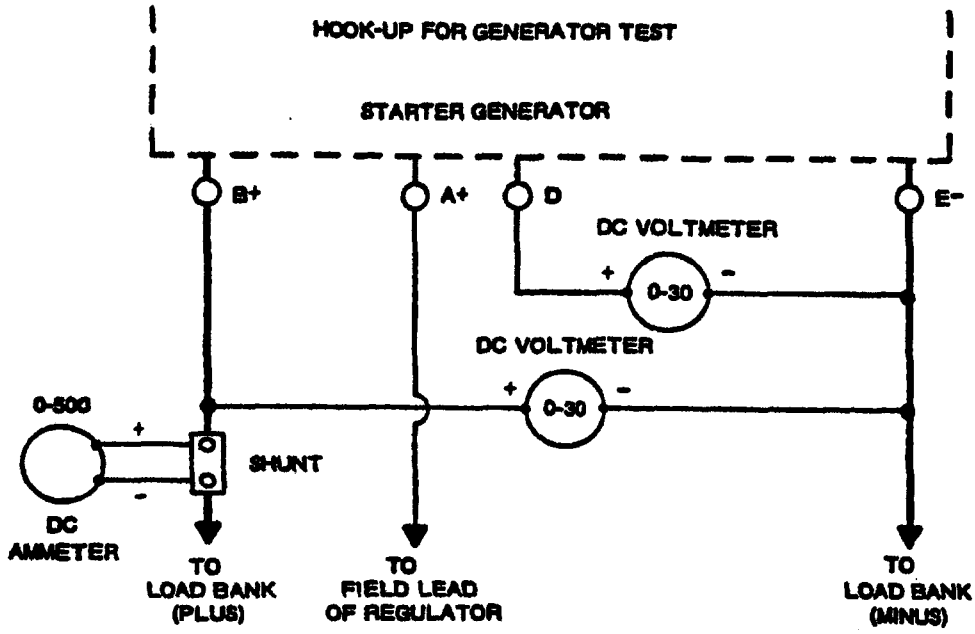

Figure 1001 - 23048 Series DC Starter-Generator Test Set-Up

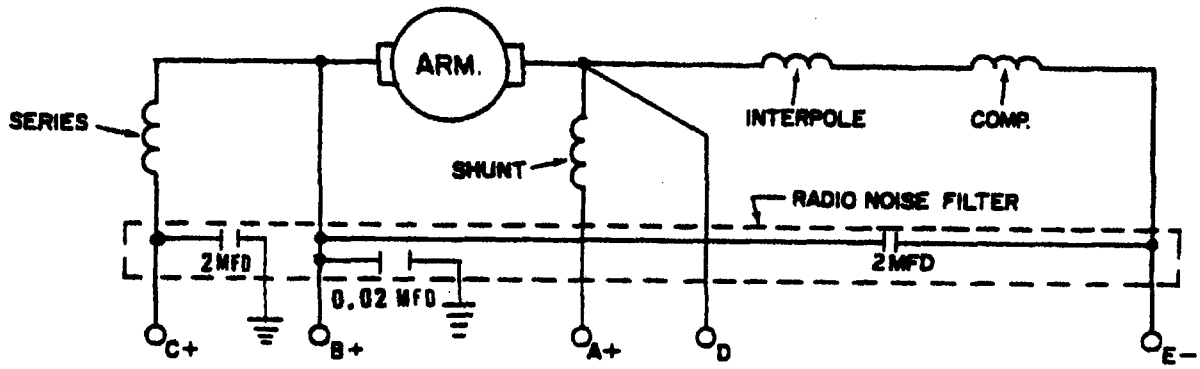

Figure 1002 - Electrical Connections

© 2000 TRW Aeronautical Systems

5. Test Procedures

This paragraph contains the required performance tests and the sequence in which they are to be accomplished.

WARNING: DURING OPERATION, THE STARTER-GENERATOR PRODUCES A VERY HIGH AMPERAGE OUTPUT THAT CAN CAUSE SEVERE SHOCK OR DEATH. MAKE SURE THAT ALL POWER IS SHUT OFF TO THE STARTER-GENERATOR BEFORE REMOVING OR REPLACING COMPONENTS OR ASSEMBLIES. TAKE EXTREME CARE WHEN PERFORMING "LIVE" CIRCUIT TESTS AND TROUBLESHOOTING PROCEDURES.

A. Maximum Speed for Regulation (All models except 23048-017, 23048-020, 23048-022).

NOTE: Perform this test without operational warm-up.

(1) With regulator connected to the starter-generator, operate the starter-generator self-excited with no load, at 13,000 rpm and 30 VDC.

(2) Record the following:

- field current
- commutation
- frame temerature

(3) Shunt field current shall not be less than 0.81 amperes.

(4) Commutation shall be black.

B. Maximum Speed for Regulation (Models 23048-017, 23048-020, 23048-022 only).

NOTE: Perform this test without operational warm-up.

(1) With regulator connected to the starter-generator, operate the starter-generator self-excited with no load, at 13,000 rpm and 30 VDC.

(2) Record the following:

- field current
- B to A voltage
- commutation

(3) Calculate resistance between terminals B and A.

$$\text{B to A Resistance} = \frac{\text{B to A Voltage}}{\text{Field Current}}$$

© 2000 TRW Aeronautical Systems

(4) B to A resistance shall not be greater than 35 ohms.

(5) Commutation shall be black.

C. Continuous Operating Speed and Equalizing Voltage.

(1) With regulator connected to the starter-generator, operate the starter-generator self-excited with no load, at the following RPM and voltage until the frame temperature shows no more than 2°F rise in five (5) minutes.

23048 Model	RPM	VDC	Amp Load	D-E Max.
23048-001, 23048-006	12,000	30	200	Fig. 1003
23048 -004/M/T/TM, 23048-008	12,000	30	200	Fig. 1004
23048-012, 23048-014, 23048-015, 23048-016, 23048-018, 23048-021, 23048-023, 23048-027 and 23048-028	12,000	30	250	Fig. 1005
23048-017	12,000	30	250	Fig. 1006
23048-020	12,000	30	250	Fig. 1007
23048-022	12,000	30	250	Fig. 1008

(2) Record the following

- voltage between terminals D and E,
- field current
- air inlet temperature,
- winding or frame temperature.

(3) Frame temperature shall not exceed air inlet temperature by more than 175 °F (97.2 °C).

(4) The equalizing voltage between terminals D and E shall be a value between lines in figures referenced in table above.

NOTE: In Figures 1003 thru 1008, the left-most graph line is minimum range and the right-most line is maximum range. An acceptable voltage falls between the two lines on the graph.

(5) Commutation should be no more than pinpoints on the edges of the brushes.

(6) If voltage is not within the limits, refer to Table 1009, Fault Isolation Table for possible remedies.

D. Compounding.

(1) Operate starter-generator with the regulator connected, at the following RPM and voltage.

Model	RPM	VDC	Ampere Loads
23048-001, 23048-004/M/T/TM, 23048-006, 23048-008	12,000	30	0, 50, 100, 150, 200
23048-012, 23048-014, 23048-015, 23048-016, 23048-018, 23048-021, 23048-023, 23048-027, 23048-028	NA	NA	NA
23048-017, 23048-020, 23048-022	12,000	30	0, 62.5, 125, 187.5, 250

(2) Apply ampere loads as noted in the table above

(3) Record field current for each load.

(4) Field current must rise with increasing load.

(5) Commutation shall not exceed pinpoint sparking.

E. Minimum Speed for Regulation.

(1) Disconnect forced air supply tube, if used.

(2) Operate the starter-generator for 15 minutes with no load, at the following RPM, voltage, and ampere load (stabilization not required).

Model	RPM	VDC	Amp Load
23048-001, 23048-004/M/T/TM, 23048-006, 23048-008	6500	30	200
All others except 23048-17, 23048-20, 23048-22	6900	30	250
23048-17, 23048-20, 23048-22	NA	NA	NA

(3) Record the following:

- field current
- frame temperature
- voltage between B and A

© 2000 TRW Aeronautical Systems

(4) Field current shall not exceed 8 amperes.

(5) Frame temerature must not exceed air inlet temperature by more than 280°F (155.6°C) for models 23048-012, 23048-014, 23048-015, 23048-016, 23048-018, 23048-021, 23048-023, 23048-027, 23048-028.

(6) Calculate resistance between terminals B and A.

$$\text{B to A Resistance} = \frac{\text{B to A Voltage}}{\text{Field Current}}$$

(7) B to A resistance shall be a minimum of 1.25 ohms.

(8) Commutation shall not exceed pinpoint sparking.

F. Minimum Speed

(1) With regulator connected to the starter-generator, operate the starter-generator self-cooled for 15 minutes, with no load and at the following RPM and voltage.

Model	RPM	VDC	Amp Load
23048-006, 23048-001, 23048-008, 23048-004/M/T/TM, 23048-20	5800	26	200
23048-017	6200	26	200
23048-012, 23048-014, 23048-015, 23048-016, 23048-018, 23048-021, 23048-023, 23048-027, 23048-028	6200	26	250
23048-022	NA	NA	NA

(2) Record the following:

- field current
- frame temperature
- voltage between B and A

(3) Field current shall not exceed 8 amperes.

(4) Calculate resistance between terminals B and A.

$$\text{B to A Resistance} = \frac{\text{B to A Voltage}}{\text{Field Current}}$$

(5) B to A resistance shall be a minimum of 1.25 ohms.

© 2000 TRW Aeronautical Systems

G. Overspeed Test (Models 23048-001, 23048-004/M/T/TM, 24038-006, 24038-008)

(1) With starter-generator hot and field circuit open, operate at 14,000 RPM for five (5) minutes.

(2) Reduce speed to 12,000 RPM at 30 VDC and 200 amperes.

(3) Record the following:

- field current
- frame temperature
- commutation

(4) Commutation shall not exceed pinpoint sparking.

H. Overspeed Test (All models except 23048-001, 23048-004/M/T/TM, 23048-006, 23048-008)

(1) With starter-generator hot and field circuit open, operate at 14,000 RPM for five (5) minutes.

(2) Reduce speed to 12,000 RPM at 30 VDC and 250 amperes.

(3) Record the following:

- field current
- frame temperature
- commutation

(4) Commutation shall not exceed pinpoint sparking.

I. Commutation Test

(1) With forced air supply and regulator connected, operate the generator at 30 VDC for speeds of 6500, 10,000, and 12,000 RPM, and at the following loads.

(a) 0.0 amps, 100 amps, and 200 amps. (Models 23048-001, 23048-004, 23048-006, 23048-008)

(b) 0.0 amps, 125 amps, and 250 amps. (All other models)

(2) Record the worst condition for commutation.

(3) Commutation shall not exceed pinpoint sparking.

J. Dielectric Test.

This test is to be done only to a clean machine after overhaul.

© 2000 TRW Aeronautical Systems

WARNING: **FAILURE TO USE NECESSARY SAFETY PRECAUTIONS WHEN HANDLING HIGH VOLTAGE ELECTRICAL EQUIPMENT DURING HIGH POTENTIAL TESTING CAN CAUSE SERIOUS INJURY OR DEATH TO THE OPERATOR.**

CAUTION: Failure to turn OFF the high potential tester power before connecting or disconnecting high voltage electrical leads can cause serious damage to the generator.

CAUTION: Capacitors imbedded in radio noise filters in terminal block will be damaged if subjected to dielectric test. Always disconnect stator leads from terminal block when conducting dielectric test.

(1) Remove power from tester and remove starter-generator from test stand.

(2) Disconnect starter-generator stator leads from starter-generator terminal block.

(3) Reconnect stator leads to a dummy terminal block.

(4) While still hot from testing, conduct a hi-potential-to-ground test as follows.

(a) Test is performed by connecting hi-pot leads between each terminal block terminal and starter-generator frame.

(b) At each terminal, apply 250 VAC rms, 60 Hz to test connection for one minute, or apply 600 VAC rms, 60 Hz for one (1) second.

(c) No evidence of insulation break-down shall occur as a result of this test.

(5) Disconnect dummy terminal block and reconnect stator leads to starter-generator terminal block.

(6) Install starter-generator onto starter test stand.

K. Starter Tests

(1) Remove power from tester.

(2) Connect starter-generator as shown in Figure 1009.

NOTE: Make sure starter-generator is properly mounted by its flange.

© 2000 TRW Aeronautical Systems

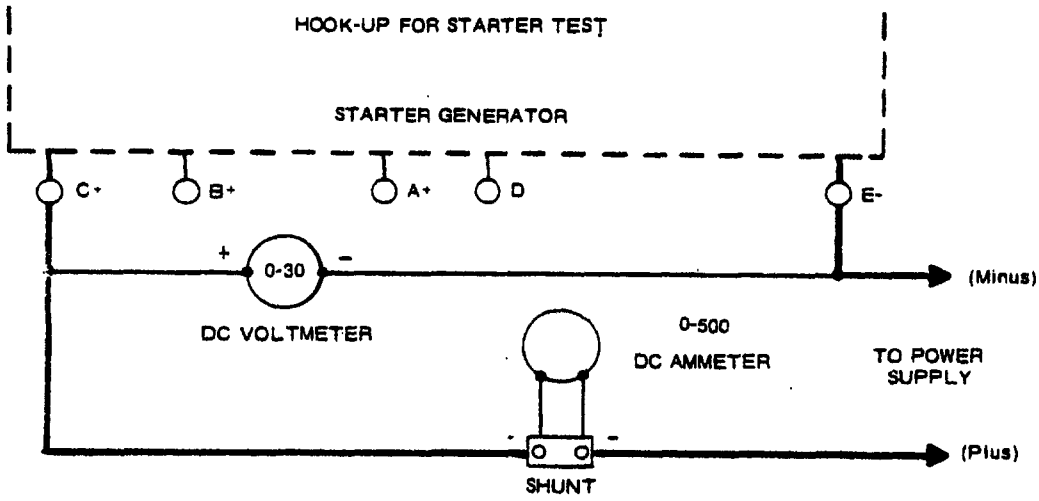

Figure 1009 - Starter Test Set-Up

(3) If applicable in the following table, connect a 1.25 ohm resistor between terminals A and B. Otherwise the A terminal is left open.

(4) Before turning on power supply, set power supply output to minimum.

(5) Turn on power supply.

(6) With no load, gradually increase starter voltage between terminals C and E until voltage reaches values in the following table.

Model	A to B Load Resistor	VDC	Minimum RPM
23048-001, 23048-004/M/T/TM, 23048-006, 23048-008	1.25 Ω	24	3500
23048-012, 23048-014, 23048-015, 23048-016, 23048-017, 23048-020, 23048-021, 23048-022, 23048-023, 23048-027, 23048-028,	None	15	4800

(7) At voltage specified, no-load speed shall be equal to or greater than associated RPM value.

L. Locked Rotor Test

(1) Remove power from tester.

© 2000 TRW Aeronautical Systems

(2) Make sure the starter-generator is securely mounted on the test stand and the rotor is locked.

NOTE: Shunt field (A+) is must be open (no connection) for this test, except for models 23048-001 and 23048-006, which require a 1.25Ω resistor be placed between the A and B terminals.

(3) If testing a model 23048-001 or 23048-006, install a 1.25Ω resistor between the A and B terminals.

(4) Before turning on power supply, set power supply output to minimum.

(5) Turn on power supply.

NOTE: Do not energize generator for more than five (5) seconds.

(6) With no load, gradually increase voltage between terminals C and E until the output torque is 20 ft-lb.

(7) At 20 ft-lb of torque, C-to-E voltage shall not exceed 13 VDC and current shall not exceed 500 amps.

(8) If testing a model 23048-001 or 23048-006, remove the 1.25Ω resistor between the A and B terminals and repeat steps (6) and (7) with the A terminal open. The test results must be the same.

M. Commutator Run-Out.

(1) Remove test stand power and remove the starter-generator from the test stand.

(2) Rotate armature of starter-generator on its own bearings and record commutator total indicated run-out and the maximum bar-to-bar difference.

(a) Total indicated run-out shall not exceed 0.0008 inch.

(b) Bar-to-bar run-out shall not exceed 0.0002 inch (0,0051 mm).

© 2000 TRW Aeronautical Systems

6. Fault Isolation Table

Table 1003 lists faults that may occur during acceptance testing, performance testing, or while in service. For each fault, probable causes are listed along with related corrective actions. When a fault is detected, perform the corrective actions necessary to return the starter-generator to a serviceable condition. A complete acceptance test is required after the corrective action is accomplished.

FAULT	PROBABLE CAUSE	CORRECTIVE ACTION
Unit fails to operate or does not attain normal speed.	Low voltage power source.	Check the power source to make certain that full voltage is being applied to starter-generator terminals.
	Defective switch in power supply line.	Replace switch.
	Damaged armature.	Replace the armature.
	Short circuited or open stator windings.	Replace the stator and housing assembly.
	Improperly seated brushes.	Check brush seats and accomplish brush seating. Refer to REPAIR section for brush seating instructions.
	Eccentric commutator.	Refinish commutator. Refer to REPAIR section.
Excessive sparking at brushes.	Short circuited or grounded field windings.	Replace stator assembly.
	Excessive clearance in bearings or rough bearing races.	Replace bearings.
	Damaged or eccentric commutator	Refinish commutator. Refer to REPAIR section for commutator refinishing instructions.
	Armature out of balance	Balance or replace armature.
	Short circuit in armature windings.	Replace armature.
	Brushes incorrectly installed with top bevel reversed.	Reverse and reseat brushes. Refer to REPAIR section for brush seating instructions..
	Severe overload or short circuit in electrical system.	Locate and correct fault.

Table 1003 - Fault Isolation Table

© 2000 TRW Aeronautical Systems

FAULT	PROBABLE CAUSE	CORRECTIVE ACTION
Excessive sparking at brushes. (Continued)	Brushes sticking in holders.	Free-up brushes. Refer to REPAIR section for brush spring tension checks and brush repacement instructions.
	Weak brush springs.	Replace brush springs.
Noisy operation.	Rough bearings.	Replace bearings.
	Scored or worn drive splines.	Replace drive shaft.
	Armature rubbing in stator.	Repair or replace defective parts.
	Fan blades bent and rubbing.	Replace fan assembly.
Unit vibrates.	Unbalanced armature.	Balance or replace armature. Refer to REPAIR section for armature balancing instructions..
	Excessive run-out of armature bearings.	Replace armature bearings.
	Fan blades rubbing or damaged.	Check and replace fan or fan cover if necessary.
Starter-Generator produces full voltage, but with reversed polarity.	Voltmeter leads reversed.	Connect voltmeter correctly. See Figure 1001.
	Residual magnetism in field poles creates wrong polarity.	Flash the field. Refer to REPAIR section for field flashing instructions.
Starter-Generator overheats (frame temperature 175 degrees F. (97.2°C) in excess of inlet air temperature.	Continuous overload or restricted air inlet.	Check electrical test set-up for grounds, etc. Make corrections as necessary. See Figure 1002.
D to E equalizing voltage not within limits specified in 5.C.(4)	Insufficient cooling air.	Check for air inlet temperature as required per Table 1001.
	Air flow obstruction.	Dirt accumulation in generator ducting. Check ducting and generator air inlet.
	Wrong load applied during testing.	Check testing procedure and correct condition.
Starter-generator fails starting test.	Short circuited or open stator winding.	Replace stator and housing assembly.
	Open circuit in armature.	Replace armature.

DISASSEMBLY

1. Introduction

This section gives the disassembly instructions for Model 23048 family of DC Starter-Generators. Additional disassembly of major components is not necessary unless further disassembly is indicated in the CHECK or TESTING AND FAULT ISOLATION sections. Do not open or desolder permanent connections unless you need to replace worn, damaged or defective parts.

2. Disassembly Tools

In addition to normal shop tools, the tools and materials listed in Table 3001 are needed for generator disassembly

WARNING: BEFORE USING ANY OF THE FOLLOWING MATERIALS, BE AWARE OF ALL HANDLING, STORAGE, AND DISPOSAL PRECAUTIONS RECOMMENDED BY THE MANUFACTURER OR SUPPLIER. FAILURE TO COMPLY WITH THE RECOMMENDATIONS MAY RESULT IN SERIOUS INJURY, PHYSICAL DISORDER, OR DEATH.

Tool Description	Reference
Arbor press	Not illustrated
Anti-drive end end bell hub support	Figure 9002
Dampener hub driver	Figure 9003
Inner race bearing driver	Figure 9006
Leather or plastic mallet	Commercially available
Retaining ring pliers	Commercially available
Bearing puller	Commercially available
Spline Wrench	Figure 9001
Drive end armature shaft adapter	Figure 9004
Anti-drive end armature shaft adapter	Figure 9005

Table 3001 - Disassembly Tools

© 2000 TRW Aeronautical Systems

3. Disassembly

The following procedures detail the basic disassembly of the DC Starter-Generator. Numbers in parentheses () refer to item numbers in Figure 10001 of the ILLUSTRATED PARTS LIST unless otherwise specified.

Do not remove the identification plate (345) or decals (335 or 340) unless damaged or unreadable.

Do not disassemble any of the following components unless they are damaged.

- Bearing and brush support assembly (200)
- Drive-end end bell assembly (115)
- Housing and stator assembly (275)

During disassembly, inspect component parts in accordance with procedures in the CHECK section of this manual.

A. If used, remove preformed packing (90) from drive shaft and discard. (Models 23048-016 and 23048-020)

B. If used, remove air inlet assembly (5) and fan cover (25). (Models 23048-001, 23048-006, 23048-017, 23048-020, 23048-022, 23048-027, 23048-028)

(1) Loosen and remove rim clenching clamp (10) and remove air linlet from end bell.

(2) Twist fan cover (25) to unlock and remove from fan.

NOTE: Do not disassemble air inlet unless damaged. Screws (15) and washers (20) allow disassembly of the air inlet.

C. If used, remove fan cover assembly (30). (Models 23048-004/M/T/TM, 23048-008, 23048-012, 23048-014, 23048-015, 23048-016, 23048-018, 23048-021, 23048-023, 23048-027, 23048-028)

(1) Loosen and remove four screws (40) and remove fan cover from end bell.

D. Remove brush cover (50) from housing (275).

(1) Loosen screw (55) and separate from slot.

(2) Slide brush cover off of anti-drive end of unit.

E. Remove brushes (60) from brush holders (255).

(1) Remove four screws (65) that secure brush and field leads.

(2) Remove four brushes (60) from brush holders.

F. Remove fan assembly (70) from drive shaft (85).

(1) Use a suitable spline wrench (Figure 9001) to hold drive shaft (85).

© 2000 TRW Aeronautical Systems

(2) Remove nut (75) and washer (80).

(3) Remove fan assembly (70) from drive shaft.

G. Remove drive shaft (85) and associated dampener parts.

(1) Tap drive shaft (85) out of driven end of stator and housing assembly by using a plastic or leather hammer.

(2) Remove dampener plate (95) and friction ring (105).

NOTE: Remove dampener hub (100) from drive shaft only if damaged and replacement is necessary.

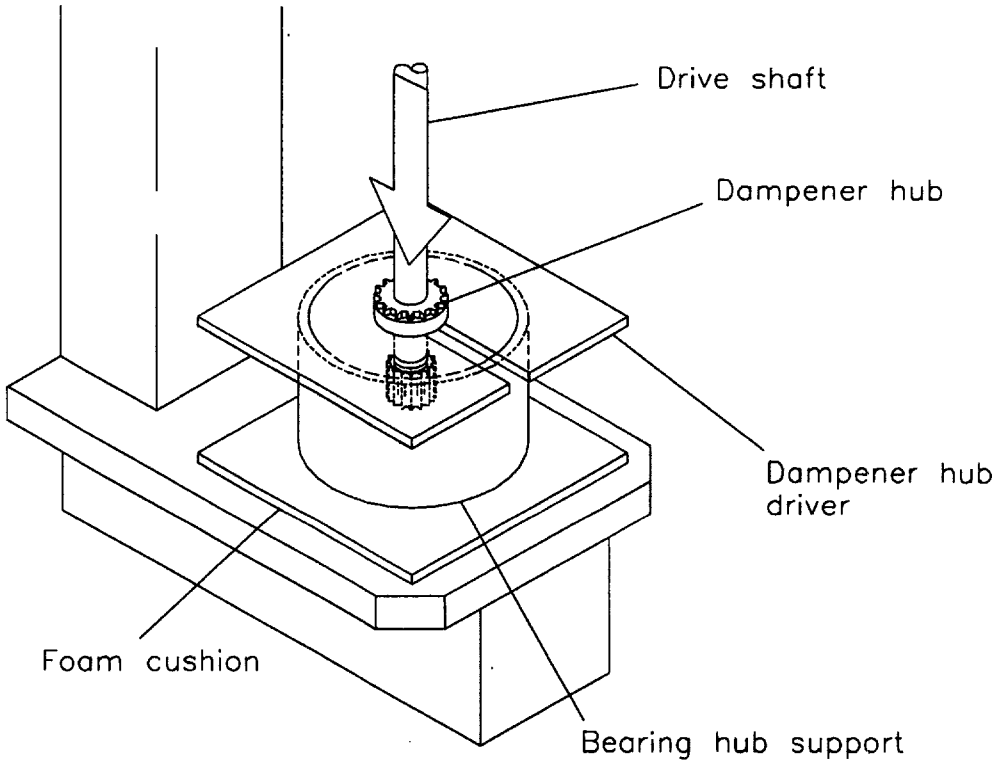

Figure 3001 - Dampener Hub Removal

CAUTION: Put a foam cushion under the drive shaft to prevent the drive shaft from being damaged.

(a) Put a foam cushion and a anti drive end hub support (Figure 9002) on the table of an arbor press.

(b) Position a dampener hub driver (Figure 9003) on the flat side of the dampener hub.

(c) Insert the drive spline through the center of the bearing hub support until the dampener hub driver rests on the bearing hub support.

© 2000 TRW Aeronautical Systems

(d) Press down gently on the anti-drive end of the drive shaft with the arbor press until the dampener hub disengages from the drive shaft.

CAUTION: Tape jaws of bearing puller to prevent damage to chamfered face of back plate during removal.

Figure 3002 - Dampener Backplate Removal

(3) Using a suitable bearing puller, and drive end armature shaft adapter (Figure 9004) carefully remove dampener back plate (110) from armature shaft.

H. Remove drive-end end bell assembly (150) or (155)).

(1) End Bell (150). Remove eight screws (120), washers (125), and lock washers (130) and carefully remove drive-end end bell assembly from stator and housing assembly (275).

(2) End Bell (155). Remove 12 screws (120) and carefully remove drive-end end bell assembly from stator and housing assembly (275).

(3) If repair of end bell is necessary, remove four drive screws (140), four washers (145), and screen (135) from end bell (105).

I. Remove brush holder support assembly (220).

(1) Remove eight screws (205), washers (210), and lock washers (215).

(2) With armature (175) attached, carefully remove armature and bearing and brush holder support assembly from stator and housing assembly.

© 2000 TRW Aeronautical Systems

J. Separate and remove support assembly end bell (270) from armature (175)

(1) Using a hub support, place armature, drive end down, into support until bearing and brush support rest on top of support.

(2) Using a anti-drive end armature shaft adapter, (Figure 9005) press armature (175) out of bearing (190).

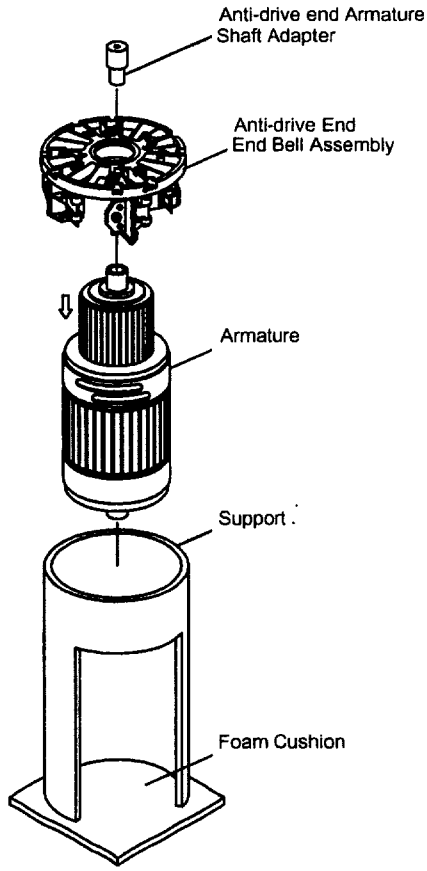

Figure 3003 - Removing the Armature from the Anti-drive End End Bell

K. Disassemble bearing from the armature (175).

(1) At drive end of armature, remove retaining ring (160) and baffle disc (165) from armature shaft.

(2) Using a suitable bearing puller, and drive end armature shaft adapter, remove bearing (170) from armature shaft.

(3) Remove remaining baffle disc (165) from armature shaft.

L. Disassemble brush support assembly (220).

(1) Remove four screws (185) and remove bearing retainer (180).

© 2000 TRW Aeronautical Systems

(2) Using hub support (Figure 9002) and an inner race bearing driver (Figure 9006), press ball bearing (190) out of end bell (270).

(3) Do not remove brush holder assemblies (255) and springs (245) from support assembly unless inspection reveals that replacement of parts is required. If necessary, disassembly is performed as follows.

NOTE: There are studded and studless styles of brush holder. The studded type contains threaded studs (250) that go through the end bell and are secured with a nut (230) on the fan side of the end bell. The studless type uses a mounting bolt (225) that screws into the brush holder through the end bell.

(a) Remove brush holder assemblies (255) by removing bolts (225) or nuts (230), washers (235), non-metallic washers (240), insulation sleeves (260), and insulation plates (265).

(b) Unclip and remove brush springs (245) from brush holder.

M. Disassemble the stator and housing assembly (275).

NOTE: Do not disassemble stator and housing assembly beyond removing the terminal block assembly (280).

(1) If removal of terminal block (190) is necessary, proceed as follows.

(a) Remove the large terminal stud nuts (300) and washers (305) from terminal studs B, C, and E.

(b) Remove the small terminal stud nuts (310) and washers (315) from terminal studs A and D.

(c) Remove two terminal block mounting bolts (285), washers (290), and lock washers (295).

(d) Carefully disconnect stator lead wires from the terminal block studs and position out of the way to allow removal of the terminal block.

N. If damaged, remove decal (335) or identification plate (345).

(1) Remove plate (345) by removing four drive screws (350).

(2) Remove decal (335) using an appropriate scraper and cleaning gum residue with isopropyl alcohol.

© 2000 TRW Aeronautical Systems

CLEANING

1. Introduction

This section provides cleaning procedures for the 23048 Series of DC Starter-Generators.

2. Cleaning Materials

WARNING: BEFORE USING ANY OF THE FOLLOWING MATERIALS, BE AWARE OF ALL HANDLING, STORAGE, AND DISPOSAL PRECAUTIONS RECOMMENDED BY THE MANUFACTURER OR SUPPLIER. FAILURE TO COMPLY WITH THE RECOMMENDATIONS MAY RESULT IN SERIOUS INJURY, PHYSICAL DISORDER, OR DEATH.

Table 4001 lists the materials required to clean the generator.

NOTE: Equivalent materials may be used for those listed in Table 4001.

Material	Description/Specification	Source
Brush	Non-metallic, soft bristle	Commercially available
Cleaning pads/Wiping cloths	Lint-free, soft fabric	Commercially available
Detergent Refer to the material technical data sheet for recommended dilution and application temperature.	Formula 815 GD Applications: (1) Hot tanks - aluminum safe (2) Steam cleaning (3) Pressure sprayers (4) Ultrasonic cleaning	The Brulin Corporation Indianapolis, IN
The detergent used must not be destructive to the finish or material of the part.	Formula 1990 GD Application: (1) Spray wash cleaning	The Brulin Corporation Indianapolis, IN
Isopropyl alcohol	TT-I-735, Grade A See the **WARNING** above before using this material. Flash point: 53°F (11.7°C), flammable Refer to the material safety data sheet for the material for additional safety information.	Commercially available

Table 4001 - Cleaning Materials

© 2000 TRW Aeronautical Systems

Material	Description/Specification	Source
Cleaning solvent	Fed. Spec P-D-680 Type I - Stoddard Solvent Type II - 140°F Solvent See the **WARNING** above before using this material. Flash Point: Type I, 100°F Type II, 138°F Refer to the material safety data sheet for the material for additional safety information.	Commercially available

Table 4001 - Cleaning Materials (Continued)

3. Cleaning Procedures

Before performing the CHECK, REPAIR, ASSEMBLY, acceptance testing, and final inspection procedures, the components of the generator must be cleaned, rinsed, and dried. All signs of moisture, oil, and other contamination must be removed from the internal structure of the generator to make sure all parts and circuits function correctly. Clean the starter-generator according to the following procedures.

WARNING: WHEN USING COMPRESSED AIR FOR CLEANING OR DRYING, DO NOT EXCEED 30 PSIG (207 kPa). WEAR GOGGLES OR A FACE SHIELD TO PROTECT EYES. DO NOT AIM COMPRESSED AIR AGAINST SKIN OR BODILY OPENINGS. CARELESS USE OF COMPRESSED AIR CAN RESULT IN SERIOUS INJURY OR DEATH.

A. Blow out dirt particles.

(1) Put the air inlet, metal dampener components, drive shaft, armature assembly, drive-end and anti-drive-end end bells, and the stator and housing assembly into a ventilated air spray booth.

(2) Blow away all evidence of dirt with clean, dry, compressed air.

B. Clean the parts and assemblies.

(1) With the exception of the armature and the stator and housing, wash the parts using one or more of the approved cleaning procedures outlined in Table 4002.

CAUTION: DO NOT SOAK ALUMINUM OR IVD COATED PARTS FOR MORE THAN 30 MINUTES. A CHEMICAL REACTION MAY RESULT THAT WILL LEAVE THE PART IN AN UNSERVICEABLE CONDITION.

NOTE: Remove brushes before cleaning.

Procedure	Instruction
Spray	**CAUTION:** Make sure to limit the pressure used to clean parts. High pressure may remove or damage surface coatings, connections, and insulation.
	(1) Put the parts into a high pressure spray wash booth.
	(2) Spray the parts with a solution of detergent and water. Refer to the material technical data sheet for the recommended dilution of water and detergent and solution temperature.
Ultrasonic	**CAUTION:** Do not put aluminum parts into an ultrasonic tank. Plating, black oxide coatings, and dimensional tolerances can be damaged by ultrasonic cleaning.
	(1) Put the parts into the ultrasonic cleaning tank.
	(2) Allow the parts to soak for 15 to 20 minutes maximum. NOTE: Restrict immersion time of armature and stator to 10 minutes.
	(3) Remove all evidence of dirt with a soft bristle brush or cleaning rag.
Agitation	(1) Put all the parts in an agitation tank. NOTE: Restrict immersion time of armature and stator to 10 minutes.
	(2) Agitate until all evidence of dirt can be removed from the parts with a soft bristle brush or cleaning rag.
Soak	(1) Put all the parts into a soaking tank. NOTE: Restrict immersion time of armature and stator to 10 minutes.
	(2) Soak the parts until all evidence of dirt can be removed with a soft bristle brush or cleaning rag.

Table 4002 - Cleaning Procedures

(2) Rinse the parts.

NOTE: Use minimal pressure to rinse the parts.

(a) Put the parts into a pressure spray wash booth.

(b) Use soft bristle brush to clean foreign material from slots between commutator bars.

(c) Flush the parts using hot water or steam.

© 2000 TRW Aeronautical Systems

(3) Repeat the applicable cleaning procedure as necessary until the parts are clean and free of dirt.

(4) Dry the parts.

WARNING: WEAR INSULATED GLOVES AND OBSERVE ALL SAFETY PRECAUTIONS WHEN HANDLING HEATED PARTS TO AVOID PERSONAL INJURY.

(a) Put the cleaned parts into an oven at a temperature of 200°F (93.3°C) for 2 hours.

(b) Remove any remaining moisture from the parts with a dry, lint-free cloth.

WARNING: ISOPROPYL ALCOHOL IS TOXIC AND FLAMMABLE; DO NOT USE NEAR OPEN FLAMES, WELDING AREAS, OR ON HOT SURFACES. INHALATION OF VAPORS CAN CAUSE DROWSINESS, DIZZINESS, AND HEADACHE. CONTACT WITH SKIN CAN CAUSE IRRITATION. USE IN A WELL- VENTILATED AREA IF HANDLING LARGE QUANTITIES [1 GALLON (3.79L) OR MORE].

(c) Check each part for dirt by wiping with isopropyl alcohol on a clean, lint-free cloth.

C. Clean the armature and stator and housing.

(1) Use isopropyl alcohol with a soft bristle brush to remove oily film from the armature and stator and housingl components. A spray mist application is acceptable if immediately followed by wiping and drying.

WARNING: WHEN USING COMPRESSED AIR FOR CLEANING OR DRYING, DO NOT EXCEED 30 PSIG (207 KPA). WEAR GOGGLES OR A FACE SHIELD TO PROTECT EYES. DO NOT AIM COMPRESSED AIR AGAINST SKIN OR OTHER BODILY OPENINGS. CARELESS USE OF COMPRESSED AIR CAN RESULT IN SERIOUS INJURY OR DEATH.

(2) Dry the parts with cleaning cloths or clean, dry, low velocity, filtered compressed air, 30 psig (207 kPa) maximum pressure.

(3) Put the cleaned parts into an oven at a temperature of 200°F (93.3°C) for 2 hours.

© 2000 TRW Aeronautical Systems

CHECK

1. Introduction

This section provides initial and detailed component inspection procedures for generators returning from service for scheduled and unscheduled maintenance. Complete an initial inspection of the starter-generator before beginning any testing or disassembly. The results of this inspection will determine if a starter-generator is in satisfactory condition for a verification test or if it will need further disassembly, inspection, and/or replacement of parts.

This section provides figures and tables with information that is needed to perform a satisfactory inspection of the starter-generator components. During an overhaul of the starter-generator, you must examine all primary components to find out if they are serviceable.

A part must be rejected if wear or damage is outside the acceptance limits of if the part is not serviceable.

2. Inspection Tools and Materials

WARNING: BEFORE USING ANY OF THE FOLLOWING MATERIALS, BE AWARE OF ALL HANDLING, STORAGE, AND DISPOSAL PRECAUTIONS RECOMMENDED BY THE MANUFACTURER OR SUPPLIER. FAILURE TO COMPLY WITH THE RECOMMENDATIONS MAY RESULT IN SERIOUS INJURY, PHYSICAL DISORDER, OR DEATH.

The following tools and materials are needed to examine the starter-generator.

Tool/Material Description	Reference
Dynamic Balancer (TRW Aeronautical Systems, Lucas Aerospace SPD 1001)	Commercially available
Gauge Block	Commercially available
High Potential Tester	Table 1002
Isopropyl Alcohol	Table 4001
Lint-Free Cloth	Commercially available
Ohmmeter	Table 1002
Soft Bristle Brush	Commercially available
Surface Plate	Commercially available

Table 5001 - Inspection Tools

© 2000 TRW Aeronautical Systems

3. General Information

Check acceptance limits for individual components are found in the FITS AND CLEARANCES section. Parts that do not meet the acceptance limits are to be discarded. Use the following procedures for all inspections.

A. Inspect the generator and it's components for:

- signs of corrosion
- chipped enamel
- nicks, cracks, dents, scratches
- loose or defective attaching parts
- distortion
- discoloration due to heat or friction
- crossed or stripped threads
- rounded, stripped, or uneven wear of drive shaft spline
- loose or damaged air inlet or fan assembly

B. Inspect electrical connections and wiring for:

- loose or defective attaching parts
- chafing, cracking, or burning of wire insulation
- corroded contacts or terminals
- signs of electrical arcing

4. Initial Inspection

NOTE: If damage is found during inspection, stop the inspection immediately and begin further disassembly of the generator using the instructions in the DISASSEMBLY section.

A. Visually inspect the starter-generator in a brightly lit work area per paragraph 3A.

(1) If shipping or handling damage is evident, stop the inspection immediately and notify your supervisor.

(2) If operational damage is found, record which components need to be repaired or replaced and continue the inspection.

B. Clean the exterior of the starter-generator.

© 2000 TRW Aeronautical Systems

WARNING: **ISOPROPYL ALCOHOL IS TOXIC AND FLAMMABLE; DO NOT USE NEAR OPEN FLAMES, WELDING AREAS, OR ON HOT SURFACES. INHALATION OF VAPORS CAN CAUSE DROWSINESS, DIZZINESS, AND HEADACHE. CONTACT WITH SKIN CAN CAUSE IRRITATION. USE IN A WELL-VENTILATED AREA IF HANDLING LARGE QUANTITIES [1 GALLON (3.79L) OR MORE].**

(1) Clean the surfaces of the generator using a lint-free cleaning cloth moistened with isopropyl alcohol.

(2) If needed, loosen any dust particles or grease with a soft bristle brush.

C. Inspect the starter-generator per paragraphs 3A and 3B.

(1) If drive shaft spline is visibly damaged, discontinue inspection and proceed to DISASSEMBLY.

D. While facing the drive end, turn the drive shaft counterclockwise.

(1) The armature assembly should rotate with no scraping or bearing noise.

(2) If armature assembly will not turn, or if indications of internal damage can be heard, discontinue inspection and proceed to DISASSEMBLY.

E. Examine the seating between the housing and the brush support (270) and drive-end end bell.

(1) Make sure that the brush support (270) and end bell (115) are fully seated with the housing and stator assembly.

(2) Make sure that all attaching hardware is in place and tight.

5. Replacing Service Parts and Common Hardware

A. Service Parts

CAUTION: Failure to replace armature shaft bearings during overhaul may result in premature starter-generator failure.

Always replace the armature shaft bearings during overhaul, regardless of their condition.

B. Common Hardware

(1) During repair and overhaul, replace all exposed hardware and flat washers that are damaged, deformed, corroded, or have other apparent defects.

(2) Always replace retaining rings and lock washers, when removed during overhaul.

6. Inspection of Generator Parts and Assemblies

A. Overhaul Inspection

At overhaul, examine all primary components of the starter-generator.

© 2000 TRW Aeronautical Systems

B. Repair Inspection

For repair, examine only those components that have been disassembled for repair. Do not disassemble any component for inspection unless given instructions to do so in this section or in the TESTING AND FAULT ISOLATION section.

C. The following terms are referenced in this section.

- DISCARD
  If damage to the part is found or the part is outside of the acceptance limits in the FITS AND CLEARANCES section, the part must be removed and replaced with a new one.

- REPAIR
  If damage to the part is found or the part is outside of the acceptance limits in the FITS AND CLEARANCES section, the part can be replaced by a procedure found in the REPAIR section.

- DISASSEMBLE
  If damage to the part is found or part of the assembly is outside of the acceptance limits in the FITS AND CLEARANCES section, you can disassemble the part from the assembly and repair or replace the damaged part(s).

- REPLACE
  If damage that causes a part to be outside of the acceptance limits in the FITS AND CLEARANCES section or there is no repair procedure for that part, replace the part. Retain the following parts to submit for remanufacture: armature assembly and stator and housing assembly.

7. Inspection of Parts and Assemblies

The following procedures are the basic instructions for examining parts and assemblies of the starter-generator. Perform visual inspections under high-intensity lighting and 7 to 10 power magnification. Refer to FITS AND CLEARANCES for applicable component wear tolerances.

Unless otherwise specified, numbers in parentheses ( ) after assembly or component names refer to item numbers found in figure 10001 in the ILLUSTRATED PARTS LIST. Qualify individual parts and subassemblies according to the following procedures.

- Repair or replace defective components as instructed.
- Inspect only those components that are products of disassembly for repair.
- Do not perform disassembly for inspection, unless further disassembly is indicated through testing, troubleshooting, and fault isolation.

© 2000 TRW Aeronautical Systems

A. Identification plate (50)

(1) Visually examine the plate for cracks, dents, nicks, and scratches. Transfer the information from the old identification plate to a replacement identification plate. DISCARD the damaged identification plate.

(2) Make sure that you can read all information on the identification plate. Retain the identification plate if information is difficult to read. Transfer the information from the old identification plate to a replacement identification plate. DISCARD the old identification plate.

(3) Make sure the drive screws (350) are tight and in place. Remove and discard the loose drive screws.

B. Fan Covers (25) or (30) and Brush Cover (50)

(1) Visually examine all surfaces for dents or broken welds. DISCARD if damage is found.

(2) (Models 23048-012, 23048-014, 23048-015, 23048-016, 23048-018, 23048-023 only) Inspect gasket (45) in fan cover (30) for being missing or damaged. Replace gasket if necessary IAW instructions in the REPAIR section.

C. Brushes (45) and Brush Holder Assemblies (195)

(1) Visually examine the brush holders for cracks, warpage, and broken springs.

(a) REPLACE broken springs and damaged brush holders.

(2) Visually examine the brushes for cracks, chips, frayed leads, and loose rivets or loose connections. DISCARD brushes if damaged.

(3) REPLACE brushes if remaining allowable wear will be exceeded before the next overhaul. (See Figure 5001.) Seat new brushes in accordance with instructions in the REPAIR section.

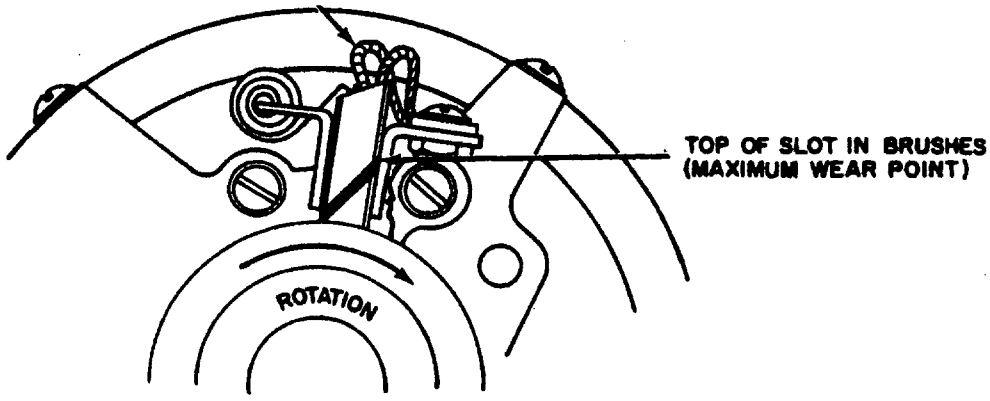

Figure 5001 - Brush Wear Check

© 2000 TRW Aeronautical Systems

(4) Check brush spring tension.

(a) Insert a small loop of wire under tang of spring.

(b) Attach a tension gauge to the wire loop.

(c) Pulling up on the tension gauge, raise the brush until the position of spring tang approximates distance it would be raised if lower end of brush were flush with lower end of brush holder assembly.

(d) In this position, the spring tension should be between 40 and 55 ounces.

(e) Take an average of several readings. If spring tension is not within this range, REPLACE the spring.

(f) Measure brush spring tension in remaining brush holders for uniformity.

D. Air Inlet (5)

(1) Visually examine all surfaces for dents, nicks, and scratches that reduce the clearance between the sidewall and fan cover (25).

(a) REPAIR the air inlet if damage is found.

(b) DISCARD the air inlet if damage extends to the mounting or inlet flanges.

(2) Visually examine the mounting and inlet flanges for gouging, scoring, or glazing.

(a) REPAIR the flange(s) if damage is found.

(b) DISCARD the air inlet if damage cannot be repaired.

E. Fan Assembly (70)

(1) Visually examine for cracks or a bent condition. If single piece die cast fan is used, inspect for chipped, damaged, or broken blades.

(a) DISCARD the fan if damage is found.

(2) Visually examine that trailing edge of blade(s) do not protrude beyond locating shoulder of fan hub more than limits in FITS AND CLEARANCES.

(a) DISCARD fan if protrusion is excessive.

F. Drive shaft (85) and Dampener hub (100)

(1) Visually examine all surfaces for cracks.

(a) DISASSEMBLE the drive shaft and dampener hub if damage is found.

(b) DISCARD the damaged part(s).

(2) Visually examine all surfaces for dents, nicks, and scratches.

© 2000 TRW Aeronautical Systems

(a) REPAIR the drive shaft and dampener hub if minor damage is found.

(3) Visually examine the drive spline and the dampener hub for rounding, stripping, or uneven wear (Figure 5002).

(a) DISASSEMBLE the drive shaft and dampener hub if damage is found.

(b) DISCARD the damaged part(s).

(4) Visually examine the screw threads for crossed or stripped threads.

(a) REPAIR the threads if two or less threads are damaged.

(b) DISASSEMBLE the drive shaft and dampener hub if two or more threads are damaged and DISCARD the drive shaft.

(5) Measure the drive spline diameter over two gauge pins. DISASSEMBLE the drive shaft and dampener hub if the diameter is not within the limits in the FITS AND CLEARANCES section. DISCARD the drive shaft.

(6) Perform a magnetic particle inspection per ASTM-E1444.

(a) DISCARD the drive shaft and dampener hub if damage is found.

NOTE: Examine the drive shaft and dampener hub mating surfaces only if the dampener hub was removed from the drive shaft.

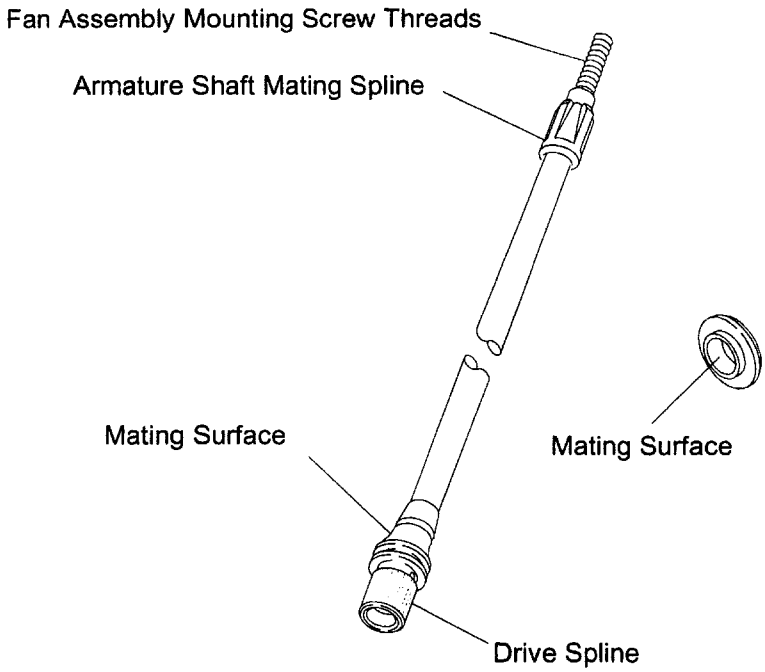

Figure 5002 - Drive Shaft and Dampener Hub

© 2000 TRW Aeronautical Systems

(7) Visually examine the mating surfaces for gouging, scoring, or glazing.

(a) DISCARD the drive shaft and dampener hub if damage is found.

G. Friction Ring (105)

(1) Visually examine all surfaces for cracks.

(a) DISCARD the friction ring if damage is found.

(2) Measure the friction ring (Figure 5003).

(a) DISCARD the friction ring if the thickness is not within the limits in the FITS AND CLEARANCES section.

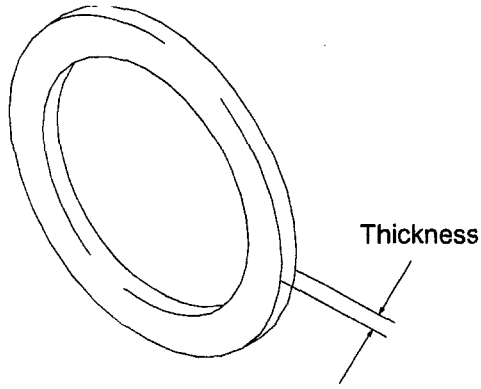

Figure 5003 - Friction Ring Thickness Check

© 2000 TRW Aeronautical Systems

H. Dampener Plate (95)

(1) See Figure 5004. Visually examine all surfaces for cracks or warpage.

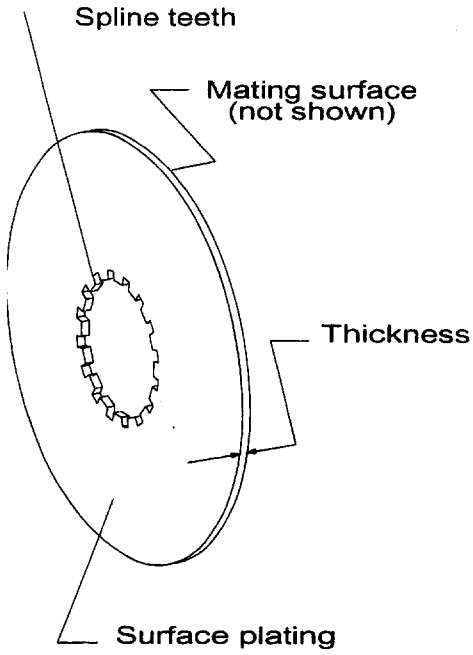

Figure 5004 - Dampener Plate Checks

(a) DISCARD the dampener plate if damage is found.

(2) Visually examine all surfaces for dents, nicks, and scratches.

(a) REPAIR the dampener plate if minor damage is found.

(3) Visually examine the mating surfaces for gouging, scoring, or glazing.

(a) REPAIR the dampener plate if minor damage is found.

(4) Visually examine the spline teeth for rounding, stripping, or uneven wear.

(a) DISCARD the dampener plate if damage is found.

(5) Measure the dampener plate thickness.

(a) DISCARD the dampener plate if it is not within acceptance limits in the FITS AND CLEARANCES section.

(6) Measure the distance between the pins of the spline teeth.

(a) DISCARD the dampener plate if the distance between pins exceeds the acceptance limits in the FITS AND CLEARANCES section.

(7) Perform a magnetic particle inspection per ASTM-E-1444.

© 2000 TRW Aeronautical Systems

(a) DISCARD the dampener plate if damage is found.

I. Dampener Backplate (110)

(1) See Figure 5005. Visually examine all surfaces for cracks.

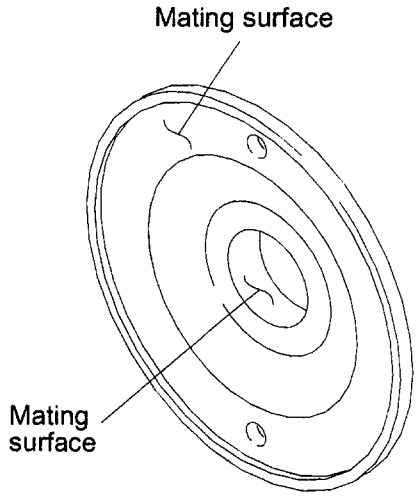

Figure 5005 - Dampener Backplate Checks

(a) DISCARD the dampener backplate if damage is found.

(2) Visually examine all surfaces for dents, nicks, and scratches.

(a) REPAIR the dampener backplate if minor damage is found.

(3) Visually examine the mating surfaces for gouging, scoring, or glazing.

(a) DISCARD the dampener backplate if damage is found.

(4) Perform a magnetic particle inspection per ASTM-E-1444.

(a) DISCARD the dampener plate if damage is found.

J. Drive-End End Bell Assembly (21 and 21A)

(1) Visually examine all end bell surfaces for cracks, warpage, dents, nicks, and scratches.

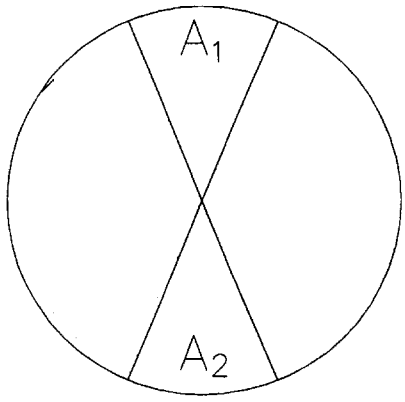
(a) DISASSEMBLE the bearing support assembly if damage is excessive.

(b) DISCARD the damaged part(s).

(2) Visually examine the following end bell mating surfaces for gouging, scoring, glazing, and fretting.

© 2000 TRW Aeronautical Systems

- Bearing liner
- Mating with the stator and housing assembly
- Mating with the mounting adapter



(a) REPAIR the end bell if damage is found.

(b) DISCARD the damaged end bell if repair is not possible.

(3) Measure the bearing liner diameter 'A' using a gage and equipment with an accuracy of 0.00004 in. (1 micron).

(a) REPAIR the drive-end end bell if the liner diameter exceeds 0.0001 in. (0.0025 mm) above the maximum limit in the FITS AND CLEARANCES section.

(b) REPLACE the end bell assembly if the bearing liner cannot be repaired.

$A_1 + A_2$ = 25% of circumference

During overhaul inspection, a bearing liner may be considered to be acceptable if up to 25% of the circumference is 0.0001 in. (0.0025 mm) above the maximum limit in the FITS AND CLEARANCES section. This criteria does not apply to new or repaired bearing liners.

K. Baffle Discs (165)

(1) Visually examine all surfaces for dents, nicks, and scratches.

(a) REPAIR the baffle disc if minor damage is found.

(2) Visually examine the mating surfaces for wear, gouging, scoring, or glazing.

© 2000 TRW Aeronautical Systems

(a) DISCARD the baffle disc if damage is found.

L. Armature Assembly (175)

(1) Visually inspect for worn, pitted or burned commutator bars.

(a) REPAIR commutator in accordance with commutator refinishing instructions in REPAIR section, if necessary.

(2) Visually inspect commutator for bar to bar concentricity and concentricity to the armature shaft.

(a) REPAIR commutator in accordance with commutator refinishing instructions in REPAIR section if concentricity is not within limits in FITS AND CLEARANCES.

(3) Visually inspect for the following indications of damage or overheating:

- lamellar coating of exposed windings cracked or flaking;
- missing, melted, or deformed insulators.

(a) REPLACE armature assembly if indications of damage or overheating are found.

(4) Check winding retainer bands for damage and tightness of fit.

(a) REPLACE armature assembly if damaged or movement of retainer bands can be detected.

(5) Visually inspect bearing journals for galling, spalling, scoring, discoloration, or other indications of bearing spin on shaft.

(a) If indications are found, check surface roughness with your fingernail.

(b) REPLACE armature assembly if surface roughness can be felt.

(6) Measure bearing journal diameters.

(a) REPLACE armature assembly If journal diameters are not within limits of FITS AND CLEARANCES.

(7) Magnetic particle inspect exposed ends of armature shaft per ASTM-E-1444.

(a) REPLACE armature assembly If indications of cracks are found.

(8) Check armature assembly balance.

(a) If balance measurements exceed limits of FITS AND CLEARANCES, balance armature assembly per applicable REPAIR instructions.

(9) Conduct a high potential test between the armature shaft and the commutator risers as follows.

© 2000 TRW Aeronautical Systems

WARNING: **FAILURE TO USE NECESSARY SAFETY PRECAUTIONS WHEN HANDLING HIGH VOLTAGE ELECTRICAL EQUIPMENT DURING HIGH POTENTIAL TESTING CAN CAUSE SERIOUS INJURY OR DEATH TO THE OPERATOR.**

CAUTION: Failure to turn OFF the high potential tester power before connecting or disconnecting high voltage electrical leads can cause serious damage to the starter-generator.

(a) Connect one hi-pot lead to the armature shaft and the other lead to a commutator risers.

(b) Apply 220 VAC rms, 60 Hz to test connection for 5 seconds.

(c) No evidence of insulation breakdown shall occur as a result of this test.

(d) REPLACE armature assembly If breakdown is evident.

(10) Conduct a high potential test between each of the two winding retaining bands and a commutator riser as follows.

(a) Connect one hi-pot lead to one of the armature winding retaining bands and the other lead to a commutator risers.

(b) Apply 220 VAC rms, 60 Hz to test connection for 5 seconds.

(c) No evidence of insulation breakdown shall occur as a result of this test.

(d) REPLACE armature If breakdown is evident.

(e) Repeat the procedure for the other retaining band.

M. Stator and Housing Assembly (275)

(1) Visually inspect exposed housing surfaces for cracks, chips, and dents.

(a) REPLACE assembly if cracks, chips, or dents cause loss or permanent deformation of base material.

(2) Visually inspect for the following indications of overheating:

- varnish coating of exposed windings cracked or flaking;
- missing, melted, or deformed insulators.

(a) REPLACE assembly if indications of overheating are found.

(3) Check for tight fit of pole shoes and damage to windings in housing.

(a) REPLACE assembly if stator parts are loose or windings are damaged.

(4) Check terminal block for cracks, and loose or damaged terminal studs.

© 2000 TRW Aeronautical Systems

(a) REPLACE terminal block if damaged.

CAUTION: Capacitors imbedded in radio noise filters in the operational terminal block will be damaged if subjected to dielectric test. Always disconnect stator leads from the operational terminal block and connect to a dummy terminal block when conducting dielectric test.

(5) Disconnect starter-generator stator leads from stator and housing terminal block.

(6) Reconnect stator leads to a dummy terminal block.

(7) Conduct a hi-potential test between frame and terminal A on the dummy terminal block as follows.

WARNING: FAILURE TO USE NECESSARY SAFETY PRECAUTIONS WHEN HANDLING HIGH VOLTAGE ELECTRICAL EQUIPMENT DURING HIGH POTENTIAL TESTING CAN CAUSE SERIOUS INJURY OR DEATH TO THE OPERATOR.

CAUTION: Failure to turn OFF the high potential tester power before connecting or disconnecting high voltage electrical leads can cause serious damage to the starter-generator.

(a) Connect hi-pot leads between terminal A and starter-generator frame.

(b) Apply 220 VAC rms, 60 Hz to test connection for 5 seconds.

(c) No evidence of insulation break-down shall occur as a result of this test.

(d) REPLACE stator and housing assembly if breakdown is evident.

(8) Disconnect hi-pot tester.

(9) Use an ohmmeter to check for an open circuit between negative field lead E and positive terminal A.

(a) REPLACE stator and housing assembly if continuity is not indicated.

(10) Disconnect dummy terminal block and reconnect stator leads to starter-generator terminal block.

N. Brush Holder Support Assembly (220)

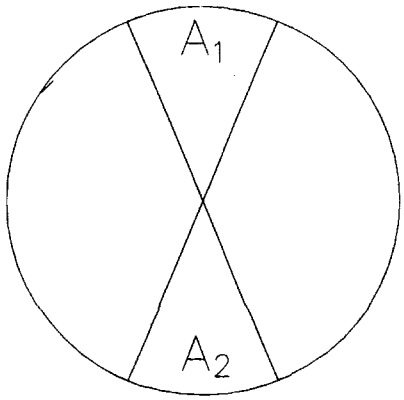
(1) Visually examine all brush holder support (220) surfaces for cracks, warpage, dents, nicks, and scratches.

(a) DISASSEMBLE the brush holder support assembly if damage is excessive.

(b) DISCARD the damaged part(s).

© 2000 TRW Aeronautical Systems

(2) Visually examine the following brush holder support mating surfaces for gouging, scoring, glazing, and fretting.



- Bearing liner
- Mating with the stator and housing assembly

(a) REPAIR the brush holder support if damage is found.

(b) DISCARD the damaged brush holder support if repair is not possible.

(3) Measure the bearing liner diameter 'A' using a gage and equipment with an accuracy of 0.00004 in. (1 micron).

(a) REPAIR the drive end bearing support if the liner diameter exceeds 0.0001 in. (0.0025 mm) above the maximum limit in the FITS AND CLEARANCES section.

$A_1 + A_2$ = 25% of circumference

During overhaul inspection, a bearing liner may be considered to be acceptable if up to 25% of the circumference is 0.0001 in. (0.0025 mm) above the maximum limit in the FITS AND CLEARANCES section. This criteria does not apply to new or repaired bearing liners.

(b) REPLACE the brush holder support assembly if the bearing liner cannot be repaired.

(4) Conduct a high potential test between the end bell casting and each brush holder assembly as follows.

© 2000 TRW Aeronautical Systems

WARNING: **FAILURE TO USE NECESSARY SAFETY PRECAUTIONS WHEN HANDLING HIGH VOLTAGE ELECTRICAL EQUIPMENT DURING HIGH POTENTIAL TESTING CAN CAUSE SERIOUS INJURY OR DEATH TO THE OPERATOR.**

CAUTION: Failure to turn OFF the high potential tester power before connecting or disconnecting high voltage electrical leads can cause serious damage to the starter-generator.

(a) Connect hi-pot leads between end bell casting (270) and each brush holder assembly (255).

(b) Apply 220 VAC rms, 60 Hz to test connection for 5 seconds.

(c) No evidence of insulation break-down shall occur as a result of this test.

(d) DISASSEMBLE and inspect non-metallic washer (240), insulation sleeve (260), and insulation plate (265) if breakdown occurs.

(e) REPLACE defective parts as necessary.

O. Bearing Retainer (180)

(1) Visually inspect bearing retainer for cracks, chips, and dents.

(a) DISCARD retainer if cracks, chips, or dents cause permanent deformation.

(2) Place bearing retainer on surface plate to check for warping.

(a) DISCARD retainer if warpage is indicated.

P. QAD Kit End Bell (365)

(1) Measure the height of the three locating dowels.

(a) Replace pin if not to the height in the FITS AND CLEARANCES.

8. Terminology

Table 5002 lists the definitions of terms used to describe damage conditions.

Term	Definition	Probable Cause
Crack	A break in material	Severe stress from overloading or shock; possible extension of a scratch
Dent	A small, smoothly rounded depression	A sharp blow or excessive pressure

Table 5002 - Terminology

© 2000 TRW Aeronautical Systems

Term	Definition	Probable Cause
Fretting/ Corrosion	Surface chemical reaction that results in discoloration, a layer of oxide, or rust	Vibration between mating surfaces
Galling	Transfer of metal from one surface to another	Result of localized lubrication breakdown between sliding surfaces
Glazing	Smoothing and creep of a surface	Result of localized lubrication breakdown between sliding surfaces
Gouging	Removal of surface metal, typified by rough and deep depressions	Protruding objects, incorrectly aligned
Nick	A sharp bottomed depression that may have rough outer edges	Dropping, banging
Rounding	Removal of surface metal at corners or dulling of edges	Result of abrasion, vibration, or incorrect tolerances
Scoring	Deep scratch following a path of part travel	Result of localized lubrication breakdown between sliding surfaces
Scratch	A very shallow furrow or irregularity, usually longer than wide	Movement of a sharp object across the surface
Short	Evidence of sparking, arcing, or high current	The result when two current carrying conductors are connected by a path of negligible resistance
Stripped Thread	Thread of a nut, stud, bolt, or screw damaged by tearing away parts of the thread	Incorrect installation of thread pitch or size
Tear	Parting of material	Excessive tension, caused by an external force
Wear	Slow removal of parent material, wear may not be visible to the naked eye	Result of abrasive substances contacting rolling surfaces and acting as a lapping compound

Table 5002 - Terminology (Continued)

THIS PAGE INTENTIONALLY LEFT BLANK

© 2000 TRW Aeronautical Systems

REPAIR

1. Introduction

This section provides authorized repair instructions for the 23048 family of DC Starter-Generators. Repairs are limited to:

- Repairing damaged surfaces
- Restoring the surface coatings of parts and assemblies
- Repairing damaged threads
- Restoring bearing liners and journals
- Repairing and refinishing the armature commutator
- Balancing the armature
- Brush seating
- Replacing fan cover gasket

Authorized repairs also include approved procedures by reference. Repair operations not referring to instructions given in this section are not authorized by TRW Aeronautical Systems, Lucas Aerospace.

CAUTION: The use of parts, materials, or processes not authorized by TRW Aeronautical Systems, Lucas Aerospace for the maintenance or overhaul of the starter-generator may affect continued flightworthiness or invalidate its certification.

2. Repair Tools

In addition to normal shop tools, the following tools are needed for starter-generator repair.

CAUTION: Steel wool and abrasives containing iron or iron oxide shall not be used at any time during repair operations.

Tool Description	Reference
Dynamic balancer	TRW Aeronautical Systems, Lucas Aerospace, SPD 1001
End mill [0.25 in (6.4 mm) diameter]	Commercially available
India stone	Commercially available
Tension gauge	Commercially available
Thread chasers	Commercially available

Table 6001 - Repair Tools

© 2000 TRW Aeronautical Systems

3. Repair Materials

Materials used for repair are listed in Table 6002. Equivalent materials may be used.

WARNING: BEFORE USING ANY OF THE FOLLOWING MATERIALS, BE AWARE OF ALL HANDLING, STORAGE, AND DISPOSAL PRECAUTIONS RECOMMENDED BY THE MANUFACTURER OR SUPPLIER. FAILURE TO COMPLY WITH THE RECOMMENDATIONS MAY RESULT IN SERIOUS INJURY, PHYSICAL DISORDER, OR DEATH.

Item	Description/Specification	Source
Alcohol, Isopropyl	TT-I-735, Grade A	Commercially available
Brush, Soft Bristle	N/A	Commercially available
Coating, Acrylic	MIL-I-406058/HumiSeal 1B31, Type AR	Chase Corp. Woodside, NY
Coating, Conversion	MIL-C-5541, Class 3 Alodine 1200 or equivalent	Commercially available
Compound, Thread Locking	Loctite, Grade D (MIL-S-22473).	Loctite Corporation Aurora, IL
Enamel, Red Insulating, Baking	Synthite ER-41	John C. Dolph Co. Box 41 Monmouth, NJ 08852
Oil, Lubricating	MIL-L-6085	Commercially available
Pads, Cleaning	Lint-free cotton	Commercially available
Paint, Gloss Enamel	Urethane per MIL-C-85285B Amendment 2 Type 1	Commercially available
Primer, Zinc Chromate	TT-P-1757, Composition G, Color Y	Commercially available
Sandpaper	5/0 or finer	Commercially available
Sandpaper	400/600 grit	Commercially available
Sealing Compound, Pipe Joint and Thread, Lead Free	Gasoila, Soft Set	Federal Process Co. Cleveland, OH
Solvent, Cleaning	MIL-PRF-680 Type I - Stoddard Solvent Type II -140°F Solvent	Commercially available
EnSolve, Cleaning Solvent	Ensolve Cleaning Solvent	Enviro Tech International, Inc. Alameda, CA 94501

Table 6002 - Repair Materials

© 2000 TRW Aeronautical Systems

4. Surface Repair

Repair corroded or damaged surfaces of parts that have qualified for repair according to the inspection criteria in the CHECK section.

A. Retreating

WARNING: ISOPROPYL ALCOHOL IS TOXIC AND FLAMMABLE; DO NOT USE NEAR OPEN FLAMES, WELDING AREAS, OR ON HOT SURFACES. INHALATION OF VAPORS CAN CAUSE DROWSINESS, DIZZINESS, AND HEADACHE. CONTACT WITH SKIN CAN CAUSE IRRITATION. USE IN A WELL-VENTILATED AREA.

(1) Thoroughly clean all surfaces to be retreated or repainted with isopropyl alcohol.

WARNING: CHEMICAL CONVERSION MATERIALS ARE EXTREMELY DANGEROUS. OBSERVE FIRE AND SAFETY PRECAUTIONS. CONTACT WITH COMBUSTIBLE MATERIALS MAY CAUSE EXPLOSION OR FIRE. ALWAYS WEAR RESPIRATORY PROTECTION, PROTECTIVE APRON, GLOVES, AND SAFETY GLASSES. AVOID DIRECT CONTACT WITH SKIN OR EYES. USE IN A WELL-VENTILATED AREA.

(2) Chemical film treat all previously painted bare metal surfaces with chemical film solution MIL-C-5541.

(3) Rinse thoroughly with hot water and dry with filtered and dried compressed air.

WARNING: ZINC CHROMATE PRIMER IS FLAMMABLE. DO NOT USE NEAR OPEN FLAMES, NEAR OPEN WELDING AREAS, OR ON HOT SURFACES. CONTACT WITH SKIN CAN CAUSE IRRITATION. VAPORS CAN CAUSE EYE IRRITATION, DIZZINESS, AND HEADACHE. USE IN A WELL-VENTILATED AREA.

(4) Apply a thin wet coat of zinc chromate primer.

(a) The coating should be smooth and semi-transparent.

(b) A full hiding coat is too heavy.

(c) Dry film thickness should be 0.3 to 0.6 mil.

(5) Air dry until tack-free.

© 2000 TRW Aeronautical Systems

B. Repainting

WARNING: GLOSS ENAMEL IS FLAMMABLE AND TOXIC. DO NOT USE NEAR OPEN FLAMES, WELDING AREAS, OR ON HOT SURFACES. CONTACT WITH LIQUIDS OR VAPOR CAN CAUSE SKIN OR EYE IRRITATION, DIZZINESS, AND HEADACHE. WEAR RESPIRATORY PROTECTION AND RUBBER GLOVES. USE IN A WELL-VENTILATED AREA.

(1) Apply gloss black enamel to a dry film thickness of 0.75 to 1.25 mils.

(2) Oven cure at 300°F for one hour.

5. Thread Repair

CAUTION: Do not use a thread cutting die. Unrepairable damage can result from using a thread cutting die.

(1) Repair damaged threads with a thread chaser.

(2) Remove any remaining sharp edges or burrs with an india stone.

WARNING: LUBRICATING OIL IS FLAMMABLE AND CAN BE HARMFUL IF SWALLOWED. DO NOT USE NEAR OPEN FLAMES OR SPARKS. USE IN A WELL VENTILATED AREA.

(3) Apply a light coating of lubricating oil to repaired threads to prevent corrosion.

6. Bearing Liner and Journal Restoration

A. Bearing Support (Drive End) and End Bell (Anti-Drive End) Bearing Liner Restoration

(1) If the bearing liner is worn beyond the limits in the FITS AND CLEARANCES section, restoration may be possible by electro deposition plating in accordance with TRW Aeronautical Systems, Lucas Aerospace Standard Practice Document (SPD) 1000.

NOTE: If bearing liner is out of concentricity, machine the liner within concentricity before plating.

(2) Maximum allowable single thickness of plating shall be 0.01 in. (0.254 mm), or 0.02 in. (0.508 mm) measured across a diameter.

(3) After plating, the bearing liner diameter must be ground to dimensions listed in the FITS AND CLEARANCES section.

(4) Liquid penetrant inspect the bearing support assemblies in accordance with (IAW) MIL-STD-6866, method A or B, sensitivity level 2 or higher. Acceptance criteria shall be IAW MIL-STD-1907, Table II, Grade C.

(5) Replacement of the drive end bearing support bearing liner is permitted if restoration is not possible. Refer to paragraph 7.

© 2000 TRW Aeronautical Systems

(6) If bearing liner cannot be repaired IAW these instructions, the entire end bell assembly must be replaced.

(7) Return the faulty end bell assembly to TRW Aeronautical Systems, Lucas Aerospace in Aurora, Ohio for examination and possible repair.

B. Bearing Journals

(1) If the armature shaft bearing journals are worn beyond the limits in the FITS AND CLEARANCES section, restoration may be possible by electro deposition plating in accordance with TRW Aeronautical Systems, Lucas Aerospace Standard Practice Document (SPD) 1000.

NOTE: If armature shaft is out of concentricity, machine the shaft within concentricity before plating.

(2) Maximum allowable thickness of plating shall be 0.01 in. (0.254 mm), or 0.02 in. (0.508 mm) measured across a diameter.

(3) Armature shaft bearing journals may be plated to final dimensions, or overplated then ground to final dimensions listed in the FITS AND CLEARANCES section.

(4) Liquid penetrant inspect the armature journals IAW MIL-STD-6866, method A or B, sensitivity level 2 or higher. Acceptance criteria shall be IAW MIL-STD-1907, Table II, Grade C.

7. Repair Procedures

A. Repairing Armature Commutator.

If inspection reveals that commutator is rough, pitted, scored, or burned, refinish in a lathe that is accurately set up and adjusted. Install 03-6010-18 bearing (170) into commutator turning fixture (Figure 9008).

(1) Remove only the material necessary to clean and true-up the commutator surface.

(2) To ensure uniformity of surface finish, a diamond tipped cutting tool with a maximum tool tip radius of 0.006 in. (0.1524 mm), including tool wear, is recommended for making the final surface cut on the commutator.

(3) Replace armature if commutator diameter must be refinished to a diameter of less than 2.055 in (52.197 mm).

(4) Hold commutator diameter concentric with bearing journals within 0.0008 in. (0.02032 mm) T.I.R., with bar-to-bar concentricity within 0.0002 in. (0.00508 mm).

B. Undercutting the Mica.

If the depth of undercut remaining after the turning operation has been completed is less than 0.045 in. (1.143 mm), the mica between the commutator bars should be undercut to 0.035 to 0.045 in. (0.889 to 1.143 mm) wide, by 0.060 in. (1.524 mm) ± .005 (0,127 mm) deep.

© 2000 TRW Aeronautical Systems

(1) Use a triangular scraper to remove all excess mica, sharp edges, and burrs from between the commutator bars.

(2) Use a bristle brush to remove metal chips and mica particles from the slots between the commutator bars.

(3) Check for concentricity as described in Paragraph 7A.

C. Armature Balancing.

After commutator refinishing, check the armature for proper balance as specified in the FITS AND CLEARANCES section. If a balance correction is required, mill the stainless steel retaining bands at each end of the lamination stack until the proper degree of balance is obtained.

(1) Use lathe setup or vee-blocks.

(2) Inspect the armature assembly as instructed in the CHECK section.

(3) Check the armature assembly balance in two planes (one plane at each bearing journal) on a balancing machine.

(4) Record balance measurements and compare to the maximum out of balance condition in the FITS AND CLEARANCES section.

(5) If the recorded armature balance is greater than the maximum out of balance condition, use the following procedure to achieve proper armature balance.

NOTE: Although balance measurements are acquired at the bearing journals, proper armature balance is achieved by removing material from the retaining bands.

(a) Clean up the armature shaft centers with a steel wire brush to ensure proper centering of the armature on the machine setup.

(b) Install the armature assembly onto the vertical mill machine setup.

WARNING: THE MACHINE OPERATOR MUST BE FULLY TRAINED IN THE SAFE OPERATION OF A VERTICAL MILL. THIS INCLUDES THE USE OF ALL SAFETY DEVICES AND PRECAUTIONS. THE USE OF APPROVED EYE PROTECTION DURING MACHINE OPERATION IS REQUIRED.

(c) Make mill cuts in retaining bands of the armature to achieve proper balance.

1 Mill cut specifications are 0.031 in. (0.7874 mm) deep maximum, and 0.25 in. (0.635 mm) wide.

2 Drive end retaining band cuts shall be at least 0.120 in. (3.048 mm) from the band edge

© 2000 TRW Aeronautical Systems

3 Only two 0.25 in. (0.635 mm) wide cuts are permitted in each band to maintain adequate hoop strength.

4 Existing cuts may be extended, or new cuts may be added in line with existing cuts.

(d) Heat the armature assembly from 350°F to 450°F (177°C to 232°C) for 2 hours minimum.

WARNING: USE EXTREME CAUTION WHEN HANDLING HOT PARTS. USE THE APPROPRIATE SAFETY AND HANDLING EQUIPMENT WHEN HANDLING HOT PARTS. CONTACT BETWEEN EXPOSED SKIN AND HOT PARTS CAN CAUSE SEVERE BURNING.

(e) While the armature assembly is still hot, overspeed the armature assembly for 5 minutes at 14,000 rpm.

(f) Re-balance the assembly if required.

(6) Replace the armature assembly if proper balance cannot be achieved.

D. Brush Seating.

NOTE: New brushes must be properly seated on the commutator surface before starting the performance tests. Failure to properly seat the brushes can affect the results obtained during test after overhaul.

New brushes installed at overhaul should be sanded to seat them properly on the commutator surface. Seating the brushes using the following procedure.

(1) See Figure 6001. Make sure that brush leads are arranged over the brush springs as shown to prevent brush hang-up.

(2) Using a stiff wire hook, lift each brush spring far enough to allow the brush to be pulled from holder.

(3) Raise the brush in the holder until the brush spring comes in contract with the side of the brush and can hold the brush in position off of commutator.

(4) Place a strip of 5/0 or finer sandpaper, slightly wider than the width of the brush, around the commutator with the sand side out.

(5) Cut the sandpaper strip to one inch longer than the commutator circumference.

(6) Secure one end of the sandpaper strip to the commutator surface with masking tape so that the taped end leads in the direction of rotation. The other end remains loose and overlaps taped end.

(7) Lower the brushes in place against the sandpaper, and carefully hand-rotate the armature counterclockwise, as viewed from the drive end.

(a) Continue to rotate until a full seat is obtained on each brush.

© 2000 TRW Aeronautical Systems

(b) Do not sand excessively.

(8) Remove the sandpaper.

(9) Remove all carbon dust with dry, compressed air.

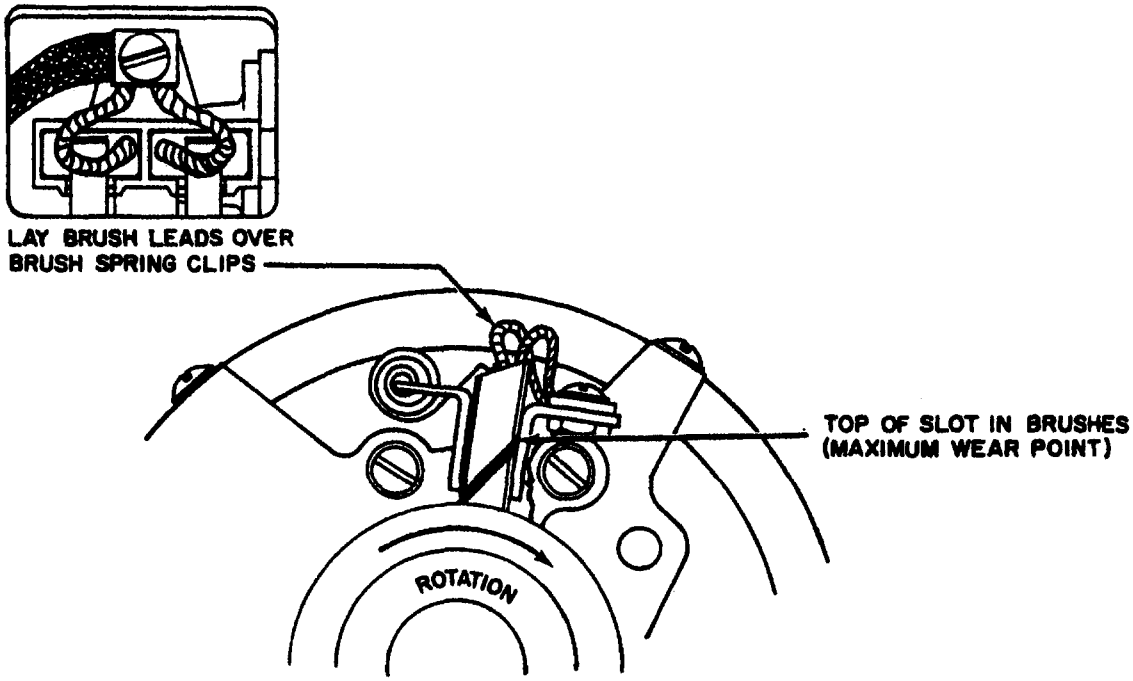

Figure 6001 - Correct Position of Brushes and Springs

E. Flashing the Field.

Starter-Generators with reversed polarity in the output voltage may be corrected by flashing the field as outlined below.

CAUTION: Do not flash the field while starter-generator is in operation.

(1) Disconnect leads to external voltage regulator.

(2) Connect negative terminal of a 1.5-to-6.0 VDC battery to terminal "E".

(3) Connect the positive terminal of battery to one side of a knife switch.

(4) Connect the other side of knife switch to terminal "A".

(5) Close the knife switch for 5 seconds.

© 2000 TRW Aeronautical Systems

(6) Open the switch and disconnect it from battery.

NOTE: If flashing the field fails to correct generator polarity, check for incorrect connections or defective field circuit.

F. Replacing Fan Cover Gasket (45).

NOTE: In this procedure, all surfaces to be bonded shall be clean and free of grease, oil, and other contaminants. All solvent must be completely evaporated before applying adhesives or primers.

(1) Remove old gasket bonding residue from fan cover (30) using a stiff wire brush.

WARNING: ENSOLVE SOLVENT CAN PRODUCE EYE AND SKIN IRRITATION. HIGH CONCENTRATIONS ARE IRRITATING TO THE RESPIRATORY TRACT AND EYES. MAINTAIN ADEQUATE VENTILATION. WEAR NEOPRENE GLOVES AND SAFETY GOGGLES/FULL FACE SHIELD. DO NOT USE NATURAL RUBBER GLOVES.

(2) Clean gasket area on fan cover using EnSolve and a lint-free cloth.

(3) Apply a thin coat of silicone adhesive primer to gasket area of fan cover. Allow to dry for 30 to 45 minutes at room temperature.

(4) Lightly coat mounting surface of gasket with silicone rubber sealant.

(5) Place gasket on fan cover.

NOTE: Only contact pressure between the gasket and fan cover is required for bonding. Best adhesion is obtained with a glue line of 15 mm (approximately).

(6) Clean excess sealant from fan cover before curing, using EnSolve and a lint-free cloth.

(7) Allow sealant to cure for 24 hours at room temperature with a minimum of 20% relative humidity.

ASSEMBLY

1. Introduction

This section gives the assembly instructions of 23048 Series of DC Starter-Generators. Assemble the Starter-Generator in a clean work area, away from machining or other metal removing operations. Make sure to clean all parts in accordance with the procedures in the CLEANING section before final assembly.

2. Assembly Tools

In addition to normal shop tools, the tools listed in Table 7001 are needed for unit assembly.

Tool Descriptions	Reference
Arbor press	Not illustrated
Support, Anti-Drive End End Bell	Figure 9002
Dampener plate driver	Figure 9010
Inner race bearing driver	Figure 9006
Outer race bearing driver	Figure 9006
Leather or plastic mallet	Commercially available
Retaining ring pliers	Commercially available
Spline Wrench	Figure 9001
Armature Support	Figure 9009
Driver, Dampener Backplate	Figure 9010
Support Stator, Vertical	Figure 9011
Support Stator, Horizontal	Figure 9012

Table 7001 - Assembly Tools

© 2000 TRW Aeronautical Systems

3. Assembly Materials

Table 7002 lists the materials required to assemble the generator. Equivalent materials may be used

WARNING: BEFORE USING ANY OF THE FOLLOWING MATERIALS, BE AWARE OF ALL HANDLING, STORAGE, AND DISPOSAL PRECAUTIONS RECOMMENDED BY THE MANUFACTURER OR SUPPLIER. FAILURE TO COMPLY WITH THE RECOMMENDATIONS MAY RESULT IN SERIOUS INJURY, PHYSICAL DISORDER, OR DEATH.

Item	Description/Specification	Source
EnSolve Solvent	EnSolve Solvent	Enviro Tech International Inc. Alameda, CA 94501
Alcohol, Isopropyl	TT-I-735, Grade A	Commercially Available
Coating, Acrylic	MIL-I-406058/HumiSeal 1B31, Type AR	Chase Corp. Woodside, NY
Coating, Conversion	Alodine 1200 or equivalent MIL-C-5541, Class 3	Commercially Available
Compound, Thread Locking	Loctite, Grade D (MIL-S-22473).	Loctite Corporation Aurora, IL
Enamel, Red Insulating, Baking	Synthite ER-41	John C. Dolph Co. Box 41 Monmouth, NJ 08852
Paper	Protective/MIL-B-121A, grade A, type II, class I	National Paper Walton Hills, OH United Packaging Cleveland, OH
Primer, Silicone Adhesive	A-4094	Dow Corning Corp. Midland, MI
Primer, Zinc Chromate	TT-P-1757, Composition G, Color Y	Commercially Available
Sealant, Silicone Rubber	Silastic RTV 732, Black	Dow Corning Corp. Midland, MI
Compound, Thread Sealing	Gasoila	Federal Process Co. Cleveland, OH

Table 7002 - Assembly Materials

© 2000 TRW Aeronautical Systems

4. Assemble Stator and Housing Assembly (275)

The following procedure details the assembly of the stator and housing assembly. Numbers in parentheses () refer to item numbers given in Figure 10002 of the ILLUSTRATED PARTS LIST unless otherwise specified.

A. Install terminal block assembly (280) if it was removed at disassembly.

(1) Position terminal block on stator housing (275) with stator leads positioned on terminal block studs.

(2) Install two bolts (285), lock washers (290) and flat washers (295) to secure terminal block to stator housing.

(3) Secure stator leads B, C, and E to large terminals with washers (305) and nuts (300).

(4) Secure stator leads A and D to small terminals with washers (315) and nuts (310).

5. Assemble Brush Holder Support Assembly (200)

The following procedure details the assembly of the brush holder support assembly. Numbers in parentheses () refer to item numbers given in Figure 10001 of the ILLUSTRATED PARTS LIST unless otherwise specified.

A. Install new bearing into end bell (270).

NOTE: When installing new bearings, make sure that the part mark on the outer race faces in toward the armature.

(1) Using an arbor press, hub support (Figure 9002), and outer race bearing driver (Figure 9006), press new ball bearing (190) into end bell (270).

WARNING: THREAD SEALING COMPOUND IS FLAMMABLE. DO NOT USE NEAR OPEN FLAMES OR SPARKS. USE IN A WELL-VENTILATED AREA.

(2) Apply thread sealing compound to threads of four screws (185).

(3) Install bearing retainer (180) over bearing (190) in end bell and secure with screws (185).

B. Install brush holder (255) on end bell (270).

NOTE: There are studded and studless styles of brush holder. The studded type contains threaded studs (250) that go through the end bell and are secured with a nut (230) on the fan side of the end bell. The studless type uses a mounting bolt (225) that screws into the brush holder through the end bell.

CAUTION: Do not wind spring further than necessary to install in position, or spring may take a permanent set, and produce insufficient pressure on brush.

© 2000 TRW Aeronautical Systems

(1) Install two brush springs (245) on brush holder assembly (255). Each spring must be wound approximately 3/4 turn before installation on brush holder spring support bar.

(2) Insert insulation sleeve (260) into each of two brush holder mounting holes in end bell (270).

(3) If using the studless brush holder, place a flat washer (235), and non-metallic washer (240) on each of two bolts (225) and insert bolts through insulation sleeves in end bell (270).

(4) Install insulation plate (265).

(a) For studded brush holders, position insulation plate (265) on brush holder studs and position brush holder studs into insulation sleeves in end bell. Place a non-metallic washer (240) and flat washer (235) on each of the studs and secure brush holder with nut (230). Tighten nuts 25 to 30 in-lbs (2.83 to 3.39 Nm).

(b) For studless brush holders, position insulation plate on mounting bolts (205) coming through the end bell.

WARNING: THREAD LOCKING COMPOUND IS HIGHLY FLAMMABLE AND TOXIC. DO NOT USE NEAR OPEN FLAMES OR SPARKS. USE IN A WELL-VENTILATED AREA.

(5) Coat threads of bolts (225) with thread locking compound.

(6) Position brush holder assembly (255) against insulation plate (265) and thread bolts (225) into brush holder assembly.

(7) Align (rotate) brush support assembly in alignment fixture per SPD 1004.

(8) Tighten bolts 25 to 30 in-lbs (2.83 to 3.39 Nm).

C. Verify insulation of brush holders by performing hi-pot test.

WARNING: FAILURE TO USE NECESSARY SAFETY PRECAUTIONS WHEN HANDLING HIGH VOLTAGE ELECTRICAL EQUIPMENT DURING HIGH POTENTIAL TESTING CAN CAUSE SERIOUS INJURY OR DEATH TO THE OPERATOR.

(1) Electrically connect all brush holders together.

(2) Connect hi-pot test leads between brush holders and end bell.

(3) Apply 250 volts for one minute.

(4) No evidence of insulation breakdown, arcing or sparking is acceptable. Failure can be detected by fluctuations and/or steady increase in leakage current.

(5) Turn off and disconnect hi-pot tester.

© 2000 TRW Aeronautical Systems

D. Coat brush holder components with red insulating enamel.

- edge of base on brush holder assembly (255),
- non-metallic washers (240),
- head of bolts (225), or nuts (230)
- washers (235),
- insulation plate (265),
- and any chipped area of end bell (270) .

(1) Permit red insulating enamel to air dry, or bake support assembly in an oven for one hour at a temperature of 150°F (66°C).

WARNING: WEAR INSULATED GLOVES AND OBSERVE ALL SAFETY PRECAUTIONS WHEN HANDLING HEATED PARTS TO AVOID PERSONAL INJURY.

(2) Remove support assembly from oven and allow to cool to room temperature.

6. Final Assembly of DC Starter Generator

The following procedure details the final assembly of the starter-generator. Numbers in parentheses () refer to item numbers in Figure 10001 of the ILLUSTRATED PARTS LIST unless otherwise specified.

A. Install baffle discs (165), bearing (170),and retaining ring (160) on armature shaft (175).

(1) Install baffle disc (165) on drive end of armature shaft, with recessed area of baffle disc facing the armature.

(2) Support armature in an arbor press using an armature support (FIgure 9009).

NOTE: In the following step, make sure the bearing part mark on the outer race faces toward the armature windings.

(3) Using a armature support (Figure 9009) and inner race bearing driver (Figure 9006), press a new bearing (170) onto drive end of armature shaft. Bearing must be fully engaged against baffle disc (160). Refer to Figure 7001.

(4) Install remaining baffle disc (165) on drive end of armature shaft, with recessed area of baffle disc facing away from armature.

(5) Install and fully seat retaining ring (160) into groove on armature shaft. Refer to Figure 7002

© 2000 TRW Aeronautical Systems

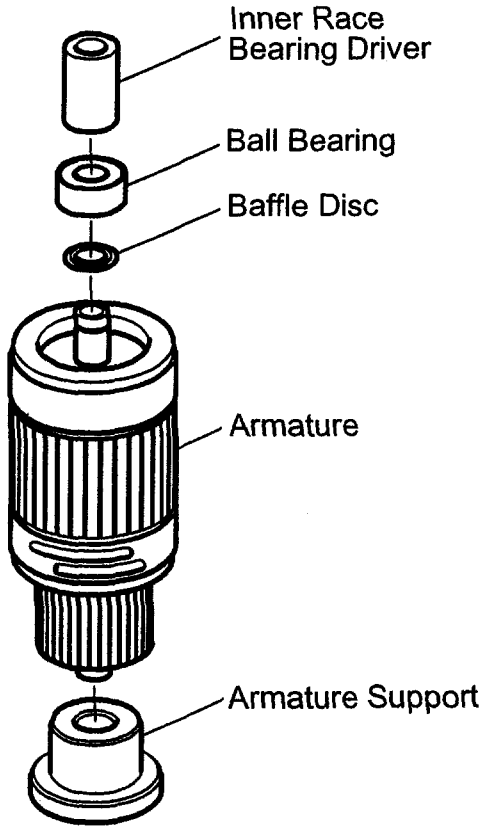

Figure 7001 - Baffle Disc and Ball Bearing Installation

© 2000 TRW Aeronautical Systems

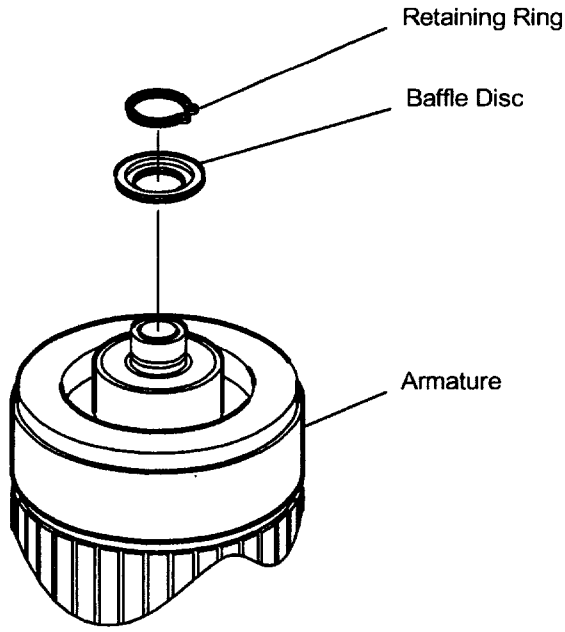

Figure 7002 - Baffle Disc, Spacer, Retaining Ring Installation

B. Press a ball bearing (190) into the bearing and brush support assembly (200).

(1) Set an anti-drive end hub support on the arbor press table.

(2) Set the bearing and brush support assembly, brush holder side down, on the anti-drive end hub support.

(3) Set a ball bearing onto the bearing liner of the bearing and brush support assembly.

(4) Set an outer race bearing driver onto the ball bearing.

(5) Press the ball bearing into the bearing liner of the bearing and brush support assembly.

(6) Make sure that the ball bearing is fully seated against the inner lip of the bearing liner.

© 2000 TRW Aeronautical Systems

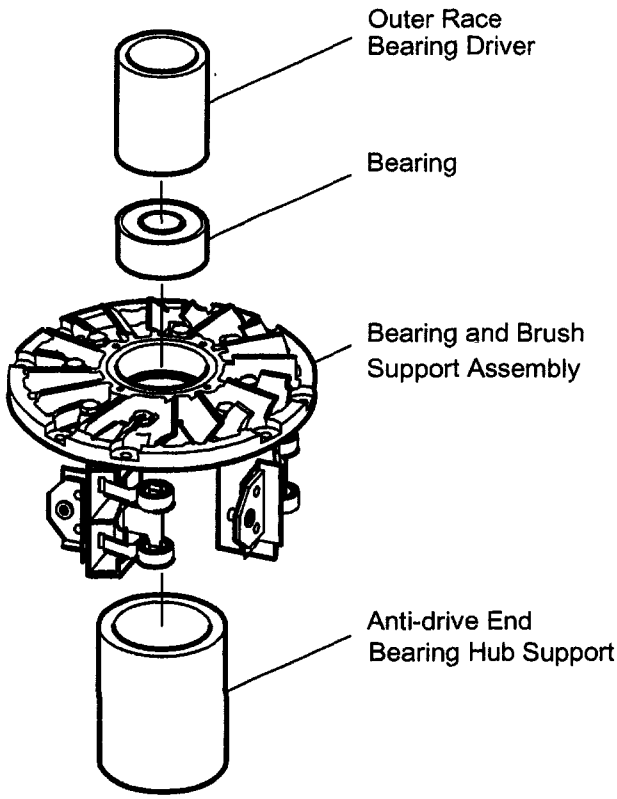

Figure 7003 - Install Bearing in Bearing and Brush Support Assembly

C. Attach the bearing retainer (180) to the bearing and brush support assembly (200).

WARNING: SEALING COMPOUND IS FLAMMABLE. DO NOT USE NEAR OPEN FLAMES, NEAR WELDING AREAS, OR ON HOT SURFACES.

(1) Apply sealing compound to the threads of the screws (185).

(2) Attach the bearing retainer to the bearing and brush support assembly using the attaching screws. See Figure 7004.

© 2000 TRW Aeronautical Systems

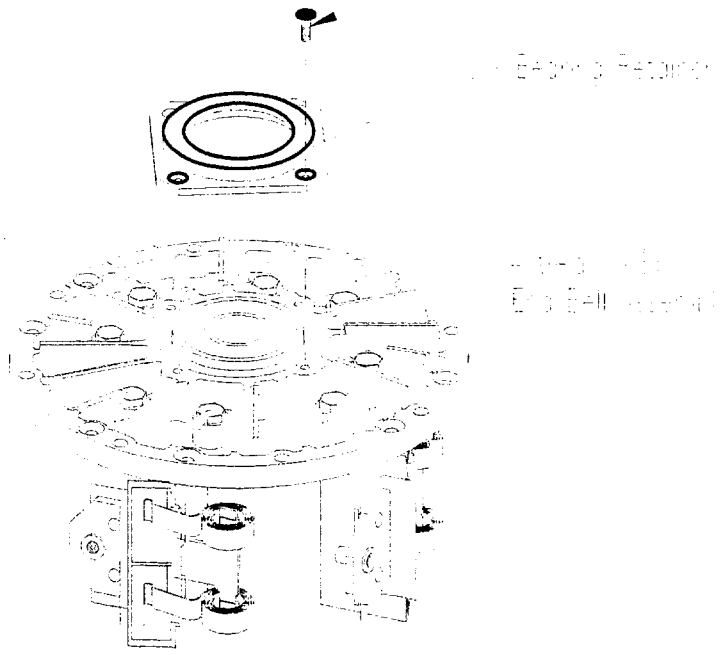

Figure 7004 - Attach Bearing Retainer to Bearing and Brush Support Assembly

D. Attach the bearing and brush support assembly (200) to the armature (175).

CAUTION: Do not touch the polished surface of the commutator with bare hands. Skin acids and oils can contaminate conducting surfaces causing corrosion and/or poor electrical contact.

(1) Set an armature support on the arbor press table. See Figure 7005.

(2) Set the armature, drive end down, onto the armature support.

(3) Set the bearing and brush support assembly, brush holder side down, onto the commutator end of the armature shaft.

(4) Set an inner race bearing driver onto the anti-drive end ball bearing installed in the bearing and brush support assembly.

(5) Press the ball bearing in the bearing and brush support assembly onto the armature shaft.

(6) Make sure that the ball bearing is fully seated against the shoulder of the armature shaft.

© 2000 TRW Aeronautical Systems

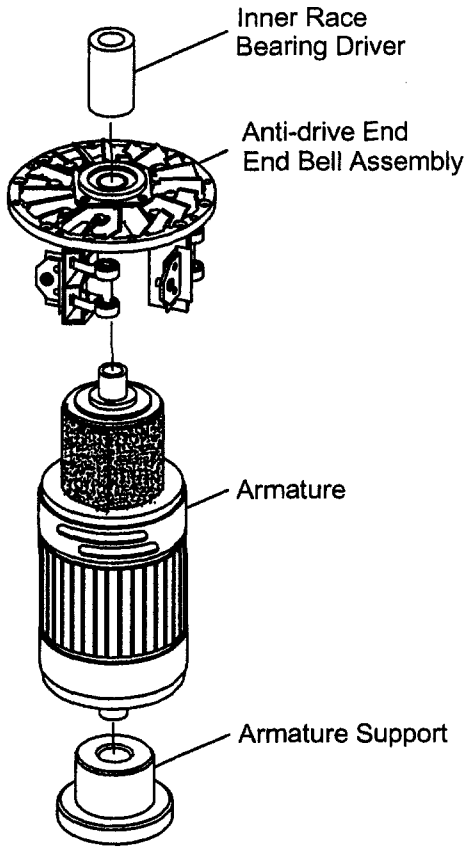

Figure 7005 - Attach Bearing and Brush Support Assembly to Armature

E. Install armature (175) and bearing and brush support assembly (200) into stator and housing assembly.

(1) Set the stator and housing assembly (275) stator end down on a vertical stator support. See Figure 7006.

(2) Set the bearing and brush support assembly (200) with its attached armature (175) into the stator and housing assembly (275) lining up the eight screw holes for attachment with screws.

(3) Apply thread sealing compound on each of the eight screws (205).

(4) Place a lock washer (210) and flat washer (215) on each of the eight screws (205) and attach them through the bearing and brush support assembly to the stator and housing assembly.

(5) Torque screws to 18-24 in. lb. (2.0 to 2.7 N·m)

© 2000 TRW Aeronautical Systems

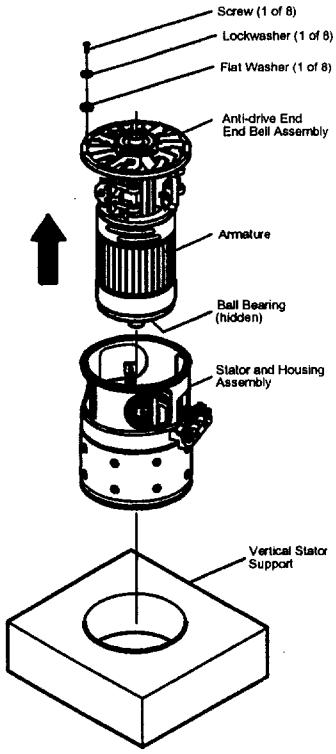

Figure 7006 - Install Armature and Bearing and Brush Support Assembly

F. Install drive-end end bell assembly (115) end bell (150) or (155) on stator and housing assembly (275).

(1) Set stator and housing assembly with armature and brush support on a horizontal stator support.

(2) Position drive end end bell assembly (150) or (155 - see note) on stator assembly Fig 9012.

NOTE: On the following models with the rounded end bell configuration (155), a dowel pin hole in the end bell must be aligned with the terminal block in a specific way for proper installation.

(Models 23048-004/M/T/TM, 23048-006, 23048-008) Looking from the drive end, a dowel pin hole must be positioned 180° away (directly opposite) from the terminal block.

(Models 23048-014 thru 23048-018, 23048-021, 23048-023, 23048-027, 23048-028) Looking from the drive end, a dowel pin hole must be positioned directly in line with the terminal block.

(3) Ensure that end bell assembly is fully seated on bearing (170).

© 2000 TRW Aeronautical Systems

WARNING: THREAD SEALING COMPOUND IS FLAMMABLE. DO NOT USE NEAR OPEN FLAMES OR SPARKS. USE IN A WELL-VENTILATED AREA.

(4) Apply thread sealing compound to threads of screws (120). Install screws (120), lock washers (125), and flat washers (130).

NOTE: End bell (150) uses eight screws with no washers and end bell (155) uses twelve screws with washers.

G. Place the dampener backplate (110) and friction ring (105) onto armature shaft.

CAUTION: Do not use the arbor press to force the dampener backplate onto the armature shaft.

(1) Hand twist the dampener backplate (110) onto the drive end of the armature shaft until it is fully seated on shaft taper. Refer to Figure 7007.

(2) Check runout of backplate radial surface while rotating armature on its bearings. Runout shall not exceed 0.003 inch T.I.R.

(3) Hand press the friction ring (105) into the recess of the dampener backplate.

(4) Place friction ring in dampener backplate.

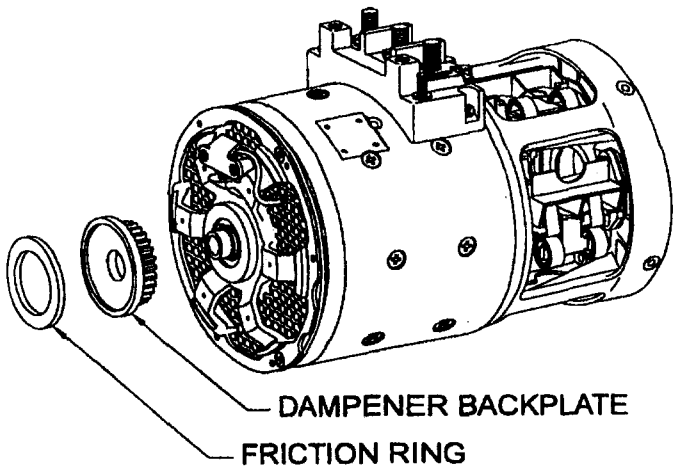

Figure 7007 - Installing Dampener Backplate

H. Assemble the dampener hub (100) and dampener plate (95) onto the drive shaft (85).

CAUTION: Do not force the dampener hub onto the mating taper of the drive shaft. The hub can fracture if excessive pressure is used.

(1) If the dampener hub (100) was removed from the drive shaft, hand twist the dampener hub onto the drive shaft taper and make sure it is fully seated.

© 2000 TRW Aeronautical Systems

(2) Put Dampener Plate into dampener plate driver. FIgure 9010. Refer to Figure 7008.

(3) Insert the drive shaft (85) through the dampener plate, while aligning the dampener plate and dampener hub splines.

(4) Lightly tap the drive end of the drive shaft using a leather or plastic mallet to seat the dampener plate onto the dampener hub.

(5) Make certain that spline on plate engages with spline on hub and fully bottoms on shoulder of hub.

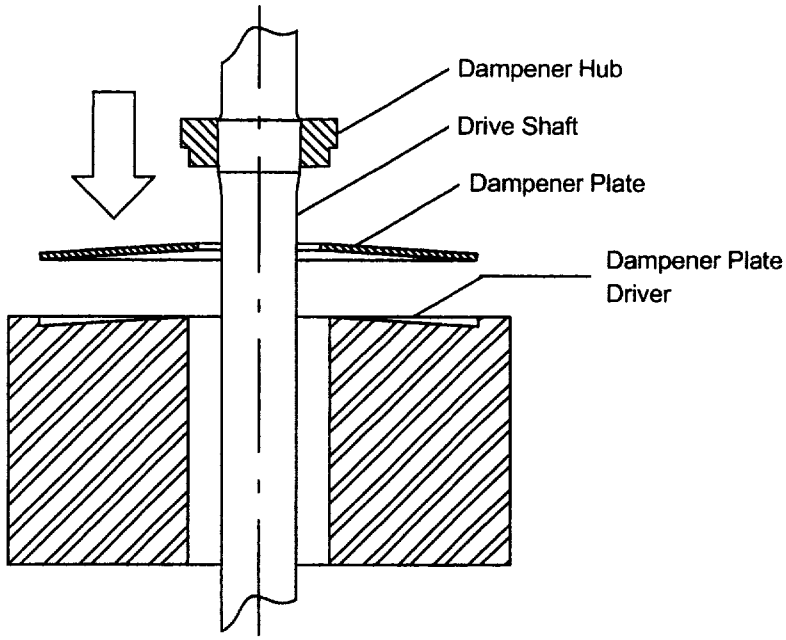

Figure 7008 - Assembling Dampener Hub and Plate

I. Install drive shaft (85) and fan assembly (70).

(1) Insert drive shaft (85) through drive end of armature, making certain that drive shaft splines fully engage armature shaft splines. Refer to Figure 7009.

© 2000 TRW Aeronautical Systems

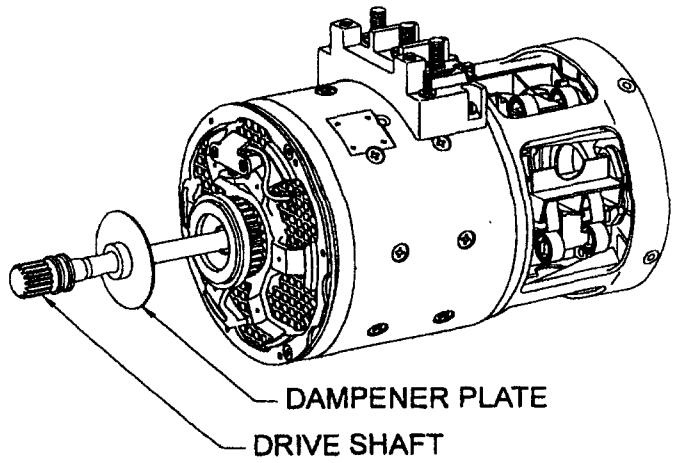

Figure 7009 - Inserting Drive Shaft into Armature Shaft

(2) Position fan assembly (70) on drive shaft and secure with washer (80) and self-locking nut (75). Refer to Figure 7010.

(3) Use a suitable spline wrench to hold drive shaft (85) and tighten nut (75) 100 to 120 in-lbs (11.3 to 13.6 Nm).

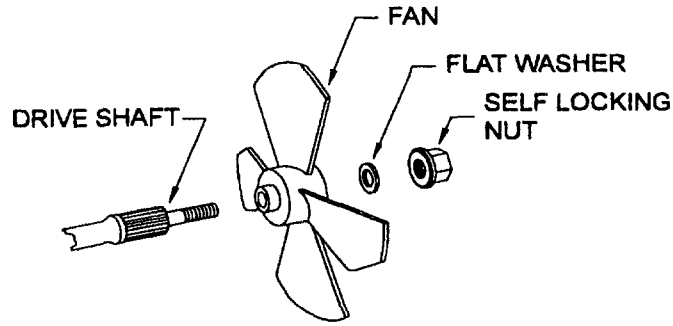

Figure 7010 - Attaching Fan to Drive Shaft

J. Install four brushes (60) and brush access cover (50).

NOTE: See REPAIR section for correct position of brush wire leads and for proper seating of brushes.

(1) Install brushes (60) into brush holders and secure brush and field leads with four screws (65).

NOTE: In the following step, the cover air bleed holes must be toward the terminal block.

© 2000 TRW Aeronautical Systems

(2) Looking from fan end, position brush access cover (50) on housing with clamp screw (55) located 90° counterclockwise from center terminal on terminal block. Secure cover with screw (55).

K. Install fan cover (25) or (30).

(1) Fan cover (25) Installation.

(a) Position fan cover on support assembly in a manner that allows grooves in cover to accomplish a locking effect.

(b) Rotate cover either clockwise or counterclockwise to lock in place.

(2) Fan cover (30) Installation.

NOTE: If installing fan cover that uses a gasket, check that gasket (45) is in place, secure, and undamaged. If missing, loose, or damaged, replace gasket IAW instruction in the REPAIR section.

(a) Position fan cover on support assembly and align screw holes in cover with screw holes in support assembly.

(b) Install four screws (40) to secure cover.

L. Attach air inlet (5), if used.

(1) Position air inlet (5) on stator housing in the correct orientation.

(2) Install rim clenching clamp (10) on air inlet and tighten nut to 25 in-lb (2.83 Nm).

M. If removed, attach the modification status label (340) and identification plate (345).

CAUTION: Do not stamp information directly onto any part of the stator and housing

NOTE: Full re-identification instructions are given in the applicable service bulletins.

(1) If the starter-generator has been modified:

(a) Put a blank modification status label on a wooden work surface.

(b) Stamp the letter "X" under the applicable letter on the modification status label.

(c) Apply the modification status label to the stator and housing assembly next to the identification plate.

(2) If the original identification plate was damaged:

(a) Put a replacement identification plate on a wooden work surface.

(b) Transfer all of the information from the original identification plate to the replacement identification plate using a 1/8-inch (3.18 mm) letter punch set and a light hammer.

© 2000 TRW Aeronautical Systems

(c) Attach the identification plate to the stator and housing assembly.

(d) Apply a coating of acrylic to the replacement identification plate.

7. Mandatory Acceptance Testing

Test the starter-generator according to the procedures in the TESTING AND FAULT ISOLATION section before it is returned to service or stored.

8. Preparation for Shipment/Storage

After mandatory acceptance testing is completed, prepare the starter-generator for shipment or storage.

A. Package the generator for shipment or storage.

(1) Wrap the drive spline with protective paper according to MIL-B-121A, Grade A, Type II, Class 1.

(2) For shipment or storage, seal starter-generator unit in suitable plastic container to protect against corrosion and airborne contaminants. Refer to STORAGE section in this manual for packing materials.

(3) For shipment, package the unit in its original shipping container if possible. Include applicable inspection, test, repair, and installation documents. Otherwise, package sealed unit in accordance with best commercial practices. Refer to STORAGE section in this manual for packing materials.

© 2000 TRW Aeronautical Systems

FITS AND CLEARANCES

1. Torque Values

Refer to Table 8001 for torque values to be used during repair and assembly.

IPL Figure and Item Number	Item	Torque lb-in (Nm)
10001-11	Fan Nut	100 to 120 (11.3 to 13.6)
10001-30	Brush Holder Bolt	25 to 30 (2.83 to 3.39)

Table 8001 - Torque Values

2. Component Acceptance Limits

Refer to Table 8002 for the acceptance limits applicable to starter-generator components and subassemblies. Paragraph designations in the CHECK column refer to the applicable inspection procedures found in the CHECK section, except where noted. Item numbers in parentheses () refer to a figure and an item number in the ILLUSTRATED PARTS LIST.

CHECK section	Item Description	Inspect for...	Acceptance Limits
7.E.	Fan assembly (10001-70) for models 23048-004/M/T/TM and 23048-008	Protrusion toward the unit locating shoulder of fan hub	0.050 in. (1.27 mm) maximum
7.F.(5)	Drive shaft - 12 tooth (10001-85) used on all models except Model 23048-023	Drive end spline dia. over two 0.1094 in. (2.7788 mm) dia. pins	0.757 in. (19.2278 mm) minimum
	Drive shaft - 16 tooth (10001-85) used on models 23048-023	Drive end spline dia. over two 0.1094 in. (2.7788 mm) dia. pins	0.958 in. (24.3332 mm) minimum
7.G.	Friction ring (10001-13B)	Thickness	0.063 in. (1.52 mm) minimum
7.H.	Dampener plate (10001-90)	Thickness	0.038 in. (0.97 mm) minimum
		Internal spline dia. over two 0.090 in. (2.28 mm) dia. pins	0.6550 in. (16.637 mm) maximum

Table 8002 - Acceptance Limits

SPECIAL TOOLS, FIXTURES, AND EQUIPMENT

1. Introduction

Table 9001 lists items that are approved for use during repair and overhaul of all 23048 Series DC Starter-Generators.

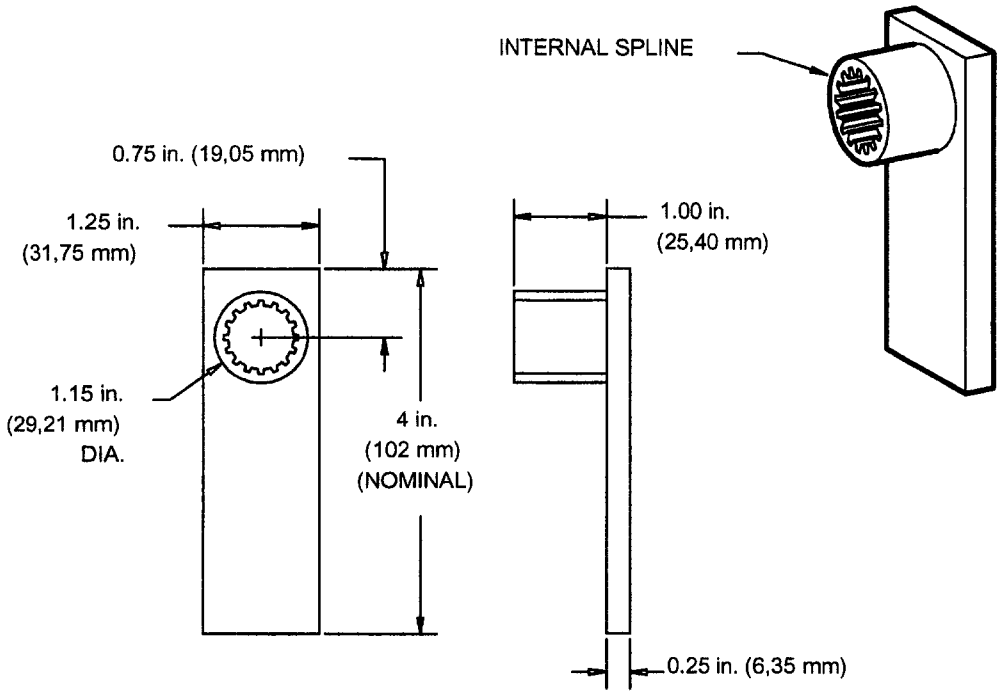
Reference Standard Practice Document (SPD) 1004 for the 23048 Series Brush Holder Alignment Fixtures.

Item	Figure No.
Wrench, Spline	9001
Support, Anti-Drive End, End Bell Assembly	9002
Driver, Dampener Hub	9003
Adapter, Armature Shaft (Drive End)	9004
Adapter, Armature Shaft (Anti Drive End)	9005
Drivers, Bearing (Inner Race and Outer Race)	9006
Adapter, Commutator Viewing	9007
Fixture, Commutator Turning	9008
Support, Armature	9009
Driver, Dampener Plate	9010
Support, Stator, Vertical	9011
Support, Stator, Horizontal	9012
Support, Anti-Drive End, End Bell Assembly Support	9013
Brush Holder, Alignment Fixture	SPD 1004

Table 9001 - Special Tools, Fixtures, and Equipment

2. Illustrated Description of Tools

Drawings in this section provide material and fabrication instructions for making tools or fixtures listed in Table 9001. Where dimensions and fabrication instructions are provided, the tool or fixture is approved for local manufacture. Unless otherwise specified, all dimensions are in inches.



The tools and fixtures cannot be procured from TRW Aeronautical Systems, TRW Lucas Aerospace. Equivalent tooling and fixture requirements meeting with TRW Aeronautical Systems, TRW Lucas Aerospace specifications can be used.

A. Spline Wrench

Material: Spline socket - AISI-01 tool steelor equivalent.
Hardened to Rockwell C 55-60
Handle: C.R.S.

Tolerances on: Decimals 0.XX ± 0.01 (0,25 mm)
0.XXX ± 0.005 (1,27 mm)

FOR ALL MODELS EXCEPT 23048-023

Internal Involute Spline Data Fillet Root Side Fit	inch	mm
Number of Teeth	12	
Diametral Pitch	20 / 40	
Pressure Angle	30 DEG.	
Pitch Diameter	0.6000	15,240
Minor Diameter (min.)	0.5550	14,097
Major Diameter (min.)	0.6500	16,510
Chord Space (min.)	0.0730	1,853
Pin Diameter	0.0720	1,829
Between three .072 Pins (min.)	0.5095	12,941

MODEL 23048-023 ONLY

Internal Involute Spline Data Fillet Root Side Fit	inch	mm
Number of Teeth	16	
Diametral Pitch	20 / 40	
Pressure Angle	30 DEG.	
Pitch Diameter	0.8000	20,320
Minor Diameter (min.)	0.7270	18,590
Major Diameter (min.)	0.8640	21,946
Chord Space (min.)	0.0728	1,849
Pin Diameter	0.0720	1,829
Between three .072 Pins (min.)	0.7096	18,024

Figure 9001 - Spline Wrench

B. Anti-Drive End Hub Support

Material: AISI-01 tool steel or equivalent
Harden to Rockwell C 35-40

Tolerances on: Decimals .XX ± 0.01 (0.25 mm)
.XXX ± 0.005 (0,127)

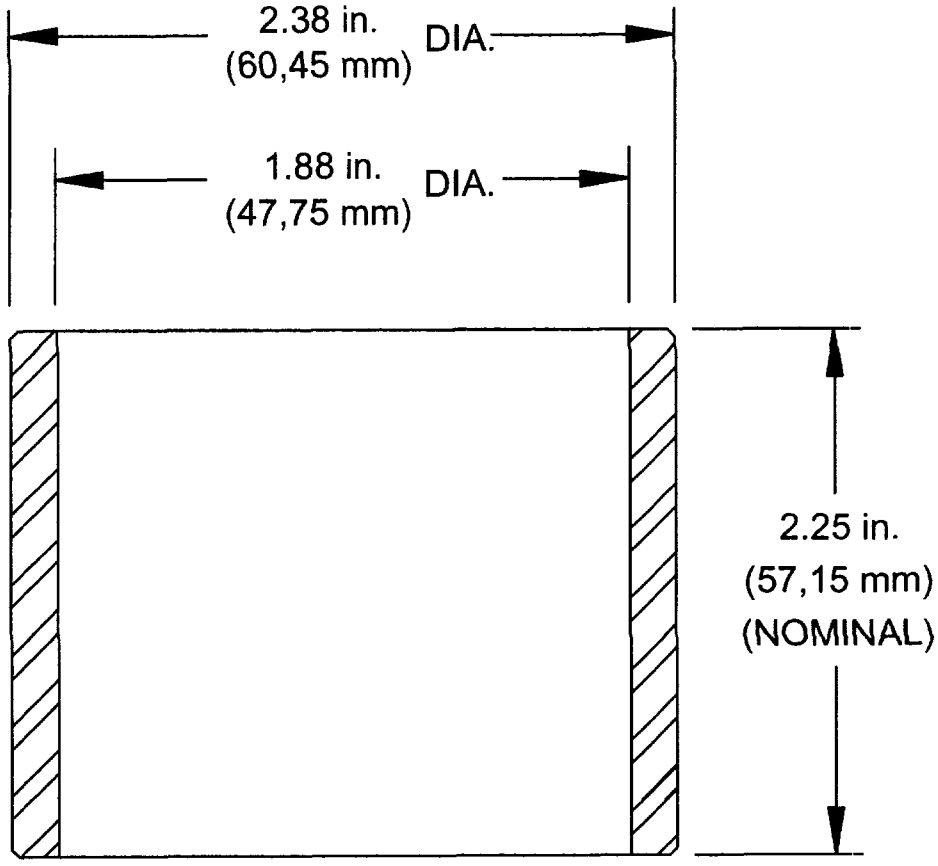

Figure 9002 - Anti-Drive End Hub Support

© 2000 TRW Aeronautical Systems

C. Dampener Hub Driver

Material: AISI-01 tool steel or equivalent

Tolerances on: Decimals .XX ± 0.01 (0.25 mm)
.XXX ± 0.005 (0,127)

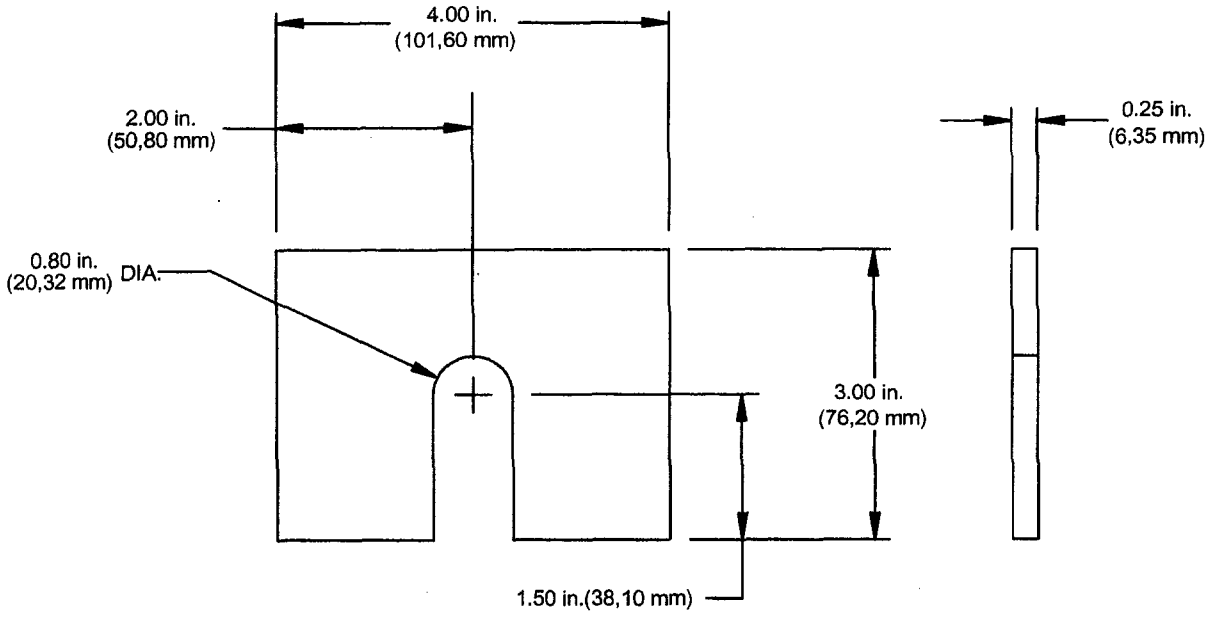

Figure 9003 - Dampener Hub Driver

© 2000 TRW Aeronautical Systems

D. Armature Shaft Adapter

Tolerances on decimals 0.XX ± 0.01 (0,25), 0.XXX ± 0.005 (0,127). Machined ends to be parallel to within 0.001 in. (0,025) and square with sidewalls within ±0.05 degree, Materials: Brass CD-260

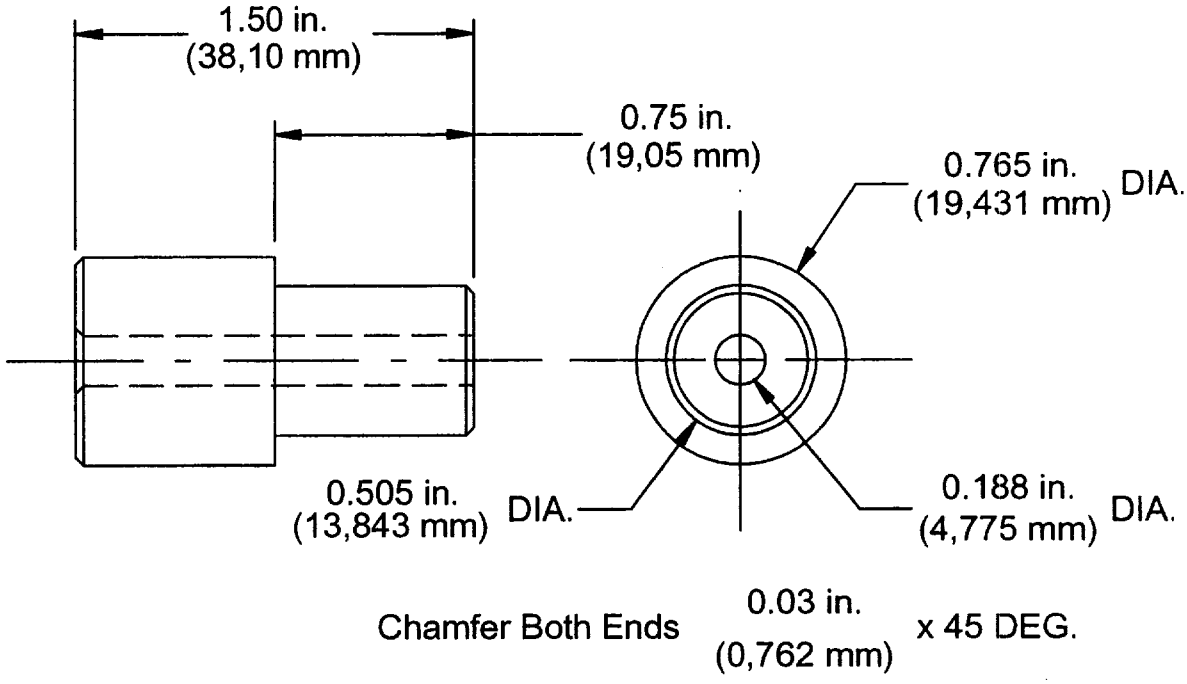

Figure 9004 - Drive End Armature Shaft Adapter

© 2000 TRW Aeronautical Systems

E. Armature Shaft Adapters

Tolerances on decimals 0.XX ± 0.01 (0,25), 0.XXX ± 0.005 (0,127). Machined ends to be parallel to within 0.001 in. (0,025) and square with sidewalls within ±0.05 degree. Materials: Brass, CD-260

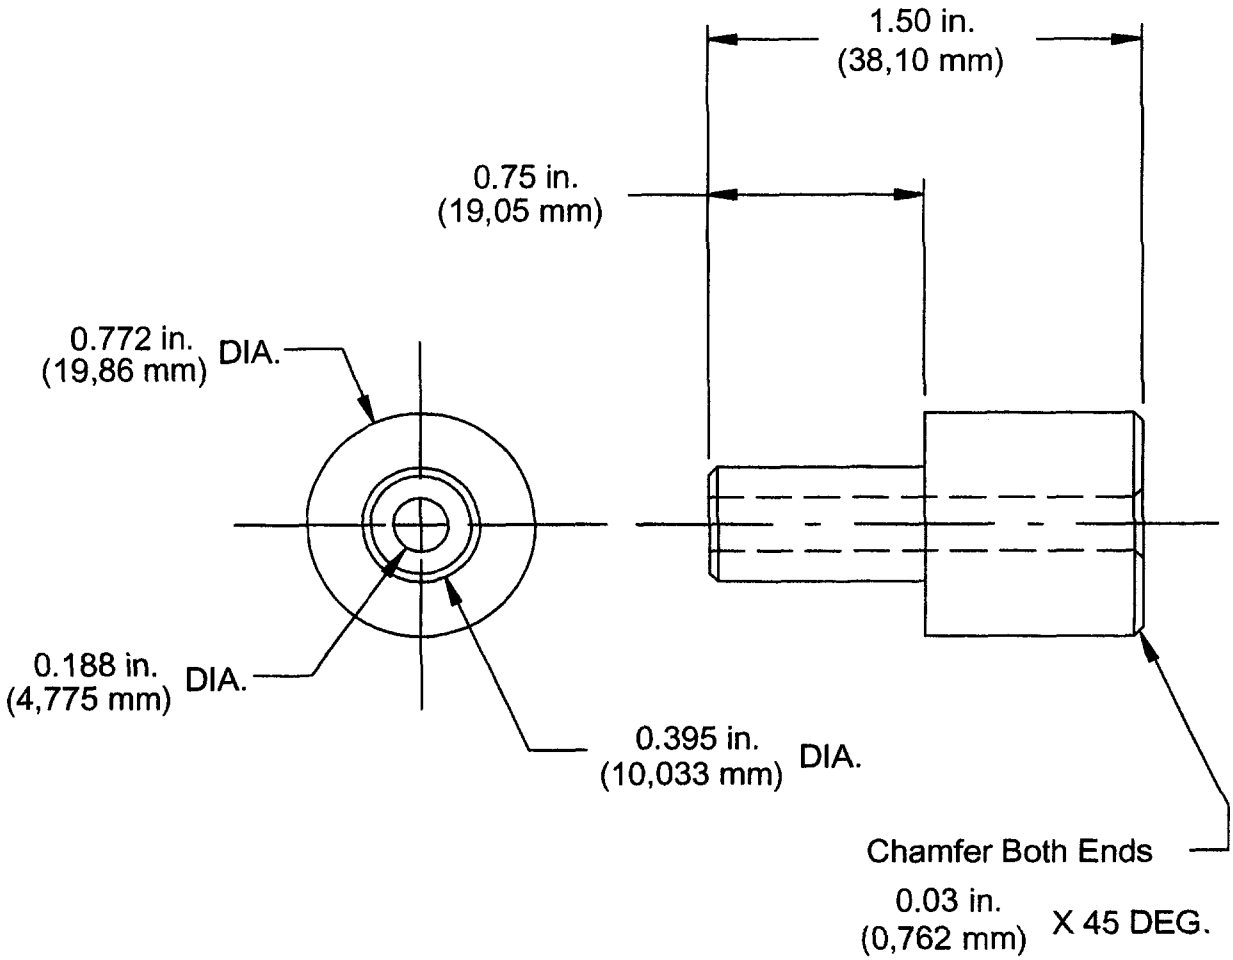

Figure 9005 - Anti-Drive End Armature Shaft Adapter

G. Commutator Viewing Adapter (Figure 9007)

Clear acrylic viewing adapter fabrication

Required Materials: Clear acrylic, 0.125 in. (3,175) thick, A dummy brush access cover, Adhesive

(1) Cut acrylic to size, 19 x 2.6 in. (482,6 x 66,04)

(2) Remove brackets from a dummy brush access cover.

(3) Apply adhesive to ends of acrylic.

(4) Attach brackets to acrylic.

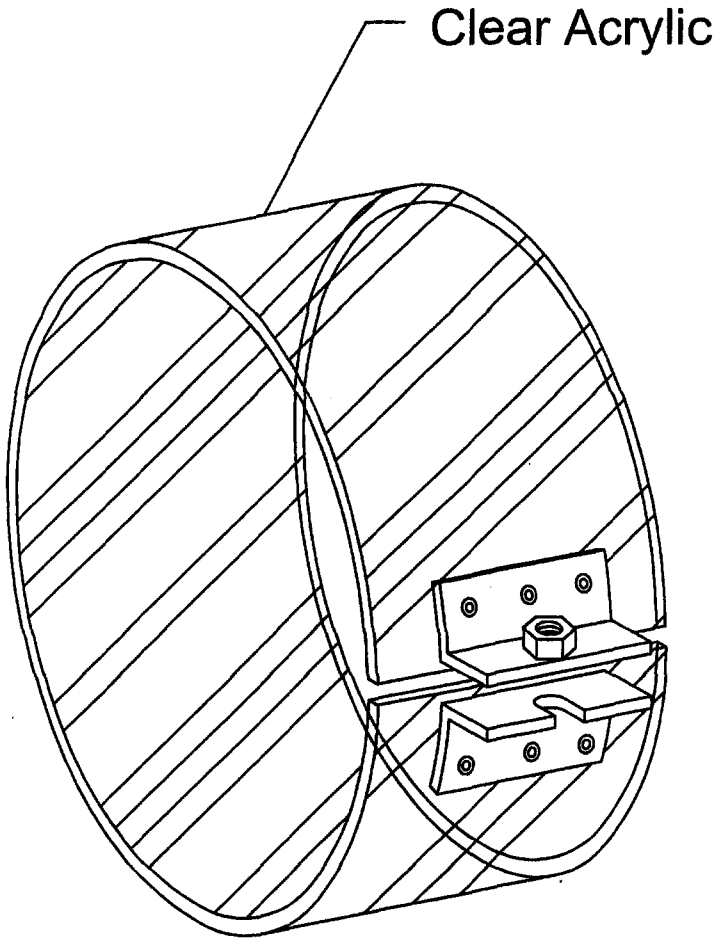

Figure 9007 - Commutator Viewing Adapter

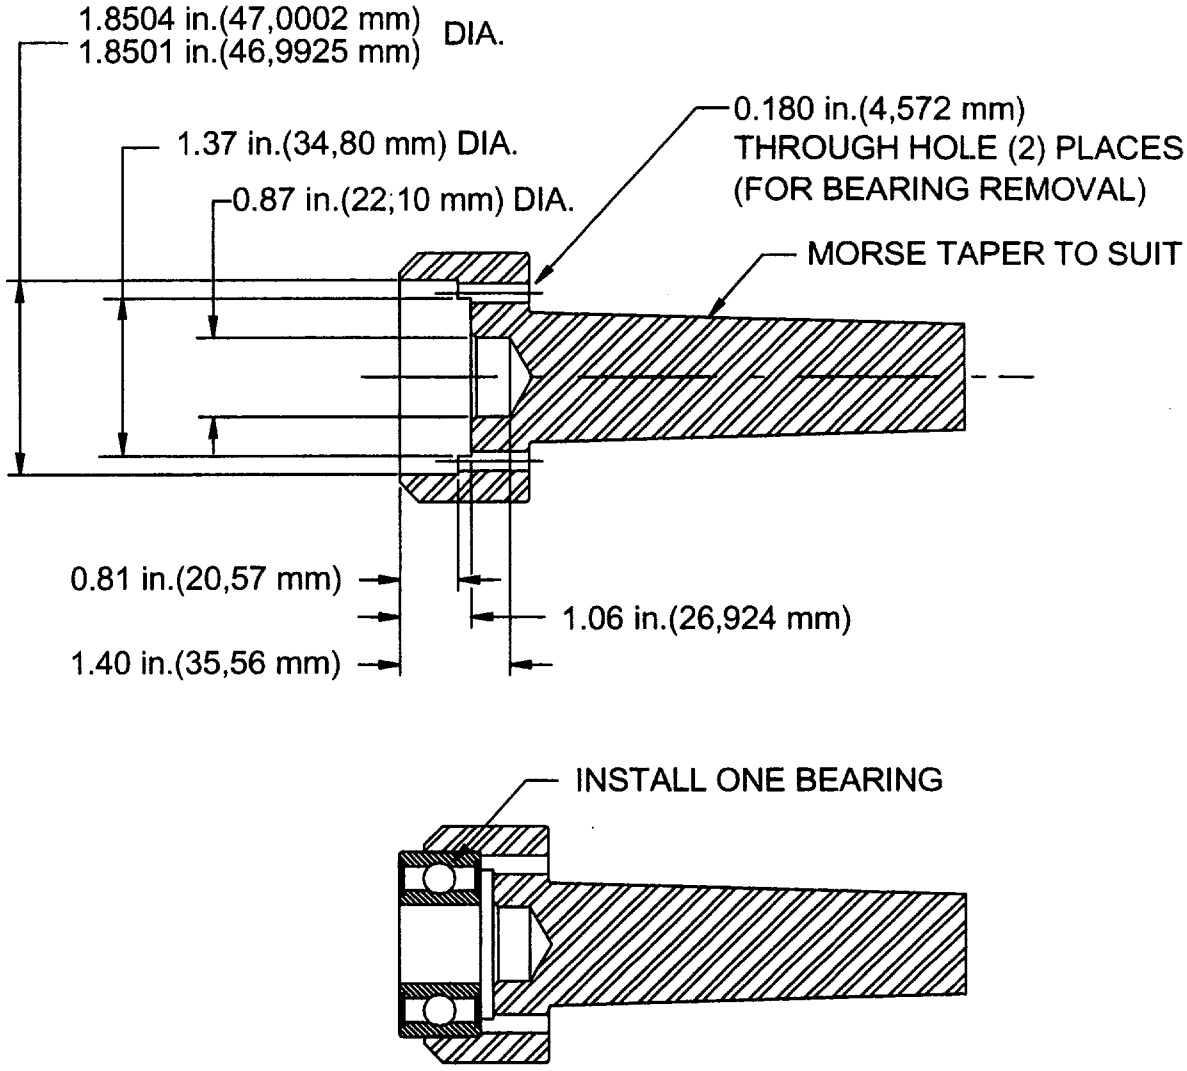
© 2000 TRW Aeronautical Systems

H. Commutator Turning Fixture (Figure 9008)

Tolerances on decimals 0.XX ± 0.01 (0,25), 0.XXX ± 0.005 (0,127). Machined ends to be parallel to within 0.001 in. (0,025) and square with sidewalls within ±0.05 degree. Harden steel to Rockwell C 35-40. Material: 1040 Steel, Stock size: 2.50 in. (63,5) diameter



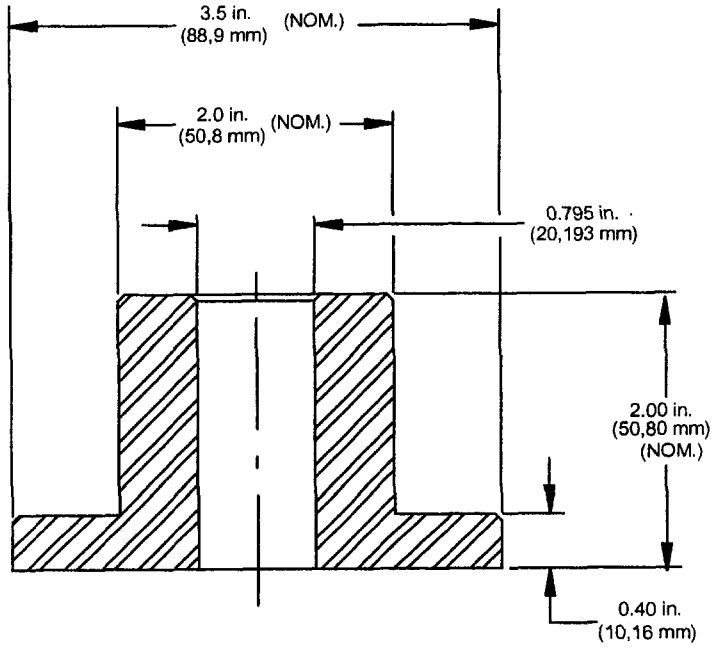


Figure 9008 - Commutator Turning Fixture

J. Dampener Plate Driver

Material:	O1 tool steel or equivalent Harden to Rockwell C 55-60.
Stock Size:	3.0 diameter (76,2 mm)
Tolerances on:	.XX ± 0.01 (0,25) .XXX ± 0.005 (0,127)
Angles:	±1°

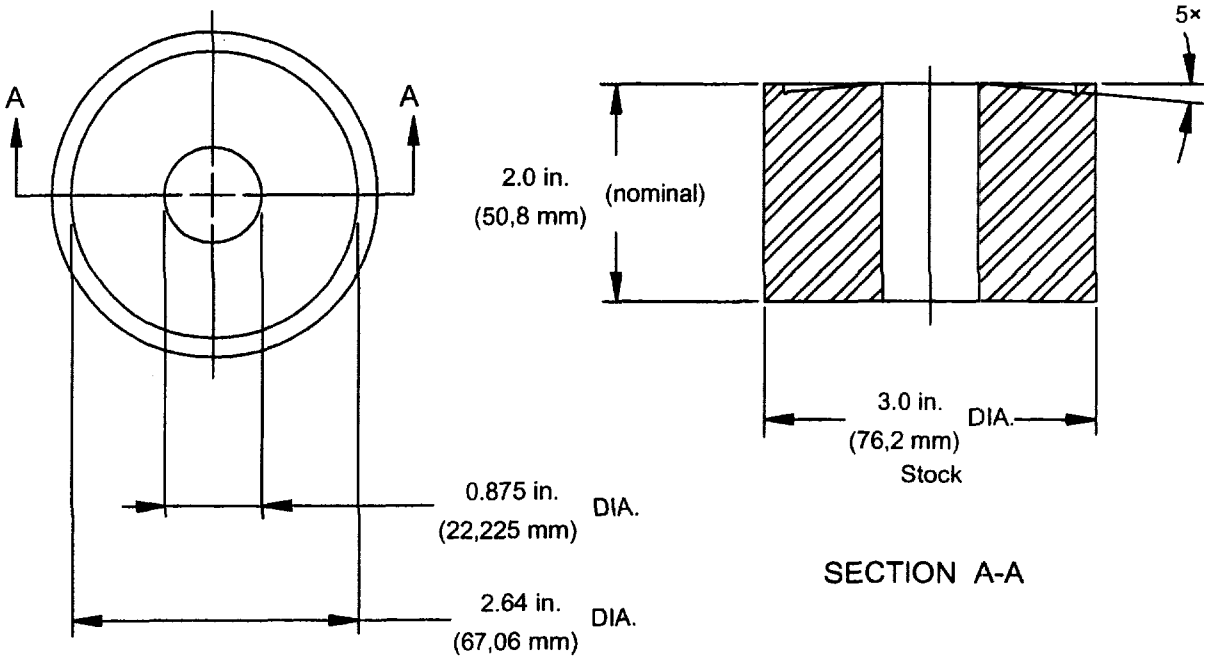

Figure 9010 - Dampener Plate Driver

© 2000 TRW Aeronautical Systems

K. Vertical Stator Support

All dimensions are nominal. The material is any suitable hardwood.

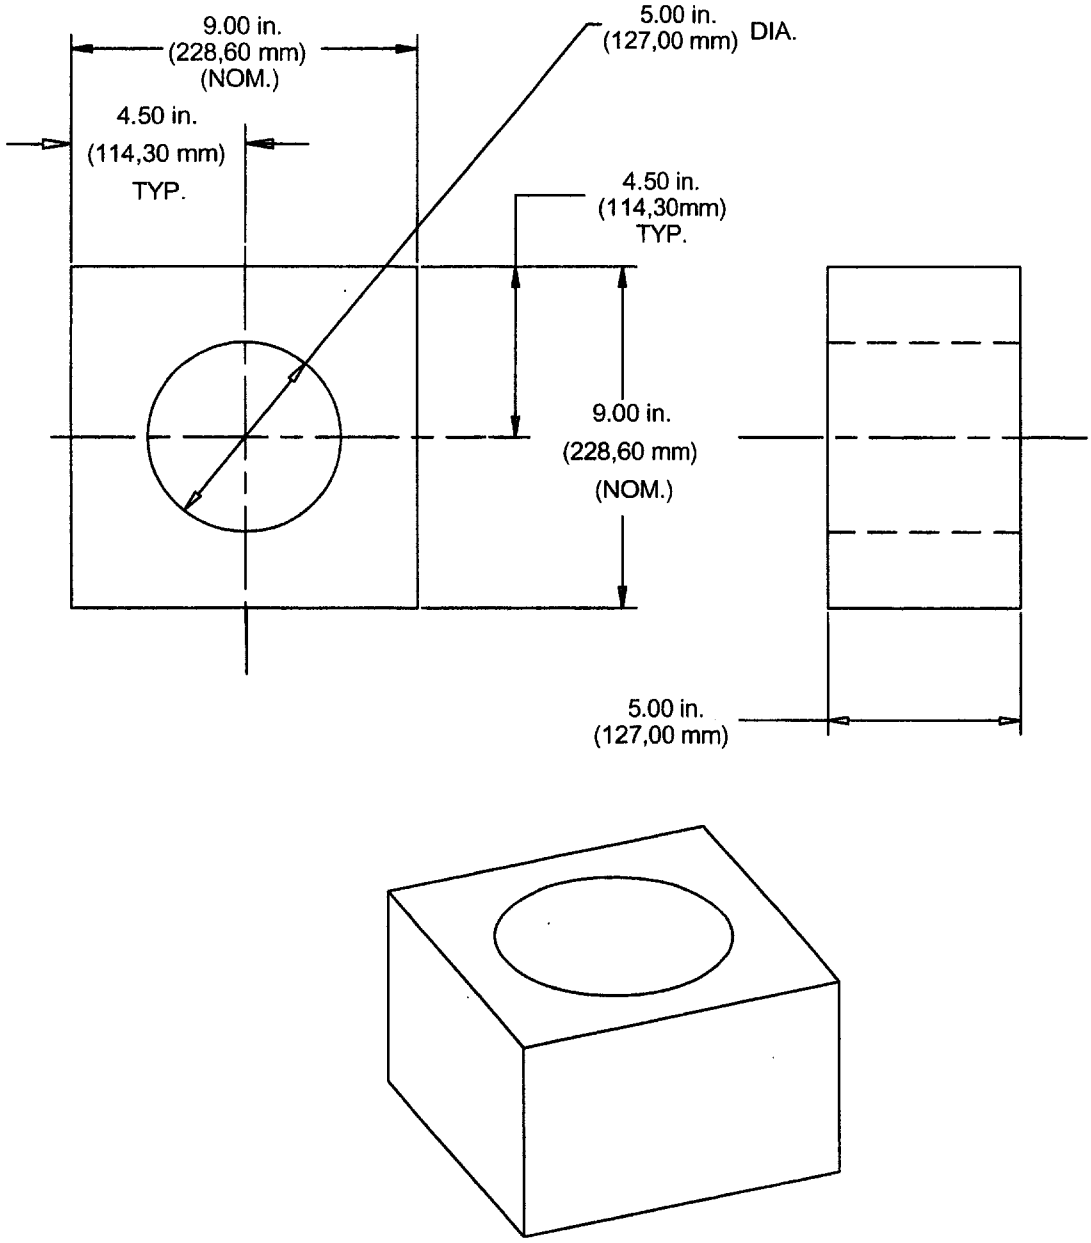

Figure 9011 - Vertical Stator Support

© 2000 TRW Aeronautical Systems

L. Horizontal Stator Support

Material:	Hardwood	
Stock Size:	7 x 4 x 3 (177,8 x 101,6 x 76.2)	
Tolerances on:	Decimals	.XX ± 0.01 (0.25 mm) .XXX ± 0.005 (0,127)
Angles:	±5°	

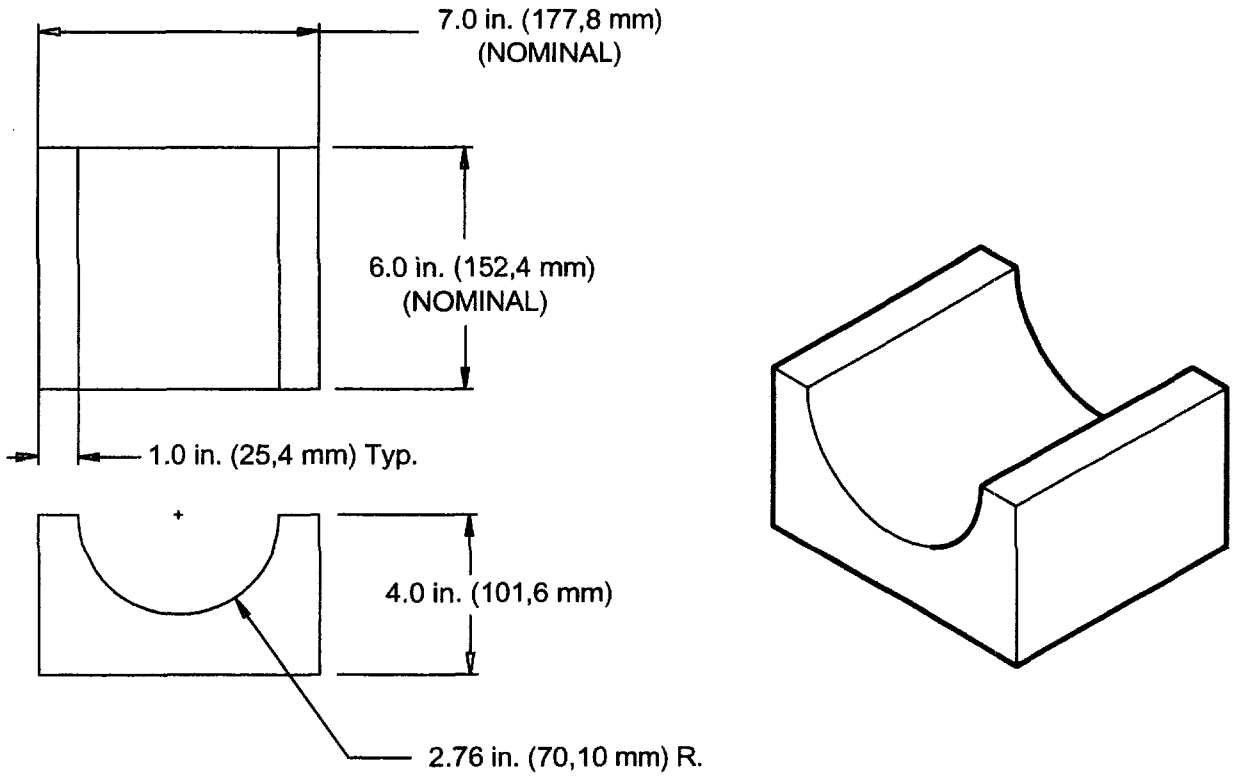

Figure 9012 - Horizontal Stator Support

ILLUSTRATED PARTS LIST

1. Introduction

This illustrated parts list provides a detailed listing of assemblies, subassemblies, and components for the 23048 Series of DC Starter-Generators. Figure 10001 illustrates the starter-generator top-assembly breakdown. The item number sequence in Figure 10001 reflects the order of disassembly in the DISASSEMBLY section. Attaching parts/hardware is listed immediately after the parts they attach.

All replacement parts are manufactured or source-controlled by TRW Aeronautical Systems, Lucas Aerospace, Aurora, OH with the exception of those parts assigned a military standard (MS), and Army Navy (AN), or a National Aerospace Standard (NAS) part number.

CAUTION: The use of parts, materials, or processes not authorized by TRW Aeronautical Systems, Lucas Aerospace for the maintenance or overhaul of the DC starter-generator may affect the continued flight worthiness of the unit and may invalidate it's certification.

2. Arrangement of the Parts List

A. Figure and Item Number

The figure number indicates the figure where the part is illustrated. Each item number corresponds to the part illustrated in the figure. Several item numbers may have a letter following the number (e.g., 10A). This letter designation indicates the part corresponds to the base item number and is the same in function and location as the base part number (e.g., 10) but may differ in form or material.

B. Part Number

The part numbers listed in this document are the only authorized parts for replacement and overhaul of the DC starter-generator. This list mainly consists of TRW Aeronautical Systems, Lucas Aerospace part numbers but does include military standards (MS), Army Navy (AN) standard, and National Aerospace Standard (NAS) part numbers.

C. Nomenclature

The correct name of each item is listed in this column. Parts are listed in the general order of disassembly with the exception of attaching hardware. When necessary, a part description or reference note is provided such as:

Replaced by:	The part number listed is discontinued and should be replaced by the new part number. The original part may be used until the current stock is depleted, and then it must be replaced by the new part listed.
Replaces:	The part number listed should be used in place of the discontinued part after the original part stock is depleted.
Alternate:	Either part may be used.

© 2000 TRW Aeronautical Systems

Superseded by:	The part number listed is obsolete and must be replaced by the new part number during the next repair or overhaul of the generator. The superseded part is not to be installed or re-installed.
Supersedes:	The part number listed must replace the obsolete part number during the next repair or overhaul of the generator.
Order separately:	The part is not furnished as part of the generator as defined in this parts list.

D. Effect Code

Each generator model is assigned a unique effectivity code (A through Z). Subsequent items within the parts list pertaining to Figure 10001 will refer to the effectivity codes that correspond to a particular model. In subsequent figures, the effectivity code is redefined for each major subassembly and remains independent of all other main assembly and subassemblies defined in figures within this section. In cases where a part is used on all assemblies, the effect code is left blank.

E. Units Per Assembly

This column indicates the quantity of parts used at the location shown. For bulk items, the abbreviation AR indicates that the part is used on an "as required" basis. The abbreviation RF indicates that the item is listed for "reference only".

STORAGE

1. Introduction

Materials required to pack the generator for storage or shipment are listed in Table 5001.

Description	Specification	Quantity
Tag	Commercially available.	1 (Domestic) 2 (Internat'l)
Bag - waterproof, vapor-proof.	Commercially available. Bag must totally enclose O-ring and instructions for installation and then be sealed.	1
Bag - waterproof, vapor-proof.	Kraft-foil or suitable equivalent. Bag must totally enclose generator and then be sealed.	1
Cushioning Material - shock absorbing, one-inch thick.	Commercially available	AR
Box - domestic class, single wall, corrugated cardboard.	PPP-B-636 or suitable equivalent. Box must be large enough to totally enclose and restrain bagged and cushioned generator.	1
Tape - waterproof, pressure sensitive.	Commercially available.	AR
Box - WC5 overseas shipping container.	PPP-B-636 or suitable equivalent. Box must be large enough to completely enclose domestic class packaging.	1

SERVICE BULLETIN

ELECTRICAL POWER - STARTER GENERATOR - MODIFICATION OF MODEL 23048-017 to MODEL 23048-021.

1. PLANNING INFORMATION

A. Effectivity

All Lear Siegler, Inc., Power Equipment Division (LSI/PED) Starter-Generator, Models 23048-017.

B. Reason

To increase air flow through Starter-Generator and associated generator output capability.

C. Description

This Service Bulletin provides the procedures for conversion of Starter-Generator Model 23048-017 to Model 23048-021. Modification consists of the following:

1) Replacement of Fan Cover Assembly PN 23048-1000 with PN 23046-1090.

2) Replacement of Support PN 23048-1010 with PN 23046-1141.

3) Replacement of Brushes PN 30300-1282 with PN 30300-1286.

4) Reidentification of Starter-Generator.

D. Compliance

The Starter-Generator modification described in this Service Bulletin is optional and may be accomplished at the convenience of the operator.

E. Approval

This Service Bulletin has the approval of Lear Siegler, Inc., Power Equipment Division.

F. Manpower

An estimated 2 manhours, excluding oven heating time, are required to accomplish this Service Bulletin.

April 20, 1981

SERVICE BULLETIN

G. Material - Cost and Availability

1) Modification Kit, LSI/PED Part No. 52-000119, required for the accomplishment of this Service Bulletin, can be obtained from LSI/PED distributors:

Avitron International Division
P.O. Box 567
Rye, New York 10580

Canadian Customers Contact:

Aircraft Appliances & Equipment
152 East Drive
Bramalea, Ontario, Canada L6T-1E1

Cost and Delivery:

Contact LSI/PED distributor (see paragraph 3A for kit contents)

2) Industry standard parts and materials required for the accomplishment of this Service Bulletin are commercially available, part numbers, material specifications, and vendor information are described in paragraph 3B. Industry standard parts and materials are to be provided by the operators overhaul shop.

H. Tooling - Price and Availability

Tools normally used in overhaul shops are required for the accomplishment of this Service Bulletin.

I. Weight and Balance

Weight --- None
Balance --- None

Overhaul Manual with IPL (LSI/PED File No. 23202) for Starter-Generator Models 23048-001, 23048-004, 23048-006, 23048-008, 23048-012, 23048-014, 23048-015, 23048-016, 23048-017, 23048-018, 23048-020, and 23048-021.

K. Other Publications Affected

None

SERVICE BULLETIN

2. ACCOMPLISHMENT INSTRUCTIONS

A. Preparation

Figure and item numbers in this Service Bulletin are the same as the identical item shown in the reference publication, Overhaul Manual with IPL (LSI/PED File No. 23202).

B. Disassembly (Ref IPL,Figure 1)

1) Disassemble the Starter-Generator in accordance with procedures in DISASSEMBLY in reference Overhaul Manual to obtain support assembly, PN 23046-366.

2) Remove eight bolts (30), eight flat washers (31), eight non-metallic washers (32), and eight nuts (30A) from support assembly.

3) Remove four brush holder assemblies, PN 23064-1283, from support assembly. Remove four insulation plates (36A) and insulation sleeves (36) from support (37).

4) Remove bearing (28) from support (37) by removing bearing retainer (26) and four screws (27) and pressing bearing from support.

C. Cleaning

Clean the Starter-Generator in accordance with the CLEANING procedures in the reference Overhaul Manual.

D. Modification and Assembly

Use Modification Kit, Part No. 52-000119.

1) Obtain new support (37), PN 23046-1141, and press new ball bearing (28), PN 03-6010-08, into support. Apply anti-sieze compound, JC-30, to threads of four screws (27). Secure bearing in support by installing bearing retainer (26) and four screws (27).

2) Insert a new insulation sleeve (36), PN 05-631145, into each of eight brush holder assembly mounting holes in the support.

3) Place a new flat washer (31), PN AN960-10L, and new non-metallic washer (32), PN 05-374094, on each of eight brush holder bolts (30) and insert bolts in support (37). Position new insulation plate (36A), PN 23014-1039, on bolts (30). Ensure that insulation plate fits over end of insulation sleeves.

SERVICE BULLETIN

4) Coat threads of bolts with Loctite, Grade D.

5) Position brush holder assemblies against new insulation plates (36A) in accordance with ASSEMBLY procedures in Overhaul Manual. Secure brush holder assemblies on support (37) by tightening bolts (30) 25 to 30 in-lbs.

6) Test bearing and brush holder support assembly in accordance with procedures in TESTING, Paragraph D(1), in reference Overhaul Manual.

7) Coat edge of base on four brush holder assemblies, non-metallic washers (32), heads of bolts (30), flat washers (31), insulation plate (36A), and brush holder area of support (37) with red insulating enamel, Part No. ER-41.

8) Permit red insulating enamel to air dry, or bake bearing and brush holder support assembly in an oven for one hour at a temperature of 150°F (66°C). Remove from oven and allow to cool to room temperature.

9) Install armature (25) and position holder support assembly on stator and housing assembly in accordance with procedures in ASSEMBLY in reference Overhaul Manual. Secure support assembly with eight new flat washers (29B), PN 05-370232, eight new lock washers (29A), PN MS35338-42, and eight new screws (29), PN 05-341303.

10) In accordance with ASSEMBLY procedures in reference Overhaul Manual, complete assembly of the Starter-Generator installing new brushes (8), PN 30300-1286, and securing new fan cover assembly (5A), PN 23046-1090, with four new screws (5B), PN 05-340122.

E. Testing

Test Starter-Generator in accordance with procedures for Acceptance Tests (after overhaul) on the DIFFERENCE DATA SHEET for model 23048-021 in reference Overhaul Manual.

F. Reidentification

Identify converted Starter-Generator as follows:

1) Remove four drive screws (51) and remove identification plate (50) from Starter-Generator.

2) Obtain new identification plate, PN 06-109264, from kit and stamp with new model number (23048-021) in MODEL NO. block.

SERVICE BULLETIN

3) In EXTERNAL START POWER block, stamp 1000 under AMPS MAX.

4) Transfer serial number, date of manufacture, and all other remaining information from old identification plate to new identification plate. Discard old identification plate.

5) Use four new drive screws (51), PN MS21318-14, to secure new identification plate to Starter-Generator.

6) Coat identification plate with MIL-V-173 varnish. Permit varnish to air dry.

SERVICE BULLETIN

3. MATERIAL INFORMATION

Modification Kit, industry standard parts, and material required per Starter-Generator to accomplish this Service Bulletin are:

A. Modification Kit No. 52-000119 consists of the following:

SERVICE BULLETIN

ELECTRICAL POWER - STARTER GENERATOR - MODIFICATION OF MODEL 23048-004 TO MODEL 23048-004M AND MODEL 23048-004T TO MODEL 23048-004TM.

1. PLANNING INFORMATION

A. Effectivity

All Lear Siegler, Inc., Power Equipment Division (LSI/PED) Starter-Generator, Models 23048-004 and 23048-004T.

B. Reason

Increase service life of Starter-Generator by providing a new drive shaft with increased spline engagement.

C. Description

This Service Bulletin provides the procedures for modification of Starter-Generator Model 23048-004 to Model 23048-004M, and Model 23048-004T to Model 23048-004TM. Modification consists of the following:

(1) Replacement of Drive Shaft Part No. 23046-1125 with Drive Shaft Part No. 23046-2153.

(2) Reidentification of Starter-Generator.

D. Compliance

The Starter-Generator modification described in this Service Bulletin is optional and may be accomplished at the next Starter-Generator repair and/or overhaul.

E. Approval

This Service Bulletin has the approval of Lear Siegler, Inc., Power Equipment Division.

F. Manpower

No additional man hours are required when this Service Bulletin is accomplished at time of Starter-Generator repair or overhaul.

SERVICE BULLETIN

2. ACCOMPLISHMENT INSTRUCTIONS

A. Preparation

Figure and item numbers in this Service Bulletin are the same as the identical item shown in the reference publication, Overhaul Manual with IPL (LSI/PED File No. 23202).

B. Disassembly (Ref IPL, Figure 1)

Disassemble Starter-Generator in accordance with procedures in DISASSEMBLY, on the DIFFERENCE DATA SHEET for Model 23048-004 in reference Overhaul Manual, to obtain drive shaft (12), Part No. 23046-1125.

C. Cleaning

Clean Starter-Generator in accordance with procedures in CLEANING in reference Overhaul Manual.

D. Modification and Assembly

Obtain new drive shaft (12), Part No. 23046-2153 and install in Starter-Generator in accordance with procedures in ASSEMBLY, on the DIFFERENCE DATA SHEET for Model 23048-004 in reference Overhaul Manual.

E. Testing

Test Starter-Generator in accordance with procedures for Acceptance Tests (after overhaul) on the DIFFERENCE DATA SHEET for Model 23048-004 in reference Overhaul Manual.

F. Reidentification

(1) Reidentify modified Starter-Generator by metal stamping the letter M after Model No. 23048-004 or 23048-004T (as applicable) in the model number block on identification plate (50).

(2) Use MIL-V-173 varnish to lightly coat area of identification plate (50) where letter M was stamped. Permit varnish to air dry.

23048-023		

Table 1 - Modification Status Effectivity

B. Reason

Introduce an improved bearing to increase reliability and reduce cost of ownership of the DC Starter-generators listed in Table 1 of this service bulletin.

C. Description

This service bulletin provides instructions for converting starter-generators to the modification status as listed in Table 1 of this service bulletin. The modification consists of replacing two bearings and identifying the applicable modification status to indicate the accomplishment of this product improvement.

D. Compliance

Lucas Aerospace Power Equipment Corporation recommends that the modification in this service bulletin be accomplished during the next overhaul of the starter-generator.

E. Approval

This service bulletin has the approval of Lucas Aerospace Power Equipment Corporation. This service bulletin contains no information that revises the approved configuration of the starter-generator and therefore does not require governmental or other regulatory agency approval.

F. Manpower

When implemented at overhaul, no additional man-power is required to accomplish the modification in this service bulletin.

SERVICE BULLETIN

I. Material Cost and Availability

Refer to paragraph 3, MATERIAL INFORMATION, for a listing of parts and material required for the modification in this service bulletin. Required parts and pricing information are available from the following Lucas Aerospace Customer Service Centers:

H. Tooling Cost and Availability

No special tooling is required to accomplish the modification in this service bulletin.

SERVICE BULLETIN

I. **Weight and Balance**

Effect on weight: none.

Effect on balance: none.

J. **Electrical Load Data**

Not affected.

K. **References**

The 23048 Series DC Starter-generator Component Maintenance Manual (CMM) with Illustrated Parts List (IPL).

L. **Publications Affected**

The 23048 Series DC Starter-generator CMM with IPL will be revised to reflect the modification in this service bulletin.

2. ACCOMPLISHMENT INSTRUCTIONS

Note: Numbers in parentheses ( ) refer to item numbers given in the 23048 Series DC Starter-generator CMM with IPL, figure 1.

A. Preparation

The starter-generator modification in this service bulletin, shall be performed in a clean, dry area free of oil, dirt, moisture, and other contamination. The starter-generator must be kept clean to ensure the operating effectiveness of the unit.

B. Disassembly

Disassemble the starter-generator to the extent necessary to remove bearings (24 and 28). Discard removed bearings.

C. Cleaning and Inspection

(1) Thoroughly clean the starter-generator according to the instructions in the 23048 Series CMM.

(2) Inspect all disassembled parts according to the instructions in the 23048 Series CMM.

CAUTION: STRICT COMPLIANCE WITH THE INSPECTION SECTION MUST BE OBSERVED WITH REGARD TO BEARING LINER AND ARMATURE BEARING JOURNAL DIMENSIONS. OUT OF TOLERANCE BEARING LINERS OR ARMATURE BEARING JOURNALS, AS WELL AS AN UNBALANCED ARMATURE, MAY LEAD TO PREMATURE BEARING FAILURE.

(3) The following tolerances are relevant to this service bulletin.

Nomenclature (IPL Item Number)	Tolerance
END BELL, Drive End (21)	Bearing liner must be within: 1.8501 to 1.8504 inches (46.993 to 47.000 mm)
SUPPORT (37)	Bearing liner must be within: 1.8501 to 1.8504 inches (46.993 to 47.000 mm)
ARMATURE (25)	Bearing Journals (both ends) must be within: 0.7872 to 0.7875 inches (19.995 to 20.003 mm)
	Balance to within 5 grain inches (8.2 gram mm) each end

D. Modification

Modification of parts is not required. Modification occurs upon bearing replacement.

E. Assembly

Assemble the starter-generator according to the procedures in the 23048 Series CMM using bearings P/N 03-6010-18.

Note: The two seals fitted to the P/N 03-6010-18 bearing are identical and therefore special attention to orientation is not required during bearing installation.

F. Testing

Test the starter-generator according to the instructions in the 23048 Series CMM.

This space intentionally left blank

SERVICE BULLETIN

G. Reidentification

Reidentification is accomplished by one of the two methods in this section.

Note: If the original nameplate is damaged and requires replacement proceed to paragraph 2.G.(2).

(1) Use a Modification Status Label (figure 1) to identify the accomplishment of this product improvement.

(a) Use an 1/8" letter punch set and a light hammer to stamp information onto the modification status label and to stamp through information on the original nameplate.

(b) Place a modification status label on a wooden work surface.

(c) Identify the starter-generator with the MOD status for the product improvement in this service bulletin. Stamp the letter "X" in the block under the letter 'B' on the modification status label.

(d) Clean the area of the stator housing below the identification plate thoroughly.

(e) Affix the modification status label to the stator housing directly below the nameplate. Press label firmly with a hard faced roller to ensure good adhesion.

(f) Insert a stainless steel strip under the nameplate to absorb impact and avoid puncture.

(g) Stamp the letter "X" through all modification status information in the MOD block on the nameplate (figure 2A or 2B).

Note: It is not required to paint over the modification status label with acrylic coating.

(h) Using HumiSeal type 1B31 acrylic coating (or equivalent), paint the MOD block area (or the serial number area) of the nameplate.

(i) Allow the coating to air dry.

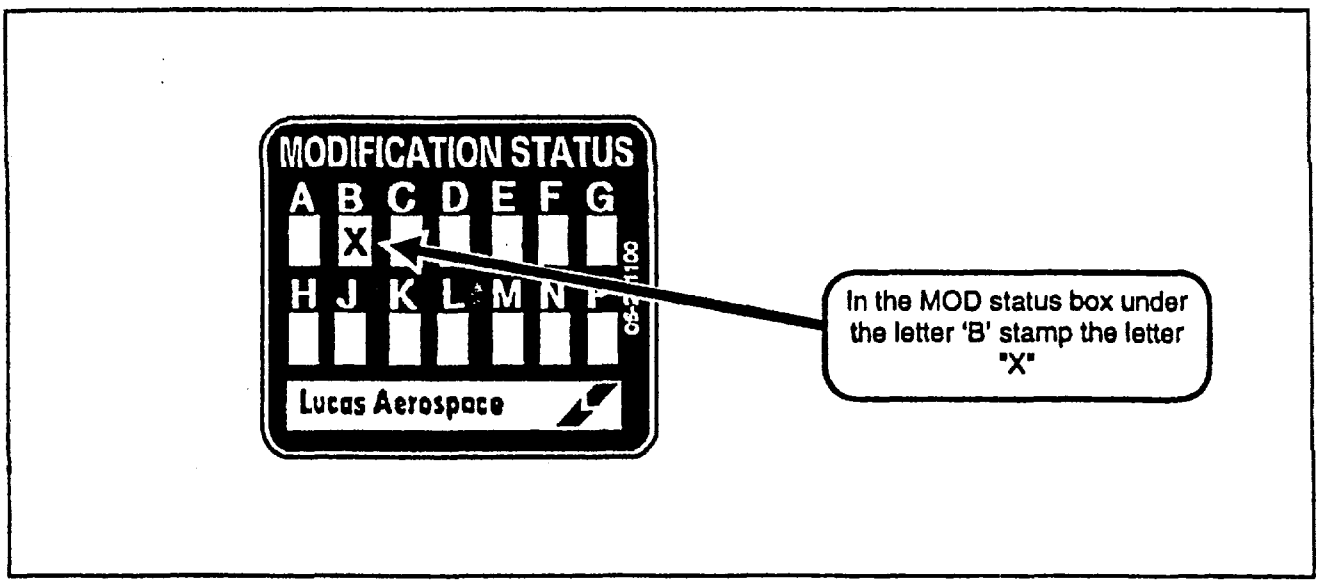

Figure 1 - Modification Status Label

SERVICE BULLETIN

(2) Use a LAPEC style replacement nameplate to identify the accomplishment of this product improvement.

Note: A modification status label is not required when using a LAPEC style replacement nameplate.

(a) Use an 1/8" letter punch set and a light hammer to stamp information onto the replacement nameplate.

(b) Position a replacement nameplate (figure 2) on a wooden work surface.

(c) Identify the starter-generator with the MOD status for the product improvement in this service bulletin. Stamp the letter "X" in the block under the letter 'B' on the replacement nameplate.

(d) Transfer all other information from the original nameplate to the replacement nameplate.

(e) Attach the replacement nameplate to the stator housing using four drive screws (51).

(f) Using HumiSeal type 1B31 acrylic coating (or equivalent), paint the entire replacement nameplate.

(g) Allow the coating to air dry.

TRW Aeronautical Systems, Lucas Aerospace

Service Bulletin

NUMBER 23048-0XX-24-03

ELECTRICAL POWER – 23048 DC STARTER-GENERATOR ARMATURE CHANGE

1. Planning Information

A. Effectivity

This Service Bulletin applies to all TRW Aeronautical Systems, Lucas Aerospace, DC Starter-Generators listed in Table 1.

23048-004	23048-004T	23048-004M	23048-004TM	23048-016
23048-018	23048-021	23048-023	23048-28	

Table 1 – Model Number Effectivity

B. Concurrent Requirements

The modification described in Service Bulletin 23048-0XX-24-02 must be accomplished in conjunction with the modification in this Service Bulletin for the models listed in Table 1.

C. Reason

This Service Bulletin introduces armature P/N 23048-1032 as a replacement for armature P/N 23048-1030 or P/N 23048-1031 which are no longer manufactured.

D. Description

This Service Bulletin provides instructions for using armature P/N 23048-1032 in the Starter-Generators listed in Table 1.

E. Compliance

RECOMMENDED

TRW Aeronautical Systems, Lucas Aerospace, recommends that the armature change in this Service Bulletin be performed during overhaul and after existing inventory of P/N 23048-1030 and 23048-1031 armatures have been depleted or at the discretion of the customer.

F. Approval

This Service Bulletin has the approval of TRW Aeronautical Systems, Lucas Aerospace.

© 2000 TRW

G. Manpower

When the armature change provided by this Service Bulletin is implemented at overhaul, no additional man-hours are required.

H. Weight and Balance

Effect on weight: None
Effect on balance: None

I. Electrical Load Data

Not Changed

J. References

Refer to the 23048 Series DC Starter-Generator Overhaul Manual (OM) with Illustrated Parts List (IPL).

K. Publications Affected

The 23048 Series DC Starter-Generator OM with IPL will be revised to reflect the contents of this Service Bulletin.

2. MATERIAL INFORMATION

A. Material - Price and Availability

Required parts and pricing information are available from TRW Aeronautical Systems, Lucas Aerospace Customer Service Centers, as listed in paragraph 2.B of this Service Bulletin.

FAX (1) 330 995-1117

NOTE: While the P/N 23048-1030 and P/N 23048-1031 armatures can be re-manufactured, they can not be modified to the 23048-1032 configuration.

© 2000 TRW

C. Material Requirements

TRW Aeronautical Systems, Lucas Aerospace parts and materials required are listed below:

New Part Number	Qty	Nomenclature	Old Part Number	Instruction/ Disposition
23048-1032	1	Armature	23048-1030 23048-1031	Discard the old part

D. Tooling

No special tooling is required.

E. Re-identified Parts

Re-identification of parts is not required to accomplish the modification in this Service Bulletin.

3. ACCOMPLISHMENT INSTRUCTIONS

A. Preparation

The Starter-Generator armature change shall be performed in a clean, dry area free of oil, dirt, moisture, and other contamination. The Starter-Generator must be kept clean to ensure the operating effectiveness of the unit.

B. Disassembly

Disassemble the Starter-Generator according to the instructions provided in the 23048 Overhaul Manual and to the extent required to remove the armature. Discard the armature or submit it for remanufacture to the TRW Aeronautical Systems, Lucas Aerospace Repair and Overhaul (R&O) facility.

C. Cleaning

Fully clean all disassembled parts according to the instructions in the 23048 Overhaul Manual.

D. Inspection

Fully inspect all disassembled parts according to the instructions in the 23048 Overhaul Manual.

© 2000 TRW

Service Bulletin

E. Modification

Modification of parts is not required.

F. Assembly

Assemble the Starter-Generator according to the instructions in the 23048 Overhaul Manual using a P/N 23048-1032 armature.

G. Testing

A complete acceptance test is required according to the instructions in the 23048 Overhaul Manual.

SERVICE BULLETIN

NO. 132

ELECTRICAL POWER----INCREASED ELECTRICAL BRUSH-COMMUTATION LIFE BY USING NEW SPRINGS ON LSI/PED MODELS 23048-004, -008 STARTER GENERATORS.

1. PLANNING INFORMATION

A. Effectivity

This Service Bulletin is applicable to LSI/PED Models 23048-004, and -008 Starter Generators used on the DeHavilland Twin Otter and Turbo Beaver airplanes.

B. Reason

To provide brush springs that have lower specified pressure thus alleviating brush and commutator wear.
Old brush spring pressure (23033-1120) 45 to 63 oz.
New brush spring pressure (23033-1121) 40 to 55 oz.

C. Description

This Service Bulletin outlines service instructions for installing new brush springs, P/N 23033-1121 in the LSI/PED Starter Generator Models 23048-004 and 23048-008.

D. Compliance

Procedures outlined in this bulletin are recommended for replacement at next overhaul.

E. Approval

None required.

F. Manpower

Approximately 1/2 man-hour per unit is required to perform the change outlined in this bulletin.

LEAR SIEGLER, INC.
POWER EQUIPMENT DIVISION

G. Material - Cost and Availability

The material required to perform this change is available through your LSI/PED distributor, or may be obtained direct from Lear Siegler, Inc., Power Equipment Division, P.O. Box 6719, Cleveland, Ohio 44101.

H. Tooling

No special tooling is required to perform this change.

I. Reference

Lear Siegler Overhaul Manual File No. 23202.

2. ACCOMPLISHMENT INSTRUCTIONS

A. Removal of old springs and replacement with new should be accomplished by referring to instructions contained in above referenced overhaul manual. See paragraphs 2B through 2C on page 2, with reference to Figure 5 therein.

B. After new brushes are installed, run-in in accordance with instructions in overhaul manual as indicated in paragraphs 5F through 5H.

CAUTION: Do not mix brush springs removed with new brush springs. (New springs identified with blue dye).

SERVICE BULLETIN

NO. 141

ELECTRICAL POWER--MODIFICATION OF MODEL 23048-001, STARTER GENERATOR TO MODEL 23048-006.

1. Planning Information

A. Effectivity

This Service Bulletin is applicable to LSI/PED (Lear Siegler, Inc. - Power Equipment Division) Model 23048-001 Starter Generator. Employment of the modification described herein effects a model change to 23048-006.

B. Reason

To modify the 23048-001 to accommodate the quick-attach-detach mounting.

C. Description

This bulletin provides instructions for:

1. Modifying the 23048-001 to the 23048-006 quick-attach-detach configuration.

2. Installation of the 23046-512 quick-attach-detach kit and starter generator on the aircraft.

D. Compliance

Compliance with this bulletin is optional for operators using LSI/PED Starter Generator Model 23048-001.

E. Approval

None required.

F. Manpower

When this modification is accomplished at the time of overhaul, no additional man-hours are required.

NO. 141

1. Planning Information (Continued)

G. Material - Cost and Availability

The materials required to perform this modification are available through your LSI/PED distributor and prices will be quoted upon request. Material required per unit -

Part No.	Description	Quantity
52-000069	Kit, Modification, consisting of:	1
23046-1670	End Bell	1
05-350208	Screw	12
23046-512	QAD Kit	1

NOTE: The 23046-512 Kit is not furnished as part of Model 23048-006.

H. Tooling

No special tooling required.

I. Weight and Balance

Additional weight - 0.6 lbs., when QAD Kit is included.

J. Reference

Lear Siegler, Inc., Overhaul Manual File No. 23202.

2. Accomplishment Instructions

A. Disassembly (See Figure 1 in this bulletin)

1. Loosen clamp (2) sufficiently, then remove air inlet assembly. Twist fan

File No. 23411
June 15, 1968

SERVICE BULLETIN

NO. 141

2. Accomplishment Instructions (Continued)

cover either clockwise or counter-clockwise to unlock, then drop off from around fan. If necessary to separate air inlet castings, remove screws (3) and washers (4).

2. Loosen screw (7) and separate from slot and remove brush cover (6) from housing.

3. Remove the two-piece lock nut (11) and fan (10) from drive-shaft.

4. Tap out drive-shaft (12) using a plastic hammer, then remove clutch-dampener (13) and dampener back-plate (14).

5. Remove screws (15), lock washers (16) and washers (17), then remove drive-end end-bell assembly (21). Discard these parts.

B. Reassembly (See Figure 2 in this bulletin)

1. Install drive-end end-bell assembly (1) against stator, secure with screws (2). Make certain end-bell is fully seated on bearing.

2. See Figure 1. Install dampener back-plate (14) on armature and make certain back-plate taper is fully seated on drive-shaft taper.

3. Install clutch-dampener (13) over small spline end of drive-shaft (12), and make certain dampener taper is fully seated on drive-shaft taper.

4. Install drive-shaft through armature, making certain splines of drive-shaft are fully engaged with splines of armature.

5. Install fan (10) and secure with two-piece nut (11). Tighten inner nut to 70-80 inch-pounds and outer nut to 70-80 inch-pounds.

6. Install brush cover (6) and secure with screw (7). Cover may be assembled in any angular position.

SERVICE BULLETIN

NO. 141

2. Accomplishment Instructions (Continued)

7. Install fan cover (5), then position so that grooves will accomplish a locking effect. Turn clockwise or counter-clockwise to lock.

   NOTE: Do not assemble air inlet to unit until Starter Generator is installed in the aircraft.

8. After installing air inlet (1), secure with clamp (2). Torque nut to 25 inch pounds.

9. On nameplate carefully stamp a "6" over the "1" on the Model No. 23048-001.

C. Installing Unit On Aircraft

1. From QAD Kit 23046-512 remove drive-end pad, end-bell, Item 3B, Figure 2 and install on engine using standard mounting bolts.

2. With the "T" bolt on "V" band Item 3A, Figure 2, unlatched place the "V" band on the Starter Generator between the mounting flange and the terminal block.

3. Holding the Starter Generator flush up against the drive-end pad end-bell, Item 3B, Figure 2, position the "V" band over the mating flanges and securely latch with "T" bolt. Tighten latch firmly in preparation to torquing.

4. Tap "V" band at several places around circumference with soft mallet to accomplish true alignment and tighten nut to 2/3 recommended final torque - approximately 30 inch pounds.

5. Repeat tapping around circumference of "V" band and tighten to final recommended torque of 50 inch pounds.

   CAUTION: Keep Starter Generator flush up against drive-end pad end-bell, Item 3B, Figure 2, during installation. Do not permit the Starter Generator to hang loosely or without "V" band being tightened. This will cause undue bending force on drive-shaft shear section, resulting in damage and possible in-flight failure.

FILE NO 23416

SERVICE BULLETIN

NO. 160

ELECTRICAL POWER---D.C. GENERATORS AND STARTER GENERATORS, INSTRUCTIONS FOR ASSEMBLING THE DRIVE SHAFT AND DAMPENER ASSEMBLY.

1. PLANNING INFORMATION

A. Effectivity

This service bulletin is applicable to the following Lear Siegler, Inc., Power Equipment Division (LSI/PED) Starter Generator Models:

23032-007, -010, -011, -012, -020, -022
23046-001, -004, -006, -007, -009, -012, -014, -015, -016, -040
23048-001, -004, -006, -008, -012, -014
23064-001, -002
30059-001, -002, -010, -011

B. Reason

Various service-overhaul personnel have expressed a need for explicit instructions detailing the assembly of dampener, and backplate to the drive shaft for the models listed above. This service bulletin is issued to further clarify the procedures thus precluding possible misalignment of assembly.

C. Description

This service bulletin provides supplementary information to the instructions appearing in LSI/PED overhaul manuals for the LSI/PED starter generators also generator models listed above. This information is presented herein as tabular data and references usage of special tools in illustrations, for assembly of dampener and for assembly of backplate.

"IN SERVICE TO THE AIRLINES"

D. Compliance

The use of "homemade" tools or, guessing at the relative mating faces of the drive shaft dampener assembly parts, is very uncertain and should not be attempted.

SERVICE BULLETIN

NO. 160

1. PLANNING INFORMATION (Continued)

D. Compliance (Continued)

The special tools described in this service bulletin were designed not only to facilitate the installation of the dampener backplate on the armature and the clutch dampener on the drive shaft, but to remove any "guess-work" that may be employed in their assembly.

Lear Siegler earnestly recommends these tools be employed to assure proper relationship between these parts when accomplishing overhaul. Future revisions of service manuals affecting these models will reflect the instructions contained herein.

E. Approval

None required.

F. Manpower

When replacement of dampener and backplate is accomplished at overhaul, no additional manhours are required.

G. Material - Cost and Availability

The tools required for each LSI/PED model are referenced in the tables on pages 6 and 7.

Prices for the tools can be obtained from either the D. C. Product Support Manager of LSI/PED or their authorized distributors listed below. (A set of tool drawings may be purchased from LSI/PED at $250.00 net).

Aircraft Appliances & Equipment, Ltd.
American Avitron, Inc.
Airwork Corporation
Pacific Airmotive Corporation

Delivery will be 180 days or less.

SERVICE BULLETIN

NO. 160

1. PLANNING INFORMATION (Continued)

H. Tooling

No tooling, other than those listed on pages 6 & 7 , are required to properly install the dampener backplate and clutch dampener.

I. Weight and Balance

No change.

J. References

Applicable service manuals for models referenced in tables are Files 23202, 23203, 23206, 23207 and 30203.

2. ACCOMPLISHMENT INSTRUCTIONS

A. Installing the Dampener Backplate.

Refer to Figure 1 and Table of Special Tools/Installing Backplate.

1. Mount the Lower Adaptor in the base of an arbor press that provides frim support.

2. Mount the Ram Adaptor securely in the arbor press head, making certain it is aligned with the Lower Adaptor.

3. Place the starter generator or generator in proper position in the arbor with the anti-drive end down and with bearing resting flush upon the base of the Lower Adaptor.

4. Insert the Set Gage into hollow armature shaft with small O. D. end of the tool downward and in alignment with anti-drive end ball bearing.

5. Carefully position the dampener backplate on the armature assembly. MAKE CERTAIN THAT THE BACKPLATE IS EVENLY SEATED ON THE TAPERED SHAFT OF THE ARMATURE.

LEAR SIEGLER, INC. / POWER EQUIPMENT DIVISION
P. O. BOX 6719
CLEVELAND 1, OHIO

SERVICE BULLETIN

NO. 160

2. ACCOMPLISHMENT INSTRUCTIONS (Continued)

6. Lower the arbor press until the Ram Adaptor contacts the backplate, then continue the seating operation until the Ram Adaptor rests solidly on the end of the Set Gage.

CAUTION: The pressure on the Ram Adaptor should be applied steadily and without sudden jerk of press handle. Discontinue pressure on Ram Adaptor as soon as Set Gage is felt to "bottom" on ID of armature.

NOTE: Before proceeding to install the clutch dampener on drive shaft, replace the Lower Adaptor with appropriate tool referenced in table.

B. Installing the Clutch Dampener on the Drive Shaft

CAUTION: The installation of the clutch dampener on drive shaft requires precise positioning, otherwise proper mating with the backplate cannot be attained.

1. Refer to Figure 2 a and b also Table of Special Tools/Installing Clutch Dampener.

2. Mount the Lower Adaptor in the base of an arbor press that provides firm support. If not already in place, mount the Ram Adaptor securely in the arbor press head, making certain it is aligned with the Lower Adaptor.

3. Place the Set Gage on the Lower Adaptor so that it is positioned over the hole in the Lower Adaptor.

4. Slide the clutch dampener over the small end of drive shaft making certain the taper of the clutch dampener is set properly on the taper of the drive shaft. (Apply light film of oil to tapered surface).

5. Insert the clutch dampener and shaft through the Set Gage so that the clutch dampener rests upon the Set Gage, and the anti-drive end of drive shaft is either centered within hole of Lower Adaptor (See Figure 2 a) or that tapered spline is

File No. 23416

2. ACCOMPLISHMENT INSTRUCTIONS (Continued)

properly fitted into the Lower Adaptor as in Figure 2 b.

NOTE: Recheck alignment of parts and tools to be sure of their correct position when pressure is applied with the arbor.

6. Lower arbor press slowly until it contacts the drive shaft, then continue seating operation until drive shaft "bottoms" and rests solidly on or in the Lower Adaptor. tool.

7. Remove the assembled shaft and clutch dampener and install it in the starter generator, or generator, as outlined in the applicable overhaul manual.

ELECTRICAL POWER---STARTER GENERATOR LSi/PED MODEL 23048-014, MODIFICATION TO MODEL 23048-015.

1. PLANNING INFORMATION

A. Effectivity

This service bulletin is applicable to all LSi/PED Starter Generators, Model 23048-014 manufactured by Lear Siegler, Inc., Cleveland, Ohio.

B. Reason

To provide increased allowable operating temperature.

C. Description

This service bulletin contains instructions for replacing the ball bearings P/N 03-6010-08 in the modification of the 23048-014 Starter Generator.

D. Compliance

It is recommended that the new ball bearings, P/N 03-6010-08, be installed at the next scheduled overhaul or as soon as practicable.

E. Approval

Not required.

CHANGE NOTICE

The attached pages supersede the entire previous issue. Discard the basic bulletin and replace with this reprinted issue.

SB 167-1

Page No.	Issue Date	Nature of Change	Reason
1	3/10/71	Paragraph 1.C has been changed to read, "The depth of mica undercut has been changed from .032 inches max width by .032 inches deep, to .037/.045 width by .064 + .005 deep."	Revised dimensions are compatible with actual practice.
3	3/10/71	Paragraph 2A & 2B changed by deleting note under 2A and rewording 2B to be consistent with changes on page 1.	Simplify wording of instructions.

SERVICE BULLETIN

NO. 167-1

ELECTRICAL POWER - D. C. STARTER GENERATORS - MODELS 23046, 23048 SERIES AND 23070-001 - REPAIR OF ARMATURE COMMUTATOR

1. PLANNING INFORMATION

A. Effectivity

This service bulletin affects Lear Siegler (LSI/PED) starter-generators employing armatures P/N 23046-1030, 23048-1030, and 23069-342.

B. Reason

A new minimum commutator diameter has been established for overhaul to provide longer useful armature life. The mica undercut dimension has been increased also to accommodate in-service brush change.

Compliance with this bulletin will result in increased useful life of armature and reduced service costs.

C. Description

The minimum serviceable commutator diameter is reduced from 2.135 inches to 2.055. The depth of mica undercut has been changed from .032 inches maximum width by .032 inches deep,.. to .037/.045 width by .064+.005 deep. (See ACCOMPLISHMENT INSTRUCTIONS in this bulletin for complete details.)

D. Compliance

LSI/PED recommends the changes provided in this bulletin be accomplished at the next scheduled overhaul of these starter-generators.

2. ACCOMPLISHMENT INSTRUCTIONS

Refer to the above listed overhaul manuals, under References, for disassembly cleaning, reassembly and testing of units. The instructions in this bulletin are to be used in lieu of those in these manuals for Inspection also Repair and Replacement.

A. Repair Armature Commutator

If inspection reveals that commutator is rough, pitted, scored, or burned, refinish in a lathe that is accurately set up and adjusted. REMOVE ONLY THE MATERIAL NECESSARY TO CLEAN AND TRUE-UP THE COMMUTATOR SURFACE. Replace armature that necessitates turning of commutator to less than a minimum diameter of 2.055 inches. Concentricity of commutator with bearing journals must be maintained within 0.0005 inch T. I. R.

CAUTION: When the armature has been cut to 2.055 + .005-.000 it is mandatory that new brushes be installed.

B. When the commutator is turned down on the lathe, the mica between the commutator bars should be undercut to .037/.045 width, by .064 $\pm$ .005 deep.

Use a triangular scraper and a bristle brush to remove all excess mica, sharp edges and burrs from between commutator bars. Check for commutator concentricity.

C. Mount the armature in a lathe and operate at a speed of 500 to 600 RPM. Polish commutator by applying 5°0 sandpaper (not emery paper) adequately contoured and supported over entire length of commutator and one-third of its periphery. Remove dust with a bristle brush.

D. Balance the armature as indicated in the appropriate overhaul manual.

E. Proceed with scheduled overhaul and testing of unit as indicated in the appropriate overhaul manual.

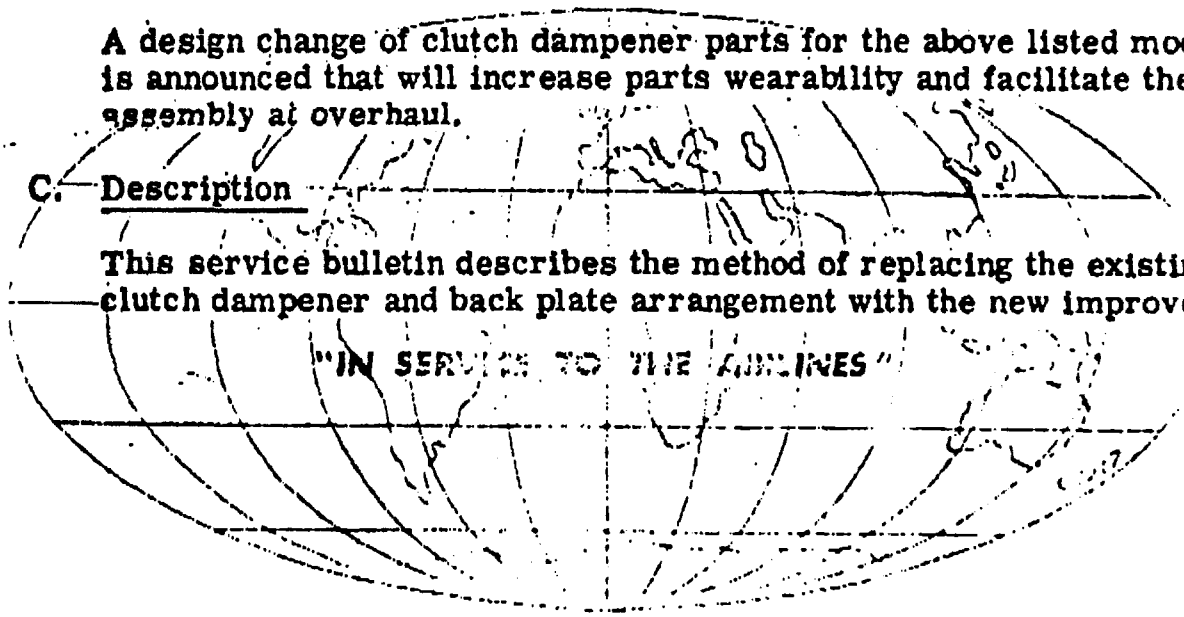
NO. 169-1

ELECTRICAL POWER---DC GENERATORS AND STARTER GENERATORS, USAGE OF NEW CLUTCH DAMPENER AND BACK PLATE ASSEMBLIES.

1. PLANNING INFORMATION

A. Effectivity

This service bulletin is applicable to the following Lear Siegler, Inc., Power Equipment Division (LSI/PED) Starter Generator and Generator Models:



23032-007, -010, -011, -012, -020, -022, -032; 23033-002;
23046-001, -004, -006, -007, -009, -012, -014, -015, -016, -017, -019, -040;
23048-001, -004, -006, -008, -012, -013, -014, -015, -016, -018;
23065-003, -004, -005, -006, -009;
23069-012, -013, -014, -016;
23064-001, -002, -003, -005;
30059-000, -001, -002, -003, -010, -011.

B. Reason

A design change of clutch dampener parts for the above listed models is announced that will increase parts wearability and facilitate their assembly at overhaul.

C. Description

This service bulletin describes the method of replacing the existing clutch dampener and back plate arrangement with the new improved

LEAR SIEGLER, INC. / POWER EQUIPMENT DIVISION

Maple Heights, Ohio 44137

Revised June 1, 1973
November 1, 1970

SERVICE BULLETIN

NO. 169-1

1. PLANNING INFORMATION (Continued)

design. The new clutch dampener consists of an individual clutch plate and a splined hub, also, a clutch back plate and a replaceable friction disc. The employment of the new arrangement simplifies the assembly of these parts and obsoletes File 23414 (S.B. 153) and File 23416 (S.B. 160); previously issued to explain clutch dampener assembly method of existing production units. See Figure 1, Cross Sectional View of new dampener assembly for parts relationship and assembly method.

D. Compliance

Compliance with this bulletin is optional, based upon individual requirements of operators. LSI recommends that the new improved design parts be ordered and installed, using interchangeably with old parts in stock as necessary for attrition. The existing design (old type) of clutch dampener and back plate has been discontinued and all parts orders will be accomplished by shipment of the new design parts. See Table I for cross reference between old and new type parts. The interchangeability of parts is described under "Material Information."

E. Approval

None required.

F. Manpower

When replacement of parts is accomplished at overhaul no additional man-hours are required.

G. Material - Cost and Availability

New parts and prices can be obtained from the following LSI/PED authorized distributors.

Delivery 180 days or less

H. Tooling

None required when installing the improved clutch dampener parts covered in this bulletin. The special tools listed in LSI/PED Service Bulletin No. 160 are no longer required and should be disregarded, unless old parts still in stock are employed.

I. Weight and Balance

No change.

J. References

Applicable service manuals for models referenced in tables are File. Nos: 23201, 23202, 23203, 23206, 23207, and 30203.

SERVICE BULLETIN

NO. 169-1

2. ACCOMPLISHMENT INSTRUCTIONS

1. Removal of Old Parts. (Refer to Figure 2)

A. Disassemble the starter generator, or generator, in accordance with the instructions provided in the applicable overhaul manual.

B. Remove and discard old clutch dampener (14) and old clutch back plate (15), as referenced by index numbers in Figure 2.

2. Installation of New Parts. (Refer to Figure 1)

A. Assemble the starter generator, or generator, in accordance with the instructions provided in the applicable overhaul manual.

NOTE: For the purpose of this service bulletin disassemble only to the extent necessary to remove clutch dampener and back plate.

CAUTION: DO NOT USE AN ARBOR PRESS TO FORCE DRIVE SHAFT TAPER INTO TAPERED HOLE OF CLUTCH HUB DURING ASSEMBLY.

B. Install the new clutch back plate on the armature making sure the new back plate is properly seated on the shaft taper.

C. Install the new clutch hub over small spline end of the drive shaft, making certain the hub taper is fully seated on the taper of drive shaft.

D. Install the new clutch plate over small spline end of drive shaft making certain it engages with the spline on the new clutch hub and fully bottoms on the shoulder of the clutch hub.

E. Install the new friction disc in the recess on the clutch back plate. Hold the friction disc in place while installing the drive shaft through the armature, making certain splines of drive shaft are fully engaged with splines of armature and the clutch plate captures and holds the friction disc in place.

File No. 23421
November 1, 1970
Revised March 5, 1971

SERVICE BULLETIN

NO. 169-1

2. ACCOMPLISHMENT INSTRUCTIONS (Continued)

F. Complete the assembly of the starter generator or generators in accordance with instructions provided in the applicable overhaul manual.

NOTE: Make certain that friction disc does not slip out of its recess in the clutch back plate and remains captured as illustrated in Figure 1.

NOTE: Tightening of the nut (12, Figure 2) on drive shaft will cause tapered fit of drive-shaft to clutch-hub, also armature-shaft to back-plate to seat properly.

G. Test the starter generators, or generator, in accordance with instructions in the applicable overhaul manual.

NOTE: There are no manuals for Models 23065 Series or 23069 Series Starter Generators. These models are tested generally the same as Model 23046 Series except as follows:

	23046 Series	23065 Series	23069 Series
Max Speed for Regulation	Same	Same	Same
Compounding	Same	Same	Same
Min Speed for Regulation (with following conditions)	7900 rpm	7470 rpm	6650 rpm
External Resistance in Shunt Field	1.25 ohm	1.25 ohm	0.2 ohm
Max Field Current	8 amp	8 amp	10 amp

3. MATERIAL INFORMATION

The new clutch dampener parts are interchangeable with existing (old type) parts. Complete information for replacement and interchangeability of parts is provided in Table I. The new clutch dampener assembly consists of four parts, viz: clutch-

ELECTRICAL POWER --- STARTER GENERATOR LSI/PED MODELS 23048-014, 23048-015 MODIFICATION TO MODEL 23048-018

1. Planning Information

A. Effectivity

This service bulletin is applicable to (LSI/PED) Starter Generators Model 23048-014 and 23048-015 manufactured by Lear Siegler, Inc., Power Equipment Division, Maple Heights, Ohio.

B. Reason

To provide one compatible unit to operate on all Beech Series C90, E90, 99A and A100 series aircraft.

C. Description

This service bulletin, in conformity with Service Bulletin No. 166, contains instructions for replacing the ball bearings P/N 03-6010-08, and brushes P/N 30300-1284 in the modification of the 23048-014 and 23048-015 starter generators.

D. Compliance

It is very necessary that the new ball bearings P/N 03-6010-08 and new brushes P/N 30300-1284 be installed immediately on any 23048-014 or 23048-015 starter generator to be installed on Beech series "100" aircraft.

Other units may be modified at the next scheduled overhaul or as soon as practicable.

E. Approval

Not required

(Rev. Sept. 25/72)
August 15, 1972

17600 Broadway Avenue
Maple Heights, Ohio 44137

F. Manpower

No additional man hours required when performed at overhaul.

G. Material - Cost and Availability

The new ball bearings and brushes are available through your LSI/PED distributor.

H. Tooling

No special tools are required

I. Weight & Balance

Not affected.

J. Reference

LSI/PED Overhaul Manual File No. 23202

2. Accomplishment Instructions

Install new ball bearing. P/N 03-6010-08 in accordance with paragraphs 6B, 6C, 6D and follow brush procedure in paragraphs 5F, 5G and 5H in LSI/PED Overhaul Manual, File No. 23202.

3. Material Information

New Part No.	Quantity	Description	Old Part No.	Disposition
03-6010-08	2	Bearings Ball	07-111253	Discard
30300-1284	4	Brushes	30300-1282	Discard

Restamp identification nameplate from 23048-014 and 23048-015 to 23048-018 starter generator and mark the nameplate 200/250 amps.

Beech part number on nameplate must be changed from 115-389004-1 and 97-389001-1 to 100-389005-11 after modification.

On the Model 23048-014, P/N is 115-389004-1; change to a 100-389005-11.

On the Model 23048-015, P/N is 97-389001-1; change to a 100-389005-11.

SERVICE INFORMATION LETTER 02-5600-01, Revision 1

Generators - Dampener Friction Ring Replacement

1. PLANNING INFORMATION

A. Effectivity

All Lucas Aerospace Power Equipment Corporation (LAPEC) (formerly Lear Siegler Power Equipment Corporation) Generators.

B. Reason

The original service information letter dated December 21, 1988 contained an incomplete/incorrect list of generators affected by this change.

C. Description

This service information letter provides a complete list of replacement dampener friction ring part numbers.

D. Compliance

LAPEC recommends that the modifications outlined in this service information letter be accomplished when any part of the dampener assembly (dampener plate or backplate) are replaced or when the existing friction ring is damaged.

E. Approval

This service information letter has the approval of LAPEC.

F. Manpower

No additional manhours are required for this modification when it is done during overhaul or repair of the generator.

G. Material Cost and Part Availability

H. Tooling and Cost Availability

No special tools are required to accomplish the contents of this service information letter.

I. Weight and Balance

Not affected.

J. Electrical Load Data

Not affected.

K. References

Refer to the applicable Component Maintenance Manual (CMM) with Illustrated Parts List for your generator.

L. Publications Affected

All Component Maintenance Manuals with Illustrated Parts List for each generator is affected by the issuance of this service information letter through a revision to the parts list.

2. ACCOMPLISHMENT INSTRUCTIONS

A. Disassembly

Disassemble the generator to the extent necessary to remove the original friction ring as detailed in the DISASSEMBLY section of the CMM.

B. Repair

Not applicable.

C. Assembly

Assemble the generator as outlined in the ASSEMBLY section of the CMM.

D. Testing

Test the generator according to the procedures provided in the TEST section of the CMM.

3. REIDENTIFICATION

Not required.

SERVICE INFORMATION LETTER

NUMBER 03-6010-XX-01

- VENTED BEARING SEALS -

A. Effectivity

All Lucas Aerospace Power Systems, Aurora (LAPSA) (formerly Lear Siegler Power Equipment Division) starter-generators and generators that use 03-6010-10, 03-6010-14 or 03-6010-18 bearings.

B. Reason

This service information letter is being issued to provide a physical description of a new bearing seal. This seal is used with the bearings listed in Paragraph A of this service information letter.

C. Description

A small vent-hole that is visible on the surface of the bearing seal allows the air pressure inside and outside the bearing to equalize as the operating temperature of the bearing changes. When the air pressure is equalized, seal wear is reduced.

D. Weight and Balance

Effect on weight: None.

Effect on balance: None.

E. Electrical Load Data

Not affected.

F. References

There are no references for this service information letter.

G. Publications Affected

No publications are affected by this service information letter.

SERVICE INFORMATION LETTER

NUMBER 23701

ION VAPOR DEPOSITION ALUMINUM COATING

1. PLANNING INFORMATION

A. Effectivity

This service information letter is applicable to all Lucas Aerospace Power Systems, Aurora (LAPSA) (formerly Lear Siegler Power Equipment Division) generators and starter-generators with ion vapor deposition (IVD) coated parts and assemblies.

B. Reason

The introduction of IVD aluminum coatings for exterior generator and starter-generator parts and assemblies will reduce the need for and the cost of repairing exterior surfaces.

C. Description

This service information letter provides information on the superior performance characteristics of the IVD aluminum coating. It also provides information relevant to the cleaning of IVD aluminum coated parts and assemblies during overhaul.

IVD aluminum is a protective coating applied to ferrous metal parts. The IVD process was developed as a replacement for cadmium plating of steel. It is a vacuum deposition process which deposits pure aluminum on most metal substrates. It is extremely durable and is resistant to scratching and corrosion. The IVD coating is non-toxic and non-hazardous and provides excellent "sacrificial" corrosion resistance on steel with no hydrogen embrittlement. This coating is capable of withstanding high operating temperatures (see Table 1). It also provides improved electrical bonding by reducing the electrical resistance between parts and assemblies.

LAPSA has changed from the painted coating finishes of many steel exterior generator parts, including stator housings, air inlets, brush access covers, endbells, and QAD mounting adapters to IVD aluminum coating. While IVD coatings are pure aluminum which would generally appear silver or gray, LAPSA generators with IVD coated parts will have a gold appearance. This is the result of a supplementary chemical conversion coating which provides additional corrosion protection to the aluminum coating.

Coating Thickness	.001 - .002 in. (.03 - .05 mm)
Hours Tested	672 hours in 5% neutral salt
Operating Temperature Limits	925°F (495°C) maximum

Table 1 - IVD Coating Attributes

D. Compliance

Generators with IVD aluminum coatings successfully completed environmental and electrical testing with no physical or functional degradation. All IVD aluminum coated parts are manufactured in accordance with LAPSA approved drawings, specifications, instructions, and processes.

E. References

Refer to the applicable Component Maintenance Manual (CMM) with Illustrated Parts List (IPL) for all exterior starter-generator parts and assemblies.

F. Other Publications Affected

All affected CMMs will be revised to include the contents of this service information letter.

©1996 Lucas Aerospace

2. MATERIAL INFORMATION

A. Material Requirements

Materials needed for cleaning of IVD coated parts and assemblies are listed below.

Material	Description/Specification	Instruction/Disposition
Brush	Non-metallic, soft bristle	Commercially available.
Cleaning pads/Wiping cloth	Lint free, soft fabric	Commercially available.
Compressed Air	30 PSIG (207 kPa)	Commercially available.
Detergent (see **NOTE** below)	Formula 815 GD Formula 1990 GD	Clean the parts. Procure from: The Brulin Company P.O. Box 270 Indianapolis, IN 46206
Isopropyl Alcohol	TT-I-735	Commercially available.

Table 2 - Cleaning Materials

NOTE: Formula 815 GD is for use with aluminum-safe hot tanks, steam cleaning, and ultrasonic cleaning. Formula 1990 GD is for use with pressure sprayers and spray wash cleaning.

B. Cleaning

Fully clean and rinse the IVD parts with water and recommended detergent until a water-break free surface is attained. Use of the following cleaning procedure will ensure the durability of IVD aluminum coated parts and assemblies.

CAUTION: It is strongly recommended that the detergents listed in Table 2 be used when cleaning IVD coated parts. The use of improper cleaning solutions may damage the IVD coating. Parts should not be exposed to cleaning solutions longer than is necessary to remove dirt and other particles. Follow the manufacturer's recommended dilution and cleaning times.

(1) Before any surface coatings are applied, all parts are to be fully cleaned and dried. Wash the parts using one or more of the approved cleaning methods listed below.

Method	Instructions
Spray wash the parts.	**CAUTION:** Make sure to limit the pressure used to clean parts. High pressure may remove or damage surface coatings.
	(a) Put the parts into a pressure spray wash booth.
	(b) Spray the parts with a solution of detergent and water.
Clean the parts ultrasonically.	**CAUTION:** Ultrasonic cleaning tanks can remove plating from metal surfaces. Extended exposure to ultrasonic cleaning can cause parts to lose their dimensional tolerances.
	(a) Put the parts into an ultrasonic soaking tank.
	(b) Allow the parts to be ultrasonically cleaned for no more than 20 minutes.
	(c) Remove all evidence of oil, dirt and carbon residue with a soft bristle brush or a cleaning rag.

©1996 Lucas Aerospace

Method	Instructions
Soak the parts in an agitation tank.	(a) Put the parts into an agitation tank.
	(b) Remove all evidence of oil, dirt and carbon residue with a soft bristle brush or a cleaning rag.
Soak the parts and clean them by hand.	(a) Put all the parts into a soaking tank.
	(b) Remove all evidence of oil, dirt and carbon residue with a soft bristle brush or a cleaning rag.

Table 3 - Cleaning Methods

(2) Flush the parts.

NOTE: Use only minimal pressure to rinse the parts.

(a) Put the parts into a pressure spray wash booth.

(b) Flush the parts using hot water or steam.

(c) Repeat the appropriate cleaning procedure where necessary, until the parts are clean and free of dirt and carbon residue.

(3) Dry the parts.

(a) Put the parts in an oven at a temperature of 250°F (121°C) for 2 1/2 hours.

(b) Remove any moisture from the remaining parts with a dry lint free cloth.

WARNING: ISOPROPYL ALCOHOL IS FLAMMABLE AND TOXIC. VAPORS CAN CAUSE DIZZINESS, HEADACHE, AND INTOXICATION. USE RESPIRATORY PROTECTION WHEN HANDLING LARGE QUANTITIES.

(c) Check each part for carbon particles by wiping the assemblies with isopropyl alcohol using a clean, lint-free cloth.

B. Reason

LAPSA has replaced the P/N 02-4107-01 double hex self locking nut that attaches the fan to the drive shaft of most of its starter-generators with a P/N MS21042-4 single hex self locking nut. Replacement of the P/N 02-4107-01 nut with the P/N MS21042-4 nut will reduce the cost of repair and overhaul of the starter-generators listed above.

©1997 Lucas Aerospace

SERVICE INFORMATION LETTER

C. Description

This service information letter provides authorization for the use of P/N MS21042-4 self locking nut in the starter-generators listed on page 1. The change to the part number of the self locking nut establishes the P/N MS21042-4 self locking nut as the "standard" part for use in the starter-generators listed on page 1. This covers most LAPSA starter-generators.

D. Compliance

LAPSA recommends that the part introduction described by this service information letter be accomplished when the P/N 02-4107-01 double hex self locking nut requires replacement.

E. Approval

This service information letter has the approval of LAPSA and contains no modification information that revises the approved configuration of affected starter-generators and therefore does not require governmental or other regulatory agency approval.

F. Manpower

No additional man-hours are required during repair or overhaul of the starter-generator.

G. Weight and Balance

Effect on weight: None.

Effect on balance: None.

H. Electrical Load Data

Not changed.

I. References

Refer to the applicable Component Maintenance Manuals (CMMs) with Illustrated Parts Lists (IPLs) for the starter-generators listed on page 1 of this service information letter.

J. Other Publications Affected

The applicable CMMs with IPLs for the affected starter-generators will be revised to reflect the part change described in this service information letter.

2. MATERIAL INFORMATION

A. Material - Price and Availability

Required parts and pricing information are available from the following Lucas Aerospace Customer Service Centers:

REGION	ADDRESS	COMMUNICATION	
AMERICAS:	LUCAS AEROSPACE CSA 30 Van Nostrand Avenue Englewood, NJ 07631-4396 USA	PHONE AOG FAX SITA/ARINC	(1) 201-567-6400 (1) 201-567-6411 (1) 201-541-7610 (1) 201-894-1965 BDRLU7X
EUROPE/MIDEAST/ AFRICA:	LUCAS AEROSPACE CSE Brueton House New Road Solihull West Midlands B91 3TX United Kingdom	PHONE/AOG TELEX FAX SITA/ARINC	(44) 121-627-6767 334174 (44) 121-500-6405 BHXLW7X
ASIA/PACIFIC:	LUCAS AEROSPACE CSP 35 & 37 Loyang Way Singapore 1750	PHONE AOG FAX SITA/ARINC	(65) 545-9975 (65) 545-6253 (65) 545-9965 SINLU7X

B. Support Information

Support information is not required to accomplish the part replacement described in this service information letter.

C. Material Requirements

Parts and materials required to modify the starter-generators listed on page 1 are provided below. Quantities listed are for one starter-generator.

New Part Number	Nomenclature	Old Part Number	Quantity
MS21042-4	NUT, Reduced Hex, Self Locking	02-4107-01	1

D. Re-Identified Parts

Re-identification of parts on the starter-generators listed on page 1 is not required.

3. ACCOMPLISHMENT INSTRUCTIONS

A. Preparation

The nut replacement shall be performed in a clean, dry area free of oil, dirt, moisture, and other contamination. The starter-generator must be kept clean to ensure satisfactory operation of the unit.

B. Disassembly

The starter-generator shall be fully disassembled according to the instructions in the applicable CMM with IPL and to the extent necessary to remove the P/N 02-4107-01 double hex self locking nut.

©1997 Lucas Aerospace

SERVICE INFORMATION LETTER

C. Cleaning

Fully clean the starter-generator according to the instructions in the applicable CMM with IPL.

D. Inspection

Fully inspect the starter-generator according to the instructions in the applicable CMM with IPL.

E. Modification

Modification of the starter-generator, parts, or assemblies is not required to accomplish the part number change described in this service information letter.

F. Assembly

Assemble the starter-generator according to the instructions in the applicable CMM with IPL with the exception that the P/N MS21042-4 single hex self locking nut shall be installed in place of the P/N 02-4107-01 double hex self locking nut.

G. Testing

During overhaul, a complete acceptance test is required before the starter-generator is released to the aircraft operator. A complete acceptance test is recommended, but not required, when only the P/N MS21042-4 self locking nut is installed in a starter-generator.

SERVICE INFORMATION LETTER

Number 23704

ELECTRICAL POWER - DC GENERATORS/STARTER-GENERATORS

THIS DOCUMENT CONTAINS INFORMATION PROPRIETARY TO TRW LUCAS AEROSPACE AND IS FURNISHED UPON THE EXPRESS CONDITION THAT THE INFORMATION CONTAINED HEREIN WILL NOT BE USED DIRECTLY OR INDIRECTLY IN ANYWAY DETRIMENTAL TO THE INTEREST OF TRW LUCAS AEROSPACE.

1. PLANNING INFORMATION

A. Effectivity

This service information letter is applicable to all TRW Aeronautical Systems, Lucas Aerospace, DC Generators and DC Starter-Generators that use bolt, P/N AN3-7A with vendor identification letters "AFC" on the head as shown in Figure 1. See Table 1 that lists the DC Generator or DC Starter-Generator models that use this part.

B. Reason

The P/N AN3-7A bolts with vendor identification "AFC" has been identified by TRW Aeronautical Systems, Lucas Aerospace engineering as inferior and below the MIL standard specification. Small cracks in the threaded surface of the bolt and a poor cadmium layer that does not meet MIL Standard Specifications that could lead to fatigue of the bolt were found. The TRW engineering evaluation resulted in the recommendation for removal and replacement of these bolts.

C. Description

At the next repair or overhaul of the DC Generators or DC Starter-Generators listed in Table 1, check the head of the AN3-7A bolts for the vendor code "AFC". Refer to the applicable parts list of the CMM to determine the location and usage of the AN3-7A bolts. For all AN3-7A bolts with the vendor code "AFC", replace the bolt with a new one with a different vendor code. If the bolt is used for attachment of the brush holders, refer to the applicable CMM for use of special brush alignment tools. If the alignment tool is not available, contact a service facility that can offer this service. Full acceptance testing is required for the DC Generator or DC Starter-Generator.

D. Compliance

RECOMMENDED

E. Manpower

No additional manpower is required when done at the next overhaul unless special alignment of the brush holder is required after the replacement procedure.

F. Weight and Balance

Not changed.

G. Electrical Load Data

Not changed.

H. References

(1) Reference the Component Maintenance Manual (CMM) specific to the model.

(2) Reference the Special Practices Document 1004, Brush Holder Alignment Fixtures, dated September 30, 1999.

2. MATERIAL INFORMATION

A. Support Information

Replacement AN3-7A bolts can be obtained commercially or from TRW Aeronautical Systems, Lucas Aerospace.

3. ACCOMPLISHMENT INSTRUCTIONS

A. Replacement of AN3-7A with Vendor Code "AFC".

(1) Disassemble the unit as specified in the applicable CMM.

(2) Look at the head of each bolt with part number AN3-7A for a vendor code of "AFC" as shown in Figure 1. If the vendor code is "AFC", the bolt is recommended to be replaced.

NOTE: Replace the bolt with a vendor code other than "AFC".

(3) Use the CMM applicable to the specific model for the disassembly and assembly procedures. The brush holder assemblies require a precision alignment procedure. Use a special alignment tool if specified in the applicable CMM.

(4) Apply Loctite to the threads of the bolt when specified in the applicable CMM.

(5) Apply protective coatings (such as glyptol) to the area when specified in the applicable CMM.

(6) Do an acceptance test on the DC Generators or DC Starter-Generator as specified in the CMM.

B. Support Information

The 23048-XXX DC Starter-Generator Component Maintenance Manual with Illustrated Parts List, Revised March 1, 1985 may be used to repair the 23048-027 and -028 DC Starter-Generators. All the sections of the manual that apply to the 23048-021 model also apply to the 23048-027 and -028 models.

The 23048-027 and -028 have the same components as the 23048-021 with the following exceptions:

Component	IPL Item No	23048-021	23048-027	23048-028
Drive Shaft	12	23046-1121	02-6100-02	02-6100-02

GENERAL

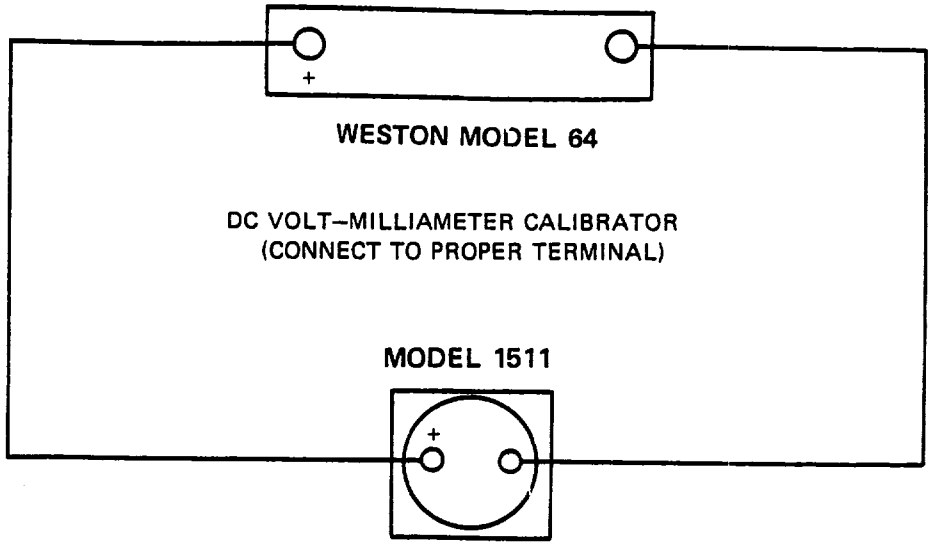
This manual contains operating, maintenance, testing and calibration instructions with replacement parts list for the Weston Model 1511 DC Millivoltmeter, part number 253198, manufactured by Weston Instruments Division, Weston Instruments, Inc., Newark, N.J.

This millivoltmeter is a sealed, ruggedized, permanent magnet, moving coil type instrument designed for use in the vicinity of shock or vibration. It is provided with a special slotted bezel to allow for external edge lighting.

The meter is calibrated and tested as a millivoltmeter but indicates Load DC, +1 to -1.

TABLE OF SPECIFICATIONS

Range	50/0/50 Millivolts DC
Scale	-1/0/+1 Load DC
Sensitivity	5 Milliamperes
Accuracy	± 2% of full scale
Case	1.5 inch dia steel barrel with rubber shock mountings



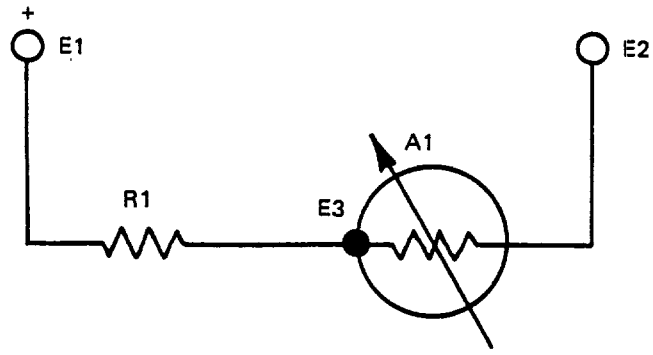


Figure 1. Calibration Circuit

A1 - Instrument Mech Assy (Resistance 2 ohms ± 20%)
E1 - Case Positive Back Connection Terminal
E2 - Case Negative Back Connection Terminal
E3 - Bracket Insulated Top Terminal
R1 - Resistance Coil (7.5 ohms ± 5%)

Figure 2. Internal Wiring Diagram.

OPERATING AND INSTALLATION INSTRUCTIONS

a. Mount the instrument on a vertical panel prepared in accordance with the drilling plan. (See Figure 3.) The panel material may be steel or a nonmagnetic material since the case provides magnetic shielding.

b. Connect the circuit lead wires to the back connection terminals, observing proper polarity.

MAINTENANCE INSTRUCTIONS

a. It is recommended that the instrument be tested for proper performance at twelve month intervals. It should always meet the requirements as stated in the Test Procedure and Calibration Check.

b. No lubrication is required of this instrument.

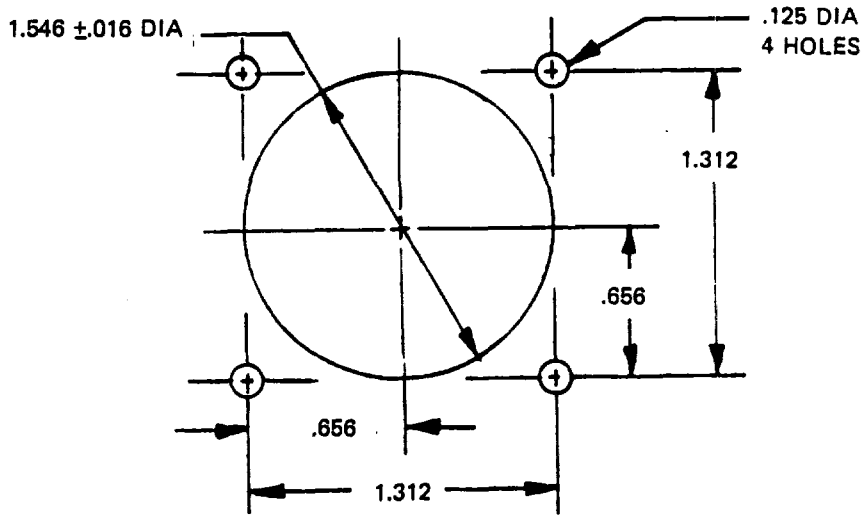

Figure 3. Panel Drilling Plan

CALIBRATION CHECK

a. Connect the instrument in circuit as illustrated in Figure 1.

b. Energize the instrument and check each cardinal point on the scale from 0 to end scale mark.

c. Each indication must be accurate to within 2% of full scale.

d. If the indications are not within the accuracy limits, refer to the following trouble shooting chart and test procedures to determine the probable cause of calibration error.

TEST PROCEDURES
