A. The single disk brake assembly is used on the main landing gear of the aircraft. The brake disk contains gear teeth at its perimeter for mating with a wheel assembly containing a gear tooth drive ring. Two interchangeable inlet ports are provided on the brake housing. Only one port is used as an inlet (depending on installation position on landing gear), and the other is used as a bleeder port.

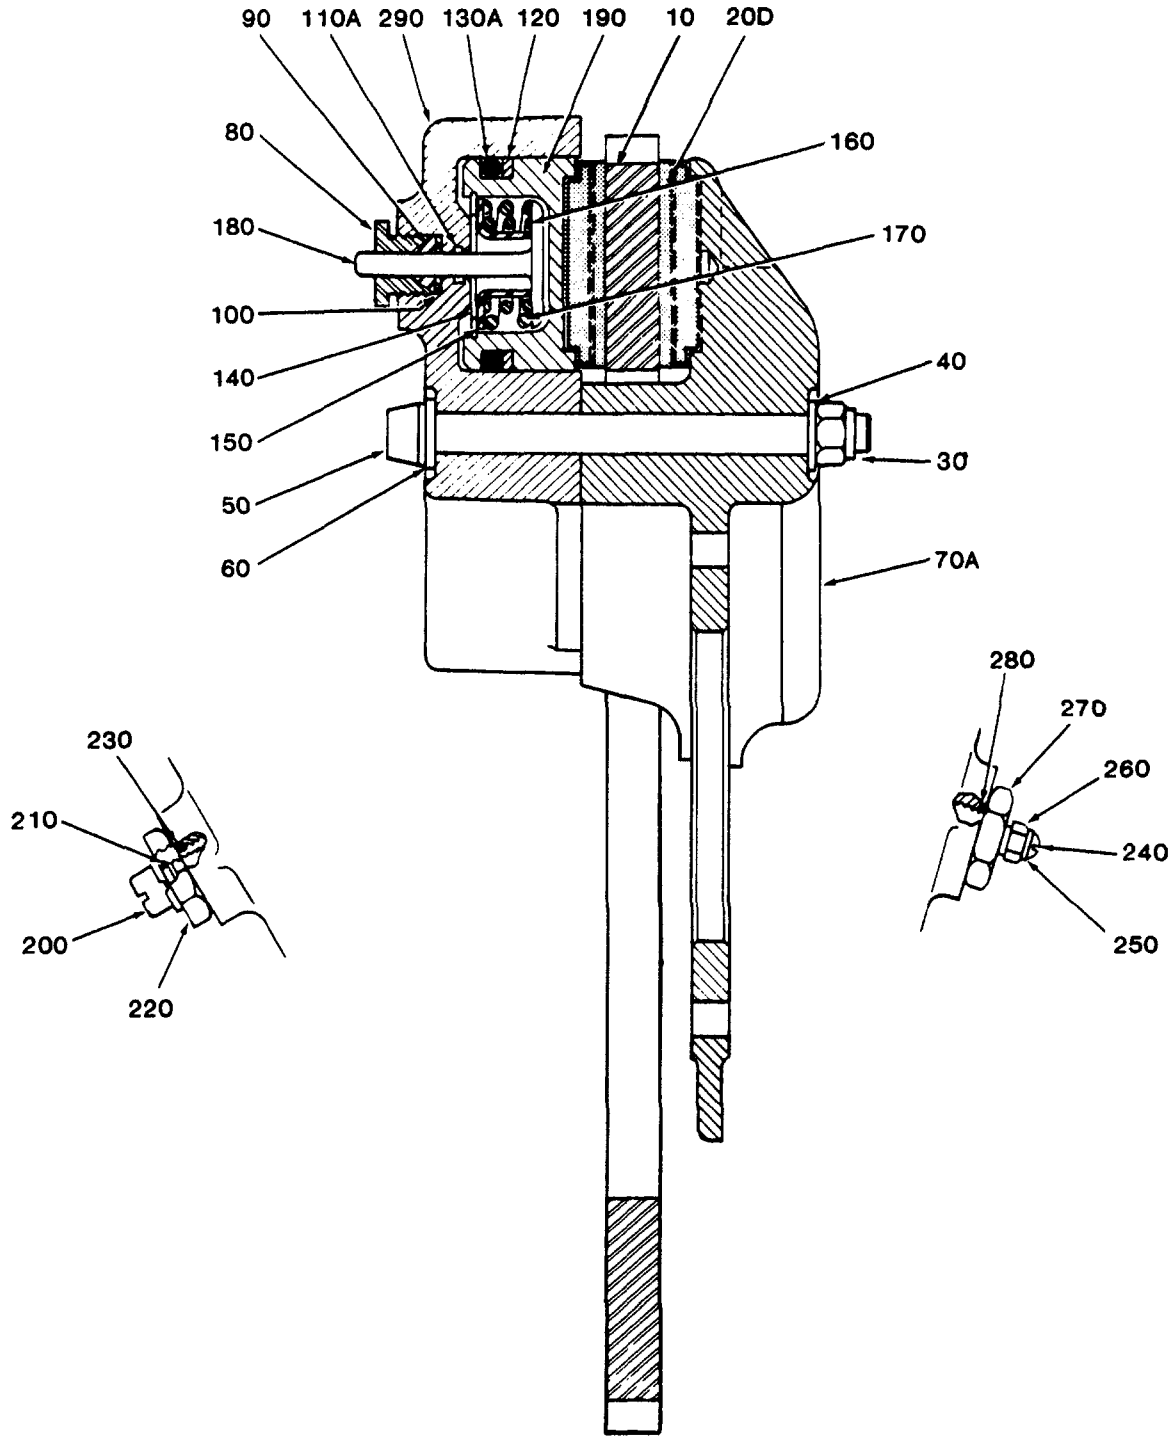
B. The brake assembly contains four pistons. Incorporated in each of the four pistons is an automatic adjustment mechanism which controls the clearance between disk and linings when the brake is in the off position, ensuring constant clearance during the life of the linings.

C. The brake pistons are sealed by means of preformed packings compounded for the type of brake fluid used in the brake system.

D. The brake housing is secured to axle torque flange by five bolts.

E. At operator's option, on Brake Assemblies 5001571, 5001571-3 and 5001571-6, an outer disk guide subassembly is available, but is not furnished unless ordered separately.

2. Operation



A. Single disk brakes operate on the principle of two opposed sections of brake lining separated by an annular disk, which is engaged to rotate with the aircraft wheel. To provide braking action, the linings are pressed against the disk by hydraulic pressure applied against the brake piston.

B. The brake linings are contained in recesses in the piston and backing plate section of the brake housing. A throat or groove is provided in the housing for the annular disk to pass through as the wheel rotates.

C. The disk floats on the wheel internal drive ring. This floating action compensates for the movement of the disk when braking pressure is applied. Only the piston side brake lining moves toward the disk, while the backing plate lining remains stationary. As the piston lining presses it, the disk moves until it contacts the backing plate lining. The disk then receives equal clamping action on both sides as pressure is increased. Optional disk guides may be installed on Brake Assemblies 5001571, 5001571-3 and 5001571-6 to minimize sideway movement and cocking of the brake disk.

D. The single disk brake is used with a wheel having an aluminum gear tooth drive ring riveted to the drive flange. When rotation of the disk is restrained by the brake unit, the torque forces are transmitted to the wheel through the drive ring.

E. Each brake contains an automatic adjustment mechanism which maintains a constant disk-to-lining clearance throughout the life of the lining, thereby ensuring a drag-free brake.

Brake Assemblies 5001571, 5001571-1, 5001571-2, 5001571-3,
5001571-4, 5001571-5 and 5001571-6

3. Handling Procedures

A. Careful handling of the brake components will assure a long service life and trouble-free operation.

B. Strictly observe torque and Lubtork values specified in this manual. Do not overtighten any bolt, nut or fitting.

C. Handle the brake parts with extreme care. Many failures can be traced to dropping or mishandling the parts during maintenance.

D. The brake should be properly maintained to protect the paint and surface finishes, as exposed surfaces are susceptible to corrosion. Nicks, scratches, and other damage caused by improper handling of the brake during maintenance invite corrosion, which if unattended will eventually lead to fatigue cracks and premature removal from service.

4. Leading Particulars

Weight (approximate)
for 5001571, 5001571-3 . . . . . 21.2 pounds (9,6 kg)
Weight (approximate)
for 5001571-1, 5001571-4 . . . . . 22.3 pounds (10,1 kg)
Weight (approximate)
for 5001571-2, 5001571-5 . . . . . 23.8 pounds (10,8 kg)
Weight (approximate)
for 5001571-6 . . . . . 25.1 pounds (11,4 kg)
Hydraulic Fluid . . . . . Specification MIL-H-5606

Operating Pressure
Brake Assembly 5001571,-1,-3, -4, -5 and -6 . . . . . 700 psi (48,3 bars)
Brake Assembly 5001571-2 . . . . . 900 psi (62,1 bars)

Back Pressure . . . . . 40 psi (2,8 bars)

Operating Clearance . . . . . 0.028 inch (0,71 mm) (minimum)
. . . . . 0.50 inch (1,27 mm) (maximum)
Material:
Brake Housing . . . . . Cast Magnesium Alloy
Brake Backing Plate . . . . . Cast Magnesium Alloy
Pistons . . . . . Cast Magnesium Alloy

Brake Disk Material . . . . . Forged Steel

5. Brake Differences

A. Brake Assemblies 5001571 and 5001571-1 differ only in the disk guide bracket subassembly. Brake Assembly 5001571 uses a disk guide bracket subassembly.

B. Brake Assemblies 5001571-1 and 5001571-2 differ only in the brake disk and linings. Brake Assemblies 5001571-1 and 5001571-2 are superceded by Brake Assemblies 5001571-4 and 5001571-5 respectively.

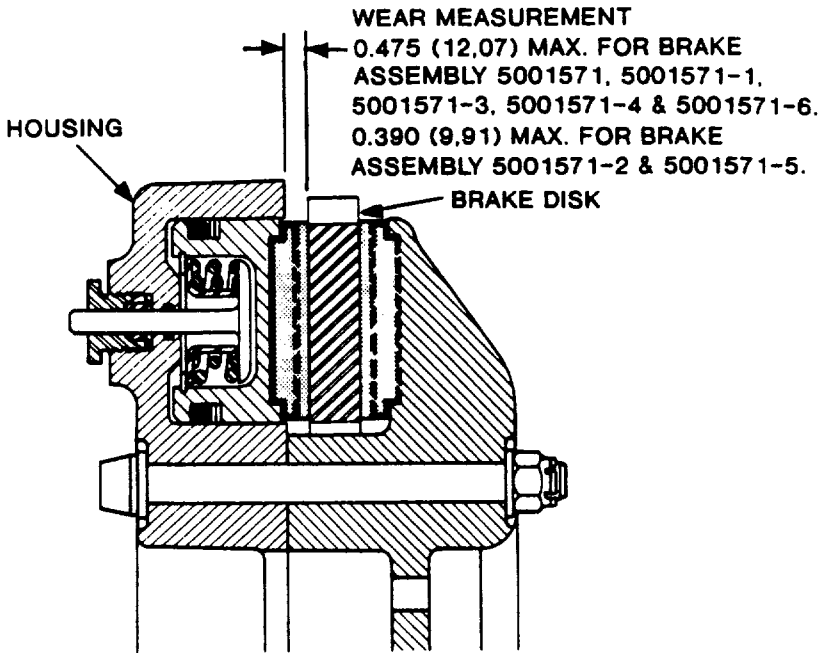
C. Brake Assemblies 5001571-3 and 5001571-4 are identical except that a disk guide bracket subassembly is available to be installed on Brake Assemblies 5001571-3 and 5001571-6. Disk guide bracket subassembly is optional and not furnished with the brake. Brake Assemblies 5001571-3 and 5001571-4 are superceded by Brake Assembly 5001571-6.

D. Brake Assemblies 5001571-5 and 5001571-6 differ only in the brake disk and linings.

6. Brake Modification

A. Modification is provided in REPAIR to convert Brake Assemblies 5001571, 5001571-1, 5001571-3 and 5001571-4 to Brake Assembly 5001571-6.

7. Brake Lining Wear Check



A. Check brake linings while the brake is on the aircraft as follows:

(1) Apply brakes and hold.

B. Measure the distance from the flat of the brake housing (parallel to the disk) to the surface of the brake disk as shown in Figure 2, at bleeder or inlet port.

CAUTION: NEVER MIX NEW AND USED BRAKE LININGS. IF NECESSARY TO REUSE WORN LININGS, REINSTALL THEM IN THEIR ORIGINAL POSITION.

C. When this dimension reaches 0.475 inch (12,07 mm) or more, for Brake Assemblies 5001571, 5001571-1, 5001571-3, 5001571-4 and 5001571-6, and 0.390 inch (9,91 mm) or more for Brake Assemblies 5001571-2 and 5001571-5, the brake linings should be replaced.

Brake Wear Measurement
Figure 2

TESTING AND FAULT ISOLATION

1. Test Equipment and Materials

NOTE: Equivalent substitutes may be used for items listed.

Hydraulic Test Stand Supplies 0 to 3,000 psi (206,84 bars) pressure gaged to read output pressure to 5 psi (0,345 bars) increments	Commercially available
Hydraulic Fluid (Red Oil) Specification MIL-H-5606	Commercially available

2. Test Setup

A. None required.

3. Operational Test and Fault Isolation Procedures

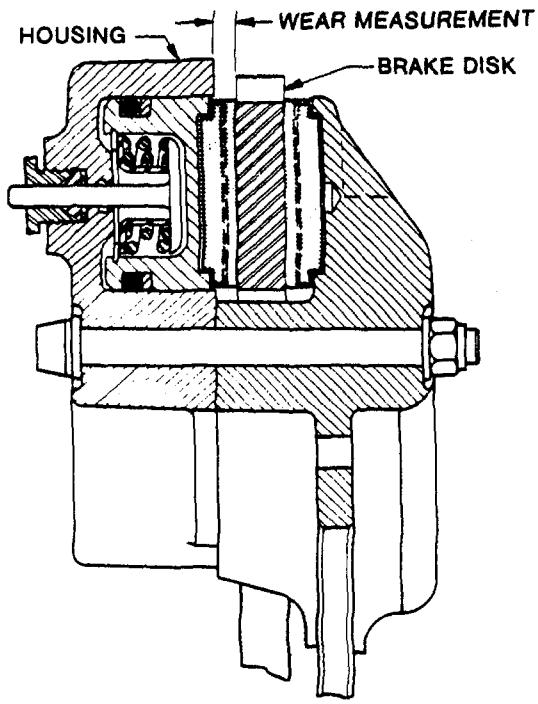
CAUTION: HYDRAULIC TEST STAND MUST CONTAIN RED OIL TO SPECIFICATION MIL-H-5606.

A. Connect brake assembly to a hydraulic test stand capable of applying 700 psi (48,3 bars) hydraulic pressure to brake.

(1) Use brake disk (10 or 10A) or a spacer of equal thickness between brake linings (20B, 20C or 20D)

B. Place brake in upright position with disk (10 or 10A) in place between linings.

(1) Apply pressure and bleed brake.



(2) Apply 5 psi (0,345 bars) hydraulic pressure at inlet for five minutes. There shall be no measurable leakage.

(3) Apply 700 psi (48,3 bars) hydraulic pressure at inlet for five minutes. There shall be no measurable leakage.

C. Apply and hold pressure for brake lining wear check.

(1) Measure the distance from the flat of the brake housing (parallel to disk) to the surface of the brake disk at inlet or bleeder port as shown in Figure 101.

(2) When this dimension reaches 0.475 inch (12,07 mm) or more, for Brake Assemblies 5001571, 5001571-1, 5001571-3, 500571-4 and 5001571-6, and 0.390 inch (9,91 mm) or more for Brake Assemblies 5001571-2 and 5001571-5, the brake linings should be replaced.

Brake Wear Measurement
Figure 101

D. *Adjusting pin slippage test.*

(1) Remove disk (10 or 10A) or spacer from brake assembly.

(2) Fully retract pistons and apply 50 psi (3,45 bars) hydraulic pressure.

(3) After the piston has advanced the amount permitted by the built-in clearance, hold this pressure for 15 seconds. If the required hydraulic pressure is held and there is no further movement of the piston, the pin grip *holding force is satisfactory.*

NOTE: If pin slippage occurs, the brake shall be rejected and the pin and grip combination replaced.

(4) Reinstall disk (10 or 10A) or spacer in brake assembly between linings.

E. Apply 700 psi (48,3 bars) pressure and then release brake checking for proper brake release. Repeat three times. The disk (10 or 10A) should be free to rotate when the brake pressure is released. The hydraulic back pressure should not be greater than 40 psi (2,76 bars).

F. Apply 700 psi (48,3 bars) pressure and release pressure to 40 psi (2,76 bars); then check brake clearance. The brake clearance measured between the lining (20B, 20C or 20D) and disk (10 or 10A) should be 0.028 to 0.050 inch (0,71 to 1,27 mm). The hydraulic back pressure should not be greater than 40 psi (2,76 bars).

4. Fault Isolation Procedures

A. Fault isolate in accordance with Figure 102.

Trouble	Probable Cause	Correction
Hydraulic fluid leaking from brake	Defective hydraulic connection	Tighten connection or replace fitting.
	Defective preformed packing	Replace preformed packing.
	Piston worn or damaged	Replace piston and/or housing.
Brake not engaging correctly	Air in brake	Bleed brake.
	Brake lining worn out	Overhaul brake.
	Obstruction in hydraulic line or fluid passage	Remove obstruction.
	Pistons sticking	Replace piston preformed packings.
	Pistons damaged	Replace pistons.
	Disk gear defective and disk not moving freely in wheel when brake pressure is released	Replace disk.
Brake not releasing correctly	Obstruction in hydraulic line or fluid passage	Remove obstruction.
	Piston sticking	Replace piston preformed packings.
	Pistons damaged	Replace pistons.
	Disk not releasing when brake pressure is released	Replace pin grip and torque pin nut to manual specification.

DISASSEMBLY

1. General (Ref. IPL Fig. 1)

   NOTE: See TESTING AND FAULT ISOLATION for operational and test and fault isolation procedures to establish condition of unit and determine extent of disassembly required.

   A. Prior to dismounting and disassembling brake, check lining for wear in accordance with the DESCRIPTION AND OPERATION section.

   B. Disassemble the brake assembly in accordance with the following instructions.

2. Disassembly Procedures

   A. Position brake assembly on a clean work surface.

   B. Remove brake disk (10 or 10A) from brake.

   C. Remove brake linings (20B, 20C or 20D).

      (1) If it is necessary to reuse linings, the linings should be replaced in the same position.

   D. Remove self-locking nuts (30), washers (40 and 60) and internal wrenching bolts (50), releasing brake backing plate (70 or 70A).

   E. Cut and remove lockwire from self-adjusting pin nuts (80) and remove nuts.

   F. Remove self-adjusting pin grips (90), flat washers (100) and preformed packings (110 or 110A) from each cylinder head on the brake housing (290).

   G. Remove pistons (190) from brake housing (290).

   H. Remove backup ring (120) and preformed packing (130 or 130A) from each piston (190).

   I. Remove flat head pin (180) from each piston (190) as follows:

      (1) Place piston in arbor press. Compress spring guide (150) and hold.

      (2) Remove spring retaining ring (140) with Truarc (or equivalent) pliers.

      (3) Carefully release arbor press and remove spring guide (150), brake release springs (160 and 170) and flat head pin (180) from piston.

   J. Remove protective plug (200), if installed, and preformed packing (210).

K. Remove inlet adapter (220) and preformed packing (230) from brake housing (290).

L. Complete the disassembly by removing bleeder screw (240 or 240A), bleeder washer (250), bleeder valve (260), bleeder valve adapter (270) and preformed packing (280) from brake housing (290).

CLEANING

1. Cleaning Materials

NOTE: Equivalent substitutes may be used for items listed.

Dry-Cleaning Solution Specification P-D-680 Type I, Stoddard Solvent Type II, 140°F Solvent	Commercially available
Isopropyl Alcohol Specification TT-I-735	Commercially available
Soft Lint-free Cloth	Commercially available
Soft Bristle Brush	Commercially available
Polyplus Plastic Media Screen Size 20/40 (Primary)	Inventive Machine Corporation (I.M.C.) P.O. Box 369 Bolivar, OH 44612
Plastic Reclaimable Abrasive Machine (PRAM)	See SPECIAL TOOLS, FIXTURES AND EQUIPMENT section.
Plastic Media (Dry Stripping Abrasive)	U.S. Technology Corporation A Subsidiary of U.S. Plastic and Chemical Corporation 328 Kennedy Drive Putnam, CT 06260
Paint Removing Solvent (Alternate) Specification MIL-C-19853	Turco Products Division of Purex Corporation 24600 South Main Street P.O. Box 6200 Carson, CA 90749

2. Cleaning Procedures (Ref. IPL Fig. 1)

WARNING: CLEANING SOLVENTS ARE TOXIC AND VOLATILE. USE ONLY IN WELL-VENTILATED AREAS. AVOID PHYSICAL CONTACT WITH SOLVENT AND DO NOT INHALE VAPORS.

CAUTION: A THOROUGH CLEANING OR IMMERSION OF BRAKES MAY CAUSE ENTRAPMENT OF SOLVENT IN PASSAGE HOLES.

A. Clean all metal parts with dry-cleaning solvent, Specification P-D-680. Use a soft bristle brush when necessary.

B. Dry all metal parts thoroughly after cleaning, using filtered and dried compressed air.

NOTE: Ensure foreign materials have been removed from all cavities, threaded holes, pockets and other areas where entrapment might occur.

C. Clean all preformed packings with isopropyl alcohol, Specification TT-I-735. Dry with a clean, soft cloth.

NOTE: It is recommended new preformed packings be installed at each brake overhaul.

D. Brake disks (10 or 10A) may be cleaned with the aid of compressed air and a soft wire or bristle brush.

E. Clean brake linings (20B, 20C or 20D) by brushing with a soft bristle brush.

3. Paint Removal Procedures

A. Strip brake housing as follows - Method I (Dry Stripping).

WARNING: THE DRY STRIPPING PROCESS IS OPERATOR-SENSITIVE AND ONLY AN EXPERIENCED, TRAINED OPERATOR SHOULD BE PERMITTED TO PERFORM THE PAINT REMOVAL OPERATION IN ACCORDANCE WITH EQUIPMENT MANUFACTURER'S RECOMMENDATIONS.

NOTE: This procedure covers general information of dry stripping process of pneumatic blast removal of paint utilizing ground plastic particles. The procedure provides suggested control parameters to safely and effectively remove paint from aircraft component parts using the dry stripping process.

Paint must be stripped from parts before inspecting by Zyglo, dye penetrant or eddy-current methods; otherwise, inaccurate readings will result.

(1) Completely disassemble the part to be stripped. Remove all parts from brake housing in accordance with DISASSEMBLY.

(2) Clean the part to be stripped per Cleaning Procedures.

(3) Plug and seal off any threaded holes and piston cavities as required.

(4) Remove paint using the dry stripping procedure in accordance with Figure 401 as follows:

(a) The media dry stripping abrasive is effective only when used with the appropriate equipment. Depending on operator requirements, it is advised that the operator check with these (or other suitable) *manufacturers for advice and application information concerning their* particular equipment.

(b) Refer to Cleaning Materials for recommended dry stripping abrasive and equipment.

CAUTION: FLUSH MEDIA FROM CAVITIES, THREADED HOLES, POCKETS AND OTHER AREAS WHERE ENTRAPMENT MIGHT OCCUR.

(5) Remove part from solvent and rinse thoroughly, two times, with water heated to a temperature of 160° to 180°F (71° to 82°C).

(6) Dry the part thoroughly with filtered and dried compressed air.

NOTE: After paint stripping, the parts must be re-treated and repainted in accordance with instructions in REPAIR.

B. Strip brake housing as follows - Method II (Wet Stripping).

WARNING: PAINT REMOVAL SOLVENTS ARE TOXIC AND VOLATILE. USE ONLY IN WELL-VENTILATED AREAS. AVOID PHYSICAL CONTACT WITH SOLVENT AND DO NOT INHALE VAPORS.

NOTE: Paint must be stripped from brake assembly before inspecting by Zyglo, dye penetant or eddy-current methods; otherwise, inaccurate readings will result.

(1) Completely disassemble the part to be cleaned to prevent solvent from being entrapped between mating surfaces. Remove all parts from brake housing in accordance with DISASSEMBLY.

(2) Clean the part to be stripped in accordance with Cleaning Procedures.

CAUTION: PARTS MUST BE COMPLETELY IMMERSED IN SOLVENT. CONTACT WITH WATER BLANKET DURING IMMERSION WILL CAUSE SEVERE CORROSION OF THE PART.

(3) Immerse part in paint removing solvent, Specification MIL-C-19853, for a period of 30 minutes to two hours. Immersion time depends upon condition of paint. Carefully follow the manufacturer's instructions for the particular solvent being used.

NOZZLE TYPE/SIZE	NOZZLE PRESSURE	NOZZLE DISTANCE	MEDIA TYPE	ANGLE OF APPROACH
1 BMLV-8 1/2 inch 4 (12,7 mm)	45 - 55 PSI (3,10-3,79 bars) 3	36 - 48 inch (914-1219 mm)	POLYPLUS 20/40	45 - 75°
2 VENTURI 5/16 inch 4 (7,94 mm)	UNDER 30 PSI (2,07 bars) 3	6 - 8 inch (152,4-203,2 mm)	POLYPLUS 20/40	45 - 75°

PHYSICAL REQUIREMENTS OF MEDIA

	POLYEXTRA	POLYPLUS
HARDNESS (MOH SCALE)	3.0 ± .25	3.5 ± .25
SPECIFIC GRAVITY (GMS/CC)	1.15 ± 10%	1.50 ± 10%

NOTES:

1. STAND-OFF, OPEN BLASTING.
2. CLOSED-CYCLE BLASTING (PERFORMED IN PRESSURE BLAST EQUIPMENT CHAMBER).
3. PRESSURE READINGS MUST BE TAKEN AT THE NOZZLE RATHER THAN ESTIMATED FROM REGULATOR GAGE READINGS. RECHECK PRESSURE EVERY FOUR HOURS AND EACH TIME PRESSURE IS CHANGED AT REGULATOR.
4. PROCESS VARIABLES INCLUDE PRESSURE, DISTANCE FROM NOZZLE TO WORK PIECE, ANGLE OF ATTACK AND NOZZLE SIZE. PARAMETERS SELECTED WILL VARY WITH PAINT COATING AGE, TYPE AND NUMBER OF COATINGS, BUT THE FOLLOWING PARAMETERS HAVE SUCCESSFULLY REMOVED VARIOUS COATING TYPES WITH NO EFFECT ON SUBSTRATE.
5. RECOMMENDED PLASTIC MEDIA TYPE AND SIZE IS POLYPLUS 20/40. POLYEXTRA 12/20 OR 20/30 PRODUCES A SMOOTHER FINISH BUT PAINT REMOVAL RATE IS LOWER. TYPE III PLASTIC MEDIA TYPE IS NOT TO BE USED ON THE SUBJECT AIRCRAFT COMPONENTS.

Recommended Dry Stripping Variables
Figure 401

CAUTION: FLUSH SOLVENT FROM CAVITIES, THREADED HOLES, POCKETS AND OTHER AREAS WHERE ENTRAPMENT MIGHT OCCUR.

(4) Remove part from solvent and rinse thoroughly in water heated to a temperature of 160° to 180°F (71° to 82°C).

(5) Dry the part thoroughly with filtered and dried compressed air.

NOTE: After paint stripping, the part must be re-treated and repainted in accordance with instructions in REPAIR.

CHECK

1. Check Materials

NOTE: Equivalent substitutes may be used for items listed.

Type	Penetrant	Developer	Supplier
Fluorescent	Zyglo ZL-16	Zyglo ZP-13 (wet) optional	Magnaflux Corporation 7330 West Lawrence Street Chicago, IL 60656
	Penetrex ZL-2A with emulsifier ZE-4	Penetrex ZP-4 (dry) or ZP-13 optional	
Red Dye	Spot Check	Spot Check	
	Dy-Chek	Dy-Chek	Turco Products Division of Purex Corporation P.O. Box 6200 24600 South Main Street Carson, CA 90749
	Met-L-Chek	Met-L-Chek	Met-L-Chek 1639 Euclid Street Santa Monica, CA 90404

2. General (Ref. IPL Fig. 1)

A. Check all components of the brake assembly for wear, cracks, corrosion, structural damage, distortion and thread damage. Replace all parts that show evidence of cracks, excessive wear, severe corrosion and structural and thread damage. Repair minor scratches and corrosion.

B. Perform the specific checks listed referring to REPAIR for appropriate repair procedures.

3. Brake Disk (10 or 10A)

A. Check brake disk (10 or 10A) as follows.

(1) Measure thickness of disk.

(a) Brake disks (10) that are worn to a thickness of 0.490 inch (12,45 mm) or less must be replaced.

(b) Brake disks (10A) that are worn to a thickness of 0.586 inch (14,88 mm) or less must be replaced.

(2) Check disk for warpage. Disks that have warped or dished to the extent they cause brake drag can be surface ground and reused if they exceed the minimum thickness of 0.490 inch (12,45 mm) for disk (10) and 0.586 inch (14,88 mm) for disk (10A) after grinding.

NOTE: It is recommended the disk be reversed in the brake housing at each tire change to minimize dishing.

(3) Measure outside diameter of disks. Replace disks which have shrunk to an outside diameter of 13.025 inches (330,83 mm) or less.

(4) Check disk for heat checks. Disks containing heat checks of less than 1.25 inches (31,75 mm) in length that do not extend to within 0.25 inch (6,35 mm) of the inside or outside diameter edge can be continued in service. Check disks with such heat checks at time of each lining change.

4. Brake Lining (20B, 20C or 20D)

CAUTION: NEVER MIX NEW AND USED BRAKE LININGS. IF NECESSARY TO REUSE WORN LININGS, INSTALL THEM IN THEIR ORIGINAL POSITION.

A. Measure thickness of brake linings at center of lining.

(1) Replace linings (20B or 20D) if worn to a thickness of 0.220 inch (5,58 mm) or less. On anvil side, if one lining requires replacement, always replace all four linings.

(2) Replace linings (20C) if worn to a thickness of 0.200 inch (5,08 mm) or less. On anvil side, if one lining requires replacement always replace all four linings.

B. Replace linings when the lining cup is found to be deformed and out of round.

NOTE: The lining cup is designed to wear away with lining.

5. Self-Adjusting Pin Nut (80)

A. Check self-adjusting pin nut for stripped threads or other damage and distortion. Replace damaged parts.

6. Self-Adjusting Pin Grip (90) and Steel Washer (100)

A. Check for damage and distortion. Replace any unserviceable parts.

7. Preformed Packing (110A, 130A, 210, 230, 250 and 280)

   A. Check preformed packings for distortion and wear. It is recommended all gaskets and packings be replaced at each overhaul.

8. Retaining Ring (140) and Spring Guide (150)

   A. Check retaining ring and spring guide for structural damage, corrosion and distortion. Replace any damaged parts.

9. Brake Release Spring (160 and 170)

   A. Check brake release springs as follows:

      (1) Measure force required to compress springs.

      (2) Replace brake release spring (160) when compression force is less than 60 pounds (267 N) at a height of 0.538 inch (13,66 mm).

      (3) Replace brake release spring (170) when compression force is less than 115 pounds (512 N) at a height of 0.538 inch (13,66 mm).

10. Flat Head Pin (180)

   A. Check flat head pins (180) for nicks, rough spots, distortion or damage which might injure preformed packing. Depressions of 0.003 inch (0,076 mm) deep and 0.060 inch (1,52 mm) in length or less are acceptable. However, raised metal from such nicks should be removed by polishing. If grip holding surfaces of pins are tapered or reduced in diameter more than 0.0005 inch (0,013 mm) in the operating length, the pins should be replaced.

   B. If grip holding surfaces of pins are reduced in diameter in the operating length to 0.245 inch (6,22 mm) or less, the pins should be replaced.

11. Piston (190)

   A. Check contacting surfaces of pistons for wear or scratches which might injure preformed packing and cause leaks. Measure piston diameter at three different places. If piston is worn to a diameter of 2.112 inches (53,64 mm) or less, replace piston.

12. Protective Plug (200) and Inlet Adapter (220)

   A. Check protective plug and inlet adapter for stripped threads or other damage. Replace if damaged.

13. Bleeder Valve (260) and Bleeder Valve Adapter (270)

   A. Check bleeder valve and valve adapter for stripped threads or other damage. Replace damaged parts.

14. Brake Housing (290)

A. Check brake housing for cracks using a dye-penetrant method. Replace housing if cracked.

NOTE: Pay particular attention to housing throat section.

B. Visually check housing for corrosion and scratches. Blend out minor corrosion and scratches. See REPAIR.

C. Check cylinder wall for damage to threads and packing seat. See REPAIR.

D. Check lining recesses in the anvil section of the brake housing for wear and damage. See REPAIR.

15. Bolts (50) and Self-Locking Nuts (30)

A. Check all bolts and nuts for stripped threads. Replace all bolts and nuts that have stripped or damaged threads.

B. Magnetic-particle check bolts (50) for cracks, particularly under head and in threads adjacent to shank. Replace all cracked bolts.

C. Measure torque required to turn self-locking nuts on bolts to check self-locking feature.

(1) Replace self-locking nuts when torque value is less than 9.5 pound-inches (1,1 N-m).

16. Disk Guide Lining (320)

A. Check disk guide linings for wear if installed. Replace disk guide lining when thickness reaches 0.140 inch (3,56 mm) or less.

17. Disk Guide Bracket (310)

A. Check disk guide bracket for distortion or damage. Replace damaged parts.

REPAIR

1. Repair Materials

NOTE: Equivalent substitutes may be used for items listed.

Surface Treat Solution Specification MIL-M-3171, Type VI	Commercially available
Methyl Isobutyl Ketone (MIBK) Specification TT-M-268	Commercially available
Zinc Chromate Primer Specification TT-P-1757	Commercially available
Aluminum Lacquer Specification TT-L-32	Commercially available
Aluminum Topcoat/Primer Combination (FA-10242) Aeroprite	Contact your local distributor of aviation products and supplies.
Aeroprite Reducer TH-89	Contact your local distributor of aviation products and supplies.
Aluminum Oxide Cloth (320 to 420 grit, wet or dry)	Commercially available
Wash Primer Specification MIL-C-8514	Commercially available
Butyl Alcohol Thinner Specification TT-B-846	Commercially available
Ethyl Alcohol Thinner Specification O-E-760, Type III	Commercially available

2. General (Ref. IPL Fig. 1)

A. Repair of the brake assembly is limited to the replacement of worn or damaged parts and to the specific repairs listed in this section. Replace all cracked parts. No attempt should be made to repair cracked, severely corroded or badly damaged parts. Components that cannot be repaired within the limits defined in this section should be replaced.

3. Repair of Brake Housing (290) and Brake Backing Plate (70 or 70A)

CAUTION: REMOVAL OF CORROSION AND SURFACE DAMAGE WILL PREVENT STRESS CONCENTRATIONS. HOWEVER, ANY REMOVAL OF MATERIAL WILL SHORTEN THE LIFE OF THE BRAKE HOUSING. THEREFORE, IT IS RECOMMENDED THAT MATERIAL REMOVED BY BLENDING BE LIMITED TO THE MINIMUM REQUIRED FOR REMOVING CORROSION OR SURFACE DAMAGE.

A. Remove corrosion, scratches, nicks and abrasions with aluminum oxide cloth. Remove all corrosion and surface damage on the brake housing according to limits defined in Figure 601. Blend out any damage that might become a source of corrosion or stress cracks. Remove any corrosion from threads with a soft wire brush.

NOTE: Since removal of metal in Areas 1, 2, and 6 can shorten the ultimate life of the part, it is recommended that removal in these areas be kept to a minimum.

B. Thoroughly clean surface. Treat and repaint reworked areas of housing in accordance with Re-Treating and Repainting.

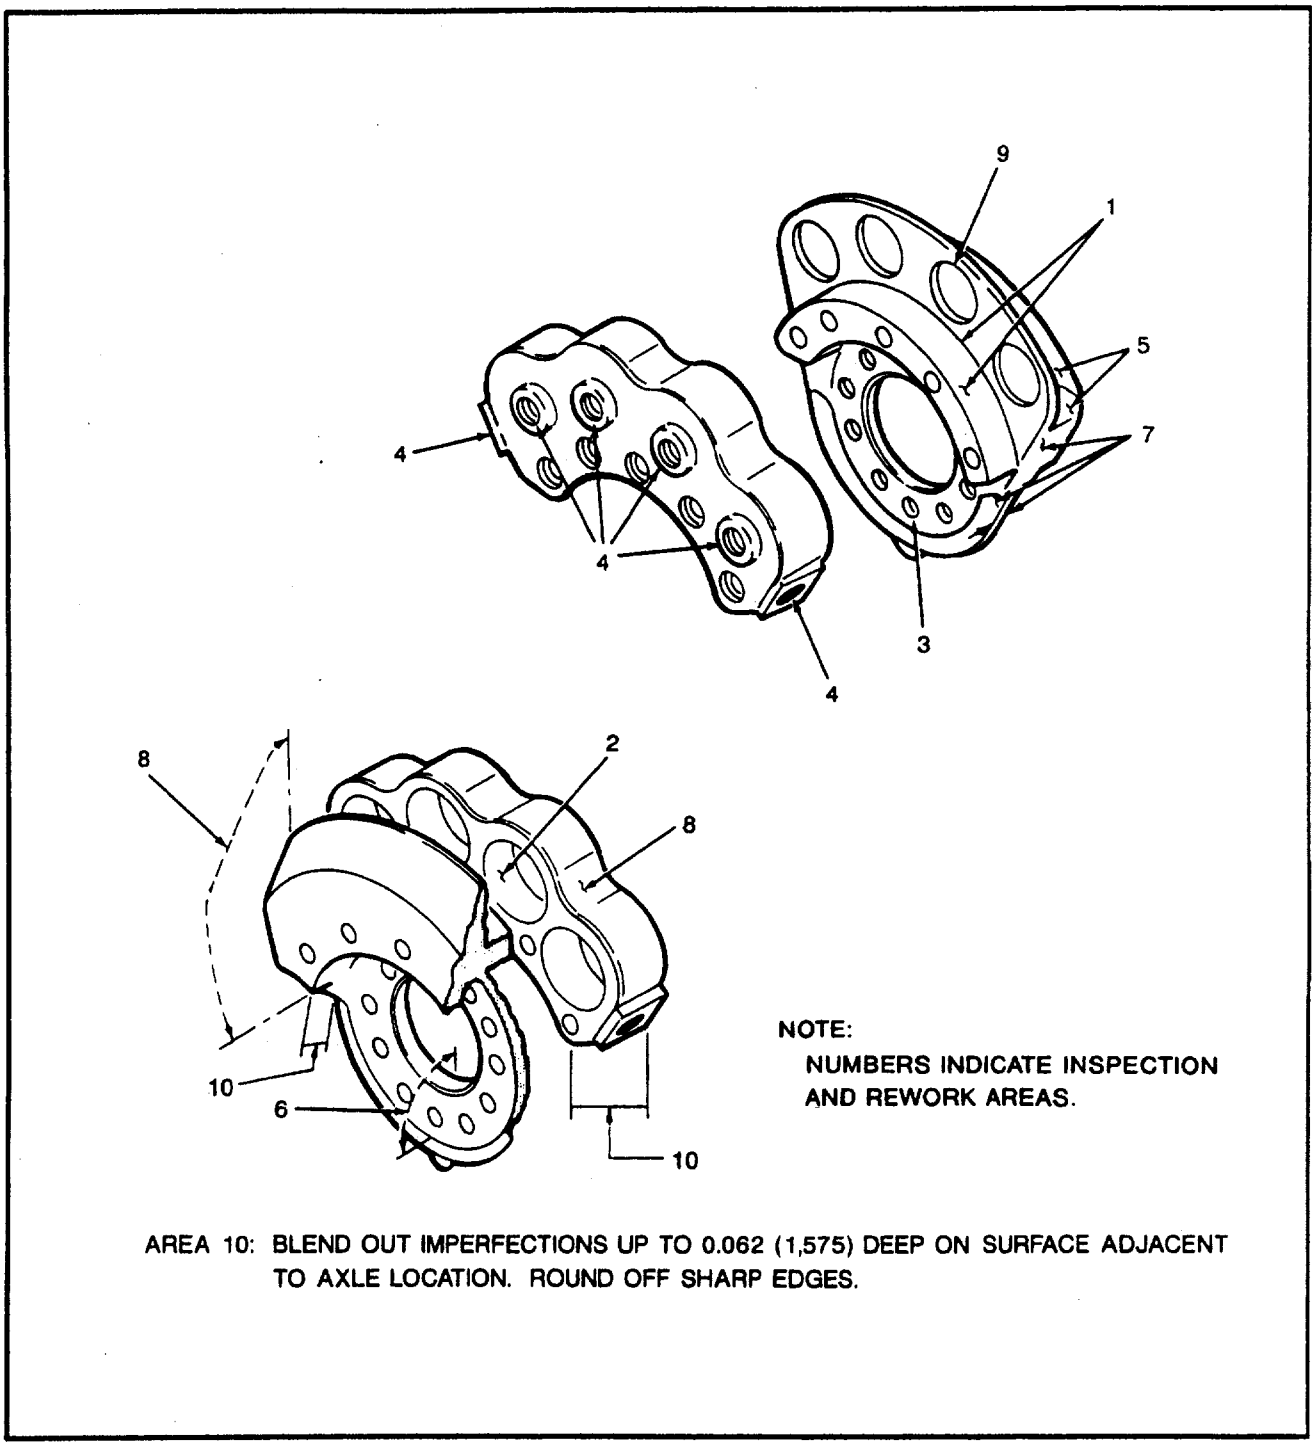
C. If piston cavity is worn or damage exists beyond the 2.136 inch (54,25 mm) inside diameter, replace brake housing.

D. If lining recess is worn or damage exceeds limits as shown in Figure 602, repair lining recesses as follows.

4. Repair of Worn Lining Recesses

A. If damage on one side of lining recess is beyond the limits of 0.062 inch (1,57 mm) deep and 0.145 inch (3,7 mm) wide, rework as follows:

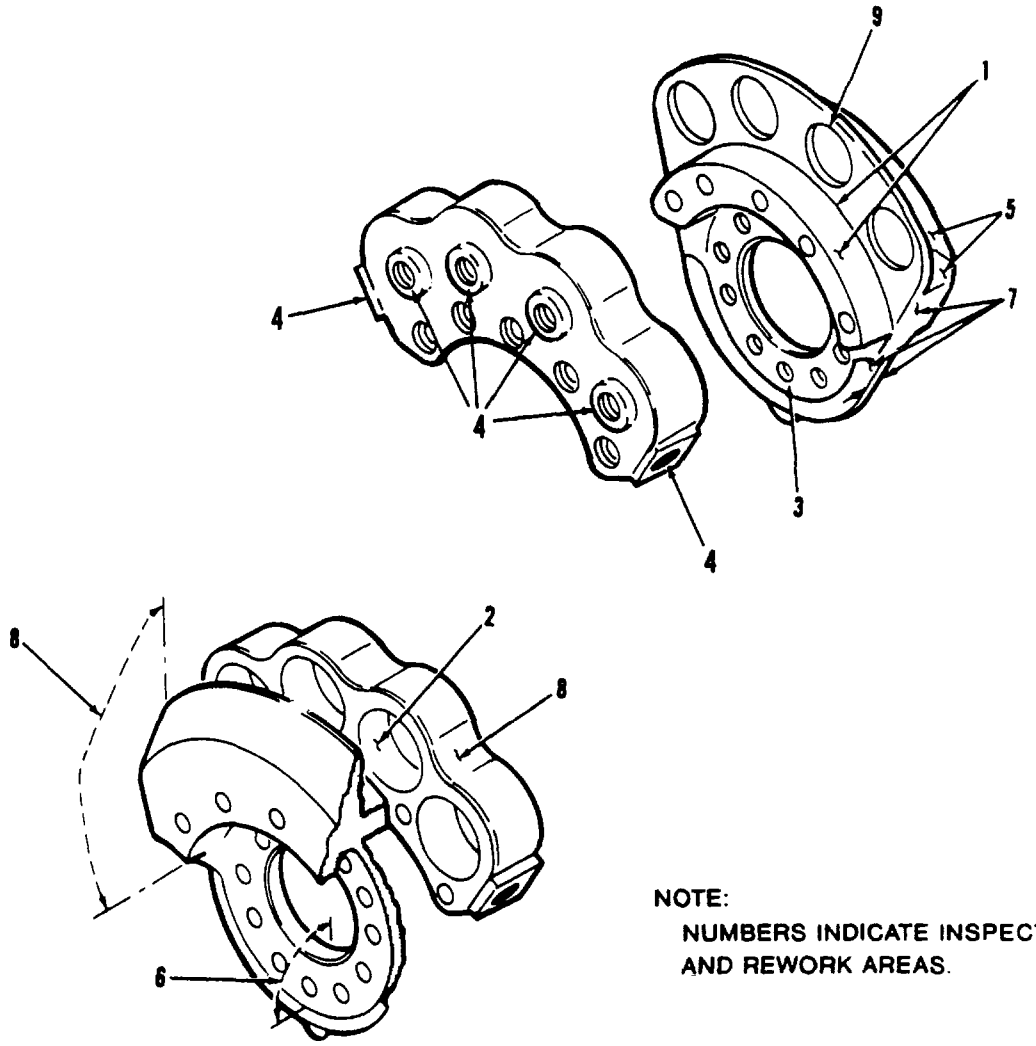
B. Fabricate ring from No. 1117 Steel Bar, Federal Specification QQ-S-633, as shown in Figure 603. Cadmium plate (Federal Specification QQ-P-416, Type II, Class 3) to 0.0002 inch (0,0051 mm) maximum to 0.0003 inch (0,0076).



CAUTION: MAINTAIN ORIGINAL CENTER POINT OF LINING RECESS.

B. Machine lining recess diameter to 2.047 +0.000, -0.001 inch (52,00 + 0,000, -0.025 mm) as shown in Figure 603.

TEMPORARY REVISION NO. 32–2

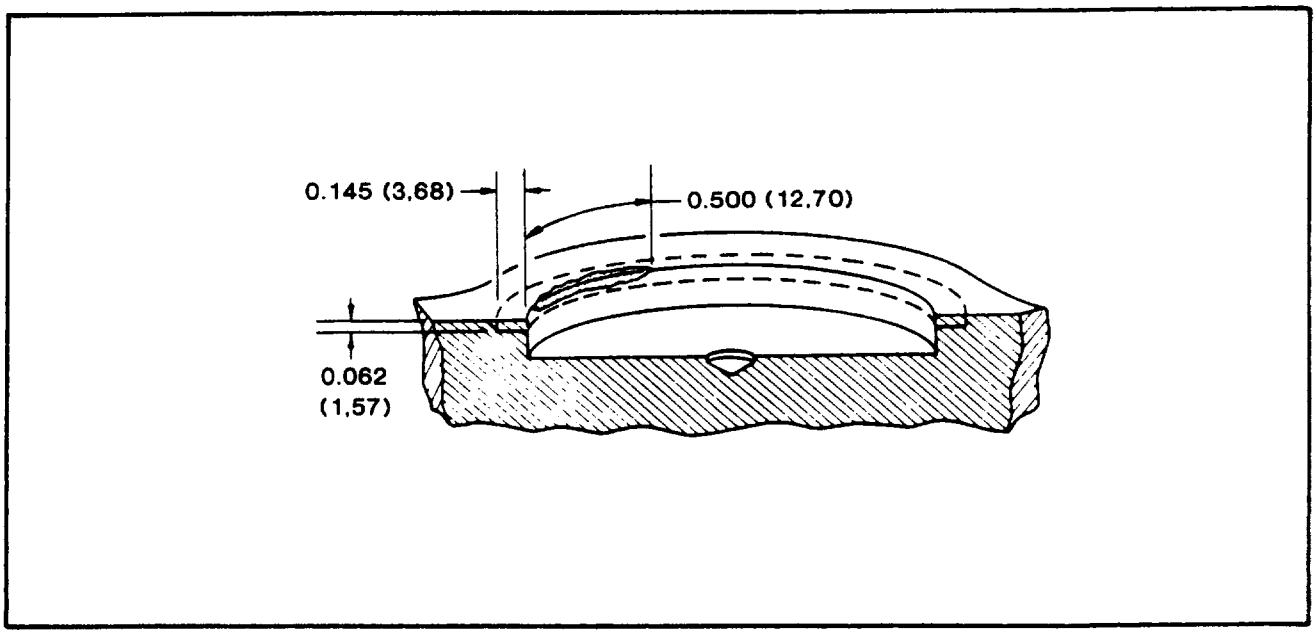


FILING INSTRUCTIONS: Insert facing page 603 (32–43–12).

DESCRIPTION: Added "Area 10" brake housing repair limits in Figure 601.

AREA 10: BLEND OUT IMPERFECTIONS UP TO 0.062 (1,575) DEEP ON SURFACE ADJACENT TO AXLE LOCATION. ROUND OFF SHARP EDGES.

Rework Areas for Brake Housing
Figure 601



NOTE:
NUMBERS INDICATE INSPECTION AND REWORK AREAS.

Rework Areas for Brake Housing
Figure 601

NOTE: Please see the TEMPORARY REVISION that revises this page.

Key to Figure 601

General:	Repairs are limited in each marked area to the following limits. The material removed by blending is limited to the minimum required for removing corrosion or surface damage. Except where restricted by length or locale when damage depth is less than 0.015 inch (0,381 mm) deep, all blend type repairs should be blended with a depth to width ratio of 1 to 100 in surface width. Where not possible, use as generous a width to depth ratio as practical with the area being repaired.
Area 1:	Carefully check by Zyglo, dye-penetrant or other methods suitable for use with cast magnesium. Replace cracked housings. Grooves or scratches to 0.010 inch (0,254 mm) maximum deep in throat area of brake should be blended and polished out with 340 grit, aluminum oxide cloth.
Area 2:	Polish out minor scratches and/or pits with 360 grit, aluminum oxide cloth. Do not polish beyond 2.136 inches (54,25 mm) inside diameter at any location in the piston cavity.
Area 3:	Rework holes as required to 0.015 inch (0,381 mm) maximum oversize. Do not exceed 0.345 inch (8,767 mm) diameter. Round off sharp edges.
Area 4:	Clean and remove housing and replace if threads are stripped or badly damaged.
Area 5:	Blend out and polish imperfections up to 0.03 inch (0,762 mm) deep.
Area 6:	Blend out imperfections up to 0.03 inch (0,762 mm) deep. In area covered by mounting bolt washers, blend out nicks or scratches up to 0.010 inch (0,254 mm) deep.
Area 7:	Blend out and polish imperfections up to 0.03 inch (0,762 mm) deep. Do not blend opposite surfaces.
Area 8:	Blend out imperfections up to 0.03 inch (0,762 mm) deep, other than in the bolt hole area, 0.010 inch (0,25 mm) allowable in the bolt hole area.
Area 9:	Blend out imperfections up to 0.062 inch (1,575 mm) deep, 0.145 inch (3,687 mm) wide and 0.500 inch (12,700 mm) long on edge of lining recess as shown in Figure 602. One repair to above limits is permissible per recess. Refer to Repair of Worn Lining Recesses paragraph 4. for rework of lining recess damaged beyond above limits.

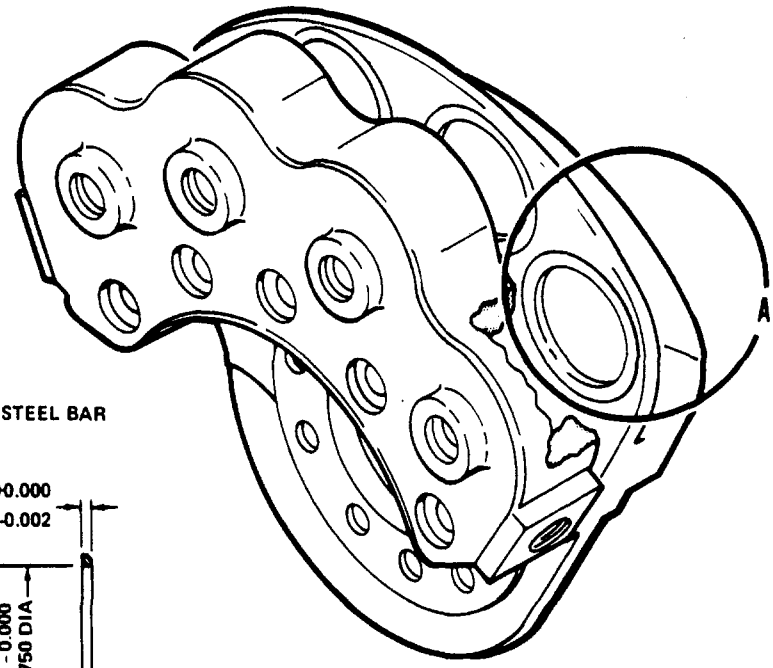
Lining Recess Edge Repair Limits
Figure 602

C. Treat machined surfaces of housing with surface treat solution, Specification MIL-M-3171, Type VI.

D. Heat housing in an oven to 225°F (106°C).

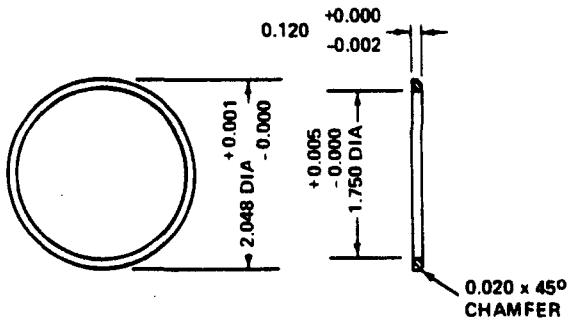
E. Apply one coat of zinc chromate primer, Specification TT-P-1757, to reworked area of housing.

F. Insert ring, fabricated in paragraph A., chamfered edge first, into reworked recess of heated housing as shown in Figure 603.



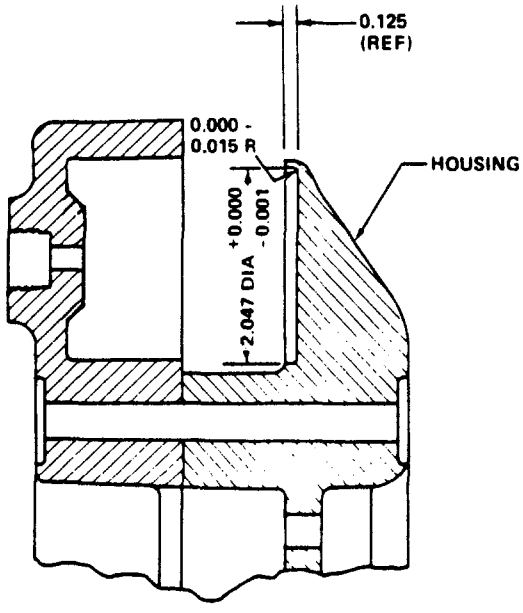
5. Repair of Flat Head Pin (180)

A. Repair damaged flat head pins as follows:

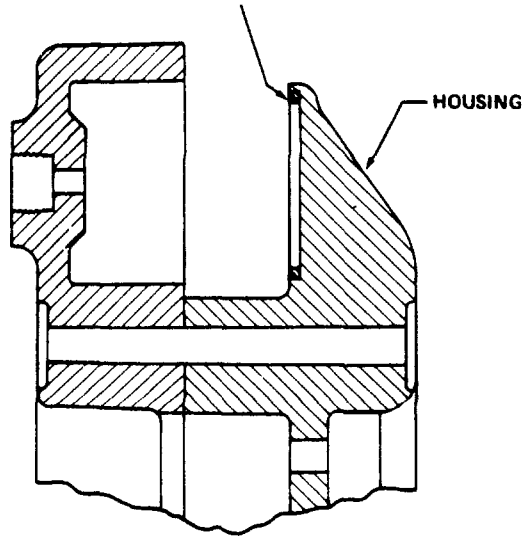


(1) Flat head pins with small nicks or imperfections on the seal contacting surfaces of 0.003 inch (0,076 mm) or less in depth and 0.060 inch (1,52 mm) in length are acceptable; however, raised metal from nicks should be removed by polishing with 400 grit, aluminum oxide cloth.

(2) If grip holding surfaces of pins are tapered more than 0.0005 inch (0,013 mm), the pins should be replaced.



(3) Measure diameter of pins at grip holding surface. If diameter is less than 0.245 inch (6,22 mm), replace pins.



(1) FABRICATE A RING FROM 1117 STEEL BAR SPECIFICATION QQ-S-633.

(2) MACHINE HOUSING

(3) HEAT HOUSING TO 225° F AND INSERT RING IN PLACE WITH CHAMFERED EDGE INSIDE. TOUCH UP REWORKED AREAS OF HOUSING WITH ONE COAT ZINC CHROMATE PRIMER.

DETAIL A

Lining Recess Repair
Figure 603

6. Replacing Disk Guide Lining

A. Using a 5/32 (0.156) inch drill, drill out shop head of rivet (330)

B. Remove rivet from disk guide bracket (310) being careful to avoid enlarging the rivet hole.

C. Insert new rivet (330) through lining (320) and disk guide bracket (310) and form shop head of rivet against disk guide.

D. Shop head of rivet must have an outside diameter of 80 percent (minimum) of the outside diameter of the manufactured head. Disk guide lining is to be tight under finger pressure.

7. Re-Treating and Repainting

A. Repaired areas of brake housing and brake backing plate and those having paint and treated finish removed, should be re-treated and repainted in accordance with following procedures:

B. Re-Treating

WARNING: CLEANING SOLVENTS ARE TOXIC AND VOLATILE. USE ONLY IN WELL-VENTILATED AREAS. AVOID PHYSICAL CONTACT WITH SOLVENT AND DO NOT INHALE VAPORS.

(1) Thoroughly clean surface to be re-treated and repainted. Clean with hot water or methyl isobutyl ketone, Specification TT-M-268, and dry thoroughly with compressed air.

(2) Re-treat all exposed magnesium surfaces with surface treat solution conforming to Specification MIL-M-3171 in accordance with the manufacturer's instructions. Refer to Repair Materials for recommended solution.

C. Repair and touchup painting should be performed as follows.

(1) The part or area requiring touchup painting must be thoroughly clean and free of all contaminants.

(2) Prepare area to be painted (scratches, nicks, chipped paint, etc) by sanding lightly to feather out all edges of adjacent finish, using 320 to 360 grit, wet-or-dry aluminum oxide cloth. Wet sanding is preferred. Avoid removing more primer than absolutely necessary from damaged area.

WARNING: CLEANING SOLVENTS ARE TOXIC AND VOLATILE. USE ONLY IN WELL-VENTILATED AREAS. AVOID PHYSICAL CONTACT WITH SOLVENT AND DO NOT INHALE VAPORS.

(3) Wipe repaired surface with a cloth moistened with methyl isobutyl ketone, Specification TT-M-268, and wipe surface dry with clean cheesecloth.

WARNING: CLEANING SOLVENTS ARE TOXIC AND VOLATILE. USE ONLY IN WELL-VENTILATED AREAS. AVOID PHYSICAL CONTACT WITH SOLVENT AND DO NOT INHALE VAPORS.

(3) Wipe repaired surface with a cloth moistened with methyl isobutyl ketone, Specification TT-M-268, and wipe surface dry with clean cheesecloth.

CAUTION: IF BARE METAL IS EXPOSED BY SANDING, IT MUST BE RE-TREATED BEFORE APPLYING WASH PRIMER.

(4) Starting with the last intact paint layer, reapply paint coats in accordance with repainting.

NOTE: The gloss must be removed in the area to be touched up with an abrasive material, the defective area smoothed and edges feathered. The area must then be cleaned removing all loose and foreign material.

D. Repaint brake housing and brake backing plate as follows.

WARNING: CLEANING SOLVENTS ARE TOXIC AND VOLATILE. USE ONLY IN WELL-VENTILATED AREAS. AVOID PHYSICAL CONTACT WITH SOLVENT AND DO NOT INHALE VAPORS.

(1) Thoroughly clean all surfaces to be treated and/or painted. Housing subassembly should be vapor degreased or washed with methyl isobutyl ketone, Specification TT-M-268.

(2) Treat all exposed metal surfaces of wheel subassemblies with surface treat solution conforming to Specification MIL-M-3171, in accordance with manufacturer's instructions. Refer to Repair Materials for recommended solution.

CAUTION: DO NOT PAINT INTERIOR OF PISTON CAVITIES, INLET OR BLEEDER OPENINGS.

(3) Mask all threaded holes and hydraulic cavities to avoid getting paint on these surfaces.

E. Repaint reworked and treated areas with one coat of wash primer as follows.

(1) Wash primer is supplied in two separate containers; one contains the base primer, the other the acid component. Both must be thoroughly mixed before use.

(2) Mix wash primer, Specification MIL-C-8514 as follows.

(a) The resin component should be well stirred to redisperse any settled pigment. Then add the acid component slowly to the resin while stirring; never add in reverse order. One volume of acid component is always used with four volumes of the resin. Add the water to the alcohol (ethyl), do not reverse this admix procedure. Mix and stir well. Add only enough of the water alcohol mix to the resin mix to reduce the specific gravity to a range of 0.885 to 0.915.

NOTE: If either of the admix procedures are reversed, scrap the material and start over.

(b) Formula to be used when humidity is below 90 percent:

16 ounces (453,6 grams) resin component
4 ounces (113,4 grams) acid component
12 ounces (340,2 grams) ethyl alcohol, Specification O-E-760, Type III
1/2 ounce (14,18 grams) distilled water

Batch life under four hours

(c) Formula to be used when humidity is above 90 percent:

16 ounces (453,6 grams) resin component
4 ounces (113,4 grams) acid component
9 ounces (255,15 grams) ethyl alcohol, Specification O-E-760, Type III
3 ounces (85,05 grams) butyl alcohol, Specification TT-B-846
1/2 ounce (14,18 grams) distilled water

Batch life under two hours

Specific gravity range 0.885 to 0.915.

(3) Application

NOTE: All surfaces should have received anodic or chemical treatment. All surfaces must be clean of all contaminantes by degreasing and/or solvent washing prior to applying the wash primer.

(a) Apply a single wet coat of wash primer to a dry film thickness of approximately 0.0002 to 0.0003 inch (0,005 to 0,007 mm). Do not attempt to obtain a full hiding coat. If such a coating is produced, it should be immediately removed with alcohol and replaced with a properly applied coating.

(b) Air dry one hour minimum to four hours maximum. Subsequent topcoats should be applied as soon as practical after the minimum drying time but no later than four hours after the application of the wash primer. If subsequent primer coats are not applied within the specified time, the parts should be stripped and recoated with wash primer.

F. Method I (Primary) - Repaint brake housing and brake backing plate with two coats of aluminum topcoat/primer combination as follows.

(1) Surface Preparation

(a) Parts must be clean and have received the surface treatment required and one coat of wash primer before the application of paint.

(2) Mixing

(a) Mix the aluminum topcoat/primer combination until a viscosity of approximately 25 seconds in a No. 2 Zahn cup is obtained.

NOTE: Aluminum topcoat/primer combination should be at the proper viscosity. If required, thinning can be accomplished using Aeroprite Reducer TH-89.

(3) Application

(a) Spray one full wet cross coat to a dry film thickness of approximately 0.0004 to 0.0006 inch (0,010 to 0,015 mm).

(b) Air dry for a minimum of 45 minutes before applying a second coat.

(c) Spray a second full cross coat to a dry film thickness of approximately 0.0004 to 0.0006 inch (0,010 to 0,015 mm).

(d) Air dry 45 minutes before handling. Paint will reach full cure in 72 hours.

G. Method II (Alternate) - Repaint brake housing and brake backing plate with two coats of zinc chromate primer, Specification TT-P-1757, and two coats of aluminum lacquer, Specification TT-L-32, as follows.

(1) Surface Preparation

(a) Parts must be clean and have received the surface treatment required and one coat of wash primer before the application of paint.

(2) Apply two coats of zinc chromate primer, Specification TT-P-1757.

NOTE: Do not exceed the recommended thickness for the applied topcoats. If the humidity should drop below 20 percent, primer application should be stopped until steps are taken to raise the percent humidity.

(a) Apply one coat of primer to obtain a dry film thickness of 0.0003 to 0.0004 inch (0,00762 to 0,0102 mm).

(b) After a minimum flash off period of five minutes, apply second coat of primer to obtain a total dry film thickness of 0.0006 to 0.0008 inch (0,015 to 0,020 mm).

(c) Allow the primed surface to dry a minimum of two hours and a maximum of 12 hours before topcoating with aluminum lacquer, Specification TT-L-32.

(3) Apply two coats of aluminum lacquer, Specification TT-L-32.

(a) Spray one full wet cross coat to a dry film thickness of approximately 0.0004 to 0.0006 inch (0,010 to 0,015 mm) over the primer coating.

(b) After a minimum flash off period of five minutes, apply second coat of aluminum lacquer to obtain a total thickness of 0.0008 to 0.0012 inch (0,020 to 0,030 mm).

(c) Air dry 45 minutes before handling. Paint will reach full cure in 24 hours.

8. Modification of Brake Assembly 5001571, 5001571-1, 5001571-3 and 5001571-4 to Brake Assembly 5001571-6

A. At operator's option, Asbestos-Free Linings 9523331-1 may be replaced with improved Asbestos-Free Linings 5008993 as follows:

(1) At the next brake overhaul or next lining replacement, replace Linings 9523331-1 with improved Asbestos-Free Linings 5008993.

(a) Operators are advised that old asbestos-free linings may be used until stock depletion. The improved asbestos-free linings are to be used as a set, they are not to be mixed with the old linings in any one assembly.

(2) Reidentify Brake Assemblies as follows:

(a) *Reidentify Brake Assemblies 5001571 or 5001571-1 by grinding off the* "-1" and metal stamping a "-6" after brake assembly number in 0.12 inch (3,05 mm) characters to read "5001571-6".

NOTE: Where necessary, the part should be suitably supported for stamping.

(b) Reidentify Brake Assemblies 5001571-3 or 5001571-4 by grinding off "-3" or "-4" and metal stamping a "-6" after brake assembly number in 0.12 inch (3,05 mm) characters to read "5001571-6".

NOTE: Where necessary, the part should be suitably supported for stamping.

(3) Re-treat and repaint any displaced metal in accordance with Re-Treating and Repainting.

(4) After installing the improved Asbestos-Free Linings 5008993 the disk surface should be checked for toughness or material buildup. The disk should be resurfaced to remove the lining transferred material or install a new disk to mate with new linings.

9. Modification of Brake Assembly 5001571-2 to Brake Assembly 5001571-5

A. At operator's option, Asbestos Linings 5004562 may be replaced with Asbestos-Free Linings 5004562-1.

NOTE: Asbestos linings are no longer manufactured. The new asbestos-free linings will be readily identified by their white color.

(1) At the next brake overhaul or next lining replacement, replace Linings 5004562 with Asbestos-Free Linings 5004562-1.

(a) Operators are advised that old asbestos linings may be used until stock depletion. The new asbestos-free linings are to be used as a set, they are not to be mixed with the old linings in any one assembly.

(2) Reidentify Brake Assembly 5001571-2 by grinding off "2 and by metal stamping a "-5" after brake assembly number in 0.12 inch (3,05 mm) characters to read "5001571-5."

NOTE: Where necessary, the part should be suitably supported for stamping.

(3) Metal stamp repair number "5R87-060" in 0.09 inch (2,3 mm) characters adjacent to the assembly number.

NOTE: Where necessary, the part should be suitable supported for stamping.

(4) Re-treat and repaint any displaced metal in accordance with Re-Treating and Repainting.

(5) After installing the improved Asbestos-Free Linings 5004562-1, the disk surface should be checked for roughness or material build up. The disk should be resurfaced to remove the lining transferred material or install a new disk to mate with linings.

ASSEMBLY AND STORAGE

1. Assembly and Storage Materials

NOTE: Equivalent substitutes may be used for items listed.

Pliobond 5001	W. J. Ruscoe and Company 483 Kenmore Boulevard Akron, OH 44301
Lockwire (MS20995C32)	Commerically available
Hydraulic Preservative Fluid Specification MIL-H-6083	Commercially available
Hydraulic Fluid (Red Oil) Specification MIL-H-5606	Commercially available
Antiseize Compound (Lubtork) Specification MIL-T-83483 (Prime)	Armite Laboratories 1845 Randolph Avenue Los Angeles, CA 90001
Antiseize Compound Specification MIL-T-5544 (Alternate)	Armite Laboratories 1845 Randolph Avenue Los Angeles, CA 90001
Rust Veto 4214	E. F. Houghton and Company Madison and Van Buren Street Valley Forge, PA 19482
Naphtha or Lead-Free Gasoline	Commercially available

2. General (Ref. IPL Fig. 1)

A. It is recommended that new preformed packings be installed at each overhaul.

B. It is recommended that brake linings be replaced at time of overhaul.

NOTE: Brake linings must be similar and not intermixed with alternate brake linings. Alternate brake linings must be replaced as a set.

3. Assembly Procedures (Ref. IPL Fig. 1)

A. Assemble the brake assembly in accordance with the following procedures.

CAUTION: ASSEMBLE THE BRAKE ON A CLEAN, FLAT SURFACE BEING CAREFUL NOT TO NICK, SCRATCH OR SCUFF THE PAINT OR PROTECTIVE FINISH. ENSURE PROPER PARTS ARE USED FOR EACH BRAKE ASSEMBLY.

B. Install bleeder as follows:

(1) Lubricate preformed packing (280) with a light coat of hydraulic preservative fluid, Specification MIL-H-6083.

(2) Place lubricated preformed packing (280) on bleeder valve adapter (270) then install in brake housing (290) bleeder port.

(3) Tighten bleeder valve adapter (270) to a torque value of 30 pound-feet (41 N-m).

(4) Install bleeder valve (260) into bleeder valve adapter (270) and tighten to a torque value of 120 pound-inches (13,6 N-m).

(5) Place bleeder washer (250) on bleeder screw (240 or 240A) and install in bleeder valve (260).

C. Install inlet as follows:

(1) Lubricate preformed packing (230) with a light coat of hydraulic preservative fluid, Specification MIL-H-6083.

(2) Place lubricated preformed packing (230) on inlet adapter (220) and install in brake housing (290) inlet port.

(3) Tighten inlet adapter to a torque value of 30 pound-feet (41 N-m).

(4) Lubricate preformed packing (210) with a light coat of hydraulic preservative fluid, Specification MIL-H-6083.

(5) Place lubricated preformed packing (210) on protective plug (200) and install in inlet adapter.

D. Assemble each of the piston units as follows:

NOTE: If letter "R" has been stamped after brake assembly number on housing, assembly has been reworked for oversize piston.

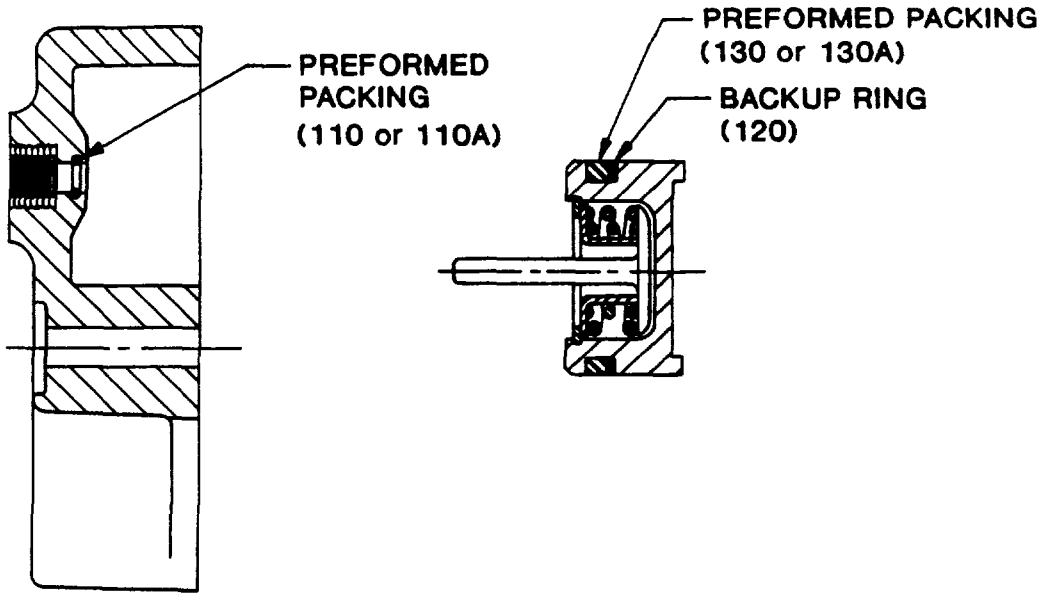
(1) Place the head of flat head pin (180) into piston (190).

(2) Place brake release spring (170) over pin into piston.

(3) Place brake release spring (160) over flat head pin (180) and inside brake release spring (170).

(4) Place spring guide (150) over flat head pin (180) and on the inside brake release spring (160).

(5) With piston opening up, place retaining ring (140) on top of piston over opening.



(6) Place tool (tubing used in disassembly) over flat head pin (180), inside retaining ring (140) and against spring guide (150).

(7) Place piston unit into arbor press and apply force to tool (tubing), against spring guide (150), compressing the springs just enough to enable the installation of retaining ring (140) into groove of piston. Release arbor press slowly and ensure retaining ring is seated. Remove piston unit from arbor press.

E. Install piston units as follows:

(1) Lubricate preformed packings (130 or 130A) and preformed packing (110 or 110A) with hydraulic preservative fluid, Specification MIL-H-6083.

(2) Install lubricated preformed packing (130 or 130A) and backup ring (120) in seal groove of piston (190) (Ref Fig. 701).

Preformed Packing Installation
Figure 701

(3) Install lubricated preformed packing (110 or 110A) in brake housing (290) (Ref. Fig. 701).

(4) Lubricate contacting surfaces of pistons and piston cavity with light coat of hydraulic preservative fluid, Specification MIL-H-6083.

(5) Install lubricated piston unit with preformed packing (130 or 130A) and backup ring (120) in brake housing.

(6) Install flat washer (100) on flat head pin (180).

(7) Dip self-adjusting pin grip (90) into clean hydraulic brake fluid, Specification MIL-H-5606 and install on flat head pin (180), large end first.

(8) Install self-adjusting pin nut (80) over flat head pins (180) and screw into brake housing (290) but do not tighten.

(9) Push pistons (190) completely back against brake housing (290) and tighten self-adjusting pin nuts (80) to a torque value of 25 pound-feet (34 N-m) and back off several times to seat parts and final torque.

(10) Lockwire self-adjusting pin nuts (80) in series, using Lockwire MS20995C32 (Ref. Fig. 1).

F. Install brake fasteners as follows:

(1) Lubricate bolt threads and bearing surfaces of bolts (50), countersunk washers (60), plain washer (40) and self-locking nut (30) with antiseize compound, Specification MIL-T-83483.

(2) Assemble backing plate (70 or 70A) on brake housing (290) and install internal wrenching bolts (50) and countersunk washer (60) through brake housing side. Secure with plain washer (40) and self-locking nut (30).

(3) Tighten bolts (50) to a Lubtork value of 20 pound-feet (27,1 N-m).

G. Install brake linings as follows:

(1) Apply Pliobond 5001 cement to back of brake linings. Use naphtha or lead-free gasoline to remove cement that may accidentally drip on lining wear surface.

(2) For Brake Assemblies 5001571-3 and 5001571-4, install brake lining (20B) in piston and anvil recesses of brake housing.

(3) For Brake Assembly 5001571-5, install brake lining (20C) in piston and anvil recesses of brake housing.

(4) For Brake Assembly 5001571-6, install brake lining (20D) in piston and anvil recesses of brake housing.

H. Install brake disk (10 or 10A) into position between brake linings.

NOTE: Brake disk (10) P/N 5001585 is used on Brake Assemblies 5001571-, -1, -3, -4 and -6, Brake Disk (10A) P/N 5004272 is used on Brake Assemblies 5001571-2 and 5001571-5.

I. Test brake assembly in accordance with applicable TESTING AND FAULT ISOLATION instructions.

4. Installation of Disk Guide Bracket Subassembly (300)

NOTE: Disk guides are installed at operator's option on Brake Assemblies 5001571, 5001571-3 and 5001571-6 after installation of brake assembly on aircraft.

A. Install disk guides as follows:

(1) Install disk guide bracket subassembly using brake mounting bolts in the two adjacent bolt holes in bottom of brake housing. Install disk guide with lining toward brake disk (10) (Ref. Fig. 1).

5. Storage Instructions

A. The brake assembly should be stored as follows:

CAUTION: BRAKES EQUIPPED WITH QUICK-DISCONNECT FITTINGS SHOULD HAVE THE FITTINGS PROTECTED DURING SHELF STORAGE BY SUITABLE CAPS OR OTHER MEANS.

(1) The brake assembly should be stored in moisture-barrier material and a sealed corrugated cardboard container, or equivalent.

(2) The brake assembly should be stored in a clean, dry storeroom. The desirable storeroom temperature range is from 50° to 70°F (10° to 21°C). If this temperature range cannot be maintained, temperatures as high as 125°F (+52°C) and as low as -20°F (-29°C) can be tolerated for short periods. Total time above 100°F (38°C) should not exceed three months.

(3) When brake disk is stored separated, insert cardboard between brake linings to hold them in position.

B. Housing, backing plate and disk:

(1) Housings and disks that are to be stored for an indefinite period should be treated as follows:

(a) Vapor degrease metal parts to remove all oil and residue.

WARNING: RUST INHIBITORS ARE HIGHLY FLAMMABLE AND MUST BE USED ONLY IN AN OPEN OR WELL-VENTILATED AREA. EXERCISE EXTREME CARE.

(b) Immerse parts in Houghton's Rust Veto 4214 or equivalent. Use in the "as-received" condition without dilution. Allow parts to drip and air dry for five minutes. Clean compressed air may be used to speed drying.

(c) Wrap parts in moisture-barrier material and package in a cardboard container.

(d) Prior to placing parts back into service, degrease in a vapor degreaser.

FITS AND CLEARANCES

Item No. (Ref. IPL Fig. 1)	Compressed Length	Minimum Load
160	0.538 inch (13,66 mm)	60 pounds (267 N)
170	0.538 inch (13,66 mm)	115 pounds (512 N)

Spring Values
Figure 801

Item No. (Ref. IPL Fig. 1)	Nomenclature	Replacement Dimension
10	Brake Disk Thickness (minimum) Outside diameter (minimum)	 0.490 inch (12,45 mm) 13,025 inches (330,83 mm)
10A	Brake Disk Thickness (minimum) Outside diameter (minimum)	 0.586 inch (14,88 mm) 13,025 inches (330,82 mm)
20C or 20D	Brake Lining (Thickness)	0.220 inch (5,6 mm) 0.200 inch (5,1 mm)
180	Flat Head Pin (Diameter at grip holding surface)	0.245 inch (6,22 mm)
190	Piston (Diameter)	2.112 inches (53,64 mm)
320	Disk Guide Linings (Thickness)	0.140 inch (3,56 mm)

Wear Tolerances
Figure 802

Item No. (Ref. IPL Fig. 1)	Nomenclature	Torque Value
30	Self-Locking Nuts	25 pound-feet (34 N-m)
80	Self-Adjusting Pin Nuts	25 pound-feet (34 N-m)
220	Inlet Adapter	30 pound-feet (41 N-m)
260	Bleeder Valve	120 pound-inches (13,6 N-m)
270	Bleeder Valve Adapter	30 pound-feet (41 N-m)

Torque Values

SPECIAL TOOLS, FIXTURES AND EQUIPMENT

The following special tools will facilitate the disassembly and reassembly of the brake.

NOTE: The following type of equipment is recommended for paint removal using the dry-stripping procedure.

Model - PRAM31
Pauli and Griffin
907 Cotting Lane
Vocaville, CA 95688

ILLUSTRATED PARTS LIST

1. Introduction

A. General

(1) The Illustrated Parts List (IPL) section illustrates and lists the procurable parts of the assembly(ies) in this publication.

B. Parts List

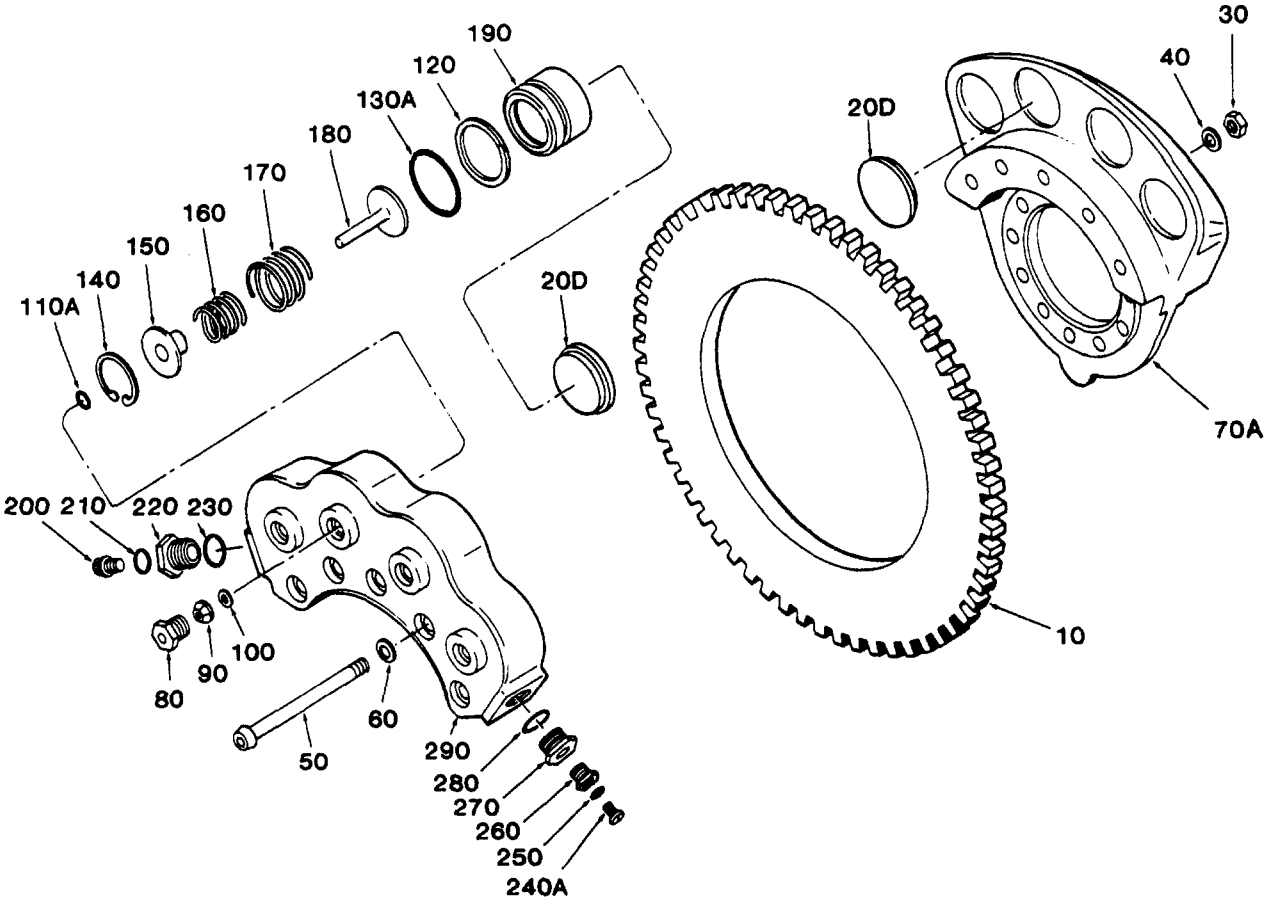
(1) The illustration is an exploded view of assembly(ies) covered by the parts list.

(2) Components in the parts list are listed in order of disassembly.

(3) The Figure and Item column provides the cross reference between the parts list and the associated IPL Figure(s).

(4) The Part Number column gives the part number of the item, which is stamped on the part when practical. This number should be used when ordering parts.

(5) The Airline Stock Number column is provided for the convenience of the operator to enter individual part numbers.



(6) The Nomenclature column gives the basic noun name of each part, together with any descriptive or dimensional information and specifications required to identify part listed. Parts are indented under the numbered sub-column heading showing the relationship of the parts to their subassemblies and to the assembly. When an alternate part or repair part exists for the recommended part, it is indicated in parentheses following the part nomenclature. A federal supply code number is given for all vendor-supplied items.

(7) The Effect Code column shall establish parts relationship with units or assemblies which are essentially the same but have minor variations. These units or assemblies are the lead items. These units or assemblies shall be assigned reference letters such as A, B, C, D, etc. Parts which are not common to all configurations, but are associated with one or more of the coded lead items, shall carry the letter or letters assigned to the lead item with which it is associated. If a part is common to all lead items, the Effect Code column shall be blank.

(8) The Units Per Assembly column gives the number of parts required for each assembly or subassembly.

C. Federal Supply Codes for Manufacturers

(1) A list of vendor/manufacturer names and addresses is provided following the parts list.

5001571-6 SHOWN

2. Parts List

TEMPORARY REVISION NO. 32–4

TO: HOLDERS OF AP–309 (32–40–24) COMPONENT MAINTENANCE MANUAL WITH ILLUSTRATED PARTS LIST FOR MAIN WHEEL ASSEMBLIES 9544382 AND 9544382–1 USED ON THE DE HAVILLAND TWIN OTTER AIRCRAFT.

PURPOSE: This Temporary Revision is issued to correct a part number in the Illustrated Parts List.

FILING INSTRUCTIONS: Record applicable data on the RECORD OF TEMPORARY REVISIONS sheet in front of the manual. Insert page 1 facing the RECORD OF TEMPORARY REVISIONS.

Retain this Temporary Revision until normal revision service incorporates this information into the Component Maintenance Manual.

This Temporary Revision affects page 1004 (32–40–24).

Attached to this transmittal letter is Revision No. 6 of AP-309 (basic issue dated 15 January 1969).

REVISION NO. 6 DATED 30 OCTOBER 1988

HIGHLIGHTS

REVISION NO. 6 CONTAINS ALL PAGES OF THE MANUAL. Pages which have been added or revised are outlined below, together with the Highlights of the revision.

Please retain all previous HIGHLIGHTS pages inserting them into this manual for future reference.

Chapter/Section and Page No.	Description of Change
All pages	Changed masthead from Goodyear to Loral Aircraft Braking Systems. Multiplied all figure item numbers by 10. Added metrics.
Cover	Revised to latest format and added Wheel Assembly 9544382-2.
Title Page	Revised to latest format and added Wheel Assembly 9544382-2.
Record of Revisions, page 1/2	Added Revision No. 6.
Service Bulletin List, page 1/2	Added Service Bulletins considered.
List of Effective Pages, pages 1 and 2	Revised to reflect current revision.
Table of Contents, pages 1 thru 3/4	Revised to reflect current revision.
Introduction, pages 1 thru 4	Revised to reflect current revision and field office addresses. Deleted pages 5/6.

Chapter/Section and Page No.	Description of Change
32-40-24	
page 1	Deleted Goodyear and part numbers from paragraph 1., General. Revised paragraph 2.C. and added paragraph 2.D.
pages 2 and 3	Changed Figure 1 to Sheet 1 of 2 and added Sheet 2 for Wheel Assembly 9544382-2. Multiplied all figure items by 10. Changed figure item 9A to 95 and added item 165 (Sheet 1). Relocated text.
page 4	Revised Key to Figure 1, multiplying all figure items by 10. Added item 1 as "Not Used", deleted item 1A, changed item 9A to 95, added items 165, 170B, 215 and 230A. Distinguished items 230 and 230A as aluminum and steel disk drive rings respectively. Added new paragraph 5.B. Relocated text.
page 101	Revised paragraph 1., Test Equipment and Materials.
page 102	Relocated text.
page 103	Deleted reference to Goodyear in paragraph 4.B.(1) NOTE. Changed figure item 9A to 95 in paragraph 4.B.(2). Relocated text.
pages 104 thru 106	Relocated text.
page 302	Added figure item s 120A and 140A to paragraph 2.H. Added figure item 230A to paragraph 2.I.
page 401	Deleted vapor degrease solution, Specification MIL-T-81533, 1,1,1-Trichloroethane from paragraph 1., Cleaning Materials and paragraph 3. B., Paint Removal Procedure. Added materials equipment and instructions for primary Paint Removal using dry-stripping method and making solvent method an alternate.
page 502	Revised paragraph 2.C.(1)(a).
page 503	Added figure item 170B to paragraph 3. Revised paragraph 4.B. Relocated text.
page 504	Added figure item 230A in title and new paragraph 5.B. Renumbered previous paragraph 5.B. to 5.C.

Chapter/Section and Page No.	Description of Change
pages 504 thru 506	Added new paragraph 6. and renumbered paragraphs 6. thru 10. to 7. thru 11. Relocated text.
page 505	Corrected Figure 503.
page 506	Added new paragraph 12.
pages 601 and 602	Revised and added information to paragraph 1., Repair Materials. Relocated text.
page 602	Added figure item 170B to paragraph 3. Relocated text.
page 603	Added Wheel Subassembly 9544383-2 to Figure 601.
pages 607 and 608	Added figure item 170B. Revised and added omitted text to paragraph 4. Relocated text.
pages 608 thru 616	Added Figure 603. Completely revised paragraph 5., *Replacing Disk Drive Ring, by adding instructions for* replacing steel disk drive ring (230A). Added Figures 605, 606 and 607. Renumbered Figure 604 and 605 references to 608 and 609. Relocated text.
pages 617 and 618	Changed Figures 607 and 605 to Figures 608 and 609. Added pages for relocated text.
pages 619 thru 621	Added pages for renumbered figure references and relocated text.
pages 621 thru 623/624	Added pages for new paragraph 7. Rework of Wheel Assemblies 9544382 and 9544382 -1 to Wheel Assembly 9544382-2 and new Figure 610.
Repair No. 1 page 601	Added figure item 170B to paragraph 1.A.
page 701	Added new paragraphs 2.B. thru 2.D. Relocated text.
page 702 thru 707	Revised paragraphing throughout the section. Deleted paragraph titles 3. thru 7. Relocated text.
pages 702, 703	Changed title of paragraph 3. from Assembly Inboard Wheel Subassembly to Assembly Procedures. Relocated assembly of *bearing cups and disk drive ring to REPAIR section.* Deleted Figure 701. Added assembly of overinflation instruction plate (165) and valve subassembly as paragraphs B. and C. Changed paragraph 5. to paragraph 3.D., paragraph 6. to paragraph 3.E. and subparagraphs. Added figure item 170B to paragraphs 3.D.(9) and 3.E.(7). Changed paragraph 7. to paragraph 3.F. and renumbered subparagraph (1). Relocated text.

Chapter/Section and Page No.	Description of Change
page 704	Renumbered paragraph 3.F. text. Changed CAUTION to WARNING and added NOTE for paragraph 3.G. Relocated text.
pages 705, 706	Combined steps (1) thru (5) under new paragraph 3.J. Added NOTE to step (1) and steps (3) and (5). Added new paragraph 3.K. Renumbered previous paragraph 8. to 4. Wheel Balancing and paragraph 9. to 5. Storage Instructions. Renumbered Figure 702 and references to Figure 701. Renumbered Figure 703 references to 702.
page 707	Renumbered Figure 703 to Figure 702. Relocated text.
page 708	Relocated text.
page 801/802	Added figure item 215 to Figure 801 and figure item 230A to Figure 802.
page 901/902	Changed application for Tool No. 1-71409 to use with aluminum disk drive ring only. Deleted Goodyear reference in NOTE.
page 1001	Revised paragraph 1., IPL Introduction to latest format.
page 1002	Revised IPL Figure 1 adding part number 9544382-2 to title. Changed figure item references to agree with Parts List.
pages 1003 thru 1005	Revised paragraph 2., Parts List as follows: Multipled all figure items by 10. Items 1 and 1A - Added with "Order 1 or 2". Item 1B - Added with Effect Code. Items 10 and 10A - Was 1 and 1A. Item 20 - Was 2. Item 30 - Was 3. Item 40 - Was 4. Item 50 - Was 5. Item 60 - Was 6. Item 60A - Added as replacement for Effect Code B only. Item 70 - Was 7. Item 80 - Was 8. Item 90 - Was 9. Item 95 - Was 9A. Item 95A - Was 9B. Item 100 - Was 10.

Chapter/Section and Page No.	Description of Change
pages 1003 thru 1005 (continued)	Item 110 - Was 11. Item 120 - Was 12. Item 120A - Was 12A. Item 130 - Was 13. Item 140 - Was 14. Item 140A - Was 14A. Item 150 - Was 15. Item 160 - Was 16. Item 160A - Was 16A. Item 165 - Added. Item 170 - Was 17. Item 170A - Was 17A. Item 170B - Added with Effect Code. Item 180 - Added Effect Code AB. Item 190 - Was 19. Item 200 - Was 20. Item 200A - Was 20A. Added Effect C. Item 201 - Was 20B. Item 210 - Was 21. Added Effect Code AB. Item 211 - Was 21A. Item 215 - Added with Effect Code C. Item 220 - Was 22. Item 220A - Added with Effect Code C. Item 230 - Was 23 and illustrated. Added Effect Code AB. Item 230A - Added with Effect Code C. Item 240 - Was 24. Item 241 - Was 24A. Items 201, 211, 241, 250, 260, 270 thru 270E, 280 thru 280B - Added asterisk (*) for items not furnished; order separately. Relocated text.
page 1006	Updated vendor names and addresses in pararaph 3. Relocated text.

TO: HOLDERS OF AP-309 (32-40-24) OVERHAUL MANUAL WITH ILLUSTRATED PARTS LIST FOR MAIN WHEEL ASSEMBLIES 9544382 and 9544382-1 USED ON THE DE HAVILLAND TWIN OTTER AIRCRAFT.

Attached to this transmittal letter is Revision No. 5 of AP-309 (basic issue dated 15 January 1969).

REVISION NO. 5 DATED 30 JULY 1985

HIGHLIGHTS

REVISION NO. 5 CONTAINS ALL PAGES OF THE MANUAL. Pages which have been added or revised are outlined below, together with the Highlights of the revision.

Please retain all previous HIGHLIGHTS pages inserting them into this manual for future reference.

Chapter/Section and Page No.	Description of Change
All pages	This manual has been prepared with automated word processing equipment. Shifting of text may have occurred. Marking of the shifted text has been eliminated. Marking of text pages reflect only actual changes. Changed the format of Overhaul Manual to Component Maintenance Manual, renumbering and relocating sections in compliance with ATA-100. Changed the masthead to Component Maintenance Manual. Changed O-ring to preformed packing and wheel half to wheel subassembly throughout the text.
Cover	Revised to reflect current revision.
Title Page	Revised to reflect current revision.
Record of Revisions, page 1/2	Added Revision No. 5.
List of Effective Pages pages 1 and 2	Revised to reflect current revision.
Table of Contents, pages 1 and 2	Revised to latest format. Expanded table for clarification. Added TESTING AND FAULT ISOLATION section, combined ASSEMBLY and STORAGE into one section, added SPECIAL TOOLS, FIXTURES, AND EQUIPMENT section.
Introduction, pages 1 thru 5/6	Revised to reflect current revision and field office addresses.

Chapter/Section and Page No.	Description of Change
32-40-24	
page 1	Relocated last sentence of paragraph 1.A. to Wheel Differences. Deleted titles to paragraphs 2.A., B., and C. Changed disk drive ring to internal drive ring in paragraph 2.C.
page 2	Added new Figure 1. Relocated text.
page 3/4	Added new paragraph 5. for Wheel Differences. Added figure item 9.A. in Key to Figure 1. Changed disk drive ring to internal drive ring, figure item 23.
pages 101 thru 106	Added new TESTING AND FAULT ISOLATION Section.
pages 301 and 302	Revised and relocated DISASSEMBLY section from page 101 to 301. Revised paragraph 1. Deleted previous paragraphs 1.(1), (2), and (3).
page 401	Relocated CLEANING section from page 201 to 401. Renumbered and revised entire section. Added Specification MIL-T-81533 and soft wire brush to Cleaning Materials, paragraph 1.
page 402	Added (Ref. IPL Fig. 1) to paragraph 2. title and added CAUTION. Added new paragraph 2.A. Renumbered paragraphs 2.C. to 2.B. and 2.D. NOTE to 2.B. Added new NOTES for paragraphs B. and C. and paragraph 2.D.
page 403/404	Revised paragraph 3., Paint Removal Procedures. Deleted reference to carbon throughout paragraph 3. Added page for revised paragraph 3. text. Relocated text.
page 501	Relocated CHECK section from page 301 to 501. Renumbered and revised entire section. Added new paragraphs 2.B. and 2.C. Relocated NOTE to follow new paragraph 2.C. and changed Figure 301 reference to Figure 501. Deleted paragraph 3. Examination.
pages 502 and 503	Renumbered Figure 301 to 501 and renumbered figure references 401 and 402 to 601 and 602. Deleted paragraphs 3.B. thru 3.E. Added new subparagraphs 2.C.(1) thru (3).
page 503	Added new paragraph 3., Wheel Subassembly.

Chapter/Section and Page No.	Description of Change
pages 503 and 504	Added new paragraphs 4. thru 7. for checking main wheel components. Relocated Figure 302 and renumbered to Figure 502.
pages 505 and 506	Added new Figure 503, Bearing Seal Wear Limits. Added new paragraphs 8. thru 10. for checking main wheel components.
page 601	Relocated REPAIR section from page 401 to 601. Revised and renumbered entire section. Expanded Repair Materials List, paragraph 1.
page 602	Relocated paragraph 2. General. Changed paragraph 3. title to Repair of Wheel Subassemblies, and revised text. Relocated previous paragraph 4. text into new paragraph 3. Relocated paragraph 5. text into new paragraph 4., Replacing Defective Tapered Roller Bearing Cups.
page 603	Relocated and renumbered Figure 401 to Figure 601. Revised title to Repair Areas for Inboard Wheel Subassemblies 9544393 and 9544383-1.
page 604	Revised and relocated repair areas, as Key to Figure 601, for Inboard Wheel Subassembly.
page 605	Relocated and renumbered Figure 402 to Figure 602. Revised title to Repair Areas for Outboard Wheel Subassembly 9543052.
page 606	Revised and relocated repair areas, as Key to Figure 602, for Outboard Wheel Subassembly.
page 607	Added expanded text for new paragraph 4. Replacing Defective Bearing Cups.
pages 607, 608, and 610	Added new paragraph 5., Replacing Internal Drive Ring.
page 609	Added new Figure 603, Installing Internal Drive Ring.
pages 610 thru 615/616	Renumbered paragraph 7. to paragraph 6., Re-Treating and Repainting.
page 611	Added new Figure 604, Painting Diagram (Method I).
page 612	Added new Figure 605, Painting Diagram (Method II).
pages 613 thru 615/616	Added new text for Re-Treating and Repainting paragraph 6.

Chapter/Section and Page No.	Description of Change
REPAIR NO. 1	
pages 601 thru 603/604	Relocated previous paragraph 5. to REPAIR NO. 1. Expanded text.
page 602	Relocated and renumbered Figure 403 to 601.
REPAIR NO. 2	
pages 601 thru 604	Relocated previous paragraph 6. to REPAIR NO. 2. Expanded text.
page 602	Relocated and renumbered Figures 404 and 406 to 601 and 602.
page 603	Added new Figure 603, New Fairing Mounting Hole Rework (Metal Set-A4).
REPAIR NO. 3	
pages 601 and 602	Relocated previous paragraph 8. to REPAIR NO. 3. Added new Figures 601, Drive Flange Rivet Hole Repair and Figure 602, Drive Flange Rivet Hole Repair Bushing 5006511.
REPAIR NO. 4	
pages 601 and 602	Added text for Drive Flange Tee Bar Plunger Hole Repair.
page 701	Relocated section from pages 501 and 901. Changed title of section to ASSEMBLY AND STORAGE.
page 703	Relocated and renumbered Figure 501 to Figure 701.
page 706	Relocated and renumbered Figure 502 to Figure 702. Relocated text.
page 707	Added paragraph 8., Wheel Balancing. Relocated paragraph 9. Storage Instructions, from previous STORAGE section.
page 708	Added Figure 703 Balance Weight Installation for inboard and outboard wheel subassemblies.
page 709/710	Relocated Storage Instructions, paragraph 9.
page 801/802	Relocated FITS AND CLEARANCES section from page 601 to 801. Renumbered Figures 601 and 602 to Figures 801 and 802 respectively. Changed Disk Drive Ring to Internal Drive Ring in Figure 802.

Chapter/Section and Page No.	Description of Change
page 901	Added SPECIAL TOOLS, FIXTURES, AND EQUIPMENT section.
page 1001	Added latest Illustrated Parts List Introduction.
page 1002	Identified figure item 6 in Figure 1.
page 1003	Revised Parts List as follows: Item 1 - Added (order-1) and effect code A to Main Wheel Assembly 9544382. Added effect code B to Main Wheel Assembly 9544382-1. Item 2 - Added tapered roller bearing and (Class 2 or 4 only) to nomenclature. Item 8 - Corrected part number to AN6230-49 and changed nomenclature to preformed packing. Item 9A - Added figure item number for valve subassembly TR757-03. Added vendor code 79934. Item 9B - Added figure item number for valve subassembly. Added vendor code 79934. Item 12A - Added part. Item 14A - Added part. Item 16 - Added tapered roller to nomenclature. Item 16A - Added figure item number for bushing-cup subassembly. Item 17 - Added effect code A. Deleted (for 9544382). Item 17A - Added effect code B. Deleted (for 9544382-1). Item 20 - Added effect code A. Item 20A - Added effect code B. Deleted (for 9544382-1). Item 20B - Added figure item -20B, Flange Bushing 5007112 for repair only. Item 21A - Corrected to not illustrated. Item 23 - Changed Disk Drive Ring to Internal Drive Ring. Item 24 - Added tapered roller bearing and (Class 2 or 4 only) to nomenclature. Item 24A - Added for bushing-cup subassembly, part number 5R3-4-167. Item 25 - Added nut for balancing. Item 26 - Added washer for balancing. Item 27, A thru E - Added balance weights. Item 28, A and B - Added screws for balance weights.
page 1005/1006	Updated vendor addresses in paragraph 3.

TO: HOLDERS OF AP-309 (32-40-24) OVERHAUL MANUAL WITH ILLUSTRATED PARTS LIST FOR MAIN WHEEL ASSEMBLIES 9544382 and 9544382-1 USED ON THE DE HAVILLAND TWIN OTTER AIRCRAFT.

Attached to this transmittal letter is Revision No. 4 of AP-309 (basic issue dated 15 January 1969).

REVISION NO. 4 DATED 16 AUGUST 1982

HIGHLIGHTS

Pages which have been added or revised are listed below together with the Highlights of the revisions. Please delete the affected pages and insert Revision No. 4 pages dated August 16, 1982. Enter Revision No. 4 dated August 16, 1982 and insertion date on the Record of Revisions sheet.

Please retain all previous HIGHLIGHTS pages inserting them into this manual for future reference.

REVISION NO. 3 DATED 1 APRIL 1982

HIGHLIGHTS

REVISION NO. 3 CONTAINS ALL PAGES OF THE MANUAL. Pages which have been added or revised are outlined below, together with the Highlights of the revision.

Please retain all previous HIGHLIGHTS pages inserting them into this manual for future reference.

Chapter/Section and Page No.	Description of Change
All pages	This manual has been prepared with automated word processing equipment. Shifting of text may have occurred. Marking of the shifted text has been eliminated. Marking of text pages reflect only actual changes. Changed masthead to Goodyear Aerospace.
Cover	Revised to reflect current revision.
Title Page	Revised to reflect current revision.
Record of Revision, page 1/2	Added Revision No. 3.
Record of Temporary Revisions, page 1/2	Added Temporary Revisions 32-1, 32-2, and 32-3.
List of Effective Pages, page 1/2	Revised to reflect current revision.
Table of Contents pages 1 and 2	Expanded table for clarification and added Introduction.
Introduction, pages 1 thru 4	Revised to reflect current revision and field office addresses.

Chapter/Section and Page No.	Description of Change
32-40-24	
page 1	Relocated text. Added Operation to paragraph 2. title. Added paragraph 3. Handling Procedures.
page 2	Relocated text. Changed paragraph 3. to 4. Added wheel size, material, and lubricant information to paragraph 4. Added 1A Alternate Outboard Bearing Seal, incorporating TR32-1, to Key to Figure 1.
page 3/4	Added figure item 1A to Figure 1., incorporating TR32-1.
page 101	Relocated text. Changed Schrader 4722 to 4277 in paragraph 2.A. Added paragraph 2.B. and renumbered paragraphs B. thru E. to C. thru F. Added or 1A to paragraph 2.B. NOTE., incorporating TR32-1.
page 102	Relocated text. Renumbered paragraphs F., G. and H. to G., H. and I.
page 201	Added paragraph 1. Cleaning Materials. Changed paragraph 1. title and number to paragraph 2. Cleaning Procedures and renumbered subparagraphs. Relocated text.
page 202	Relocated text. Added or 1.A. to paragraph 2.E., incorporating TR 32-1. Changed paragraph 2. to 3. Paint and/or Carbon Removal Procedures. Added paint removal instructions to paragraph 3. and renumbered subparagraphs. Changed Specification MIL-C-25107 to MIL-C-19853, Type II in paragraph 3.B.
page 301	Deleted Figure 302 information is now incorporated in paragraph 1. - Check Materials. Changed paragraph 1. to 2. and 2. to 3. Added or 1.A. to paragraph 3.A., incorporating TR32-1. Relocated text.
page 302	Relocated text.
page 303	Relocated text. Renumbered figure references and Figure 303 to 302.
page 304	Relocated text.

Chapter/Section and Page No.	Description of Change
page 401	Added paragraph 1. - Repair Materials. Renumbered paragraphs 1. and 2. to 2. and 3. and subparagraphs. Revised paragraph 2. Added CAUTION to paragraph 3. Relocated text.
page 402	Relocated text. Renumbered paragraph 3. subparagraphs.
page 403	Renumbered paragraph 3. to 4. and subparagraphs. Relocated text.
page 404	Renumbered paragraphs 4. and 5. to 5. and 6. and subparagraphs. Deleted Dow 1. and added Type VI in paragraph 5.A.(3). Relocated text.
page 406	Changed Specification MIL-P-8585 to TT-P-1757 in Figure 405 NOTE.
page 407	Renumbered paragraph 6. to 7. Deleted Dow 1 and added Type VI in paragraph 7.A. Changed Specification MIL-P-8585 to TT-P-1757 in paragraphs 7.B. and 7.C. Added paragraph 8. Drive Flange Rivet Hole Repair. Relocated text.
page 408	Added page for new Figures 406 and 407.
page 501	Added paragraph 1. - Assembly Materials. Renumbered paragraphs 1. and 2. to 2. and 3. and subparagraphs. Changed Specification MIL-P-8585 to TT-P-1757 in paragraph 3.A.(1)(b). Relocated text.
page 502	Relocated text. Renumbered paragraph A subparagraphs. Added included angle -21 places to paragraph 3.A.(2)(d). Changed paragraph C. to B.
page 503	Relocated text. Added 21 places for counterboring, Counterbore tool: 5T1-71409, and No counterbore this location, 3 places to Figure 501, incorporating TR 32-3.
page 504	Renumbered paragraph D. and E. to C. and D. Renumbered paragraphs 3. and 4. to 4. and 5. Renumbered paragraph 4. subparagraphs. Changed Specification MIL-P-8585 to TT-P-1757 in paragraph 4.A.(1)(b). Relocated text.
page 505	Renumbered paragraphs 5. and 6. to 6. and 7. Relocated text.
page 506	Relocated text. Added or 1.A. to paragraph 7.E.

Chapter/Section and Page No.	Description of Change
page 507/508	Relocated text.
page 601/602	Added Figures 601 and 602 using deleted paragraphs 1 and 2 information.
page 901/902	Revised STORAGE INSTRUCTIONS to reflect the latest information.
page 1101	Revised IPL Introduction to reflect the latest information. Relocated text.
page 1102	Added figure item no. 1A to IPL Figure 1.
pages 1103 and 1104	Renumbered paragraph 3. to 2. Parts List. Relocated text. Revised Parts List, incorporating TR 32-1, as follows: Added figure item no. 1A, Alternate Outboard Bearing Seal 9533856. Changed figure item no 6, Washer COML3954771 to MS20002-6. Added (for 9544382) to figure item no 17. Added (for 9544382-1) to figure item no. 17A. Added figure item no. 21A, Rivet Bushing 5006511.
page 1105/1106	Renumbered paragraph 2. to 3. and revised vendor addresses. Added page for relocated text.

OVERHAUL MANUAL WITH IPL
WHEEL ASSEMBLY PART NO. 9544382

TO: HOLDERS OF AP-309 - OVERHAUL MANUAL AND ILLUSTRATED PARTS LIST - MAIN WHEEL ASSEMBLY 9544382 AND BRAKE ASSEMBLY 9550377 FOR DE HAVILLAND TWIN OTTER AIRCRAFT.

Attached to this transmittal letter is Revision No. 2 of AP-309 (basic issue dated 15 January 1969).

REVISION NO. 2 DATED 1 NOVEMBER 1973

REVISION NO. 2 CONTAINS ALL PAGES OF THE MANUAL. Pages which have been revised are outlined below, together with the Highlights of the revision. Retain Highlights pages in manual for future reference.

HIGHLIGHTS

Chapter/Section/Page	Description of Change
Cover	Changed to new format and deleted Brake Assembly 9550377. Added 9544382-1 Wheel Assembly.
Title	Changed revision date.
List of Effective Pages	Revised to reflect current revision.
Record of Revisions	Added Revision 2.
Service Bulletin List	Revised to indicate service bulletins considered.
Introduction, pages 1 thru 4	Revised to reflect current changes.
Contents	Revised to reflect current changes.
All pages	Changed masthead and "disc" to "disk."
32-40-24, page 1	Added 9544382-1 Wheel Assembly and reference to Figure 1. Relocated text.
32-40-24, page 2	Added page for Key to Figure 1 and relocation of text.

OVERHAUL MANUAL WITH IPL
WHEEL ASSEMBLY PART NO. 9544382

Chapter/Section/Page	Description of Change
32-40-24, page 3/4	Added page for Figure 1.
32-40-24, page 101	Added reference to IPL Fig. 1, WARNING and revised CAUTION to paragraph 1. Revised paragraph 2A. Relocated text.
32-40-24, page 102	Relocated text. Changed item numbers in paragraph H.
32-40-24, page 103/104	Deleted.
32-40-24, page 201	Changed to IPL Fig. 1 reference in paragraph 1. Changed grease specification in paragraph 1B. Changed denatured to isopropyl alcohol in paragraph 1 C & D. Relocated text.
32-40-24, page 202	Changed grease specification in paragraph 2C. Relocated text.
32-40-24, page 301	Relocated text. Changed Inspection/Check to Check. Changed Inspect to check in all paragraphs. Changed reference to IPL Fig. 1 in paragraphs 1 & 2. Added item number to paragraph E.
32-40-24, page 302	Revised Fig. 302. Relocated text.
32-40-24, page 303	Relocated text.
32-40-24, page 401	Relocated text. Added 9544383-1 Wheel Subassembly to Figure 401.
32-40-24, pages 402 & 403	Relocated text.
32-40-24, page 404	Relocated text and added paragraph 5.
32-40-24, page 405	Revised Figure 403.
32-40-24, page 406	Added page for Figures 404 & 405.

Chapter/Section/Page	Description of Change
32-40-24, pages 407/408	Added page for relocation of text. Paragraph 6 was 5.
32-40-24, page 501	Added reference to IPL Fig. 1 in paragraph 2. Relocated text.
32-40-24, page 503	Relocated text. Added item number and NOTE to paragraph 2C. Added paragraph 2E.
32-40-24, page 504	Relocated text. Added reference to IPL Fig. 1 to paragraphs 3 & 4. Changed denatured to isopropyl alcohol in paragraph 4A.
32-40-24, page 505	Relocated text. Changed grease specification in paragraph 4G. Added item number to paragraph 4I & 5G. Changed IPL Fig. 1 reference number in paragraphs 5 & 6. Changed denatured to isopropyl alcohol in paragraph 5A.
32-40-24, page 506	Relocated text. Changed grease specification and revised CAUTION in paragraph 6C.
32-40-24, page 507	Relocated text. Revised Figure 502 title.
32-40-24, page 601/602	Changed reference to IPL Fig. 1.
32-40-24, page 901/902	Revised Storage Instructions.
32-40-24, page 1101	Revised Illustrated Parts List.
32-40-24, page 1102	Changed Figure 1101 to 1 and revised picture.
32-40-24, page 1103/1104	Revised Parts List.

INTRODUCTION

This manual is published in accordance with Air Transport Association Specification No. 100 for the guidance of personnel responsible for the overhaul and/or maintenance of the assembly(ies) covered in this publication. The procedures described in this manual may be altered if better and/or more economical equivalent methods can be employed by the individual facilities. However, the alternate procedures must not lessen the performance or efficiency of operation of the assembly, and all torque and specific limits or values contained herein must be strictly observed.

All dimensions and other values are expressed in U.S. units followed, where applicable, by the appropriate SI (International System) metric units in parentheses. All illustration dimensions are in inches with millimeter conversions in parentheses unless otherwise specified. Dimensions of standard tools or parts such as drills, taps, bolts, nuts, etc. where there are no equivalent metric tools or parts for the application, appear in U.S. units. Illustrations are for reference only and are not drawn to scale. Attempt is made to illustrate relationship to adjoining parts in proper proportion.

The following precautions apply to all procedures in this manual:

NOTICE

Any alteration to or substitution of any part contained in any wheel and/or brake affecting those assemblies could result in unit malfunction, or other adverse effects.

If alteration to or substitution of any part contained in any Loral Aircraft Braking Systems wheel and/or brake affecting those assemblies is necessary, obtain prior written Loral Aircraft Braking Systems authorization and instruction before performing such alteration or substitution.

LORAL AIRCRAFT BRAKING SYSTEMS ASSUMES NO LIABILITY WHATSOEVER, WHETHER CONTRACTURAL, WARRANTY, TORT OR OTHERWISE, FOR ANY UNAUTHORIZED SUBSTITUTION OF OR ALTERATION TO ANY PART CONTAINED IN ANY WHEEL AND/OR BRAKE OR FOR ANY ALTERATION NOT PERFORMED IN ACCORDANCE WITH LORAL AIRCRAFT BRAKING SYSTEMS APPROVED PROCEDURES.

While Loral Aircraft Braking Systems represents the information contained in this manual was current at the time of publication of this issue, and verified by comparison to engineering documentation, the user is cautioned that he must inquire of the nearest authorized distributor or dealer of Loral Aircraft Braking Systems wheels and brakes as to whether a more recent publication is in existence before proceeding with overhaul or maintenance operations. If you cannot locate a dealer or distributor, make your inquiry directly to our Customer Support Department, Loral Aircraft Braking Systems, 1204 Massillon Road, Akron, Ohio 443306-4186.

Users outside the United States and Canada should contact the nearest Loral Aircraft Braking Systems International Field office as listed in this manual or the closest Loral Aircraft Braking Systems distributor.

The aircraft maintenance manual shall take precedence for the component's interface connections with the functional features as used in the aircraft. This manual may also describe functional features that may or may not be used when installed as a component of a system in the aircraft.

TSO NOTICE

This assembly for commercial transport usage carries a "TSO" marking which identifies it as hav'ng been fully laboratory tested and qualified to the applicable Federal Aviation Administration (FAA) regulations. As a commercial transport category assembly, it is also tested and qualified to the specification requirements of the applicable airframe manufacturer and, finally, is certified on the applicable aircraft.

After final certification, any substitution of or alteration to any part and/or any change of process or material is not permitted without complete requalification of this assembly and resubmittal of the test data to the FAA for approval.

The FAA regulations subject Loral Aircraft Braking Systems the airframe manufacturer and the operator to constant surveillance to assure that proper Quality Assurance material and processing controls are maintained in order to provide replacement parts that are the same quality as the parts originally certified in this assembly.

SAFETY SUMMARY

Adhere to all manufacturer's Warnings and Cautions for all materials specified in this manual. Wear protective clothing (gloves, apron, etc.) approved for the materials and tools being used.

DATA RIGHTS

The unit charge for this manual covers reproduction and handling costs only and does not constitute purchase of the data or design contained herein, nor does it convey to the purchaser any rights, patent or otherwise, to reproduce or manufacture from said data.

DESCRIPTION AND OPERATION

1. General

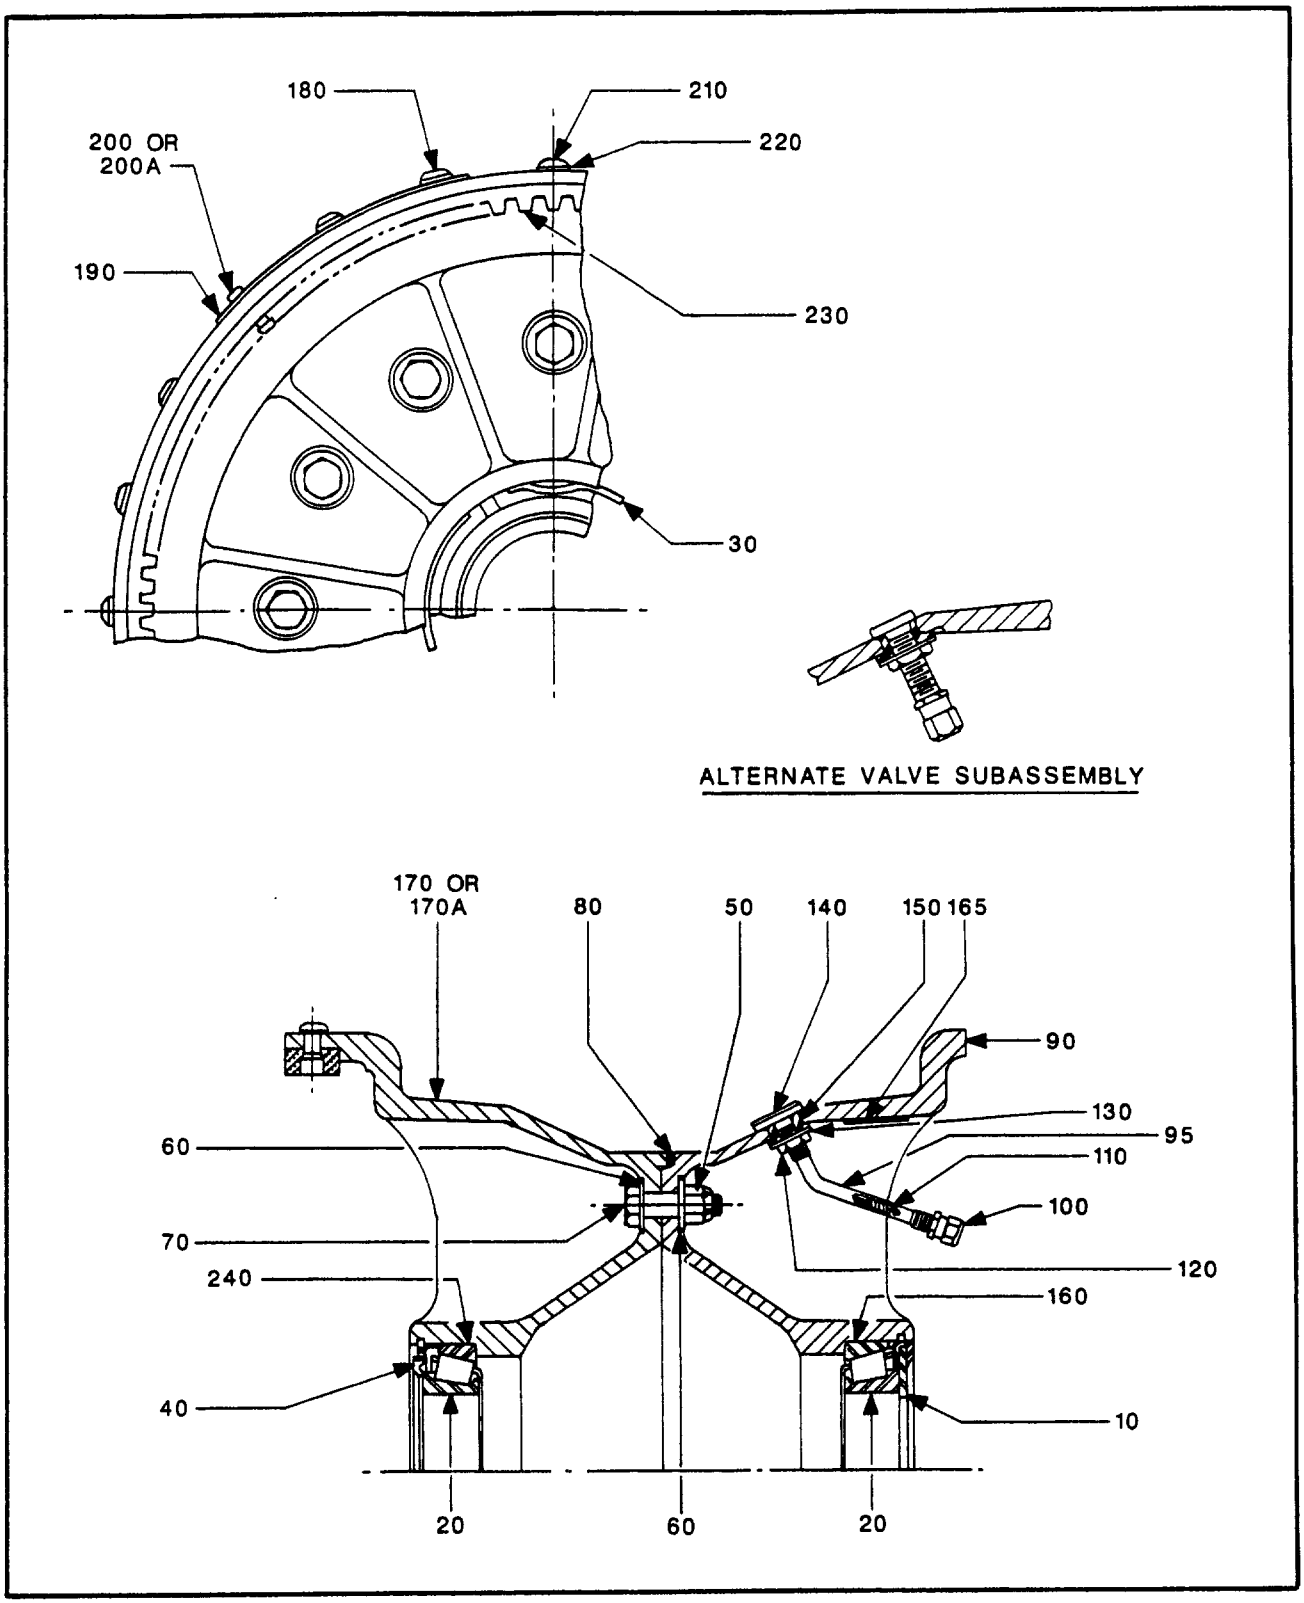
A. The main wheel assemblies are 11.00 x 12 wheels designed for tube or tubeless Type III tires. The wheels are manufactured from magnesium alloy castings.

2. Description and Operation (Ref. Fig. 1)

A. The wheel is the divided type to facilitate tire installation and removal. The two wheel subassemblies (inboard and outboard) are held together with 12 bolts and self-locking nuts, with a washer under each bolt head and nut. A preformed packing mounted on the outboard subassembly, provides the air seal at the juncture of the two wheel subassemblies. A special valve assembly is installed in the outboard wheel subassembly to inflate and deflate the tubeless tire. With tube-type tires, neither the preformed packing nor valve assembly are used.

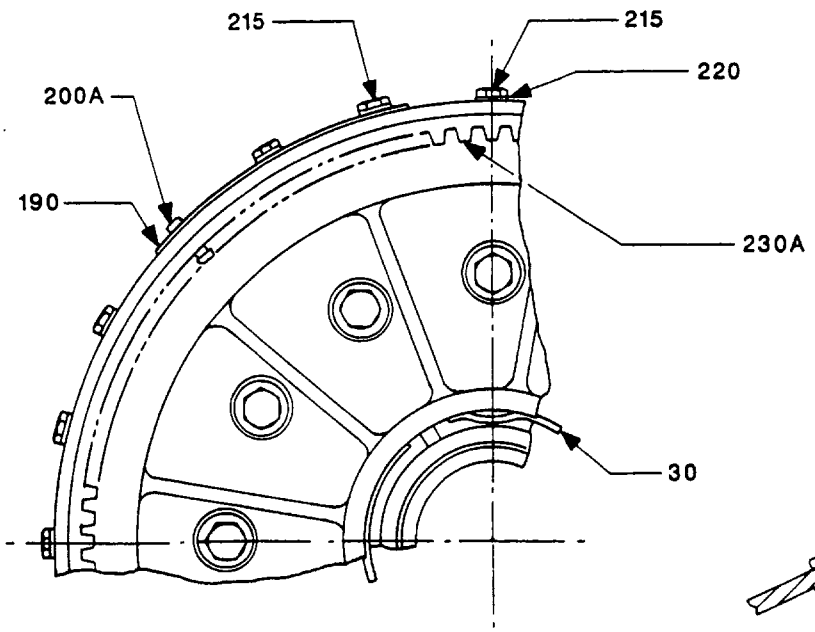
B. When the assembly is installed on the aircraft, the tapered cone and roller bearings, on which the wheel rotates, seat inside the bearing cups. The bearing cups are shrink-fitted into the hubs of each wheel subassembly. The bearings are protected against the loss of grease or entrance of foreign material by rubber-lipped bearing seals. The outboard bearing and seal are held in position by the axle nut, and the inboard bearing seal is held in position by a retaining ring.

C. An aluminum alloy or steel internal drive ring is shrink-fitted into the inboard wheel subassembly and is secured with rivets or bolts and washers. It engages the brake disk when the wheel and brake are installed on the aircraft. Three steel disk springs and three tee bar plungers are secured to the flange of the inboard wheel subassembly to align the disk in the wheel and eliminate noise.

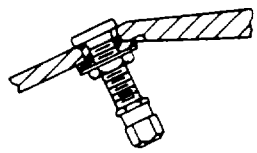


D. Each wheel subassembly is balanced individually at the time of manufacture. This permits one wheel subassembly to be assembled in any position in relation to the other wheel subassembly and allows interchanging of wheel subassemblies without rebalancing the assembly.

3. Handling Procedures

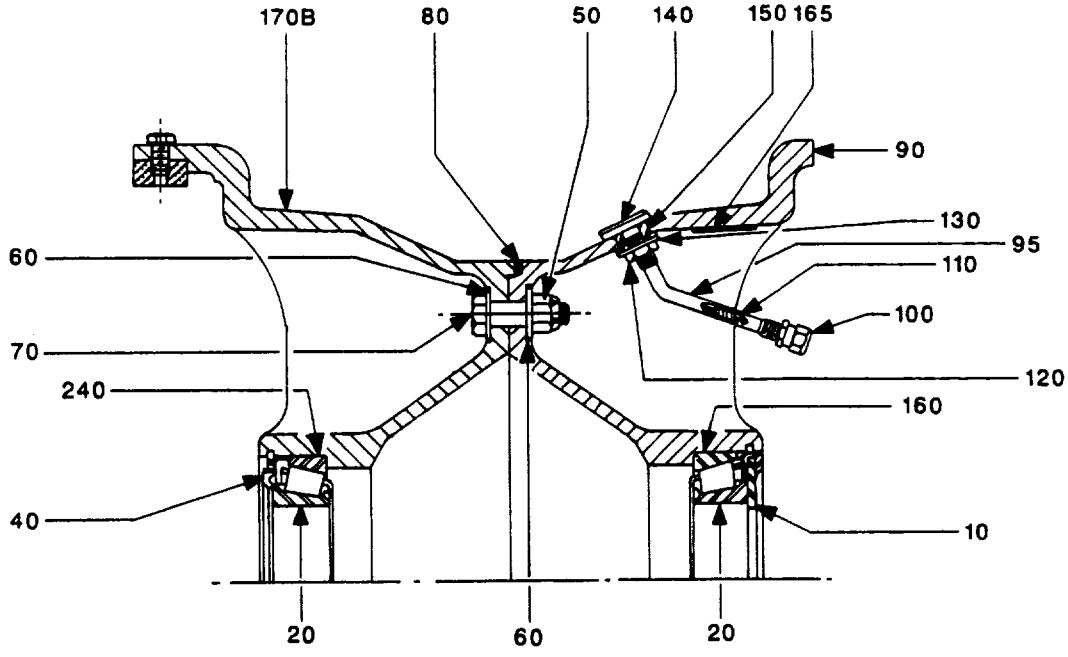


A. Careful handling of the wheel components will assure a long service life and trouble-free operation.



B. Strictly observe the inflation and deflation procedures and the torque values specified in this manual. Do not overtighten any bolt or nut. Do not use impact or power wrenches to remove or tighten any threaded parts.

C. Handle the wheel bearing cones with extreme care. Dropping or mishandling the cones during maintenance or overhaul may cause bearing failures. Do not drive bearing cones onto aircraft axle. Never overtighten the axle nut.



Main Wheel Assemblies 9544382 and 9544382-1
Figure 1 (Sheet 1 of 2)

ALTERNATE VALVE SUBASSEMBLY

Main Wheel Assemblies 9544382-2
Figure 1 (Sheet 2 of 2)

Key to Figure 1

-1.	Not Used	140.	Valve Stem
10.	Outboard Bearing Seal	150.	Rubber Grommet
20.	Tapered Roller Bearing Cone and Rollers	160.	Tapered Roller Bearing Cup
30.	Wire Retaining Ring	165.	Instruction Plate
40.	Inboard Bearing Seal	170.	Inboard Wheel Subassembly
50.	Self-Locking Nut	170A.	Inboard Wheel Subassembly
60.	Washer	170B.	Inboard Wheel Subassembly
70.	Bolt	180.	Rivet
80.	Preformed Packing	190.	Disk Spring
90.	Outboard Wheel Subassembly	200.	Tee Bar Plunger
95.	Valve Subassembly	200A.	Tee Bar Plunger
100.	Valve Cap	210.	Rivet
110.	Valve Core	215.	Bolt
120.	Hex Nut	220.	Washer
130.	Ring Washer	230.	Internal Drive Ring (Aluminum)
		230A.	Internal Drive Ring (Steel)
		240.	Tapered Roller Bearing Cup

- Item not illustrated.

D. Handle and maintain the wheel subassemblies properly to protect the paint and surface finishes. Exposed magnesium is susceptible to corrosion. Nicks, scratches, and other damage caused by improper handling of the wheel subassemblies invite corrosion, which if unattended will lead eventually to fatigue cracks and premature removal from service.

4. Leading Particulars

Wheel (Tire) Size and Type . . . . . 11.00 x 12 (Type III), tube or tubeless
Material . . . . . Magnesium Alloy
Wheel Bolt Nut Torque. . . . . 90 pound-inches (10,2 N-m) Lubtork*
Bearing and Packing Lubricant . . . . Bearing Grease, Specification MIL-G-81322

*Lubtork- At each installation, lubricate bolt threads and bearing surfaces of bolt heads, washers, and nuts with antiseize compound conforming to Specification MIL-T-5544.

5. Wheel Differences

A. Main Wheel Assembly 9544382-1 is identical to Main Wheel Assembly 9544382 except for the tee bar plunger.

B. Main Wheel Assembly 9544382-2 with a steel disk drive ring differs from Main Wheel Assembly 9544382-1 with an aluminum disk drive ring. Also, bolts instead of rivets are used on Main Wheel Assembly 9544382-2.

TESTING AND FAULT ISOLATION

1. Test Equipment and Materials

NOTE: Equivalent substitutes may be used for items listed below.

Tire Pressure Gage - Capable of measuring up to 225 psi (15,51 bars). Scale may be greater than 1 psi (0,068 bars) increments but scale should be readable to 1 psi.	Commercially available
Inflation Cage	Commercially available
Tire Deflator Schrader No. 4277	Schrader Automotive, Incorporated Division of Arvin Industries 566 Mainstream Drive P.O. Box 675 Nashville, TN 37202-0675
Grease Specification MIL-G-81322	Commercially available
Antiseize Compound Specification MIL-T-5544 (or)	W J Ruscoe and Company 483 Kenmore Boulevard Akron, OH 44301
Antiseize Compound Specification MIL-T-83483	Commercially available
Soap Solution 30 percent soap solution	Commercially available
Soft Bristle Brush	Commercially available
Cellulose Sponge	Commercially available
Hardness Tester Rockwell (B Scale preferred), Model 4YSPL or 3QR-146	Page-Wilson Corporation 929 Connecticut Avenue P.O. Box 9021 Bridgeport, CT 06602
Hardness Tester King Portable Brinell	King Tester Corporation Philadelphia, PA

2. General

WARNING: TO PREVENT POSSIBLE INJURY TO PERSONNEL, EXERCISE ALL SAFETY PRECAUTIONS BEFORE CONDUCTING TESTS.

A. The purpose of this test section is to provide guidance of maintenance personnel responsible for overhaul and/or maintenance as follows:

(1) To determine the extent of disassembly required.

(2) To provide operational test (leak test) after maintenance action to verify proper wheel/tire assembly.

B. Serviceability of aircraft wheels subjected to rolling with a flat or disintegrated tire and damage to overloaded mating wheel, where applicable, should be checked in accordance with CHECK.

C. Check for missing or broken wheel bolts.

(1) If a single bolt is broken or missing, replace bolt and two adjacent bolts (one on either side). If a bolt is cracked, replaced cracked bolt only, in accordance with DISASSEMBLY.

(2) Magnetic particle check (or equivalent) all other bolts after thorough cleaning in accordance with CLEANING and CHECK.

(3) If more than one bolt is broken, all bolts are nonserviceable.

3. Test Setup

A. None required.

4. Operational Test and Fault Isolation Procedures (Ref. IPL Fig. 1)

WARNING: TO PREVENT POSSIBLE INJURY TO PERSONNEL, EXERCISE ALL SAFETY PRECAUTIONS BEFORE CONDUCTING TESTS.

NOTE: Steps A. and B. should be performed to determine the exact condition or malfunction of the main wheel assembly. All variations from the established leakage rates should be noted for future reference during testing.

A. Perform the following to determine the extent of disassembly required.

CAUTION: BEARING SEALS AND CONES MAY BE LOOSE. CARE SHOULD BE TAKEN TO PREVENT DROPPING AND DAMAGING THESE PARTS.

(1) Remove bearing seals and bearing cones in accordance with DISASSEMBLY.

(2) Clean tapered roller bearing cups (160 and 240) accordance with CLEANING, and check roller contacting surface of cups for damage in accordance with CHECK.

(3) Clean tapered roller bearing cones and rollers (20) in accordance with CLEANING and check roller surfaces in accordance with CHECK.

(4) Check bearing seals (10 or 10A and 40) in accordance with CHECK.

(5) Cover hub openings of wheel subassemblies to prevent contamination of bearing lubricant.

(6) Check interal drive ring gear teeth for damage in accordance with CHECK.

(7) Perform Hardness Test in accordance with this section if wheel paint is scorched or any other visible evidence of heat damage is apparent.

B. Operational Test (Leak Test)

WARNING: TIRE AND/OR WHEEL FAILURE MAY OCCUR CAUSING INJURY TO PERSONNEL OR DAMAGE TO EQUIPMENT IF TIRE IS OVER-INFLATED FROM ANY HIGH PRESSURE SOURCE. TIRE AND WHEEL ASSEMBLIES MUST BE SERVICED WITH INFLATION EQUIPMENT WHICH HAS BEEN SPECIFICALLY DESIGNED FOR THIS OPERATION.

(1) Place wheel/tire assembly in an inflation cage and inflate to recommended operating pressure.

NOTE: Verify and check operating pressure before handling wheel/tire assembly. Reference Aircraft Tire Manual and Data Book for specific tire data and checks.

(2) Coat juncture around valve subassembly (95) and tire beads with soap solution. Check carefully for air leaks in the form of soap bubbles.

NOTE: If air leaks are present proceed to step (5).

(3) If no leaks occur, remove all traces of soap solution from wheel/tire assembly with water and a cellulose sponge or soft bristle brush. Dry wheel thoroughly with clean, compressed air.

(4) Check pressure after 24 hours.

(a) If reduction in pressure exceeds five percent of inflation pressure, completely deflate tire. Disassemble and check preformed packing (80) and seal groove for damage. Replace wheel preformed packing (80), or if seal groove is damaged, repair and re-treat in accordance with REPAIR. Assemble in accordance with ASSEMBLY and retest wheel/tire assembly.

(b) If reduction of pressure is less than five percent, reduce tire pressure to recommended storage pressure and remove wheel/tire assembly from inflation cage.

(5) If air leaks are present, proceed with the following steps.

(a) Completely deflate tire and remove assembly from inflation cage and remove all traces of soap solution from wheel/tire assembly with water and a cellulose sponge or soft bristle brush. Dry wheel thoroughly with clean, compressed air.

(6) If leakage occurs around valve subassembly, check torque on leaking part. Torque valve stem (140) until seated. Retest the wheel/tire assembly.

(a) If leakage occurs around valve subassembly and persists after torque check, remove valve subassembly per DISASSEMBLY, check interface surfaces and replace rubber grommet (150). Reinstall valve in accordance with ASSEMBLY and retest.

(b) If leakage occurs around tire bead seat, remove tire from wheel per DISASSEMBLY, check wheel bead seat and tire bead for damage. If tire bead is cut or defective, install a new tire. If wheel bead seat is scratched, nicked, or pitted, repair in accordance with REPAIR. Retreat and repaint areas per REPAIR. Reinstall tire in accordance with ASSEMBLY, and retest the wheel/tire assembly.

5. Hardness Test (Heat Damage Test)

A. Components of the wheel assembly that are suspected of having heat damage shall be checked for hardness.

(1) Remove tire from wheel in accordance with DISASSEMBLY.

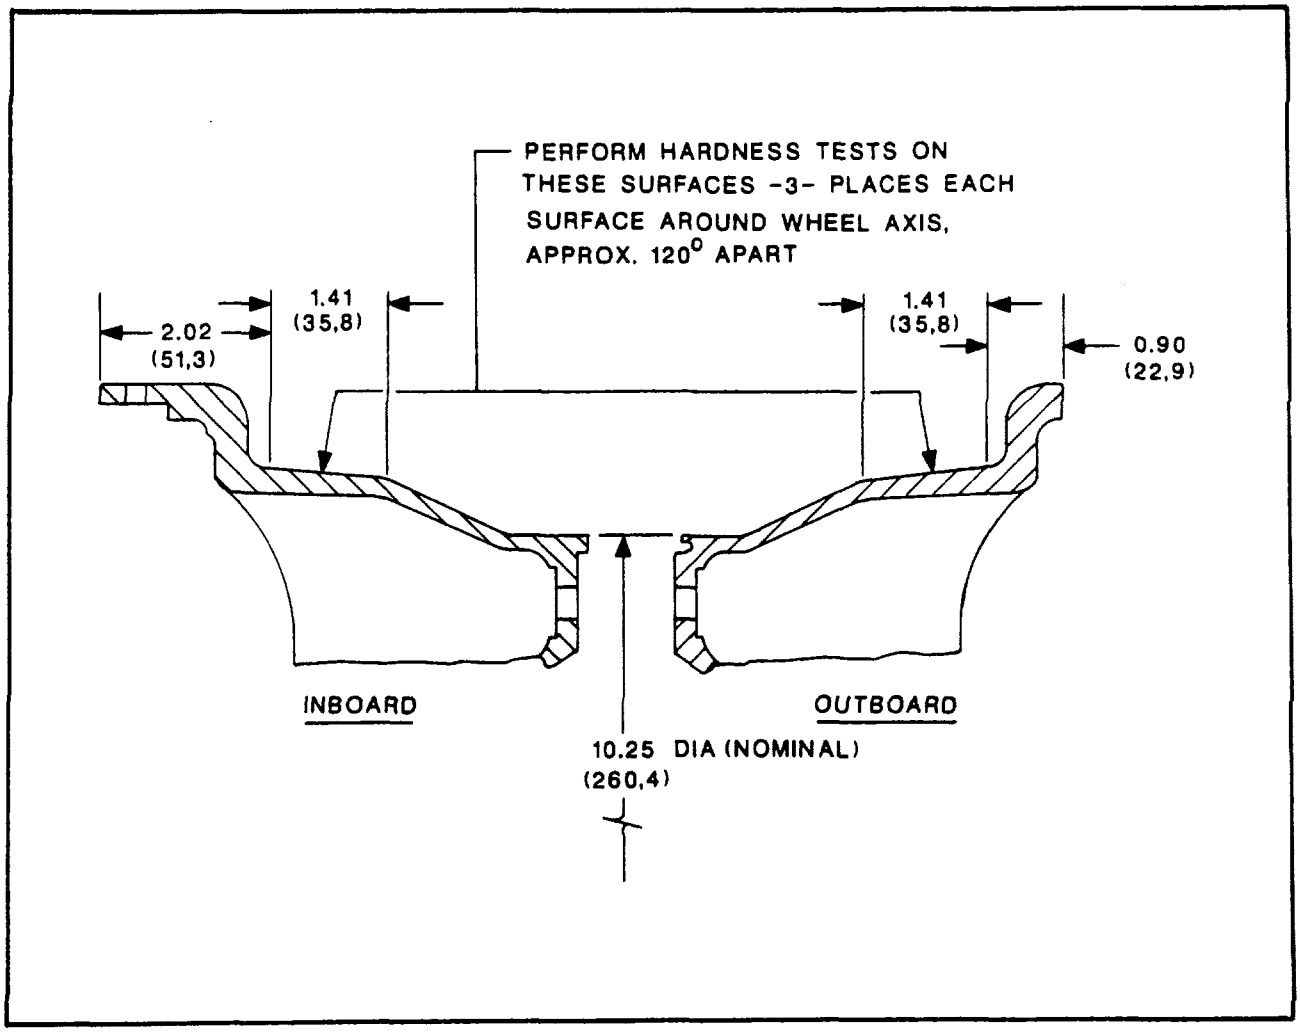
(2) Visually check wheel for discoloration, scorched paint, or other evidence of overheated condition.

(3) If any indication of an overheated condition exists, check wheel subassembly as follows:

(a) Check wheel subassembly for an out-of-round condition in accordance with CHECK.

(b) If diametral check is acceptable, perform hardness test on the inboard wheel subassembly.

B. Brinell Test



(1) Perform a hardness test on the wheel at three places, 120 degrees apart, as shown in Figure 101. Remove paint from surfaces to be checked and obtain hardness readings on three areas. Check hardness readings in accordance with Figure 102.

(2) If a reading of less than 54 BHN and greater than 52 BHN is obtained, perform a second test in tubewell area. The wheel subassembly shall be impression-stamped with the hardness value and letters "OV" (overheated). If an average value of less than B52 is obtained, or if values obtained vary more than the specified range permitted in Figure 102, replace the wheel subassembly.

NOTE: A second hardness test reading is recommended if there is any question as to the accuracy due to an inconsistent reading or excessive point spread. The second check shall be performed in close proximity to the first hardness test reading.

(3) The outboard wheel subassembly should be checked in the same manner if the inboard wheel subassembly has been excessively overheated.

(4) Refinish wheel areas where paint has been removed in accordance with REPAIR.

Heat Damage Test
Figure 101

Item	Brinell Test
Ball Diameter	10 mm
Test Load	500 kg
Number of Readings Equally Spaced	3
Acceptable Minimum Average Hardness	52 BHN
Maximum Total Range of Three Readings	2 points*

* Applicable to marginal hardness wheel only. Marginal hardness wheels are wheels with ANY ONE hardness reading of less than BHN54.

Hardness Test Readings
Figure 102

DISASSEMBLY

1. General (Ref. IPL Fig. 1)

WARNING: DO NOT ATTEMPT TO DISASSEMBLE WHEEL UNTIL TIRE HAS BEEN COMPLETELY DEFLATED; OTHERWISE, SERIOUS INJURY TO PERSONNEL OR DAMAGE TO EQUIPMENT CAN RESULT.

A. Disassemble the main wheel assembly in accordance with the following instructions.

2. Disassembly Procedures

CAUTION: DISASSEMBLE WHEEL ON A TIRE CHANGER OR A CLEAN, FLAT SURFACE, BEING CAREFUL NOT TO NICK, SCRATCH, OR OTHERWISE DAMAGE WHEEL SUBASSEMBLIES OR FLANGES.

A. Remove valve cap (100) and apply tire deflator (Schrader No. 4277 or equivalent) to completely deflate tire.

WARNING: *DO NOT ATTEMPT TO REMOVE VALVE CORE UNTIL TIRE HAS* BEEN COMPLETELY DEFLATED. VALVE CORES WILL BE EJECTED AT HIGH VELOCITY IF UNSCREWED BEFORE AIR PRESSURE HAS BEEN RELEASED.

B. Remove valve core (110).

NOTE: Outboard bearing seal (10 or 10A) and outboard tapered roller bearing cone and rollers (20) are removed when the wheel assembly is removed from the aircraft axle.

C. Remove wire retaining ring (30), inboard bearing seal (40), and inboard tapered roller bearing cone and rollers (20).

CAUTION: DO NOT PRY BETWEEN FLANGE AND BEAD WITH SHARP TOOLS OR WHEEL AND TIRE MAY BE DAMAGED, DESTROYING THEIR SEALING AND STRUCTURAL PROPERTIES.

D. Break tire beads away from both wheel flanges by applying pressure in even *increments around entire sidewall as close to tire beads as possible.*

CAUTION: DO NOT USE IMPACT OR POWER WRENCHES TO REMOVE WHEEL NUTS AND BOLTS.

E. Remove self-locking nuts (50), washers (60), and bolts (70).

F. Separate the wheel subassemblies and remove tire or tire and tube.

G. Remove preformed packing (80) if installed.

NOTE: It is recommended that a new preformed packing be installed at each overhaul. If packing must be reused, mark position of packing with respect to wheel subassembly so packing can be reinstalled in the same position. Carefully remove packing and place on a clean, flat surface. Do not hang or stretch packing.

H. If necessary, remove valve subassembly from outboard wheel subassembly (90) by removing hex nut (120 or 120A), ring washer (130), valve stem (140 or 140A) and rubber grommet (150).

NOTE: It is unnecessary to remove the valve stem and fusible plug at each tire change. It is recommended these parts be removed for checking at each overhaul and whenever it is necessary to remove the bearing cups or strip the paint from wheel.

I. Tapered roller bearing cups (160 and 240), disk spring (190), tee bar plungers (200 and 200A) and internal drive ring (230 or 230A) should not be removed from wheel subassemblies unless replacement is necessary. Refer to REPAIR for replacement procedures.

CLEANING

1. Cleaning Materials

NOTE: Equivalent substitutes may be used for items listed below.

Dry-Cleaning Solution Type I, Stoddard Solvent Type II, 140°F Solvent Specification P-D-680	Commercially available
Methyl Isobutyl Ketone (MIBK) Specification TT-M-268	Commercially available
Isopropyl Alcohol Specification TT-I-735	Commercially available
Polyplus Plastic Media Screen Size 20/40 (Primary)	Inventive Machine Corporation (I.M.C) P.O. Box 369 Bolivar, OH 44612
Plastic Reclaimable Abrasive Machine (PRAM)	See SPECIAL TOOLS, FIXTURES, AND EQUIPMENT section
Plastic Media (Dry Stripping Abrasive)	U.S. Technology Corporation A Subsidiary of U.S. Plastic and Chemical Corporation 328 Kennedy Drive Putnam, CT 06260
Paint Removing Solvent (Alternate) Specification MIL-C-19853, Type II	Turco Products Division of Purex Corporation 24600 South Main Street Carson, CA 90749
Soft Bristle Brush	Commercially available
Soft Wire Brush	Commercially available
Grease Specification MIL-G-81322	Commercially available

2. Cleaning Procedures (Ref. IPL Fig. 1)

WARNING: CLEANING SOLVENTS ARE TOXIC AND VOLATILE. USE ONLY IN WELL-VENTILATED AREAS. AVOID PHYSICAL CONTACT WITH SOLVENT AND DO NOT INHALE VAPORS.

CAUTION: CLEAN BEARING CONES CAREFULLY IN A SEPARATE CONTAINER OF CLEAN SOLVENT.

A. Clean all metal parts by immersing in dry-cleaning solution conforming to Specification P-D-680. Use a soft bristle brush to remove hardened grease, dust, and dirt. Deposits and scale on bolts (70) may be removed with a soft wire brush. If drive ring has been removed and carbon remover has not removed all of the sealant, use MIBK with light rubbing with a clean cloth.

CAUTION: DO NOT SPIN BEARING CONES WITH COMPRESSED AIR.

B. Dry all metal parts thoroughly after cleaning, using filtered and dried compressed air.

NOTE: Ensure foreign materials and solvents have been removed from all cavities, threaded holes, packets and other areas where entrapment might occur.

C. Check in accordance with CHECK section and repack bearing cones and coat bearing cups with grease, Specification MIL-G-81322, immediately after drying.

NOTE: New bearing cones and bearing cups packaged in preservative need not be degreased prior to use as the preservative is compatible with the recommended grease.

Lubrication of bearings by mechanical or other pressure methods is recommended because it is more efficient, reduces the possibility of contamination and assures a more even distribution of grease within the bearing.

D. Clean all rubber and nonmetallic parts in isopropyl alcohol, Specification TT-I-735 and dry with a clean, soft cloth.

3. Paint Removal Procedures

A. Strip wheel subassembly as follows - Method I (Dry Stripping)

WARNING: THE DRY STRIPPING PROCESS IS OPERATOR-SENSITIVE AND ONLY AN EXPERIENCED, TRAINED OPERATOR SHOULD BE PERMITTED TO PERFORM THE PAINT REMOVAL OPERATION IN ACCORDANCE WITH EQUIPMENT MANUFACTURER'S RECOMMENDATIONS.

NOTE: This procedure covers general information on dry stripping process of pneumatic blast removal of paint utilizing ground plastic particles. The procedure provides suggested control parameters to safely and effectively remove paint from aircraft component parts using the dry stripping process.

Paint must be stripped from parts before inspecting by Zyglo, dye penetrant or eddy-current methods; otherwise, inaccurate readings will result.

(1) Completely disassemble the part to be stripped. Remove all parts from wheel subassemblies, including valve, instruction and data plates, and balance weights.

NOTE: Bearing cups need not be removed during dry paint stripping.

(2) Clean part to be stripped in accordance with CLEANING section.

(3) Plug or seal off openings, threaded holes, bearing cups, and inserts as required.

(4) Remove paint using the dry stripping procedure in accordance with Figure 401 and as follows:

(a) The media (dry stripping abrasives) is effective only when used with the appropriate equipment. Depending on operator requirements, check with these (or other suitable) manufacturers for advice and application information concerning their particular equipment.

(b) Refer to Cleaning Materials for recommended dry stripping abrasives and equipment.

CAUTION: FLUSH MEDIA FROM CAVITIES, THREADED HOLES, POCKETS, AND OTHER AREAS WHERE ENTRAPMENT MIGHT OCCUR.

(5) Remove part and rinse thoroughly with water heated to a temperature of 160° to 180°F (71° to 82°C).

(6) Dry part thoroughly with filtered and dried compressed air. Apply grease, Specification MIL-G-81322, to bearing cups if installed.

NOTE: After paint stripping, the part must be re-treated and repainted in accordance with instructions in REPAIR.

NOZZLE TYPE/SIZE	NOZZLE PRESSURE	NOZZLE DISTANCE	MEDIA TYPE	ANGLE OF APPROACH
BMLV-8 1/2" 1 4	45 - 55 PSI 3	36 - 48"	POLYPLUS 20/40	45 - 75°
VENTURI 5/16" 2 4	UNDER 30 PSI 3	6 - 8"	POLYPLUS 20/40	45 - 75°

PHYSICAL REQUIREMENTS OF MEDIA

	POLYEXTRA	POLYPLUS
HARDNESS (MOH SCALE)	3.0 ± .25	3.5 ± .25
SPECIFIC GRAVITY (GMS/CC)	1.15 ± 10%	1.50 ± 10%

NOTES:

1. STAND-OFF, OPEN BLASTING.

2. CLOSED-CYCLE BLASTING (PERFORMED IN PRESSURE BLAST EQUIPMENT CHAMBER).

3. PRESSURE READINGS MUST BE TAKEN AT THE NOZZLE RATHER THAN ESTIMATED FROM REGULATOR GAUGE READINGS. RECHECK PRESSURE EVERY FOUR HOURS AND EACH TIME PRESSURE IS CHANGED AT REGULATOR.

4. PROCESS VARIABLES INCLUDE PRESSURE, DISTANCE FROM NOZZLE TO WORK PIECE, ANGLE OF ATTACK AND NOZZLE SIZE. PARAMETERS SELECTED WILL VARY WITH PAINT COATING AGE, TYPE AND NUMBER OF COATINGS BUT THE FOLLOWING PARAMETERS HAVE SUCCESSFULLY REMOVED VARIOUS COATING TYPES WITH NO EFFECT ON SUBSTRATE.

5. RECOMMENDED PLASTIC MEDIA TYPE AND SIZE IS POLYPLUS 20/40. POLYEXTRA 12/20 OR 20/30 PRODUCES A SMOOTHER FINISH BUT PAINT REMOVAL RATE IS LOWER. TYPE III PLASTIC MEDIA TYPE IS NOT TO BE USED ON THE SUBJECT AIRCRAFT COMPONENTS.

Recommended Dry Stripping Variables
Figure 401

B. Strip wheel subassembly as follows - Method II (Wet Stripping)

WARNING: PAINT REMOVAL SOLVENTS ARE CAUSTIC, TOXIC AND VOLATILE. USE ONLY IN WELL-VENTILATED AREAS IN ACCORDANCE WITH MANUFACTURER'S DIRECTIONS. OBSERVE ALL SAFETY PRECAUTIONS. AVOID PHYSICAL CONTACT WITH SOLUTION AND DO NOT INHALE VAPORS.

NOTE: Paint must be stripped from wheel subassemblies before inspecting by Zyglo, dye penetrant or eddy-current methods; otherwise, inaccurate readings will result.

(1) Completely disassemble the part to be stripped to prevent solvent from being entrapped between mating surfaces. Remove all parts from wheel subassemblies, including valve, bearing cup, disk drive ring and balance weights.

NOTE: Bearing cups need not be removed during paint stripping if a suitable mask (or other method) is used to assure contamination does not occur (behind the bearing cup) by stripping fluids.

(2) Clean the part to be stripped in accordance with Cleaning Procedures.

(3) Plug and seal off threaded holes and threaded inserts.

CAUTION: PARTS MUST BE COMPLETED IMMERSED IN SOLVENT. CONTACT WITH WATER BLANKET DURING IMMERSION WILL CAUSE SEVERE CORROSION OF THE PART.

(4) Immerse part in a paint removing solvent conforming to Specification MIL-C-19853 for a period of 30 minutes to two hours. Immersion time depends upon condition of paint. Carefully follow the manufacturer's instructions for the particular solvent being used.

CAUTION: FLUSH SOLVENT FROM CAVITIES, THREADED HOLES, POCKETS, AND OTHER AREAS WHERE ENTRAPMENT MIGHT OCCUR.

(5) Remove part from solvent and rinse thoroughly with water heated to a temperature of 160° to 180°F (71° to 82°C).

(6) Dry part thoroughly with filtered and dried compressed air. Apply grease Specification MIL-G-81322 to bearing cups if installed.

NOTE: After paint stripping, the part must be re-treated and repainted in accordance with REPAIR.

CHECK

1. Check Materials

NOTE: Equivalent substitutes may be used for items listed below.

Type	Penetrant	Developer	Supplier
Fluorescent	Zyglo ZL-16	Zyglo ZP-13 (wet) optional	Magnaflux Corporation 7310 West Lawrence Street Chicago, IL 60656
	Penetrex ZL-2A with emulsifier ZE-4	Penetrex ZP-4 (dry) or ZP-13 optional	
Red Dye	Spot Check	Spot Check	
	Dy-Chek	Dy-Chek	Turco Products Division of Purex Corporation P.O. Box 6200 Carson, CA 90749
	Met-L-Chek	Met-L-Chek	Met-L-Chek 1639 Euclid Street Santa Monica, CA 90404

2. General (Ref. IPL Fig. 1)

A. Check all components of the main wheel assembly for cracks, nicks, corrosion and other damage. Replace any cracked, severely corroded or badly damaged parts.

B. Perform the specific checks listed, referring to REPAIR for the appropriate repair procedures.

C. Serviceability of aircraft wheels subjected to rolling with a flat or disintegrated tire and damage to overloaded mating wheel, where applicable, should be checked as follows:

NOTE: Examinations listed in Figure 501 are recommended to be conducted during the life of the wheel. They are to be performed in addition to examinations conducted during wheel overhaul.

Method	Areas	Time
Using magnifying glass, visually check for cracks.	Area 1, Figure 601 Area 1, Figure 602	At each tire change.
Using Zyglo or dye-penetrant methods, check for cracks (Ref. Fig. 502).	Area 1, Figure 601 Area 1, Figure 602	At first tire change after 1,500 landings.
	Area 1, Figure 601 Area 1, Figure 602	At first tire change after 2,500 landings.
	Area 1, Figure 601 Area 1, Figure 602	At first tire change after 3,000 landings.
	Area 1, Figure 601 Area 1, Figure 602	At first tire change and each subsequent tire change after 3,250 landings.

Recommended Wheel Examinations
Figure 501

(1) Wheel Rolled with a Flat Tire

(a) Check carefully for deformation in the flange area and for tire brinelling and/or chafing damage on the flange outside diameter. Check wheel for an out-of-round condition by measuring the diameter of the flange at three places, equally spaced, around the outside diameter. The difference between the largest and smallest diameter readings shall not exceed 0.030 inch (0,76 mm); maximum bolt hole of 0.407 inch (10,3 mm) diameter (elongated). Replace any wheel with damage or deformation in excess of limits.

(2) Wheel Rolled with Disintegrated Tire

(a) Any wheel where the flanges have made direct contact with the runway due to rolling or sliding should be replaced. The high stress levels imposed on the wheel flange and bead seat area will invariably render the wheel nonserviceable even with minimal damage.

(3) Mating Wheel

(a) In the event of a wheel rolled with a flat or disintegrated tire on any aircraft fitted with dual, tandem, or dual tandem wheels, the corresponding mating wheel must also be considered. The mating wheel should be removed from service if the distance rolled was sufficient to cause any damage to the overloaded tire. Rolling in the overloaded

condition will impose additional stress on the bolts and nuts fastening the wheel subassemblies and may require early replacement. In all cases of overloaded rolling, the bolts and nuts should be replaced or checked for fatique damage at each tire change. The overpressurization relief device, where fitted, or the replaceable diaphragm, as applicable, should be replaced in all cases.

3. Wheel Subassembly (90, 170, 170A or 170B)

A. Check wheel subassemblies for cracks and structural damage. Pay particular attention to the bead seat, bolt boss, valve hole, and tubewell radius.

NOTE: Check wheel bead seats, using ultrasonic or eddy-current methods. Check all other areas of the wheel subassemblies by Zyglo or dye penetrant methods. Replace all cracked wheel castings.

B. Check wheel subassemblies for corrosion, nicks, scratches, tool marks, and other damage. Remove any corrosion and surface damage up to the limits given in REPAIR. Wheel subassemblies damaged beyond these limits should be replaced.

C. Check disk springs (190) and tee bar plungers (200 or 200A) in the inboard wheel subassembly for security, wear, or damage.

D. Check the valve hole threads in the outboard wheel subassembly (90) for damage and tightness in wheel. Check valve section of wheel for damage or corrosion. Re-treat and repaint in accordance with REPAIR section.

E. Check the threaded steel inserts in the outboard wheel subassembly hub flange for damage. If stripped or damaged, replace insert according to instructions in REPAIR.

CAUTION: HANDLE BEARING CONES WITH EXTREME CARE. MANY AIRCRAFT BEARING FAILURES OCCUR AS A RESULT OF MISHANDLING DURING SERVICING.

4. Tapered Roller Bearing Cups (160 and 240) and Tapered Roller Bearing Cones and Rollers (20)

A. Wipe bearing cups free of grease and visually check roller contacting surface of cups for looseness, scratches, pitting, brinelling, spalling, heat discoloration, rust, corrosion, and excessive wear. Replace bearing cups having any defects in accordance with instructions in REPAIR.

B. Check tapered roller bearing cones (20) and roller surfaces for nicks, scratches, rust, corrosion, spalling, flat spots, pitting, heat discoloration, and wear. Check bearing cage rib surfaces for scoring and bearing cage for nicks, dents, distortion, roller end scoring and wear in the roller pockets. Replace bearing cones having any defects.

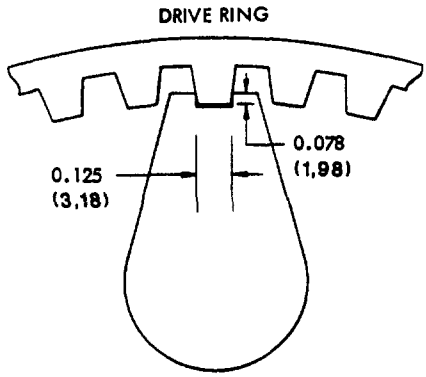
5. Internal Drive Ring (230 or 230A)

A. Check drive ring (230), rivets (210), and washers (220) for tightness. If rivets are loose or rivet holes are enlarged, see REPAIR.

B. Check disk drive ring (230A), non-locking bolts (215) and plain washers (220) for tightness. If bolts are loose or threads are stripped, see REPAIR.

C. Check drive ring gear teeth for wear or damage. Replace ring if three or more teeth are worn to a thickness of 0.125 inch (3,18 mm) less at a point 0.078 inch (1,98 mm) from top of tooth.

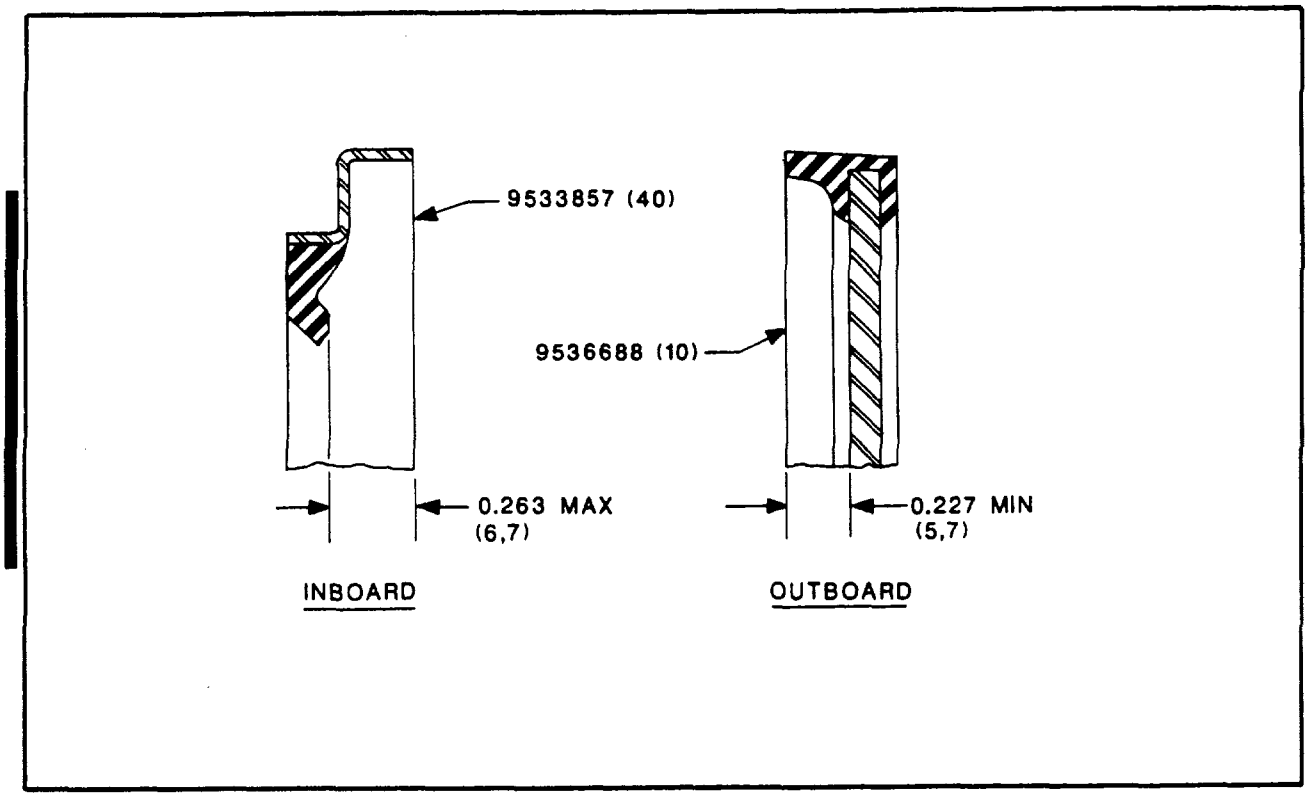
NOTE: Check worn condition of gear teeth with the drive ring wear template shown in Figure 502.



6. Disk Spring (190) and Tee Bar Plunger (200 or 200A)

A. Check disk spring and tee bar plungers for security, wear or damage. If tee bar plunger is loose due to enlarged or damaged holes, see REPAIR.

7. Valve Subassembly (95)



A. Check valve stem (140) for stripped or crossed threads and other damage. Replace valve stem if bent or damaged.

B. Replace valve cap (100) or valve core (110) if these parts are unserviceable.

NOTE: USE 1/16-INCH STOCK FOR MATERIAL
(LOCAL MANUFACTURE)

Internal Drive Ring Wear Template
Figure 502

Bearing Seal Wear Limits
Figure 503

8. Bearing Seal (10, 10A or 40)

A. Check bearing seal for wear. Measure from the metal face to the seal lip as shown in Figure 503. If this dimension measures less than 0.227 inch (5,7 mm) for outboard bearing seal, and more than 0.263 inch (6,7 mm) for inboard bearing seal at any point, or if rubbing surface is distorted, cut or grooved, or does not meet a Shore "A" hardness reading of 60 minimum or 80 maximum, the seal should be replaced.

B. Check bearing seal for grooves or damage. Replace seal if damaged.

9. Preformed Packing (80)

A. It is recommended new preformed packings be installed at each overhaul. If necessary to reuse these parts, check for cuts, permanent set, and other damage. Replace packings that are cut or damaged, or that have a permanent set.

NOTE: Cuts on packings often indicate the presence of burrs or other damage on the adjoining wheel parts. Check adjoining parts and remove burrs or other damage that may cause seal damage to reoccur see REPAIR.

10. Self-Locking Nut (50) and Bolt (70)

A. Check self-locking nuts for worn, stripped, and crossed threads. Replace if damaged. Nuts should be replaced after 15 applications. If unable to determine the number of applications, degrease the nut and bolt and check the torque required to turn nut on a nonlubricated bolt past the nut's locking section. Replace any nut requiring less than the minimum torque value as follows:

(1) Replace self-locking nut (50) when minimum torque value is less than 9.5 pound-inches (1,07 N-m).

B. Degrease and magnetic-particle check all bolts for cracks, paying particular attention to radius under the bolt head and to the threads adjacent to the bolt shank. Replace any cracked bolts and those having stripped, crossed, or damaged threads. No reworking of the bolts is permissible.

11. Wire Retaining Ring (30)

A. Check retaining ring for deformation, corrosion and damage. Replace if damaged.

12. Instruction Plate (165)

A. Check instruction plate for legibility and looseness. Replace if loose or illegible.

REPAIR

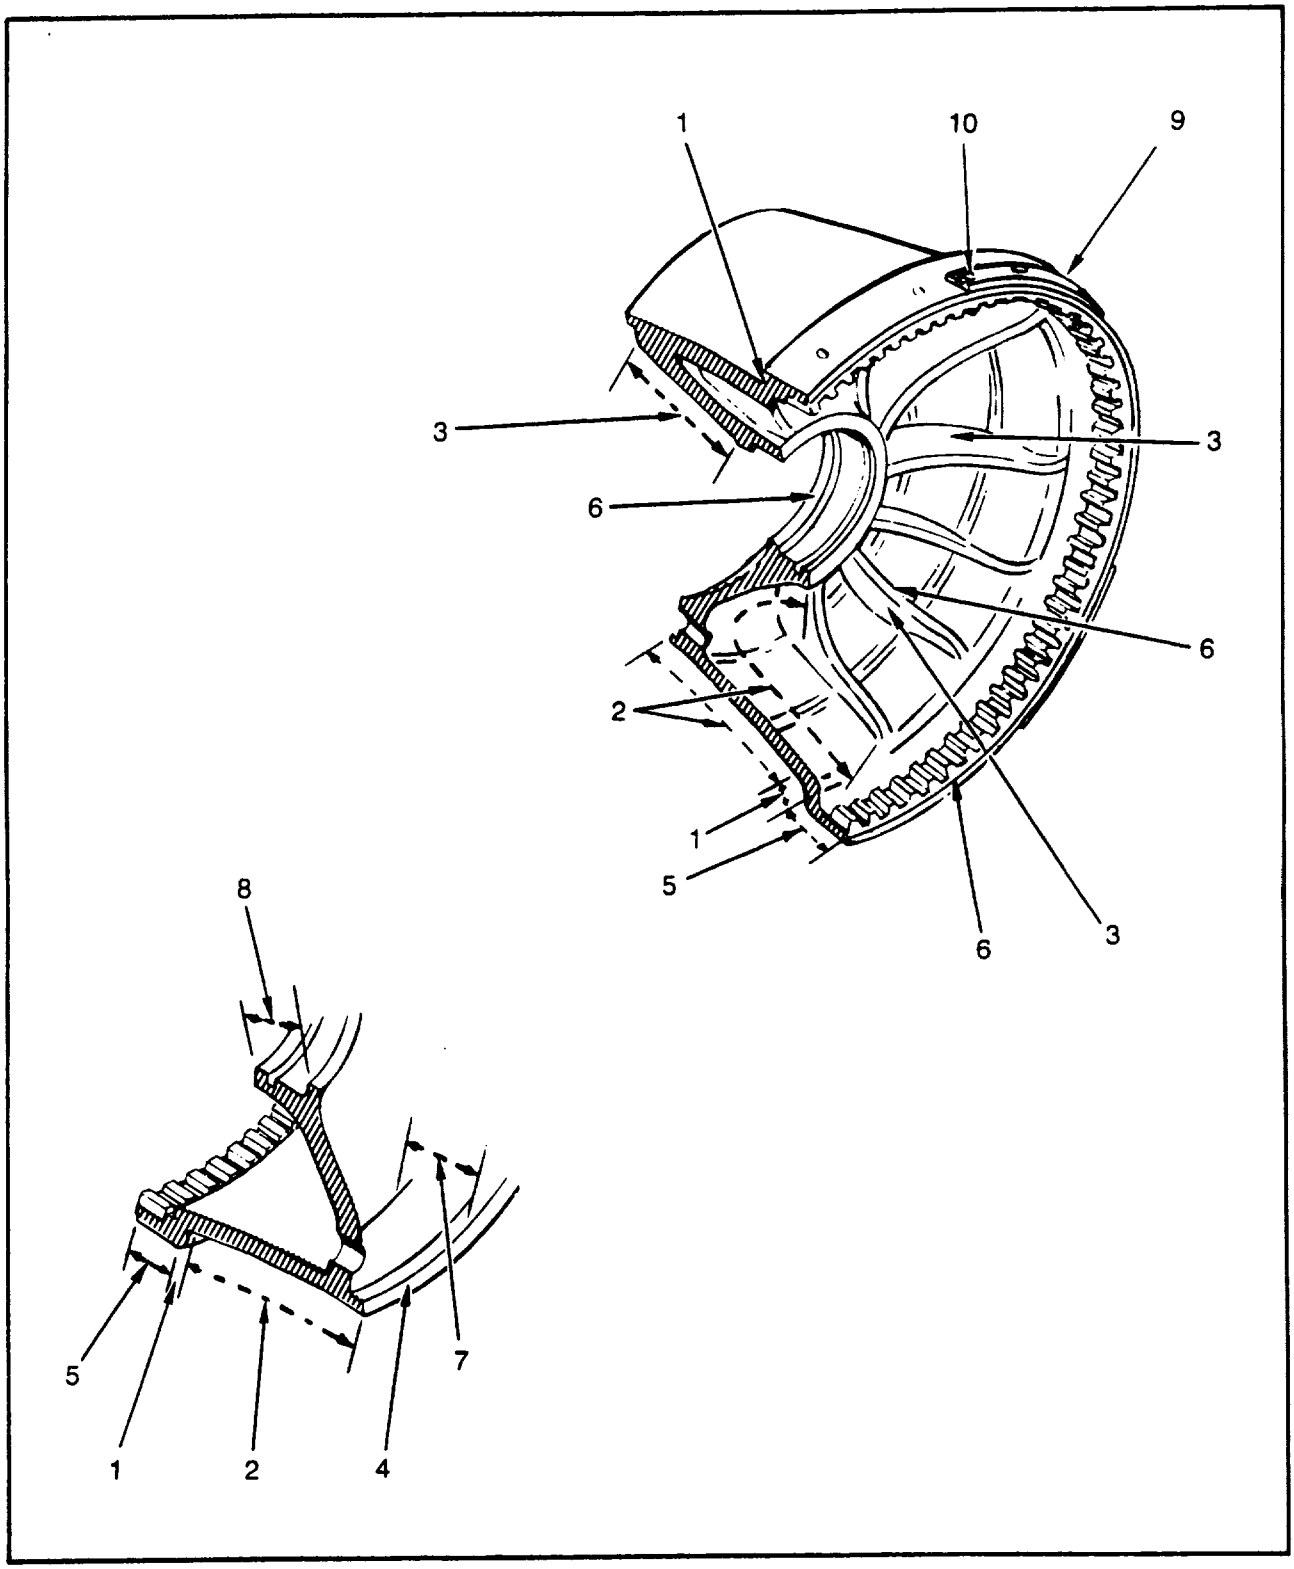
1. Repair Materials

NOTE: Equivalent substitutes may be used for items listed below.

Surface Treat Solution Specification MIL-M-3171, Type I and VI	Commercially available
Zinc Chromate Primer Specification TT-P-1757	Commercially available
Aluminum Lacquer Specification TT-L-32	Commercially available
Methyl Isobutyl Ketone (MIBK) Specification TT-M-265	Commercially available
Wash Primer Specification MIL-C-8514	Commercially available
Grease Specification MIL-G-81322	Commercially available
Antiseize Compound (Lubtork) Specification MIL-T-5544	W.J. Ruscoe & Company 483 Kenmore Boulevard Akron, Ohio 44301
Aluminum Oxide Cloth (Wet-or-dry, 320 to 400 grit)	Commercially available
Aluminum Topcoat/Primer Combination (FA 10242) Aeroprite	Contact your local distributor of aviation products and supplies.
Aeroprite Reducer TH-89	Contact your local distributor of aviation products and supplies.
Metal Set-A4	Smooth-On, Incorporated 1000 Valley Road Gillette, NJ 07933
Loctite RC/620	Loctite Company 705 North Mountain Road Newington, CT 06111
3M776 Adhesive Sealant	Minnesota Mining and Manufacturing Company Adhesive Coating and Sealer Division 3M Center St. Paul, MN

Dry Film Lubricant Sandstrom 26A	Sandstrom Products, Company 224 Main Street Port Byron, IL 61275
Solid Film Lubricant Lubribond A or B	E.M. Corporation P.O. Box 2200 Highway 52 Northwest West LaFayette, IN 47906
Lockwire MS20995C32 (160 in.)	Commercially available

2. General (Ref. IPL Fig. 1)

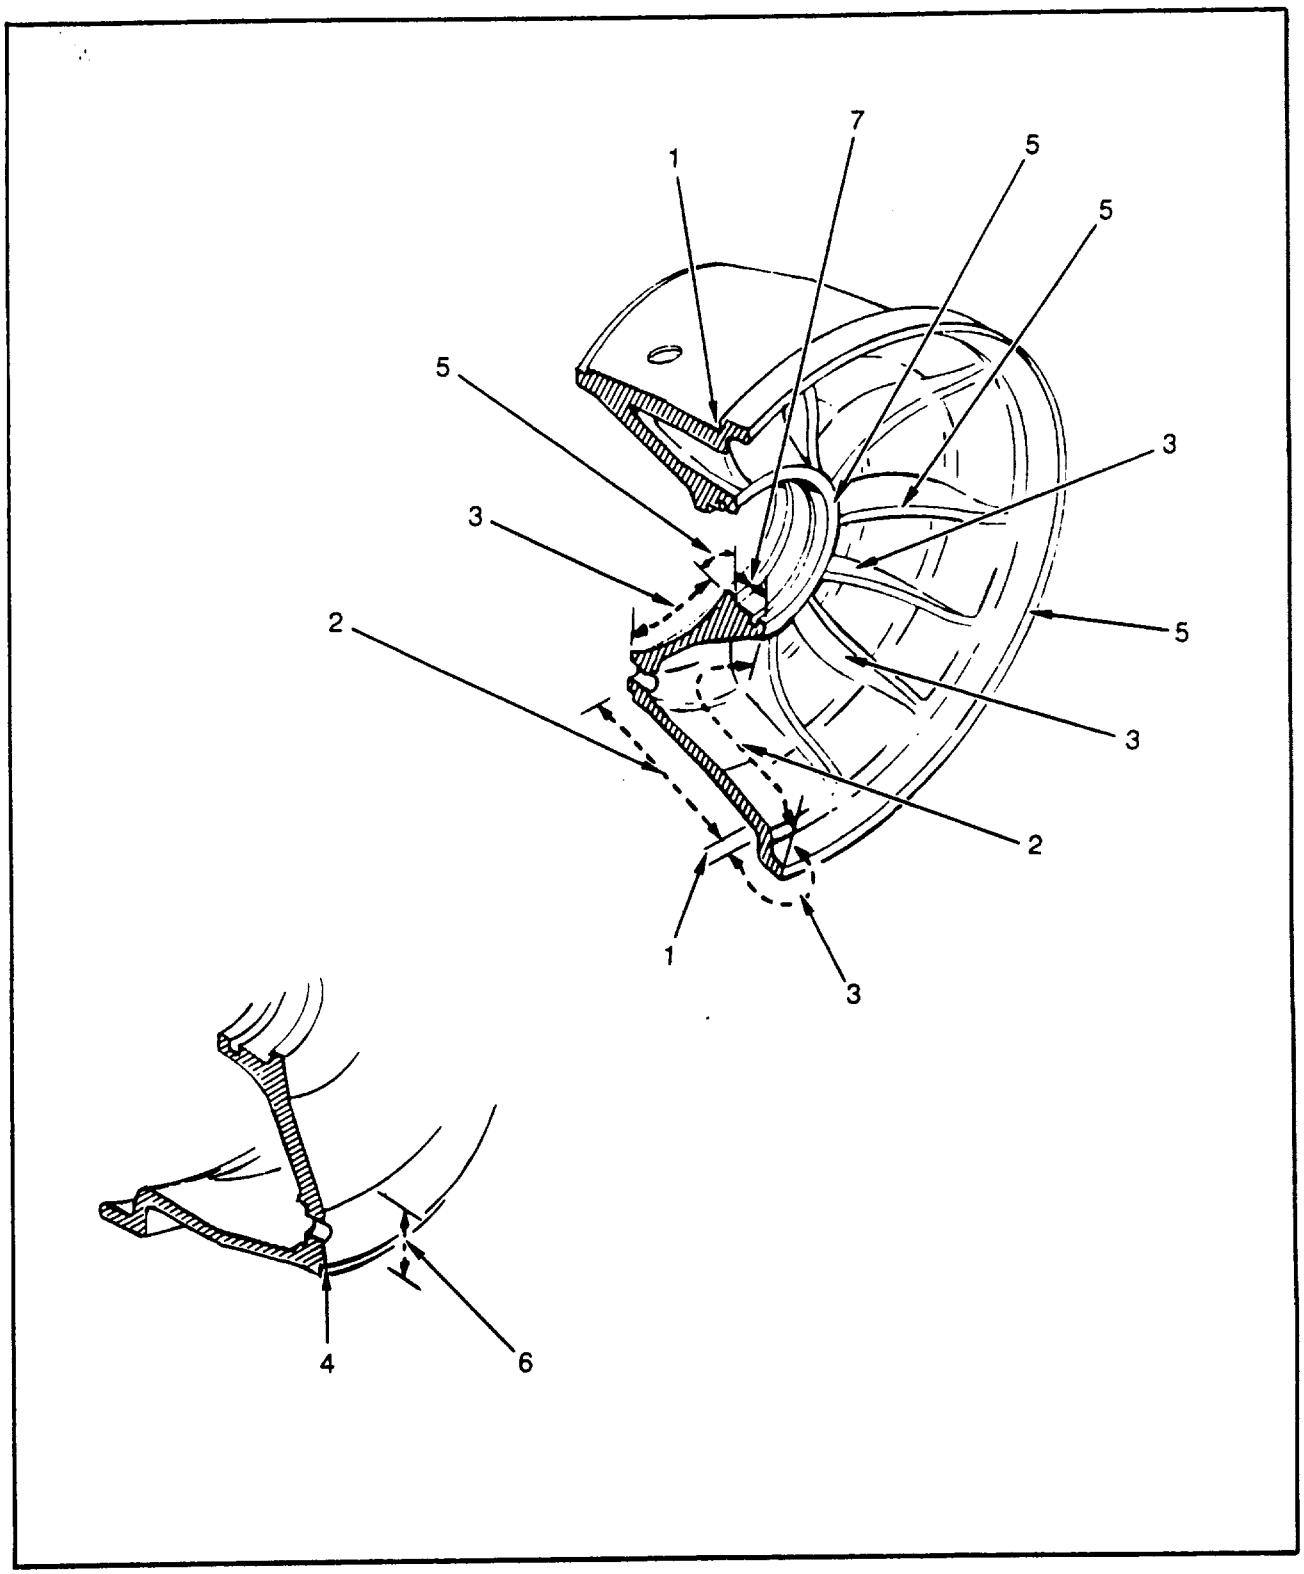


A. Repairs to the main wheel are limited to the replacement of parts and to the repairs specified in this section. No attempt should be made to repair cracked, severely corroded or badly damaged parts. Components that cannot be repaired within the limits defined in this section should be replaced.

CAUTION: REMOVAL OF CORROSION AND SURFACE DAMAGE WILL REDUCE STRESS CONCENTRATIONS AND PREMATURE WHEEL FAILURE. HOWEVER, ANY REMOVAL OF MATERIAL WILL SHORTEN THE ROLL LIFE OF THE WHEEL; THEREFORE, IT IS RECOMMENDED THAT REMOVAL OF MATERIAL BY BLENDING BE LIMITED TO THE MINIMUM REQUIRED FOR REMOVING CORROSION OR SURFACE DAMAGE.

3. Repair of Wheel Subassemblies (90, 170, 170A or 170B)

CAUTION: REMOVAL OF CORROSION AND SURFACE DAMAGE WILL PREVENT STRESS CONCENTRATIONS AND PREMATURE WHEEL FAILURE, ANY REMOVAL OF MATERIAL WILL SHORTEN THE ROLL LIFE OF THE WHEEL; THEREFORE, IT IS RECOMMENDED THAT MATERIAL REMOVED BY BLENDING BE LIMITED TO THE MINIMUM REQUIRED FOR REMOVING CORROSION OR SURFACE DAMAGE. BLENDED SURFACES SHOULD NOT BE OPPOSITE EACH OTHER.



A. Remove all corrosion and surface damage from wheel subassembly castings according to limits specified in Figure 601 and 602. Any wheel subassemblies that are corroded or damaged beyond these limits should be replaced. Imperfections should be blended out to a minimum of one quarter inch (6,35 mm) radius and then polished. Use fine, wet-or-dry, aluminum oxide cloth (320 to 400 grit) for polishing. Unless otherwise specified, surface finish of repaired surfaces should not exceed a roughness of 150 microinches RHR except in Area 1 (tire bead radius), where the surface should not exceed a roughness of 32 RHR. All reworked surfaces shall be cleaned thoroughly, then re-treated and repainted in accordance with Re-Treating and Repainting.

Repair Areas for Inboard
Wheel Subassemblies 9544383, 9544383-1 and 9544383-2
Figure 601

Key to Figure 601

General:	Repairs are limited in each marked area to the following limits. The material removed by blending is limited to the minimum required for removing corrosion or surface damage. Except where restricted by length or locale, when damage depth is less than 0.015 inch (0,38 mm) deep, all blend type repairs shall be blended with a depth to width ratio of 1 to 100. Where not possible, use as generous a width to depth ratio as practical with the area being repaired.
Area 1:	Remove tool marks or other damage up to 0.015 inch (0,38 mm) deep by polishing to remove imperfections.
Area 2:	Blend out and polish imperfections up to 0.015 inch (0,38 mm) deep.
Area 3:	Blend out and polish nicks and imperfections up to 0.031 inch (0,78 mm) deep and one-inch (25,4 mm) long. Each blemish area must not exceed one inch (25,4 mm) square. Do not blend opposite areas in any section.
Area 4:	Blend out and polish imperfections to 0.010 inch (0,25 mm) maximum depth. Sealing quality must be maintained.
Area 5:	Blend out imperfections or circumferential grooves up to 0.031 inch (0,78 mm) deep. Rework area must not exceed one inch square (25,4 mm sq).
Area 6:	Blend out nicks and imperfections up to 0.06 inch (1,5 mm) deep and one inch (25,4 mm) long.
Area 7:	Blend out and polish imperfections up to 0.015 inch (0,38 mm) deep. Rework area must not exceed 0.5 inch square (12,7 mm sq).
Area 8:	Blend out minor imperfections. Cup retention characteristics must be maintained (refer to paragraph 4).
Area 9:	Replace disk spring if worn or damaged.
Area 10:	Replace tee bar plunger if worn or damaged. Repair damaged tee bar plunger holes in accordance with REPAIR NO. 4.

Repair Areas for Outboard
Wheel Subassembly 9543052
Figure 602

Key to Figure 602

General:	Repairs are limited in each marked area to the following limits. The material removed by blending is limited to the minimum required for removing corrosion or surface damage. Except where restricted by length or locale, when damage depth is less than 0.015 inch (0,38 mm) deep, all blend type repairs shall be blended with a depth to width ratio of 1 to 100. Where not possible, use as generous a width to depth ratio as practical with the area being repaired.
Area 1:	Remove tool marks or other damage up to 0.015 inch (0,38 mm) deep by polishing to remove imperfections.
Area 2:	Blend out and polish imperfections up to 0.015 inch (0,38 mm) deep.
Area 3:	Blend out and polish nicks 0.03 inch (0,7 mm) deep and one-inch (25,4 mm) long. Each blemish area must not exceed one inch square (25,4 mm sq). Do not blend opposite areas in any section.
Area 4:	Blend out and polish imperfections to 0.010 inch (0,25 mm) maximum depth. Sealing quality must be maintained.
Area 5:	Blend out imperfections up to 0.06 inch (1,5 mm) deep and one inch (25,4 mm) long.
Area 6:	Blend out and polish imperfections up to 0.015 inch (0,38 mm) deep. Blemish area must not exceed 0.60 inch square (12,7 mm sq).
Area 7:	Blend out minor imperfections. Cup retention characteristics must be maintained.

4. Replacing Defective Tapered Roller Bearing Cups (160 and 240)

A. Remove defective bearing cups from wheel subassemblies as follows:

CAUTION: DO NOT OVERHEAT WHEEL SUBASSEMBLY OR PROLONG THE HEATING PERIOD. OVERHEATING WILL AVERSELY AFFECT THE SERVICE LIFE OF THE WHEEL. REMOVE VALVE SUBASSEMBLY (IF INSTALLED) BEFORE HEATING WHEEL SUBASSEMBLY.

(1) Heat wheel subassembly in an oven not exceeding 250°F (121°C) for 30 minutes.

CAUTION: WHEN REMOVING CUP, EXERCISE EXTREME CARE TO AVOID RAISING BURRS IN THE BEARING BORE. ALWAYS SUPPORT THE WHEEL SUBASSEMBLY ON THE HUB, NOT ON THE FLANGE.

(2) Remove wheel subassembly from heat source and immediately remove cup from bearing bore by tapping it out evenly with a fiber or phenolic punch.

(3) Carefully remove primer residue and any foreign matter from bearing bore. Make sure that bearing bore and shoulder are clean and free of burrs.

B. Allow wheel subassembly to cool to room temperature and check maximum bearing bore dimension.

(1) If the bore surface is damaged, refer to Repair No. 1 - Repair of Main Wheel Bearing Cup Bores.

(2) Check the wheel subassemblies for maximum bore dimension. The maximum dimension to be an average of three readings taken 120 degrees apart.

(a) Maximum diameter of the outboard wheel subassembly (90) hub bore shall not exceed 4.1187 inches (104,6 mm).

(b) Maximum diameter of the inboard wheel subassembly (170, 170A or 170B) hub bore shall not exceed 4.1187 inches (104,6 mm).

(3) If maximum dimension is exceeded, repair in accordance with Repair No. 1 - Repair of Main Wheel Bearing Cup Bores.

C. Install bearing cups as follows:

(1) Make sure bearing bore and shoulder in wheel hub are clean and free from burrs or any other imperfections which might prevent proper seating of bearing cup.

(2) Chill new bearing cup with dry ice.

CAUTION: DO NOT OVERHEAT WHEEL SUBASSEMBLY OR PROLONG THE HEATING PERIOD. OVERHEATING WILL ADVERSELY AFFECT THE WHEEL'S SERVICE LIFE.

(3) Heat wheel subassembly in an oven not exceeding 250°F (121°C) for 30 minutes.

(4) Remove wheel subassembly from heat source and remove bearing cup from dry ice. Dry hub bore and cup thoroughly.

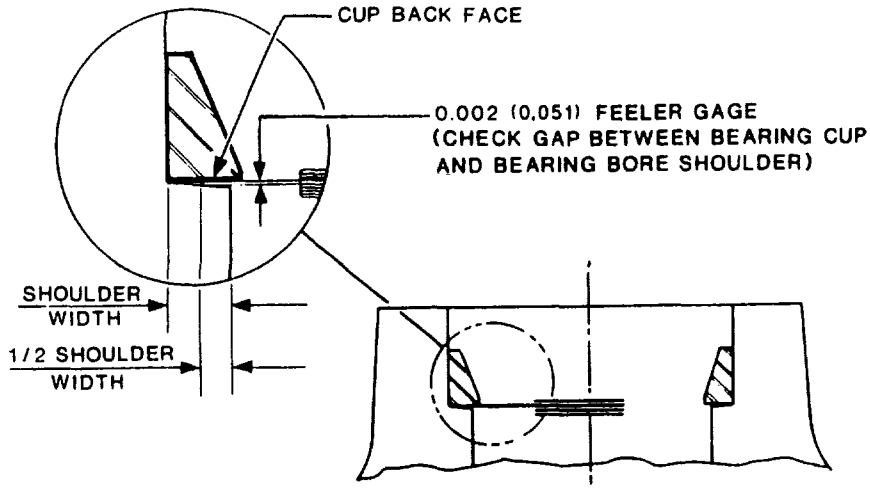
(5) Coat wheel contact surfaces of bearing cup with zinc chromate primer or paste, Specification TT-P-1757 and immediately install cup into bearing bore while primer or paste is still wet.

CAUTION: WHEN INSTALLING THE BEARING CUP, SUPPORT THE WHEEL SUBASSEMBLY ON THE HUB, NOT ON THE FLANGE.

(6) Using a fiber or phenolic punch, tap cup into bore and up tightly against shoulder. Avoid cocking the cup during installation.

(7) Cup seating should be checked after the wheel hub has cooled enough to hold the cup. To ensure the cup is adequately seated, check for any clearance (gap) between the cup back face and the shoulder (register) in the wheel hub with a 0.002 inch (0,05 mm) feeler gage. A 0.002 inch (0,05 mm) maximum clearance between cup and shoulder is permissible, provided the feeler gage cannot be inserted more than one-half the width of the shoulder at any location around back face of cup as shown in Figure 603.

NOTE: Above limits do not apply to areas of wheel hub shoulder cleaned up in accordance with Repair of Wheel Subassemblies.



(8) Allow wheel to cool to room temperature. Apply a light coat of grease, Specification MIL-G-81322, to bearing cup to prevent corrosion.

5. Replacing Disk Drive Ring (230 or 230A)

CAUTION: WHEN HEATING WHEEL SUBASSEMBLY FOR DRIVE RING REMOVAL AND INSTALLATION, ENSURE THAT CUP SEATING HAS NOT BEEN IMPAIRED.

NOTE: Remove disk drive ring only if it requires replacement or if a thorough check of the wheel subassembly is necessary. If removed for checking, mark the location of the disk drive ring to ensure reassembly in the original position.

A. Remove aluminum disk drive ring (230) from inboard wheel subassembly (170 or 170A) as follows:

Typical Bearing Cup Register Check
Figure 603

(1) Cover bearing cup with cardboard or fiber disk to prevent contamination or damage.

CAUTION: WHEN REMOVING RIVETS, BE CAREFUL NOT TO ENLARGE RIVET HOLES IN WHEEL FLANGE.

(2) Remove the two rivets (180) holding each disk spring (190) to the wheel flange; then disengage disk spring from the tee bar plunger (200 or 200A) and remove plunger from inside of wheel.

(3) Remove rivets (210) and plain washers (220).

CAUTION: DO NOT OVERHEAT WHEEL SUBASSEMBLY OR PROLONG THE HEATING PERIOD. OVERHEATING WILL ADVERSELY AFFECT THE WHEEL'S SERVICE LIFE.

(4) Heat wheel subassembly in an oven not exceeding 250°F (121°C) for 30 minutes. Tap disk drive ring carefully out of wheel subassembly with a fiber or phenolic drift pin.

(5) Check wheel subassembly rivet holes for enlarged or elongated holes or if rivets were found loose prior to removal of disk drive ring. Repair rivet holes on inboard wheel flange in accordance with Repair No. 3 - Drive Flange Rivet Hole Repair or Repair No. 4 - Drive Flange Tee Bar Plunger Hole Repair.

B. Install aluminum disk drive ring (230) in inboard wheel subassembly (170 or 170A) as follows (Ref. Fig. 604):

CAUTION: DO NOT OVERHEAT WHEEL SUBASSEMBLY OR PROLONG THE HEATING PERIOD. OVERHEATING WILL ADVERSELY AFFECT THE WHEEL'S SERVICE LIFE.

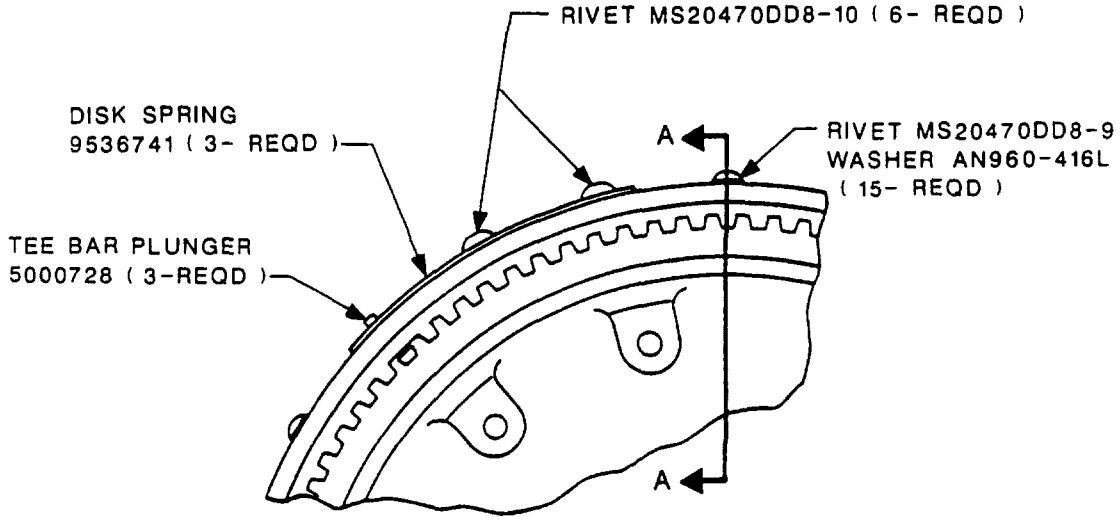
(1) Heat inboard wheel subassembly (170 or 170A) in an oven not exceeding 250°F (121°C) for 30 minutes.

(2) Remove wheel subassembly from heat source.

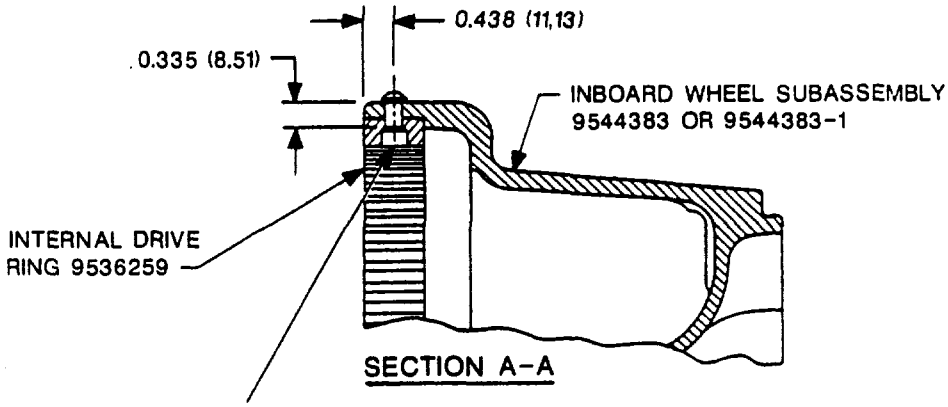
CAUTION: THE CENTERLINES OF THE DRIVE GEAR TEETH MUST BE ALIGNED WITHIN 0.008 INCH (0,203 MM) OF THE CENTERLINE OF THE EXISTING HOLES IN THE WHEEL FLANGE. THE THREE PLACES ON THE DISK DRIVE RING WITHOUT A GEAR TOOTH MUST BE ALIGNED WITH THE PROPER HOLES IN THE WHEEL FLANGE TO PERMIT INSTALLATION OF TEE BAR PLUNGERS. MAKE SURE THE DISK DRIVE RING IS PROPERLY ALIGNED AND COMPLETELY SEATED IN THE WHEEL SUBASSEMBLY.

(3) Paint contacting surfaces of wheel and disk drive ring with zinc chromate paste or primer, Specification TT-P-1757 and install disk drive ring immediately into wheel flange while zinc chromate paste or primer is still wet.

NOTE: Disk drive ring should be assembled while ring is at a temperature of 75°F (24°C) and wheel subassembly is at 250°F (121°C). Reducing temperature of disk drive ring will increase clearance and ease of assembly.



(4) Use drill bushing to locate center of holes and using rivet holes in wheel subassembly as a guide, drill size (F) 0.257 inch (6,53 mm) holes through disk drive ring to match (24 places).



(5) Counterbore holes in disk drive ring (21 places) as shown in Figure 604.

NOTE: 21 holes equally spaced on basis of 24 spaces. Counterbore not required at location of tee bar.

(6) Apply two coats of zinc chromate primer, Specification TT-P-1757 to rivet holes.

NOTE: The aluminum disk drive ring does not required sealant cooling.

DRILL 0.257 (6,53) DIAMETER THROUGH TO MATCH WHEEL SUBASSEMBLY (24-PLACES); THEN COUNTERBORE 0.38 (9,7) DIAMETER WITH 100° INCLUDED ANGLE AT 21 PLACES. COUNTERSINK TO DEPTH SHOWN, USING TOOL NO. 1-71409. NO COUNTERBORE AT TEE BAR HOLES.

Installing Aluminum Internal Drive Ring 9536259
Figure 604

(7) Rivet disk drive ring to wheel flange with 15 rivets (210) and plain washers (220).

NOTE: Do not install these rivets in holes reserved for installing disk springs.

Rivets MS20470DD8-9 and MS20470DD8-10 are known as "ice box" rivets and are usually kept in a freezer until ready for use, since the aluminum alloy of rivet work hardens at room temperature. It is recommended that rivets used at room temperature be set (squeezed) with a compression type riveter. If only impact forming can be performed, the rivet must be annealed and kept in a freezer until ready for use.

(8) Insert three tee bar plungers (200A) in place as shown in Figure 604.

(9) Slide the disk springs (190) into position with the slots holding the tee bar plungers in place. Then install six rivets (180) to secure the disk springs and tee bar plunger.

C. Remove steel disk drive ring (230A) from inboard wheel subassembly (170B) as follows:

(1) Cover bearing cup with cardboard or fiber disk to prevent contamination or damage.

(2) Cut lockwire and remove the two hex head non-locking bolts (215) holding each disk spring (190) to the wheel flange; then disengage disk spring from the tee bar plunger (200 or 200A) and remove plunger from inside of wheel.

(3) Cut lockwire and remove remaining hex head non-locking bolts (215) and plain washers (220).

CAUTION: DO NOT OVERHEAT WHEEL SUBASSEMBLY OR PROLONG THE HEATING PERIOD. OVERHEATING WILL ADVERSELY AFFECT THE WHEEL'S SERVICE LIFE.

(4) Heat wheel subassembly in an oven not exceeding 250°F (121°C) for 30 minutes. Tap disk drive ring carefully out of wheel subassembly with a fiber or phenolic drift pin.

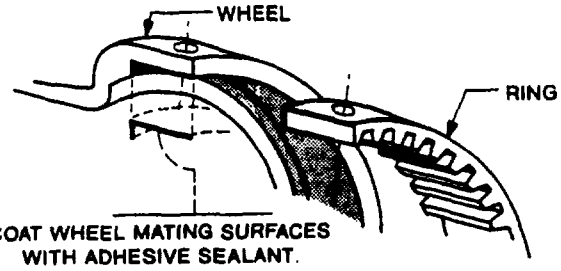
(5) If applicable, remove adhesive sealant from wheel subassembly and disk drive ring using methyl isobutyl ketone (MIBK), Specification TT-M-268.

NOTE: When disk drive ring has been removed, check wheel subassembly for cracks at radius behind the drive ring seat. Replace any wheel subassembly cracked in this area. Check threaded holes in wheel flange for damage or cracks.

D. Install steel disk drive ring (230A) in inboard wheel subassembly (170B) as follows (Ref. Figs. 605 and 606):

(1) Coat contacting surfaces of inboard wheel subassembly (170B) for disk drive ring (230A) with Adhesive Sealant 3M776 (Ref. Fig. 605).

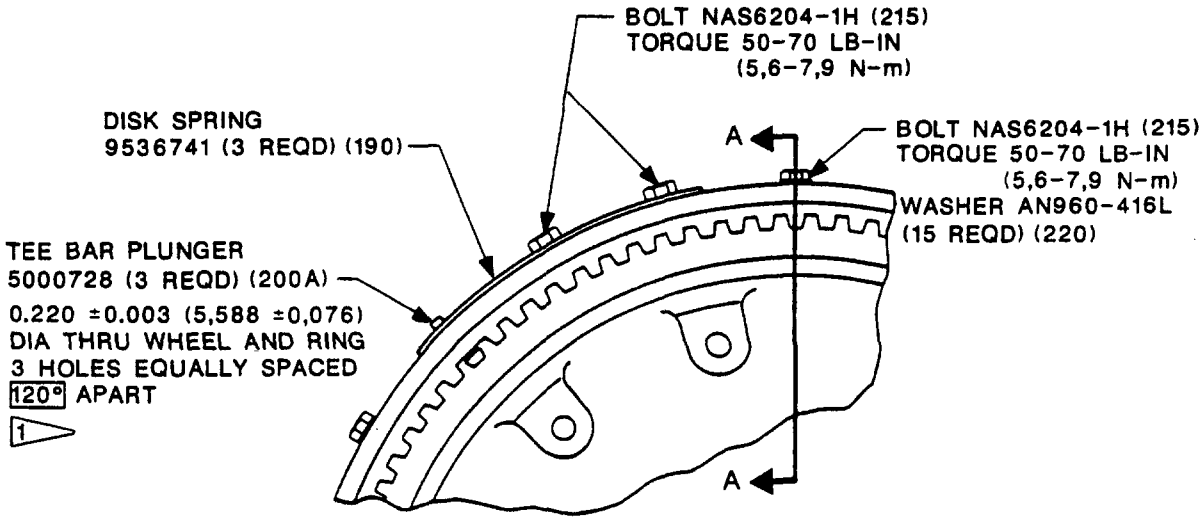
WARNING: SEALANT SOLUTIONS ARE TOXIC AND VOLATILE. USE IN WELL VENTILATED AREA IN ABSENCE OF OPEN FLAME OR ELECTRICAL SPARKS. DO NOT INHALE VAPORS OR ALLOW SOLUTION TO CONTACT SKIN OR CLOTHING.



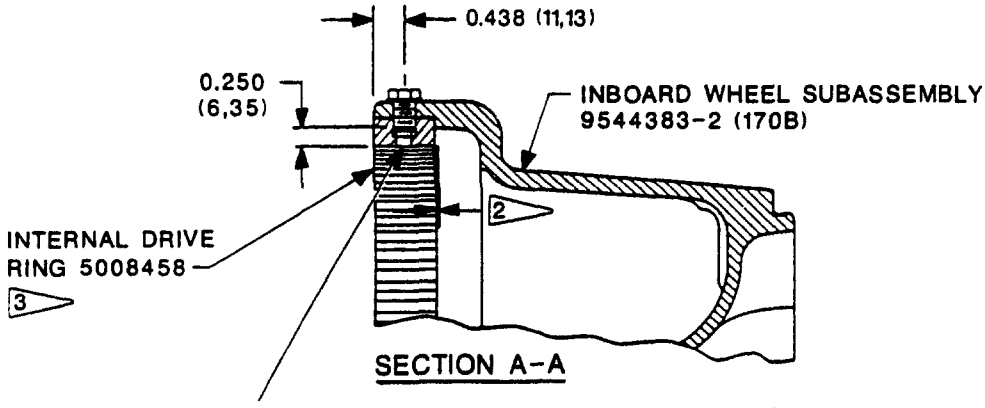
(a) Allow 24 hours drying time before assembly of disk drive ring into wheel.

(b) Excess material will not harm adjacent areas and may be removed from equipment with methyl isobutyl ketone (MIBK), Specification TT-M-268 and light rubbing with a clean cloth.

CAUTION: DO NOT OVERHEAT WHEEL SUBASSEMBLY OR PROLONG THE HEATING PERIOD. OVERHEATING WILL ADVERSELY AFFECT THE WHEEL'S SERVICE LIFE.



(2) Heat inboard wheel subassembly (170B) in an oven not exceeding 250°F (121°C) for 30 minutes.



(3) Remove wheel subassembly from heat source.

NOTES:
1. 3M776 ADHESIVE SEALANT SHALL BE APPLIED TO A THICKNESS OF 0.0005 TO 0.003 (0.013 TO 0.076) BY NATURAL BRISTLE BRUSH TO A CLEAN, DRY, GREASE FREE SURFACE.
2. IF MULTIPLE COATS ARE REQUIRED TO GET EVEN THICKNESS, ALLOW TEN MINUTES DRYING TIME BETWEEN COATS.
3. MATERIAL MAY BE REMOVED FROM EQUIPMENT WITH METHYL ISOBUTYL KETONE, (MIBK) AND LIGHT RUBBING WITH A CLEAN CLOTH.
4. ALLOW 24 HOURS DRYING TIME BEFORE ASSEMBLY OF RING INTO WHEEL.
5. NEW MATERIAL MAY BE THINNED BY ADDITION OF MIBK TO OBTAIN WORKABLE CONSISTENCY.

Application of Adhesive Sealant
Figure 605

TAP DRILL THRU COUNTERSINK 90° INCLUDED ANGLE X 0.31 (7,87) DIA
0.250-28 UNJF-3B TAP FULL THREADS 0.515 ±0.015 (13,1 ±0,38) DEEP PER SPEC MIL-S-8879.
CENTERLINES IN LINE WITH TEETH, 21 HOLES EQUALLY SPACED ON BASIS OF 24 SPACES.
THEN COUNTERBORE 0.38 (9,7) DIAMETER WITH 100° INCLUDED ANGLE. COUNTERSINK TO
DEPTH SHOWN USING TOOL NO. 1-71409 1

1 USE 0.125 (3,18) DIA LOCATOR HOLE IN DRIVE RING FOR DRILLING AND TAPPING HOLES. USE DRILL BUSHING TO LOCATE CENTER OF HOLE

2 0.005 (0,127) MAX GAP ALLOWABLE FOR 1/4 OF SEAT CIRCUMFERENCE

3 RANDOM RADIAL POSITIONING OF DRIVE RING PERMISSIBLE

Installing Steel Internal Drive Ring 5008458
Figure 606

CAUTION: THE CENTERLINES OF THE DRIVE GEAR TEETH MUST BE ALIGNED WITHIN 0.008 INCH (0,203 MM) OF THE CENTERLINE OF THE EXISTING HOLES IN THE WHEEL FLANGE. THE THREE PLACES ON THE DISK DRIVE RING WITHOUT A GEAR TOOTH MUST BE ALIGNED WITH THE PROPER HOLES IN THE WHEEL FLANGE TO PERMIT INSTALLATION OF TEE BAR PLUNGERS. MAKE SURE THE DISK DRIVE RING IS PROPERLY ALIGNED AND COMPLETELY SEATED IN THE WHEEL SUBASSEMBLY.

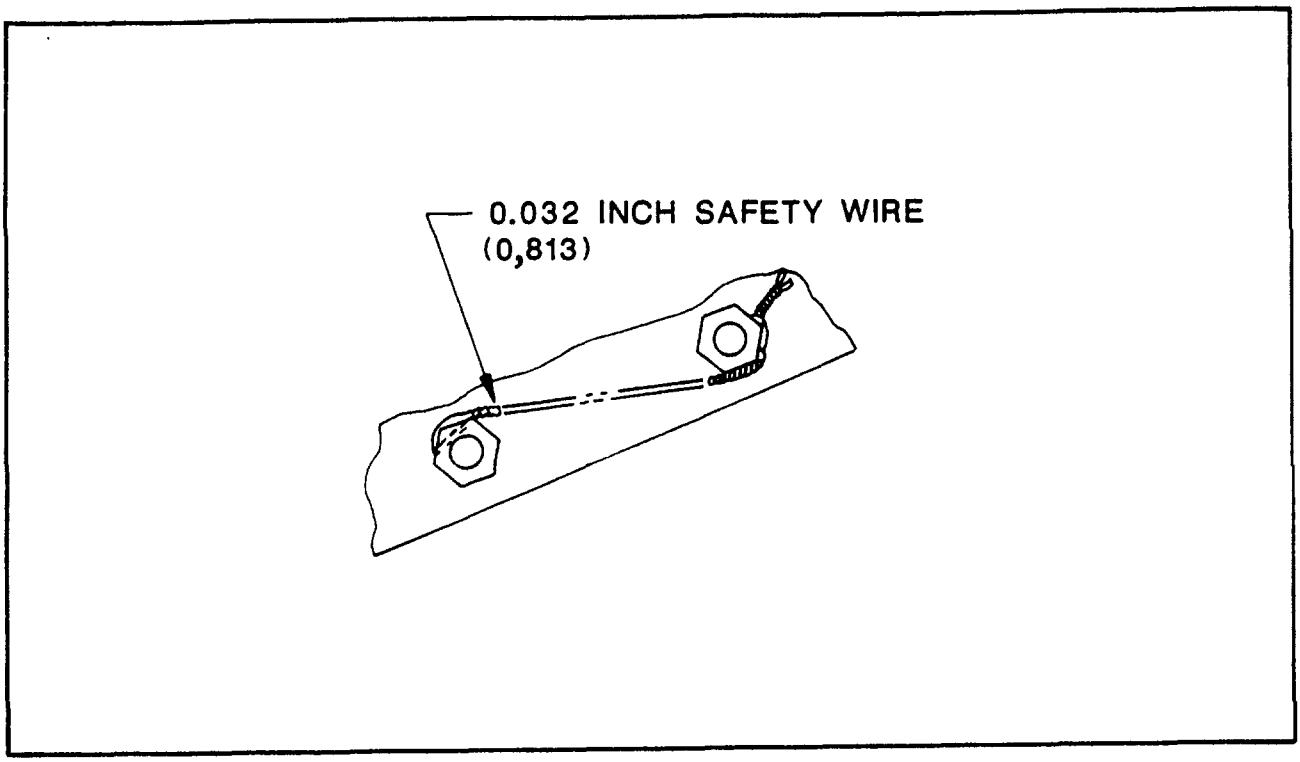
(4) Install disk drive ring, chamfered or radius end first, into heated wheel subassembly. If using the original ring, tap with a fiber drift pin to align the ring in its original position. Align a new ring so that the screw holes in the wheel flange are centered directly between the teeth of the disk drive ring. Disk drive ring must not protrude beyond face of wheel subassembly.

NOTE: Disk drive ring should be assembled while ring is at a temperature of 75°F (24°C) and wheel subassembly is at 250°F (121°C). Reducing temperature of disk drive ring will increase clearance and ease of assembly.

(5) Being careful not to damage the existing threads, use the bolt holes in the wheel flange as guides, install temporary drill guide and drill and tap holes through disk drive ring to match (24 places) as shown in Figure 606.

(6) Install drive ring non-locking bolts (215) and plain washers (220) as follows (Ref. Fig. 606):

(a) Bolt disk drive ring (230A) to wheel flange with 15 bolts (215) and plain washers (220). Tighten bolts (215) to a torque value of 50 to 70 pound-inches (5,6 to 7,9 N-m).



NOTE: Do not install bolts in holes reserved for installing disk springs.

(7) Insert three tee bar plungers (200A) in place as shown in Figure 606.

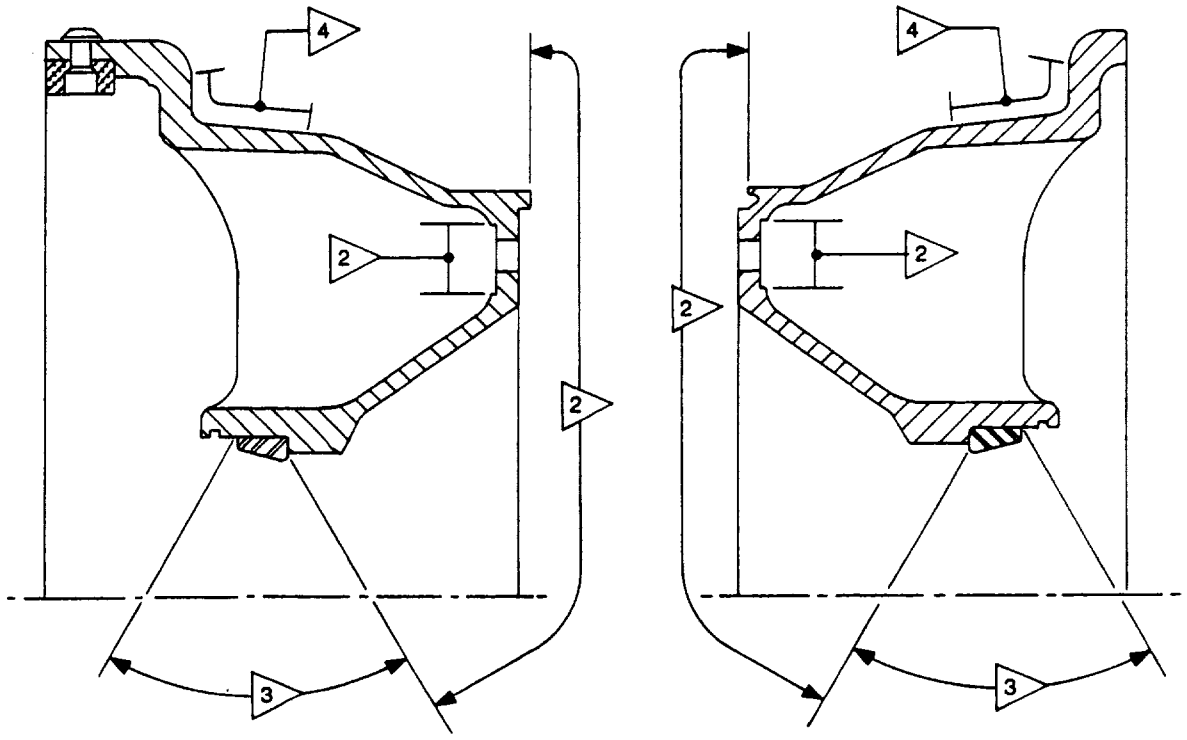
(8) Slide the disk springs (190) into position with the slots holding the tee bar plungers in place. Then install six bolts (215) to secure the disk springs and tee bar plunger (200A). Tighten bolts (215) to a torque value of 50 to 70 pound-inches (5,6 to 7,9 N-m).

NOTE: If the disk springs (190) and tee bar plungers (200A) are not used, install six bolts (215) with washers (220A) and tighten to a value of 50-70 pound-inches (5,6 to 7,9 N-m).

(9) Safetywire non-locking bolt heads (215) in pairs with Lockwire MS20995C32 and safetywire three bolts adjacent to tee bar (3 places) with Lockwire MS20995C32 (Ref. Fig. 607).

Safetywire Drive Ring Screws
Figure 607

6. Re-Treating and Repainting (Ref. Figs. 608 and 609)



A. Repaired areas of the wheel subassemblies and those having the paint and treated finish removed, should be re-treated as follows:

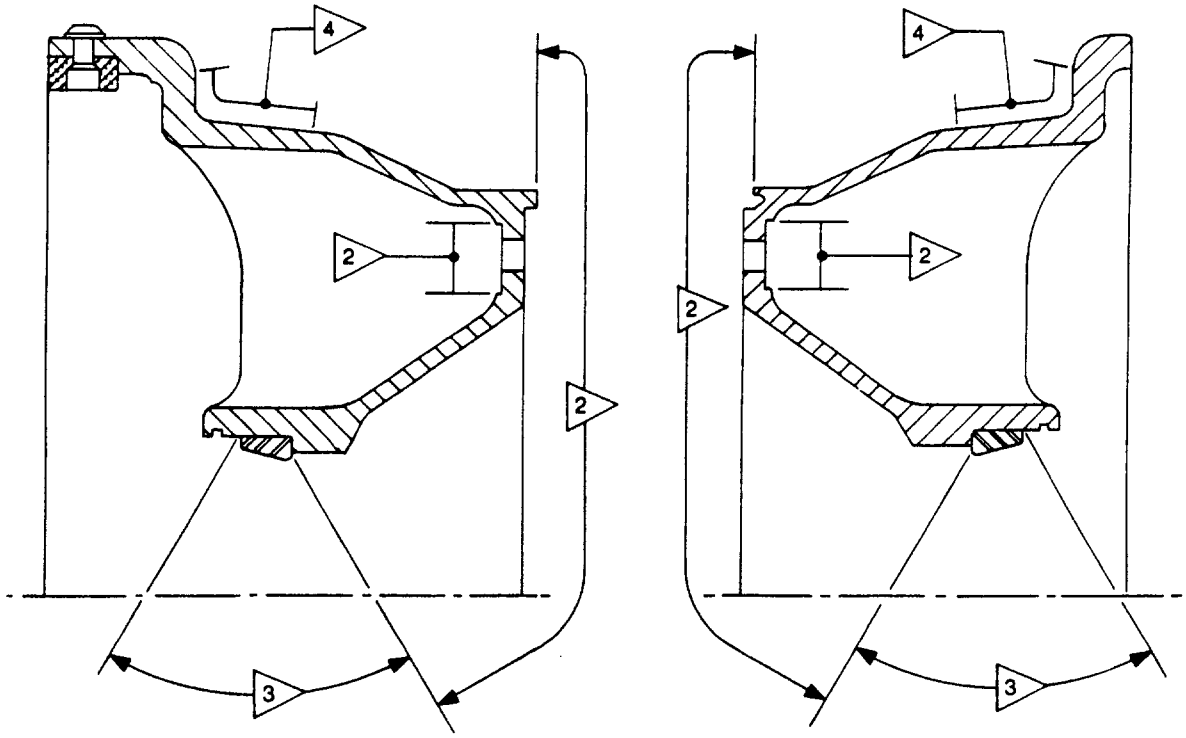
WARNING: CLEANING SOLVENTS ARE TOXIC AND VOLATILE. USE ONLY IN WELL-VENTILATED AREAS. AVOID PHYSICAL CONTACT WITH SOLVENT AND DO NOT INHALE VAPORS.

(1) Thoroughly clean surface to be re-treated and repainted. Clean with hot water or methyl isobutyl ketone, Specification TT-M-268, and dry thoroughly with compressed air.

(2) Re-treat all exposed surfaces of wheel subassemblies with surface treat solution, Specification MIL-M-3171, Type VI, in accordance with the manufacturer's instructions. Refer to Repair Materials for recommended solution.

NOTE: Specification MIL-M-3171, Type VI is a dilute chomic acid brush-on solution.

NOTES:



1. APPLY TWO COATS OF ALUMINUM TOP/COAT PRIMER COMBINATION EXCEPT AS NOTED.

2. ONE MIST COAT OF TOP/COAT PRIMER COMBINATION ONLY ON THESE SURFACES.

3. NO PAINT OR PRIMER ON THESE SURFACES, COAT WITH BEARING GREASE.

4. TIRE BEAD CONTACTING SURFACES MUST BE PAINTED THOROUGHLY.

Painting Diagram (Method I)
Figure 608

NOTES:

1. APPLY TWO COATS OF ZINC CHROMATE PRIMER, SPECIFICATION TT-P-1757 AND TWO COATS OF ALUMINUM LACQUER SPECIFICATION TT-L-32 TO ALL EXPOSED AREAS EXCEPT AS NOTED.

2. ONE MIST COAT OF PRIMER ONLY ON THESE SURFACES.

3. NO PAINT OR PRIMER ON THESE SURFACES. COAT WITH BEARING GREASE.

4. TIRE BEAD CONTACTING SURFACES MUST BE PAINTED THOROUGHLY.

Painting Diagram (Method II)
Figure 609

B. Touchup painting should be performed as follows:

(1) The part or area requiring touchup painting must be thoroughly clean and free of all contaminants.

(2) Prepare area to be painted (scratches, nicks, chipped paint, etc) by sanding lightly to feather out all edges of adjacent finish, using 320 to 400 grit, wet-or-dry, aluminum oxide cloth. Wet sanding is preferred. Avoid removing more primer than is absolutely necessary from damaged area.

WARNING: CLEANING SOLVENTS ARE TOXIC AND VOLATILE. USE ONLY IN WELL-VENTILATED AREAS. AVOID PHYSICAL CONTACT WITH SOLVENT AND DO NOT INHALE VAPORS.

(3) Wash the area to be touched up with methyl isobutyl ketone, Specification TT-M-268, and allow to air dry until no solvent odors are detectible.

CAUTION: IF BARE METAL IS EXPOSED BY SANDING, IT MUST BE RE-TREATED BY APPLYING WASH PRIMER.

(4) Starting with the last intact paint layer, reapply paint coats in accordance with repainting wheel assembly.

C. Repaint main wheel assembly as follows - Method I (Primary) (Ref. Fig. 608)

WARNING: CLEANING SOLVENTS ARE TOXIC AND VOLATILE. USE ONLY IN WELL-VENTILATED AREAS. AVOID PHYSICAL CONTACT WITH SOLVENT AND DO NOT INHALE VAPORS.

(1) Thoroughly clean all surfaces to be treated and/or painted. Wheel subassembly should be vapor degreased or washed with methyl isobutyl ketone, Specification TT-M-268.

(2) Treat all exposed metal surfaces of wheel subassemblies with chemical film solution conforming to Specification MIL-M-3171, in accordance with manufacturer's instructions.

CAUTION: DO NOT PAINT ROLLER CONTACTING SURFACES OF BEARING CUPS. PAINT ON THESE SURFACES WILL CONTRIBUTE OR RESULT IN LOSS OF BEARING PRELOAD.

(3) Mask bearing cups and threaded holes to avoid getting paint on these surfaces.

CAUTION: APPLY ONLY ONE COAT OF WASH PRIMER AND ONLY ONE MIST COAT OF TOPCOAT/PRIMER TO REGISTER SURFACES AND BOLT BOSSES. EXCESSIVE PRIMER ON THESE SURFACES MAY CONTRIBUTE TO WHEEL FAILURE.

(4) Apply one even wet coat of wash primer, Specification MIL-C-8514. The dry film thickness shall be 0.0002 to 0.0004 inch (0,0051 to 0,0102 mm). This film shall be allowed to air dry a minimum of one hour and a maximum of four hours before coating.

(5) Paint exposed metal surfaces in accordance with Figure 608 and as follows:

(a) Apply two coats of aluminum topcoat/primer combination in accordance with Figure 608.

(b) Spray one full wet cross coat to a dry film thickness of approximately 0.0005 inch (0,0127 mm). Air dry 45 minutes minimum before applying next coat. Spray another full cross coat to a dry film thickness of approximately 0.0004 inch (0,0102 mm) to 0.0006 inch (0,0152 mm).

NOTE: Due to abrasion in the tire bead contacting surfaces, it is recommended that tire bead contacting surfaces have a minimum of 0.0015 inch (0,038 mm) thickness of paint.

(c) Air dry 45 minutes before handling. Paint will reach full cure in 72 hours.

D. Repaint main wheel assembly as follows - Method II (Alternate) (Ref. Fig. 609)

WARNING: CLEANING SOLVENTS ARE TOXIC AND VOLATILE. USE ONLY IN WELL-VENTILATED AREAS. AVOID PHYSICAL CONTACT WITH SOLVENT AND DO NOT INHALE VAPORS.

(1) Thoroughly clean all surfaces to be treated and/or painted. Main wheel subassembly should be vapor degreased or washed with methyl isobutyl ketone, Specification TT-M-268.

(2) Treat all exposed metal surfaces of wheel subassemblies with surface treat solution, Specification MIL-M-3171, Type VI, in accordance with manufacturer's instructions.

CAUTION: DO NOT PAINT ROLLER CONTACTING SURFACES OF BEARING CUPS. PAINT ON THESE SURFACES WILL CONTRIBUTE OR RESULT IN LOSS OF BEARING PRELOAD.

(3) Mask bearing cups and threaded holes to avoid getting paint on these surfaces.

CAUTION: APPLY ONLY ONE COAT OF WASH PRIMER AND ONLY ONE MIST COAT OF ZINC CHROMATE PRIMER TO REGISTER SURFACES AND BOLT BOSSES. EXCESSIVE PRIMER ON THESE SURFACES MAY CONTRIBUTE OR RESULT IN LOSS OF BOLT PRELOAD.

(4) Apply one even wet coat of wash primer, Specification MIL-C-8514. The dry film thickness shall be 0.0002 to 0.0004 inch (0,0051 to 0,0102 mm). This film shall be allowed to air dry a minimum of one hour and a maximum of four hours before recoating.

(5) Paint exposed metal surfaces in accordance with Figure 609 and as follows:

(a) Apply two coats of zinc chromate primer, Specification TT-P-1757 in accordance with Figure 609.

NOTE: Do not exceed the recommended thickness for the applied topcoats. If the humidity should drop below 20 percent, primer application should be stopped until steps are taken to raise the percent humidity.

(b) Apply one coat of primer to obtain a dry film thickness of 0.0003 to 0.0004 inch (0,00762 to 0,0102 mm).

(c) After a minimum flash off period of five minutes, apply second coat of primer to obtain a total dry film thickness of 0.0006 to 0.0008 inch (0,015 to 0,020 mm).

(d) Allow the primed surface to dry a minimum of two hours and a maximum of 12 hours before topcoating with aluminum lacquer, Specification TT-L-32.

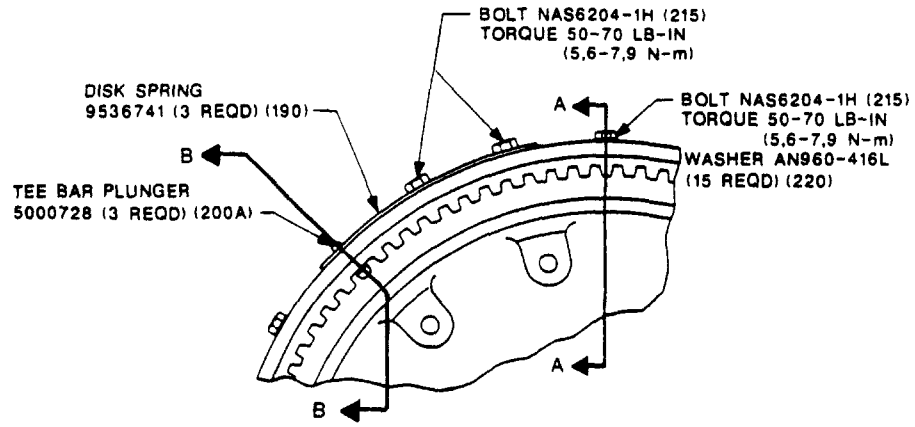
(6) Apply two coats of aluminum lacquer, Specification TT-L-32 in accordance with Figure 609.

(a) Spray one full wet cross coat to a dry film thickness of approximately 0.0004 to 0.0006 inch (0,0102 to 0,0152 mm) over the primer coating.

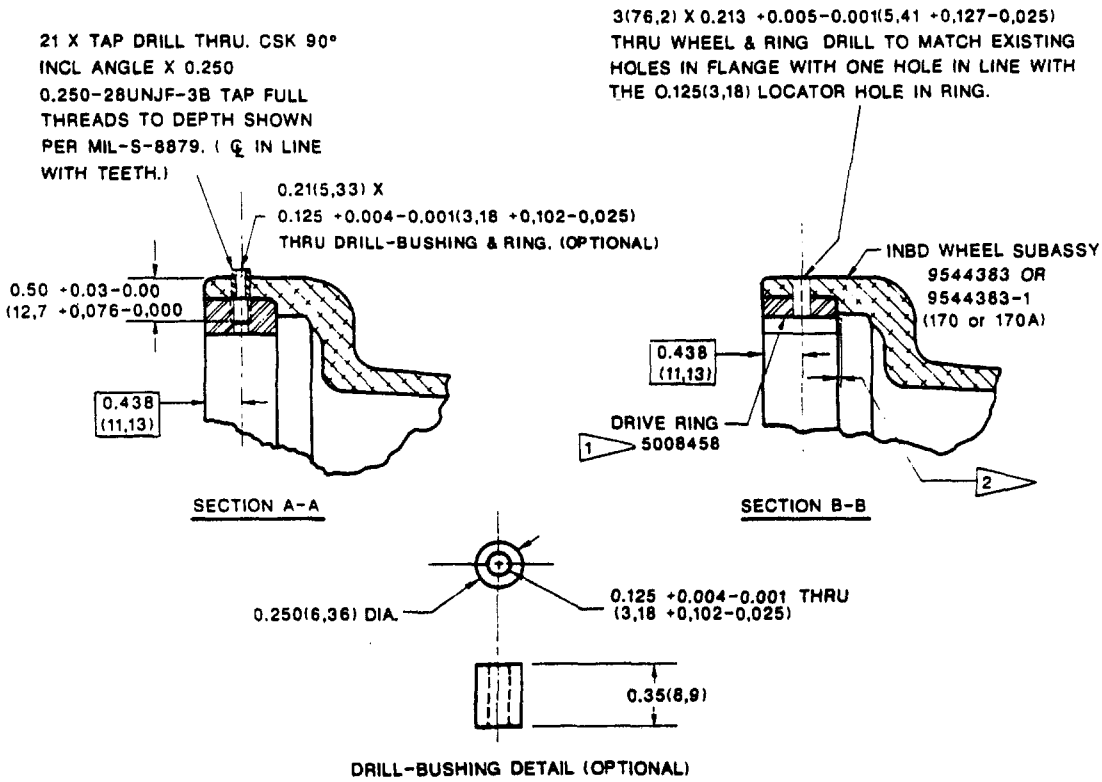
(b) After a minimum flash off period of five minutes, apply second coat of aluminum lacquer to obtain a total thickness of 0.0008 to 0.0012 inch (0,020 to 0,030 mm).

(c) Air dry 45 minutes before handling. Paint will reach full cure in 24 hours.

7. Rework of Wheel Assemblies 9544382 and 9544382-1 to Wheel Assembly 9544382-2.



A. Remove aluminum drive ring (230) in accordance with Replacing Disk Drive Ring.



B. *Machine wheel subassembly flange in accordance with Figure 610 and as follows:*

(1) Install drive ring so that centerline of the 0.125 inch (3,18 mm) diameter location hole in the drive ring is on the centerline of one of the tee-bar holes in the wheel. The threaded holes are to be in line with gear teeth.

(2) Install drill-bushings into existing rivet holes in wheel flange as an optional tool for locating centers of rivet holes for pilot drilling into steel drive ring.

(a) Remove bushings, complete tap drill and threads per Figure 610.

MATERIAL: STEEL 1010-1020
ASTM A-108 OR EQUIV

NOTES:

1. INSTALL DRIVE RING SO THAT CENTERLINE OF THE 0.125(3,18) DIA. LOCATOR HOLE IN THE DRIVE RING IS ON THE CENTERLINE OF ONE OF THE T-BAR HOLES IN THE WHEEL. THE THREADED HOLES ARE IN LINE WITH GEAR TOOTH.
2. 0.005(0,127) MAX GAP ALLOWABLE FOR 1/4 OF SEAT CIRCUMFERENCE.

Rework of Wheel Assemblies 9544382 and 9544382-1 to 9544382-2
Figure 610

C. Treat newly machined surfaces of wheel with zinc chromate paste or primer and treat adjacent areas of wheel with surface treat solution, Specification MIL-M-3171, Type I.

D. Coat newly machined surfaces of drive ring with Sandstrom 26A dry film lubricant.

E. Install steel drive ring (230A) in accordance with Replacing Disk Drive Ring.

NOTE: Disk drive ring should be assembled while ring is at a temperature of 75°F (24°C) and wheel subassembly is at 250°F (121°C). Reducing temperature of disk drive ring will increase clearance and ease of assembly.

F. Metal stamp "5R87-053" next to wheel subassembly number in 0.09 inch (2,29 mm) characters.

REPAIR NO. 1 - REPAIR OF MAIN WHEEL BEARING BORES

1. General (Ref. IPL Fig. 1)

   A. This repair is used for the repair of worn bearing bores in the inboard and outboard wheel subassemblies (90, 170, 170A or 170B).

   B. This repair provides for machining the bearing cup bore and installation of Cup Bushing 5R3-4-167 or 5R3-4-113.

   C. Disassemble as required in accordance with DISASSEMBLY.

2. Repair of Main Wheel Bearing Bores

   A. Remove loose bearing cup by following the procedures in Replacing Defective Bearing Cup.

   B. Machine bearing bore of wheel subassembly oversized to the dimensions shown in Figure 601. If bore does not cleanup at oversized dimensions, replace wheel subassembly.

   C. Thoroughly clean and then treat newly machined surfaces with surface treat solution, Specification MIL-M-3171, Type I. Apply solution in accordance with manufactuer's instructions.

   D. Install the proper repair bushing cup subassembly in the bearing bore as follows:

      NOTE: For bearing bore repairs, use Bushing Cup Subassembly 5R3-4-167 for inboard and 5R3-4-113 for outboard wheel half subassembly. Metal stamp repaired wheel half with the applicable 5R3-4 number (in 0.09 inch, (2,3 mm) characters) in area adjacent to wheel subassembly number.

      CAUTION: DO NOT OVERHEAT WHEEL HALF OR PROLONG THE HEATING PERIOD. OVERHEATING WILL ADVERSELY AFFECT THE SERVICE LIFE OF THE WHEEL.

      (1) Heat wheel half in an oven not exceeding 250°F (121°C) for 30 minutes.

      (2) Chill bushing cup subassembly on dry ice.

      (3) Remove wheel half from heat source and remove bearing cup from dry ice. Dry cup thoroughly.

      (4) Coat wheel contact surfaces of bearing cup with zinc chromate primer or paste, Specification TT-P-1757, and immediately install cup into bearing bore while primer or paste is still wet.

Wheel Bearing Bore Repair
Figure 601

CAUTION: WHEN INSTALLING THE BEARING CUP, SUPPORT THE WHEEL HALF ON THE HUB, NOT ON THE FLANGE.

(5) Using a fiber or phenolic punch, tap cup into bore and up tightly against shoulder. Avoid cocking the cup during installation.

(6) Make sure cup is seated on bore shoulder. A 0.0015 inch (0,04 mm) maximum clearance between cup and shoulder is permissible, provided that it does not extend more than one quarter of the cup's periphery.

(7) Allow wheel subassembly to cool to room temperature.

(8) Apply a light coat of grease, Specification MIL-G-81322, to bearing cup to prevent corrosion.

REPAIR NO. 2 - REPAIR OF FAIRING RETAINING SCREW THREADS, OUTBOARD WHEEL SUBASSEMBLY (METHOD I)

1. General (Ref. IPL Fig. 1)

   A. This repair is used for the repair of stripped or damaged fairing retaining screw holes on Outboard Wheel Subassembly 9543052.

   B. This repair provides for machining the fairing retaining screw holes for installation of Heli-Coil inserts for the first repair and filling existing (old) screw holes with Metal Set-A4 and tap drilling new holes for the second repair.

2. Repair of Fairing Retaining Screw Threads

   A. If the fairing retaining screw hole contains stripped or damaged threads, repair using Heli-Coil inserts (Ref. paragraph 3. First Repair (Heli-Coil Inserts)). If the fairing retaining screw hole has been repaired with Heli-Coil Inserts and contains stripped or damaged threads, repair by filling existing (old) screw holes with Metal Set-A4 and tap drilling new holes (Ref. paragraph 4., Second Repair (Metal Set-A4 Repair).

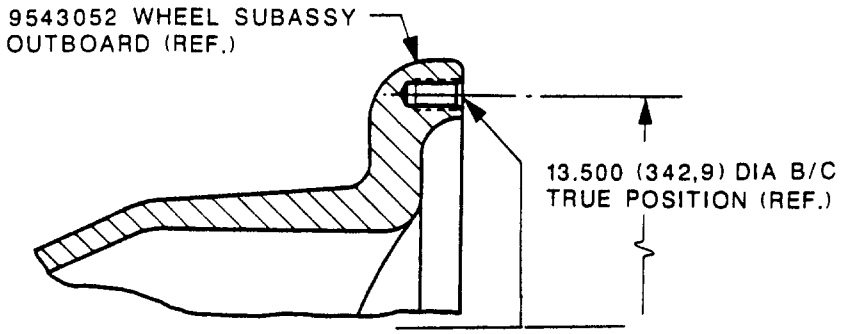
3. First Repair (Heli-Coil Inserts)

   A. The following repair consists of remachining the fairing retaining screw holes and installing Heli-Coil inserts when the fairing retaining threads are stripped or damaged (Ref. Fig. 601).

   B. Machine fairing retaining screw hole oversize to dimension in Figure 601.

   C. Install Heli-Coil inserts in accordance with Figure 602.

   D. Metal stamp 5R3-353 adjacent to subassembly number in 0.12 inch (3,05 mm) characters.



4. Second Repair (Metal Set-A4 Repair)

   A. In addition to the described Heli-Coil rework, a second repair scheme is provided. The repair consists of remachining damaged fairing retaining screw holes and filling with Metal Set-A4 and tap drilling new holes (Ref. Fig. 603).

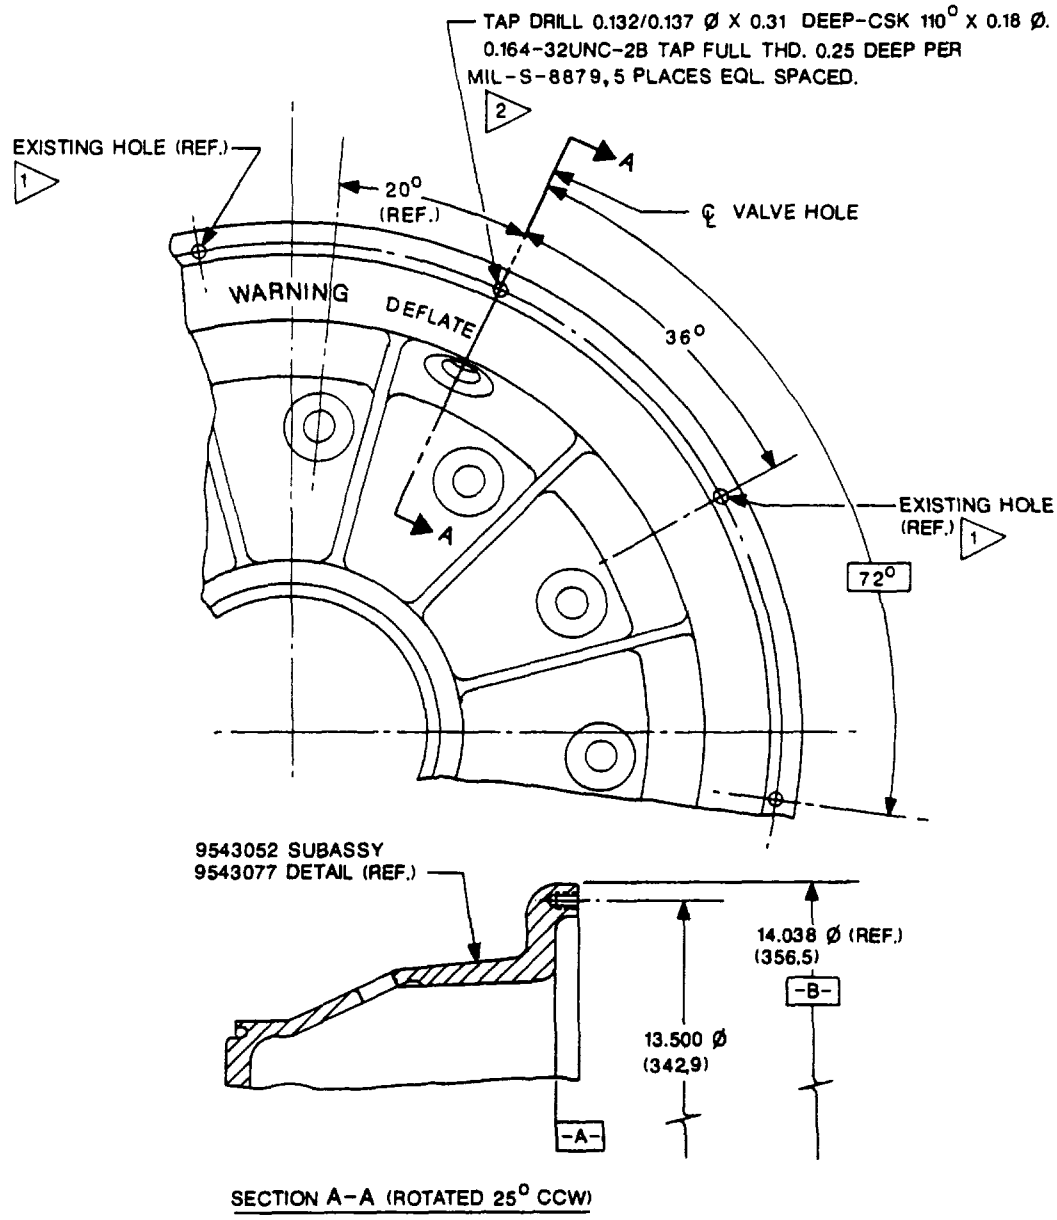
   B. Fairing mounting holes must be clean and dry prior to applying Metal Set-A4.

   C. Apply Metal Set-A4 with a putty knife, trowel, or brush to fill the existing (old) screw holes.

   D. Quickly level the top of the recess with a putty knife; the metal structure will solidify automatically.

TAP DRILL 0.174/0.180 DIA. 0.418 DEEP. C'SK 120°INCL ANGLE TO 0.200/0.230 DIA. HELI-COIL FINISHING TAP 2CPA (0.280 MIN. DEEP) FOR 8-32UNC-2B MS21208C0815 INSERT (HELI-COIL 1185-2CN0246).
REWORKED HOLES 5 PLACES EQUALLY SPACED WITHIN 0.005 OF TRUE POSITION.

NOTE: METAL STAMP 5R3-353 ADJACENT TO SUBASSY NO. IN 0.12 (3,05) CHARACTERS.



Stripped Fairing Thread Machining
Figure 601

INSTALL MS21208C0815 INSERT (HELI-COIL 1185-2CN0246), 3/4 TO 1 1/2 PITCH BELOW SURFACE.

NOTE: REMOVE TANG. USE ZINC CHROMATE PRIMER, SPECIFICATION TT-P-1757, WHEN INSTALLING INSERTS.

Heli-Coil Insert Installation
Figure 602

SECTION A-A (ROTATED 25° CCW)

NOTES:

1. FILL FIVE EXISTING (OLD) SCREW HOLES WITH 'METALSET-A4'.
2. APPROPRIATE SIZE SCREW HOLES MUST BE INSTALLED IN ASSOCIATED WHEEL FAIRING TO MATCH THESE NEW TAPPED HOLES. MODIFIED FAIRING TO BE INSTALLED SUCH THAT THE AIR CHUCK CLEARANCE HOLE IS ALIGNED WITH FILL VALVE.

E. Setting takes place in approximately 90 minutes at room temperature for a thickness up to 0.250 inch (6,35 mm). Metal Set-A4 will cure full strength in 24 hours; heating to 167°F (75°C) will greatly accelerate the reaction.

F. Tap drill new holes to 0.132 - 0.137 x 0.31 deep. Countersink 110° x 0.18° diameter, using 0.164-32 UNC-2B Tap Drill, full thread, 0.25 deep per Specification MIL-S-8879, in five places equally spaced.

G. Metal stamp the letter "R" adjacent to each tapped hole, and "5R83-044" adjacent to subassembly number in 0.09 inch (2,3 mm) characters.

H. Dichromate treat all newly machined surfaces per Specification MIL-M-3171, Type III.

REPAIR NO. 3 - DRIVE FLANGE RIVET HOLE REPAIR

1. General (Ref. IPL Fig. 1)

   A. This repair is used for the repair of enlarged or damaged rivet holes in flange of inboard wheel subassembly.

   B. This repair provides for machining damaged rivet holes and installation of Rivet Bushing 5006511.

2. Drive Flange Rivet Hole Repair

   A. If drive ring rivets were found loose, prior to drive ring removal from inboard wheel subassembly, repair enlarged or damaged rivet holes in flange of inboard wheel subassembly as follows:

      (1) Machine damaged rivet holes in accordance with Figure 601.

      (2) Treat newly machined surfaces of wheel subassembly with surface treat solution, Specification MIL-M-3171, Type VI.

      (3) Chill Rivet Bushing 5006511, with dry ice or freeze to aid installation.

      (4) Install chilled Rivet Bushing 5006511 in accordance with Figures 601 and 602.

Drive Flange Rivet Hole Repair
Figure 601

Drive Flange Rivet Hole Repair Bushing 5006511
Figure 602

(5) Metal stamp "R" in 0.12 inch (3,05 mm) characters adjacent to each repaired rivet hole.

(6) Metal stamp 5R81-033 adjacent to subassembly number in 0.12 inch (3,05 mm) characters no deeper than 0.015 inch (0,38 mm).

(7) Install internal drive ring in accordance with Replacing Internal Drive Ring.

REPAIR NO. 4 - DRIVE FLANGE TEE BAR PLUNGER HOLE REPAIR

1. General (Ref. IPL Fig. 1)

   A. This repair is used for the repair of enlarged or damaged plunger holes in the inboard wheel subassembly.

   B. This repair provides for machining damaged plunger holes and installation of Flange Bushing 5007112.

2. Drive Flange Tee Bar Plunger Hole Repair

   A. If tee bar plunger is found excessively loose or plunger hole is damaged or enlarged in the inboard wheel subassembly, and internal drive ring replacement is not required, repair plunger holes as follows:

      (1) Remove tee bar plunger in accordance with Replacing Internal Drive Ring.

      NOTE: Do not remove drive ring for this repair.

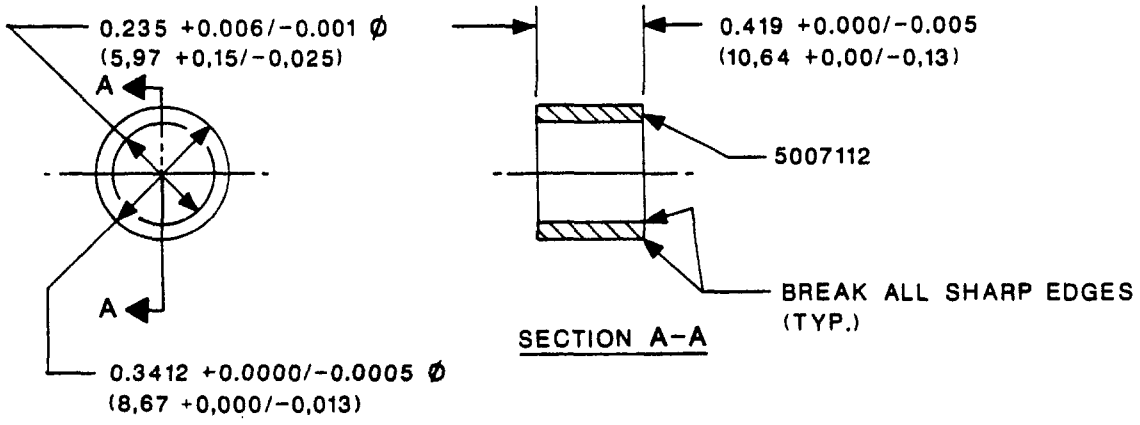
      (2) Machine damaged plunger hole in accordance with Figure 601.

      (3) Treat newly machined surfaces of wheel subassembly and internal drive ring with surface treat solution, Specification MIL-M-3171, Type VI.

NOTES:

1. THIS DRAWING IS FOR REPAIR WHEEL SUBASSEMBLY 5000482.
2. CHILL BUSHING P/N 5007112 PRIOR TO INSTALLATION, COAT WITH LOCTITE RC/620 AND INSTALL INTO WHEEL SUBASSEMBLY.

Tee Bar Hole Repair
Figure 601



(4) Chill Flange Bushing 5007112 with dry ice or freeze to aid installation.

(5) Coat chilled flange bushing and plunger hole with Loctite RC/620 and install flange bushing in accordance with Figures 601 and 602.

(6) Metal stamp "R" in 0.12 inch (3,05 mm) characters adjacent to each repaired tee bar hole.

(7) Metal stamp 5R83-008 adjacent to subassembly number in 0.12 inch (3,05 mm) characters.

(8) Replace tee bar plunger and spring disk in accordance with Replacing Internal Drive Ring.

NOTES:
1. 150 ALL OVER.
2. ANODIC TREAT TO SPEC. MIL-C-5541.
3. MATERIAL IS ALUMINUM ALLOY 6061-T6.

Tee Bar Hole Repair Bushing 5007112
Figure 602

ASSEMBLY AND STORAGE

1. Assembly Materials

NOTE: Equivalent substitutes may be used for items listed below.

Isopropyl Alcohol Specification TT-I-735	Commercially available
Grease Specification MIL-G-81322	Commercially available
Antiseize Compound Specification MIL-T-5544	Commercially available

2. General (Ref. IPL Fig. 1)

A. Assemble the main wheel in accordance with the following instructions.

CAUTION: ASSEMBLE WHEEL ON A CLEAN, FLAT SURFACE, BEING CAREFUL NOT TO NICK, SCRATCH OR SCUFF PAINT OR PROTECTIVE FINISH FROM WHEEL SUBASSEMBLIES. ENSURE PROPER PARTS ARE USED FOR EACH WHEEL ASSEMBLY.

B. It is recommended new preformed packings be installed at each reassembly.

WARNING: TIRE OVERINFLATION MAY RESULT IN EXPLOSIVE FAILURE.

C. Install balance weights if removed at disassembly. Instructions for attaching balance weights are given in Wheel Balancing paragraph of this section.

D. The use of power wrenches for wheel assembly is governed by the following:

(1) Do not use power wrenches for assembly of any threaded parts made of nonferrous material or parts threaded directly into nonferrous tapped holes.

(2) When power wrenches, other than automatic wrenching systems are used to assemble bolts and nuts, fastener tightness shall not exceed 50 percent of final torque value. Tightening to final torque value shall be accomplished using manual torque wrenches.

(3) Automatic wrenching systems which provide a preload or torque accuracy of ± 4 percent or better may be used to tighten bolts and nuts to final torque value.

3. Assembly Procedures (Ref. IPL Fig. 1)

A. If removed at disassembly, install outboard and inboard bearing cups (160 and 240), and disk spring (190), tee bar plunger (200 or 200A), and disk drive ring (230 or 230A) on inboard wheel subassembly in accordance with procedures in REPAIR.

B. Install instruction plate (165) on outboard wheel subassembly (90) as follows:

(1) Area in which plate is to be installed must be clean. Use a clean cloth dampened with isopropyl alcohol, Specification TT-I-735.

(2) Remove paper backing from adhesive surface being careful not to touch the adhesive.

(3) Apply plate to proper location, press firmly with roller (minimum 5 pounds (2,268 kg) pressure applied to roller) to ensure proper contact to both surfaces. Be sure that edges of plate are rolled down firmly.

(4) A set-up or curing time of approximately 48 hours is required to permanently set the adhesive, and plate should not be disturbed during this time.

C. Install valve subassembly (95 or 95A) on outboard wheel subassembly (90) as follows:

NOTE: If tube-type tire is installed, do not install valve subassembly.

(1) Install rubber grommet (150) on valve stem (140 or 140A) and seat tightly against stem base.

(2) Clean area of outboard wheel subassembly (90) around valve hole thoroughly with a clean cloth. Insert valve stem through valve hole with valve stem towards outside of wheel and preformed packing in valve hole.

(3) Place washer (130) over valve stem and onto rubber grommet (150). Install hex nut (120 or 120A) on valve stem and tighten until preformed packing is firmly compressed and valve hole is sealed.

D. Install "tubeless" tire as follows:

(1) To remove any foreign matter, wipe wheel flange bead seats and wheel register areas with a cloth dampened with isopropyl alcohol, Specification TT-I-735.

(2) Check tire for word "Tubeless" on sidewall.

(3) Make certain that tire is free of foreign material and that bead areas are clean.

(4) Check tire, with emphasis on the bead area, for shipping or handling damage.

(5) Check tubeless valve installation in wheel for proper sealing and security.

(6) Place outboard wheel subassembly (90) on a flat surface.

CAUTION: EQUALIZE THE PACKING AROUND THE PACKING GROOVE. BE CAREFUL PACKING IS NOT STRETCHED, TWISTED, PINCHED OR UNSEATED. REUSED PACKINGS SHOULD BE INSTALLED AS CLOSE AS POSSIBLE TO THEIR ORIGINAL POSITION.

(7) Lubricate preformed packing (80) with a light coat of grease, Specification MIL-G-81322, and install on wheel subassembly.

(8) Place tire on the outboard wheel subassembly with red balance dot aligned with valve subassembly.

(9) Position on the inboard wheel subassembly (170, 170A or 170B) in tire and align the bolt holes with those in the outboard subassembly, being careful not to disturb the preformed packing.

E. Install tube-type tire as follows:

(1) Clean wheel flange bead seats and register areas with a clean cloth dampened with isopropyl alcohol, Specification TT-I-735.

(2) Make certain tire is free of foreign material and bead areas are clean.

(3) Check tire, with emphasis on bead area, for shipping or handling damage.

(4) Place outboard wheel subassembly (90) on a flat surface.

(5) Inflate inner tube just enough to round it out and position tube in tire. Align yellow stripe on base of tube with red dot on sidewall of tire.

(6) Place tire on outboard wheel subassembly (90) and position the valve stem through the valve hole in the wheel subassembly.

(7) Position the inboard wheel subassembly (170, 170A or 170B) in the tire so the bolt holes align with those in the outboard subassembly.

F. Install wheel fasteners as follows:

(1) Lubricate threads of bolts (70), bearing surfaces of bolt heads, self-locking nuts (50) and washers (60) with antiseize compound, Specification MIL-T-5544.

CAUTION: INSTALL BOLT HEAD ON INBOARD SIDE OF WHEEL. THERE MUST BE A WASHER UNDER EACH BOLT HEAD AND EACH NUT.

(2) Install a washer (60) on each bolt (70). Compress wheel subassemblies and install four bolts (70), 90 degrees apart. Install a second washer (60) on bolt (70) and secure with self-locking nuts (50).

CAUTION: DO NOT USE IMPACT OR POWER WRENCHES TO TIGHTEN WHEEL BOLTS AND NUTS.

(3) Draw nuts up evenly until wheel subassemblies seat. Install remaining bolts, washers, and self-locking nuts.

(4) Tighten self-locking nuts equally in increments of 30 pound-inches (3,4 N-m) until a Lubtork value of 90 pound-inches (10,2 N-m) is obtained.

NOTE: Tighten nuts in a criss-cross pattern to obtain a more even torque value.

WARNING: PLACE WHEEL/TIRE IN AN INFLATION CAGE FOR INITIAL INFLATION. DO NOT INFLATE TIRE IN EXCESS OF FULL OPERATING PRESSURE TO SEAT THE BEADS. REDUCE TIRE PRESSURE TO RECOMMENDED STORAGE PRESSURE UNTIL WHEEL/TIRE ASSEMBLY IS READY FOR TESTING. TIRE AND/OR WHEEL FAILURE MAY OCCUR, CAUSING INJURY TO PERSONNEL OR DAMAGE TO EQUIPMENT IF THE TIRE IS OVERINFLATED FROM ANY HIGH PRESSURE SOURCE. TIRE AND WHEEL ASSEMBLIES MUST BE SERVICED WITH INFLATION EQUIPMENT WHICH HAS BEEN SPECIFICALLY DESIGNED FOR THIS OPERATION.

G. Install valve core (110) in valve stem. Place wheel/tire assembly in inflation cage and inflate tire just enough to seat beads.

NOTE: It is recommended that only nitrogen be used for tire inflation to preclude possible condensation buildup with air inflation; nitrogen will not sustain combustion and will reduce degradation of inner liner material due to oxidation.

H. Inflate tube-type tires to one-half of recommended operating pressure after beads are seated and then deflate tire completely. Inflate tire again to recommended storage pressure.

NOTE: This procedure permits the tube to equalize within the tire, preventing thinned and stretched sections in the base of the tube and reduces air leakage.

I. Deflate tire to storage pressure. Install valve cap (110) on valve, and remove wheel from inflation cage.

J. Install bearings completing the assembly as follows:

CAUTION: HANDLE BEARING CONES WITH EXTREME CARE. MANY AIRCRAFT BEARING FAILURES RESULT FROM MISHANDLING DURING MAINTENANCE.

USE CLASS 2 OR 4 BEARINGS ONLY. DO NOT SUBSTITUTE ANOTHER CLASS BEARING FOR CLASS 2 OR 4.

(1) Pack tapered roller bearing cones and rollers (20) and coat bearing surface of cup and lips of bearing seals with a grease, Specification MIL-G-81322.

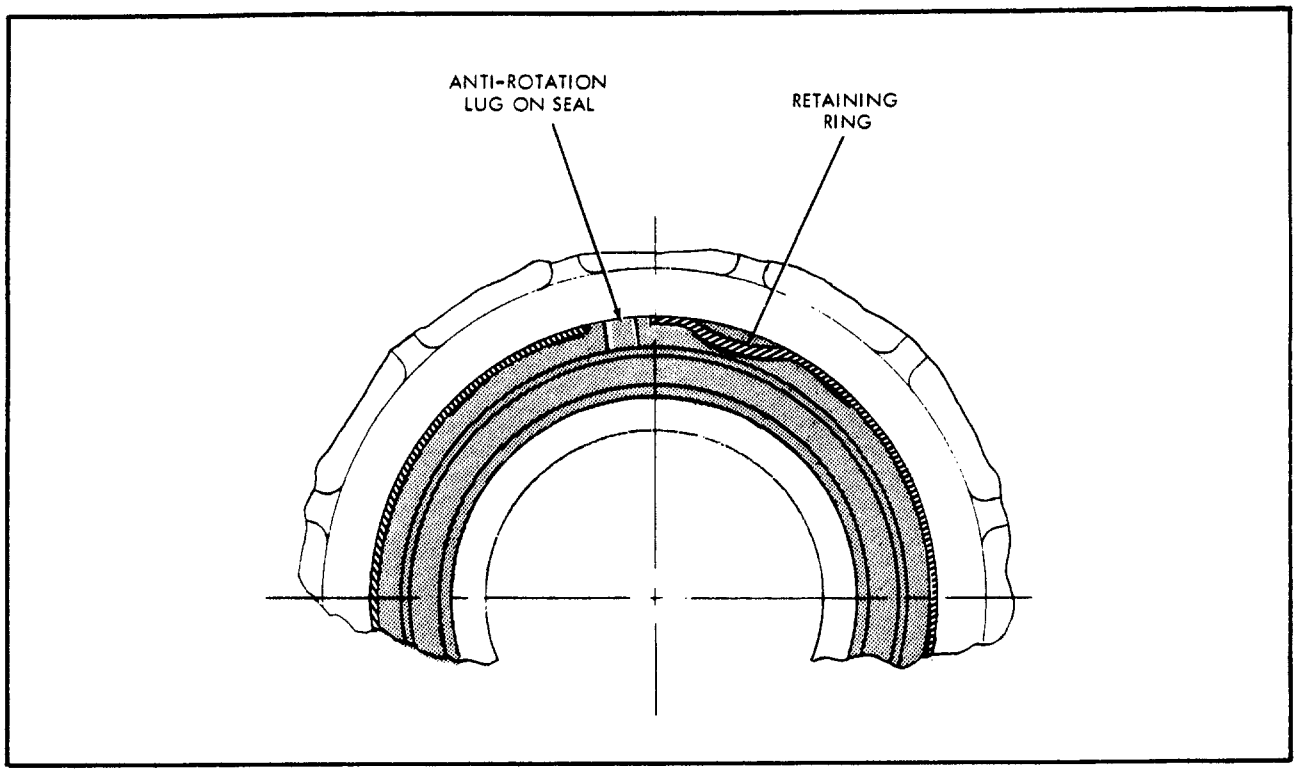
NOTE: Lubrication of bearings by mechanical or other pressure methods is recommended because it is more efficient, reduces the possibility of contamination and assures a more even distribution of grease within the bearing.

CAUTION: RETAINING RING MUST BE INSTALLED WITH RESPECT TO ANTI-ROTATION LUG OF SEAL FOR THE INBOARD WHEEL SUBASSEMBLY ONLY, AS SHOWN IN FIGURE 701.

(2) Install tapered roller cone and rollers (20) and inboard bearing seal (40) in inboard wheel subassembly, and secure with wire retaining ring (30).

(3) Cover hub opening of inboard wheel subassembly (170, 170A or 170B) to protect bearings from dirt and moisture until wheel assembly is installed on aircraft.

(4) Install tapered roller bearing cone and rollers (20) and outboard bearing seal (10 or 10A), in outboard wheel subassembly.



(5) Cover hub opening of outboard wheel subassembly (90) to protect bearings from dirt and moisture until wheel assembly is installed on aircraft.

K. Test wheel/tire assembly as required in accordance with TESTING AND FAULT ISOLATION.

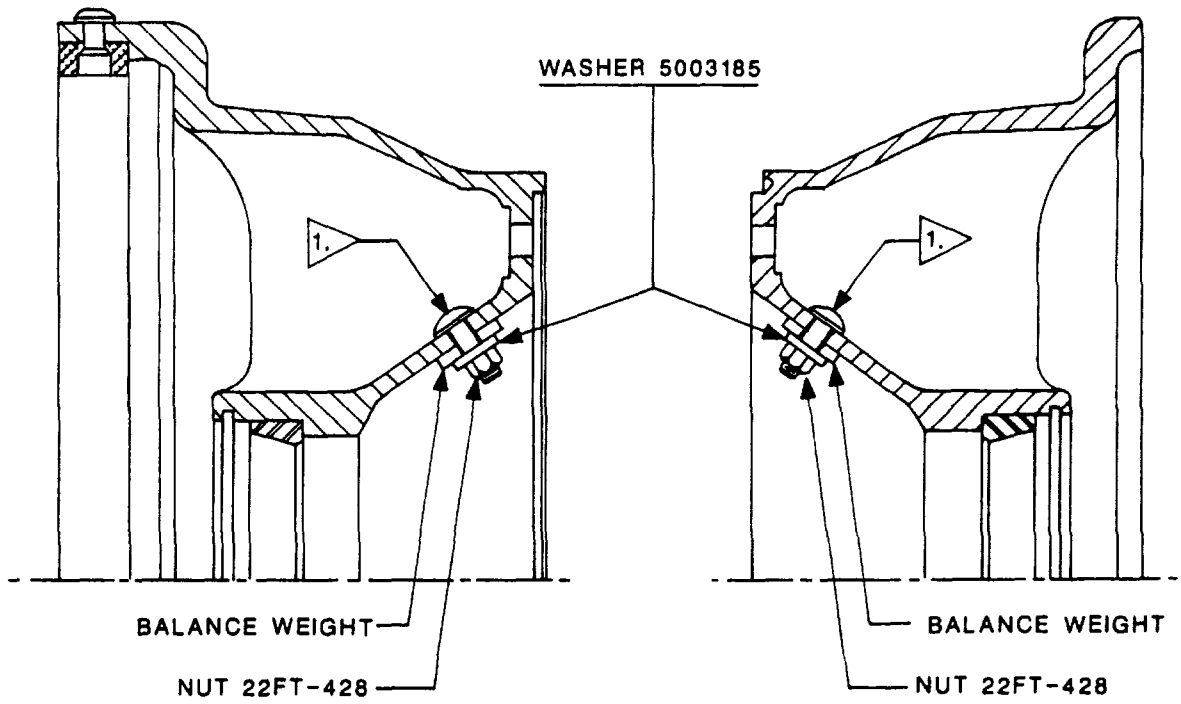
4. Wheel Balancing

A. Any permanent balance weights removed at disassembly should be reinstalled. Weight values of permanent balance weights are stamped adjacent to the hole to which the weights are bolted. See Figure 702 for installation details.

(1) If rebalancing of individual wheel subassemblies is required after wheel repair, then new permanent balance weight values followed by letter "B" should be restamped on face adjacent to weights.

Installing Retaining Ring (Inboard Wheel Only)
Figure 701

(2) Obliterate any obsolete values.



(3) Balance wheel subassembly to within 1.5 ounce-inches (108 g-cm).

B. Balance Weights are available for balancing the wheel/tire assembly. The required weight is obtained by using multiples of the balance weights. Total weight added to the inboard wheel subassembly must not exceed 3.0 ounces (85,05 g) total weight added to the outboard wheel subassembly must not exceed 3.0 ounces (85,05 g). The installed weights must not extend beyond the face of the wheel. The weights are bolted to the reinforcing flange of the wheel subassemblies as shown in Figure 702.

5. Storage Instructions

A. Wheels Stored with Tires Installed

(1) The length of time that a wheel assembly can be stored is governed by the storage life of its rubber components. The usable life may be shortened by exposure to sunlight, ozone concentration, extreme temperatures, and contamination by fluids and foreign particles.

BALANCE WEIGHT P/N	WEIGHT	SCREW LENGTH
9535339	3/4 OZ (21,3 g)	MS35207-280
9510014	1 OZ (28,3 g)	MS35207-280
9510015	1 1/2 OZ (42,5 g)	MS35207-280
9510016	2 OZ (56,7 g)	MS35207-281
9510017	2 1/2 OZ (70,9 g)	MS35207-281
9510018	3 OZ (85,1 g	MS35207-282

NOTES:

1. INSTALL MS35207 "DASH" WITH PROPER SCREW AS SHOWN IN TABLE.
2. USE EXISTING DRILLED HOLE IN WHEEL SUBASSEMBLY AND WEIGHT AS STAMPED NEAR HOLE.
3. BALANCE WEIGHTS MUST NOT EXTEND BEYOND WHEEL REGISTER EDGE.
4. TOTAL BALANCE WEIGHT ADDED FOR INBOARD WHEEL SUBASSEMBLY SHALL NOT EXCEED 3.0 OZ (85,05 g).

Balance Weight Installation
Figure 702

(2) The wheel/tire assembly should be stored in a clean, cool, dry storeroom out of direct sunlight. The desirable storeroom temperature range is 32° to 75°F (0° to 24°C). If this temperature range cannot be maintained, temperatures as high as 100°F (38°C) or even 125° (52°C) can be tolerated for short periods with only minor degradation.

(3) The recommended storage pressure for tires is 40 psi (27,6 N/cm^2).

B. Wheel Stored without Tires Installed

(1) The wheel assembly is stored without the wheel preformed packing installed between the two subassemblies. The packaged preformed packing is normally taped to the wheel for initial shipment and should be stored in this manner.

(2) Wheels stored without rubber components have an indefinite storage life.

FITS AND CLEARANCES

Item No. (Ref. IPL Fig. 1)	Nomenclature	Torque Value
50	Self-Locking Nuts	90 pound-inches (Lubtork*) (10,2 N-m)
215	Non-Locking Bolt (Steel Drive Ring)	50 to 70 pound-inches (5,6 to 7,9 N-m)
*Lubtork - At each installation, lubricate bolt threads and bearing surfaces of nuts, bolt heads, and washers with antiseize compound conforming to Specification MIL-T-5544 (W J Ruscoe & Company, 483 Kenmore Boulevard, Akron, Ohio 44301). Use full strength; do not dilute.		

Torque Value Table
Figure 801

Item No. (Ref. IPL Fig. 1)	Nomenclature	Replacement Dimension
230 or 230A	Internal Drive Ring Thickness (three or more teeth)	0.125 inch (3,18 mm) (minimum) measured 0.078 inch (1,98 mm) from top of tooth.

Internal Drive Ring Wear

ILLUSTRATED PARTS LIST

1. Introduction

A. General

(1) The Illustrated Parts List (IPL) section illustrates and lists the procurable parts of the assembly(ies) in this publication.

B. Parts List

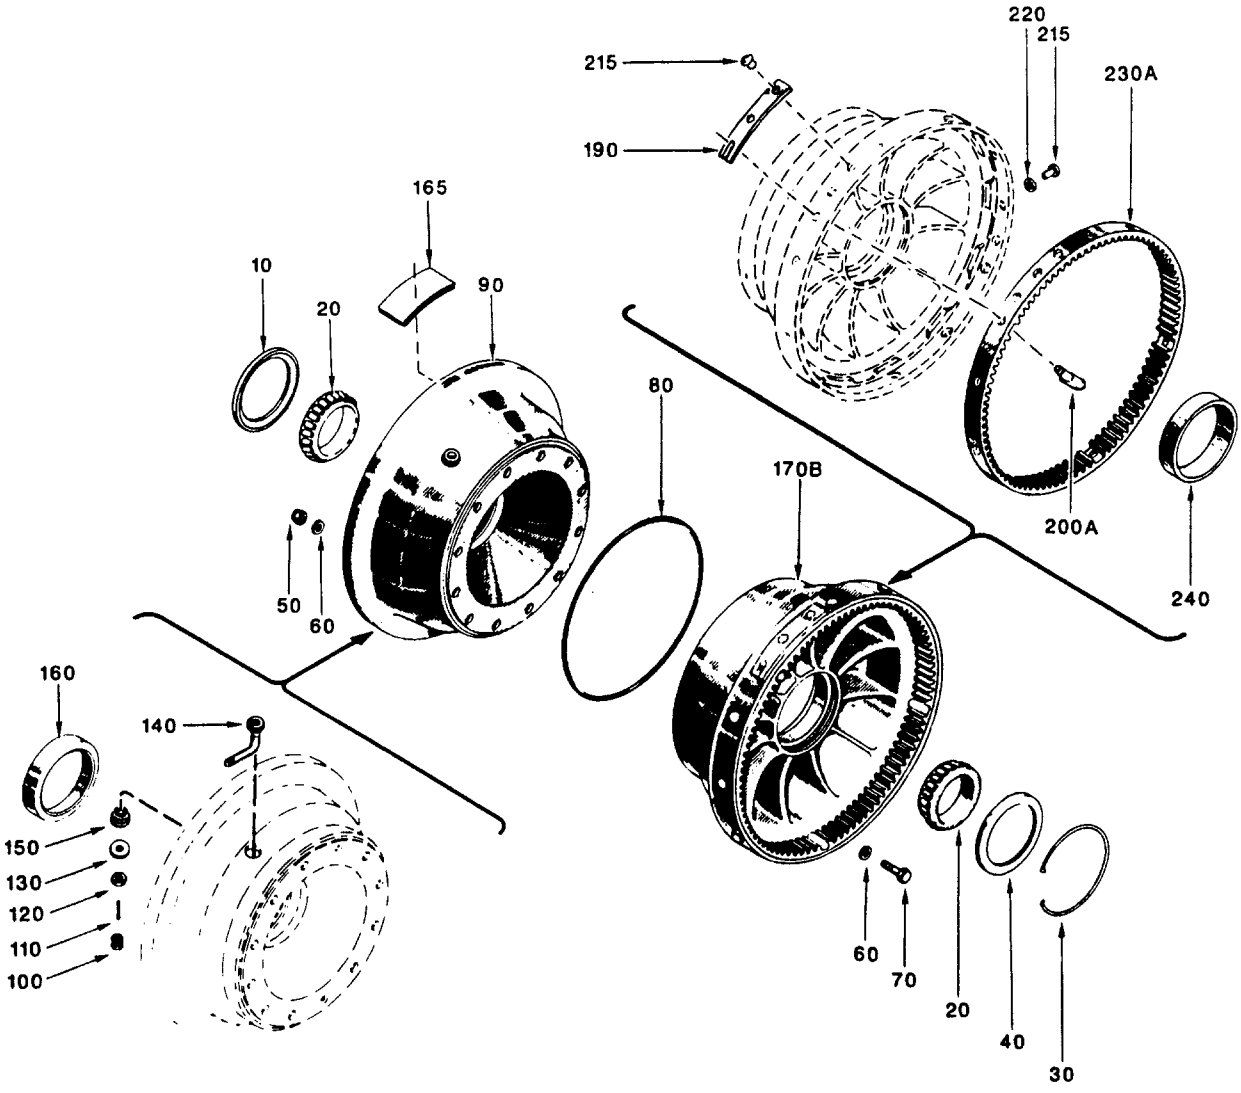
(1) IPL Figure 1 is an exploded view of assembly(ies) covered by the parts list.

(2) Components in the parts list are listed in order of disassembly.

(3) The Figure and Item column provides the cross reference between the parts list and the associated IPL Figure 1.

(4) The Part Number column gives the part number of the item, which is stamped on the part when practical. This number should be used when ordering parts.

(5) The Airline Stock Number column is provided for the convenience of the operator to enter individual part numbers.



(6) The Nomenclature column gives the basic noun name of each part, together with any descriptive or dimensional information and specifications required to identify the part listed. Parts are indented under the numbered sub-column heading showing the relationship of the parts to their subassemblies and to the assembly. When an alternate part or repair part exists for the recommended part, it is indicated in parentheses following the part nomenclature. A federal supply code number is given for all vendor-supplied items.

(7) The Effect Code column shall establish parts relationship with units or assemblies which are essentially the same but have minor variations. These units or assemblies are the lead items. These units or assemblies shall be assigned reference letters such as A, B, C, D, etc. Parts which are not common to all configurations, but are associated with one or more of the coded lead items, shall carry the letter or letters assigned to the lead item with which it is associated. If a part is common to all lead items, the Effect Code column shall be blank.

(8) The Units Per Assembly column gives the number of parts required for each assembly or subassembly.

C. Federal Supply Codes for Manufacturers

(1) A list of vendor/manufacturers names and addresses is provided following the parts list.

WHEEL ASSEMBLY 9544382-2 SHOWN

COMPONENT MAINTENANCE MANUAL
BRAKE ASSEMBLY

TEMPORARY REVISION NO. 32–6

TO: HOLDERS OF AP-420 (32-43–23) COMPONENT MAINTENANCE MANUAL WITH ILLUSTRATED PARTS LIST FOR BRAKE ASSEMBLIES 9550377, 9550377–1, 9550377–2 AND 9550377–4 USED ON DE HAVILLAND TWIN OTTER AIRCRAFT.

PURPOSE: This Temporary Revision corrects part ordering information and adds Brake Linings 5008993–1 and 5009124 as alternates for Brake Lining 5008993 to Illustrated Parts List. This Temporary Revision is also issued to correct the List of Effective Pages and to remove the Disk Guide Bracket Assembly 5008294. In addition, this Temporary Revision changes the item nomenclature in the List of Effective Pages to make clear the difference between the aluminum parts and the magnesium parts. This Temporary Revision replaces Temporary Revision No. 32–5, which can be removed.

FILING INSTRUCTIONS: Record applicable data on the RECORD OF TEMPORARY REVISIONS sheet in front of the manual. Insert page 1 facing the RECORD OF TEMPORARY REVISIONS.

Retain this Temporary Revision until normal revision service incorporates this information into the Component Maintenance Manual.

This Temporary Revision affects the List of Effective Pages, page 2 and pages 2, 3, 1002, 1003 and 1004 (32–43–23).

COMPONENT MAINTENANCE MANUAL
BRAKE ASSEMBLY 9550377

TO: HOLDERS OF AP-420 (32-43-23) COMPONENT MAINTENANCE MANUAL WITH ILLUSTRATED PARTS LIST FOR BRAKE ASSEMBLY 9550377, 9550377-1 AND 9550377-4 USED ON DEHAVILLAND TWIN OTTER AIRCRAFT.

Attached to this transmittal letter is Revision No. 4 of AP-420 (basic issue dated 1 November 1973).

REVISION NO. 4 DATED 1 JULY 1990

HIGHLIGHTS

Pages which have been added or revised are listed below together with the Highlights of the revision. Please delete the affected pages and insert Revision No. 4 pages dated July 1, 1990. Enter Revision No. 4 dated Jul 1/90 and insertion date on the Records of Revisions sheet.

Chapter/Section and Page No.	Description of Change
Reason	Revision No. 4 adds Brake Assembly 9550377-2 as a production unit. Item numbers have been revised and added throughout the manual to reflect the detail parts of the new brake assembly.
Cover	Added Brake Assembly 9550377-2.
Title Page	Added Brake Assembly 9550377-2 and Revision No. 4 date.
Service Bulletin List, page 1/2	Added Service Bulletins DHC-6-32-5 and DHC-6-32-6.
List of Effective Pages, pages 1 and 2	Revised to reflect added, revised and/or deleted pages.
Table of Contents pages 1 thru 3/4	Revised to reflect current revision. Added paragraph 9 and Repair No. 7 under REPAIR.
32-43-23 page 3	Revised figure item numbers in Key to Figure 1.
page 4	Added Brake Assembly 9550377-2 weight and material to paragraph 4. Added paragraph 5.C. describing Brake Assembly 9550377-2 differences. Relocated text.
page 5/6	Relocated text.

Chapter/Section and Page No.	Description of Change
pages 101 and 103/104	Added figure items 20C and 20D to paragraphs 3.A.(1) and 3.F.
pages 301 and 302	Added figure items 20D, 60A, 150B and 250A to paragraphs 2.C, 2.E, 2.I. and 2.L.
pages 502 and 503	Added figure items 20D, 150B, 150C and 250A to paragraphs 4., 4.A, 12., 12.A and 15.
page 504	Added paragraph 15.E. concerning check of lining retainer and rivet.
page 602	Revised paragraph 3.H., specifying magnesium housing and revised Repair No. 6 title. Added step 3.I referencing Repair No. 7 for piston lining retainer.
pages 606, 607, 608 and 609	Revised re-treating and repainting instructions to include procedures for both aluminum and magnesium parts in paragraphs 6.B, 6.C.(3), 6.D.(2), (3), (4), 6.E and 6.F(1). Relocated text.
page 610 and 611	Relocated text.
page 612	Added paragraph 9, instructions for replacing lining retainer and rivet. Relocated text.
Repair No. 1 page 601	Added figure items 250A, 150B and 150C to paragraphs 1.A, B., C.(1), C.(2) and C.(3)(a).
page 602	Added instructions for treating machined surfaces of aluminum housing. Added instructions to use aluminum Pistons 5009128 with aluminum brake Housing 5009126 in paragraphs 2.A(3) and 2.C.
Repair Nos. 2 and 3 page 601	Added figure item 250A to paragraph 1.A.
Repair No. 3 page 602	Deleted housing part number from Repair Figure 601.
Repair No. 6 page 601	Added part number to Repair No. 6 title.
Repair No. 7 pages 601 and 602	Added Repair No. 7 - Repair of Piston Lining Retainer.

Chapter/Section and Page No.	Description of Change
pages 702, 703 and 704	Added figure items 250A, 150B, 150C and 60A to paragraphs 3.B.(2), 3.C.(2), 3.D.(1), 3.E, 3.F.(3), (5), (6), (10) and (11). Changed figure items 263 and 264 to 255 and 256 in paragraphs 3.E, 3.E NOTE, 3E(1) and (2). Changed figure items 262 and 261 to 254 and 253 in paragraph 3.G. NOTE.
page 705	Revised paragraph 3.G.(1) adding Brake Assemblies 9550377, -1 and -4. Added paragraph 3.H.(3) for installing brake linings in Brake Assembly 9550377-2.
page 801	Added figure items 20D, 150B and 150C to Figure 802.
page 802	Added figure item 60A to Figure 803.
pages 1003 and 1004	Changed Brake Assembly 9550377-2 to production part incorporating SB DHC-6-32-6. Added the following parts as detail parts of Brake Assembly 9550377-2 and revised parts list as follows. Item 1B - Added effect code C. Item 20C - Changed effect code to C. Item 20D - Added Brake Lining 5009124 Item 60A - Added Cylinder Head 5009127 Item 70 - Added effect code C. Item 70A - Changed effect code to D. Item 80 - Added effect code C. Item 80A - Changed effect code to D. Item 90 - Added effect code C. Item 90A - Changed effect code to D. Item 150 - Added effect codes ABD. Item 150A - Added effect Codes ABD. Item 150B - Added Piston 5009128 Item 150C - Added oversize repair Piston 5009408. Item 200A - Added effect codes CD. Item 250 - Added effect codes ABD. Item 250A - Added Brake Housing 5009126 Item 251 - Added Repair Rivet MS20426AD-510. Item 252 - Added Repair Lining Retainer 9521519. Item 253 - Added Repair Retaining Ring 9521958. Item 254 - Was item 261. Item 255 - Was item 262. Item 256 - Was item 263. Item 257 - Was item 264.

COMPONENT MAINTENANCE MANUAL
BRAKE ASSEMBLY 9550377

TO: HOLDERS OF AP-420 (32-43-23) COMPONENT MAINTENANCE MANUAL WITH ILLUSTRATED PARTS LIST FOR BRAKE ASSEMBLY 9550377 AND 9550377-1 USED ON DEHAVILLAND TWIN OTTER AIRCRAFT.

Attached to this transmittal letter is Revision No. 3 of AP-420 (basic issue dated 1 November 1973).

REVISION NO. 3 DATED 31 MAY 1989

HIGHLIGHTS

REVISION NO. 3 CONTAINS ALL PAGES OF THE MANUAL. Pages which have been added or revised are outlined below, together with the Highlights of the revision.

Please retain all previous HIGHLIGHTS pages inserting them into this manual for future reference.

Chapter/Section and Page No.	Description of Change
All pages	The purpose of this revision is to add the conversion of Brake Assembly 9550377-1 to 9550377-4 by adding new improved asbestos-free linings. Added Repair Nos. 4 thru 6. Corrected Manual to show correct brake wear measurement location. Changes masthead logo to Aircraft Braking Systems. Added Brake Assembly 9550377-4 to manual and parts peculiar to brake assembly.
Cover	Added Brake Assembly 9550377-4 and latest format for Aircraft Braking Systems.
Title Page	Added Brake Assembly 9550377-1 and 9550377-4 and latest format for Aircraft Braking Systems.
Record of Revisions, page 1/2	Added Revision No. 3 and date.
Service Bulletin List, page 1/2	Added Service Bulletin DHC6-32-4.
List of Effective Pages, page 1/2	Added title to precede Record of Revisions. Added Repair Nos. 4 thru 6. Revised to reflect added, revised, and/or deleted pages.
Table of Contents, pages 1 thru 3/4	Added paragraph 8. to REPAIR for Modification of Brake Assembly 9550377-1 to 9550377-4. Added Repair Nos. 4 thru 6.
Introduction, pages 1 thru 4	Added latest Introduction and field office office address list.

Chapter/Section and Page No.	Description of Change
32-43-23	
Technical changes are as follows:	
pages 2, 3, 1002 1003 and 1004	Added Brake Assembly 9550377-4 and component parts to Figure 1, Key to Figure 1, IPL Figure 1 and illustrated parts list.
page 4	Added new paragraph 5.B. for brake differences between Brake Assemblies 9550377-1 and 9550377-4. Added paragraph 6.B. for Modification of Brake Assembly 9550377-1 to 9550377-4. Relocated Test.
page 102	Revised Figure 101, Brake Wear Measurement to show correct wear measurement location.
page 401 thru 405/406 and 901,902	Revised paragraph 3., Paint Removal Procedures to add Dry Stripping as (Method I) and changed Wet Stripping to (Method II). Added new Figure 401, Recommended Dry Stripping Variables. Added Dry-Stripping Materials to paragraph 1. Cleaning Materials and added equipment to SPECIAL TOOLS, FIXTURES AND EQUIPMENT section.
page 503	Added Oversize Piston 9522145 (150A) and Replacement Dimension of 2.161 inches (54,89 mm).
page 604	Revised Repair Areas 6 thru 9 to add "Maximum blending of reworked area limited to 0.50 square inch".
page 611/612	Added new paragraph 8., Modification and/or Rework of Brake Assembly 9550377-1 to Brake Assembly 9550377-4, incorporating Service Bulletin DHC6-32-4.
Repair No. 2 page 602	Revised Repair Figure 601, Lining Recess Repair to clarify.
Repair No. 4 pages 601 thru 603/604	Added Repair No. 4 - Repair of Brake Housing for Anvil Lining Retention Repair.
Repair No. 5 pages 601 and 602	Added Repair No. 5 - Repair of Brake Housing for Machining Wiper Ring Groove.
Repair No. 6 pages 601 and 602	Added Repair No. 6 - Rework of Brake Housing for Removal of Excess Casting Material, which incorporates Service Letter DHC-6-SL-4.

Chapter/Section and Page No.		Description of Change
page 703		Added new paragraph 3.E. for wiper ring installation on reworked brake housings stamped "5R86-067".
page 704		Added NOTE to new paragraph 3.G. to reference "5R85-015" repair, and installation of countersunk head screw and self-locking nut.
page 705		Added NOTE to paragraph 4. to insure that bushings are installed on housings with reworked mounting bolt holes.
page 1002		Renumbered items 20B to 20C, 70 to 70A, 80 to 80A and 90 to 90A in IPL Figure 1.
page 1003	Item no.	Revised parts list as follows:
	1	Changes (Order-1) to (Order-4)
	1A	Added (Order-4) to Brake Assembly.
	1B	Added P/N 9550377-2, NONPRODUCTION.
	1C	Added P/N 9550377-3, NONPRODUCTION.
	1D	Added P/N 9550377-4 for Brake Assembly and added effect code C.
	-20B	Added not illustrated symbol "_" to item number and added "**" to follow P/N for not procurable.
	20C	Added P/N 5008993 for brake lining. Added effect code C.
	70	Added (Alternate for item 70A) to nomenclature. Added effect codes AB.
	70A	Added P/N MS28775-228, Preformed Packing. Added effect code C.
	80	Added (Alternate for item 80A) to nomenclature. Added effect codes AB.
	80A	Added P/N MS28775-010, Preformed Packing. Added effect code C.
	90	Added (Alternate for item 90A) to nomenclature. Added effect codes AB.
	90A	Added P/N MS28775-327, Preformed Packing. Added effect code C.
page 1004	-261	Added P/N FN12L-82, Self-Locking Nut (Repair Only).
	-262	Added P/N MS24694-S9, Machine Screw (Repair Only).
	-263	Added P/N 5009211, Wiper Ring (Repair Only).
	-264	Added P/N 5009213, Wiper Ring (Oversize) (Repair Only).
	270	Changes P/N from GYR6B10 to GY16B-10* to correct.

Editorial changes are as follows:

page 5/6	Relocated text.
page 301	Editorial changes.
page 502	In paragraph 4., title and 4.A., changed brake lining (20, 20A or 20B) to brake lining (20C). Added preformed packings 70A, 80A and 90A to paragraph 8. title.
page 601	Revised vendor for Aeroprite Reducer TH-89.
page 602	Added paragraphs 3.F., 3.G. and 3.H. to reference Repair No. 4, Repair No. 5 and Repair No. 6 respectively. Relocated text.
pages 605 and 606	Relocated text.
Repair No. 1 pages 601 and 602	Editorial changes.
Repair No. 2 page 601	Added paragraph 2.B.(a) for retreating and repainting metal stamped areas. Editorial changes.
Repair No. 3 page 601	Editorial changes.
page 602	Deleted note in Assembly view of Repair Figure 601, discussed in text.
pages 703 thru 706	Editorial changes. Relocated text.
pages 801 and 802	Changes items 20, 20A or 20B to 20B or 20C and added item 150A, Piston to Figure 802. Editorial changes.
page 1001	Revised IPL Introduction to latest.
page 1002	Deleted Brake Assemblies 9550377 and 9550377-1 from IPL Figure 1 title. Added 9550377-4 SHOWN to field of illustration.
page 1005/1006	Relocated text.

COMPONENT MAINTENANCE MANUAL
BRAKE ASSEMBLY 9550377

TO: HOLDERS OF AP-420 (32-43-23) OVERHAUL MANUAL WITH ILLUSTRATED PARTS LIST FOR BRAKE ASSEMBLY 9550377 USED ON DEHAVILLAND TWIN OTTER AIRCRAFT.

Attached to this transmittal letter is Revision No. 2 of AP-420 (basic issue dated 1 November 1973).

REVISION NO. 2 DATED 15 SEPTEMBER 1986

HIGHLIGHTS

REVISION NO. 2 CONTAINS ALL PAGES OF THE MANUAL. Pages which have been added or revised are outlined below, together with the Highlights of the revision.

Please retain all previous HIGHLIGHTS pages inserting them into this manual for future reference.

Chapter/Section and Page No.	Description of Change
All pages	This manual has been prepared with automated word processing equipment. Shifting of text may have occured. Marking of the shifted text has been eliminated. Marking of text pages reflect only actual changes. This manual has been changed from an Overhaul to a Component Maintenance Manual. Sections have been relocated and pages renumbered accordingly. The technical information has not changed unless specified in the following highlights. Added metric units to all dimensions. Changed IPL figure item references adding "zero" to existing references. Clarified nomenclature in text to agree with parts list.
Cover	Changed to Component Maintenance Manual and added Brake Assembly 9550377-1.
Revision Highlights page 1	Corrected ATA number from 32-40-20 to 32-43-23.
Title Page	Changed to Component Maintenance Manual, added part number 9550377-1 and revision date.
Record of Revisions, page 1/2	Added Revision No. 2.
Record of Temporary Revisions, page 1/2	Added Temporary Revisions 32-1, 32-2 and 32-3.

Chapter/Section and Page No.	Description of Change
Service Bulletin List, page 1/2	Added Service Bulletin 32-3.
List of Effective Pages, pages 1 and 2	Revised to reflect added, revised, and/or deleted pages.
Table of Contents, pages 1 and 2	Expanded table for clarification.
Introduction, pages 1 thru 5/6	Revised to provide certification, the latest information and field office addresses.
32-43-23	
page 1	Clarified paragraph 1.A. and added paragraphs 1.B., 1.C., 1.D., and 1.E. Relocated text.
page 2	Revised Figure 1 from exploded view to cross sectional view, added figure items 260 and 300, added lockwire requirements and suggested disk wear measurements. Changed Figure 1 title to Brake Assemblies 9550377 and 9550377-1. Relocated text.
page 3	Revised Key to Figure 1 to agree with Illustrated Parts List, by adding "zero" to existing references and revising nomenclature. Added figure items 20A, 20B, 150A, 200A, 290 thru 330 and not illustrated symbol (-) and NOTE. Added paragraph 3. Handing Procedures. Relocated text.
page 4	Renumbered paragraph 3. to 4. Leading Particulars and clarified Material. Added new paragraphs 5. Brake Differences and 6. Brake Modification. Added new paragraph 7. Brake Lining Wear Check on Aircraft, which incorporates TR32-2 data previously located in CHECK. Relocated text.
pages 101 thru 103/104	Renumbered, relocated and revised entire section.
page 101	Incorporated data from previous TESTING and TROUBLE SHOOTING sections into new TESTING AND FAULT ISOLATION section. Added paragraph 1. Test Equipment and Materials, paragraph 2. Test Setup and paragraph 3. Operational Test and Fault Isolation Procedures.
page 102	Added Figure 101 and paragraph 3. text.
page 103/104	Added paragraph 3. text, paragraph 4. Fault Isolation and Figure 102.

Chapter/Section and Page No.	Description of Change
pages 301 and 302	Renumbered, relocated and revised entire section.
page 301	Added (Ref. IPL Fig. 1) to paragraph 1. title. Added NOTE and paragraph 1.A. Changed paragraph 1.A. to 1.B. Deleted paragraph 2.B. and renumbered remaining paragraphs C. thru K. to B. thru J., clarifying nomenclature to agree with parts list. Added paragraphs J.(1) and (2).
page 302	Renumbered paragraphs L. and M. to J. (3) and (4). Added paragraph K. and renumbered paragraph N. to L. and O. to M.
pages 401 and 402	Renumbered, relocated and revised entire section.
page 401	Added paragraph 1. Cleaning Materials. Changed paragraph 2. title to Cleaning Procedures and added WARNING, CAUTION, and NOTE.
page 402	Added paragraphs 2.C., 2.D. and 2.E. Added paragraph 3. Paint Removal Procedures.
pages 501 thru 504	Renumbered, relocated and revised entire section. Deleted paragraph 3. Brake Lining Check on Aircraft - relocated data to Description and Operation section.
page 501	Added paragraph 1. Check Materials from deleted Figure 301 information. Renumbered paragraph 1. to 2. General and added paragraphs 2.A. and 2.B. Renumbered paragraph 2. to 3. Brake Disk and renumbered subparagraphs.
page 502	Renumbered paragraph 2. subparagraphs. Added paragraph 4. Brake Lining. Added paragraphs 5. thru 9.
page 503	Added paragraph 10. from information in previous paragraph 1.F. Changed minimum force of 105 to 115 pounds and 55 to 60 pounds. Added paragraph 11. from information in previous paragraph 1.E. Added paragraph 12. from information in previous paragraph 1.D. Added paragraphs 13. and 14. Added paragraph 15. from information in previous paragraphs 1.B., 1.C., and 1.H.
page 504	Added paragraph 15. text. Added paragraph 16. from information in previous paragraph 4. Changed lining thickness from 0.175 to 0.205 inch, incorporating TR32-2. Added paragraph 17.

Chapter/Section and Page No.	Description of Change
pages 601 thru 610	Renumbered, relocated and revised entire section.
page 601	Added paragraph 1. Repair Materials.
page 602	Added paragraph 2. General. Added paragraph 3. Repair of Brake Housing. Revised paragraph 4. by renumbering subparagraphs.
page 603	Renumbered Figure 401 to 601, and revised by changing rework areas 1, 6, 8, 9, and 11 and added Detail A.
page 604	Added Key to Figure 601 from information in previous paragraphs 1.A. thru 1.J.
page 605	Renumbered Figure 402 to 602. Renumbered paragraph 4. subparagraphs. Added paragraph 5. from information in previous paragraphs 9. and 12. and incorporated TR32-2. Added paragraph 6. Re-Treating and Repainting.
page 606	Renumbered Figure 407 to 603. Added paragraph 6. text.
pages 607 thru 609	Added paragraph 6. text.
page 610	Added paragraph 6. text. Added paragraph 7., incorporating SB32-3.
Repair No. 1 pages 601 and 602	Added from relocated data in previous paragraph 3.
Repair No. 2 pages 601 and 602	Added from relocated data in previous paragraph 8. and renumbered Figure 404 to 601.
Repair No. 3 pages 601 and 602	Added from relocated data in previous paragraph 11. and renumbered Figure 406 to 601.
pages 701 thru 705/706	Renumbered, relocated and revised entire section. Changed section title to ASSEMBLY AND STORAGE.
page 701	Added paragraph 1. Assembly and Storage Materials and changed MIL-G-81322 grease to hydraulic preservative fluid MIL-H-6083. Added paragraph 2. General. Added paragraph 3. Assembly Procedures.

Chapter/Section and Page No.	Description of Change
page 702	Added paragraph 3.B., replacing previous paragraphs 3., 15., 16. and 17., incorporating TR32-2. Added paragraph 3.C., replacing previous paragraphs 3, and 14., incorporating TR32-2. Added paragraph 3.D., replacing previous paragraph 2. and clarifying.
page 703	Added paragraph 3.D. text. Added paragraph 3.E., replacing previous paragraphs 3. thru 13. Added Figure 701.
page 704	Added paragraph 3.E. text. Added paragraph 3.F., incorporating TR32-1. Renumbered paragraph 18. to 3.G. Added paragraph 3.H. Added paragraph 4., replacing paragraphs 19. thru 21.
page 705/706	Clarified paragraph 5. Storage Instructions.
pages 801 and 802	Renumbered, relocated and revised entire section. Renumbered Figures 601 thru 603 to 801 thru 803.
page 801	Changed item no. 120 minimum load from 55 to 60 pounds and item no 130 minimum load from 105 to 115 pounds in Figure 801. Revised Figure 802 as follows: item no. 10. - Added outside diameter or 13,025 inch; item no. 280 - added item no. 320 reference and changed dimension 0.175 to 0.205 inch; Added item nos. 20, 20A, 20B and 140.
page 802	Revised Figure 803 by adding item nos. 180, 220 and 230, incorporating TR32-3.
page 901/902	Renumbered, relocated and revised entire section.
pages 1001 thru 1004	Renumbered, relocated and revised entire section.
page 1001	Revised IPL Introduction.
page 1002	Revised Figure 1 adding "zero" to existing figure item numbers. Added part number 9550377-1 to Figure 1. title. Added figure items 300, 310, 320 and 330. Changed figure items 200 to 200A and 20 to 20B. Corrected figure item 260 to 290 and added bracket for figure item 260 subassembly.

Chapter/Section and Page No.	Description of Change
page 1003	Revised Parts List as follows: Renumbered paragraph 3. to 2., Parts List. Added "zero" after existing item numbers. Item 1 - Added **, Order -1 and effect code A. Item 1A - Added. Item 20 - Added ** and effect code A. Item 20A - Added ** and effect code A. Item 20B - Added. Item 40 - Added "self". Item 50 - Changed "adjusting pin" to "steel". Item 70 - Changed O-ring packing to O-ring gasket. Item 90 - Deleted piston. Item 100 - Deleted spring. Item 120 - Changed return to release. Item 130 - Changed return to release. Item 150A - Added "only". Item 160 - Changed V65301 to V79555 and shipping to protective. Item 170 - Changed O-ring to preformed. Item 180 - Changed inlet bushing to screw thread insert. Item 190 - Changed O-ring to preformed. Item 200 - Added effect code A. Item 200A - Added. Item 240 - Changed O-ring to preformed. Item 260 - Clarified nomenclature. Item 270 - Changed GY16B12 to GYR6B10. Item 300 - Deleted lockwire MS20995C32. Added Bracket Subassembly, Disk Guide, part number 5008294. Item 310 - Added. Item 320 - Added. Item 330 - Added.
page 1004	Renumbered paragraph 2. to 3. Federal Supply Codes for Manufacturers. Deleted Code No. 65301 and added Code No. 79555.

OVERHAUL MANUAL WITH IPL
PART NO. 9550377

TO: Holders of AP-309, Overhaul Manual and Illustrated Parts List, Main Wheel Assembly 9544382 and Brake Assembly 9550377 for DeHavilland Twin Otter Aircraft, dated 15 January 1969 (revised 1 May 1970).

Attached to this transmittal letter is AP-420, Overhaul Manual with Illustrated Parts List, Brake Assembly 9550377 for DeHavilland Twin Otter Aircraft, dated 1 November 1973. This manual replaces the brake overhaul section (32-40-2) of AP-309 dated 15 January 1969 (revised 1 May 1970), which should be removed and destroyed.

Service Bulletins issued for AP-309, applicable to Brake Assembly 9550377, have been incorporated into AP-420, dated 1 November 1973, and are listed in the AP-420 Service Bulletin List.

Following are brief highlights of the changes which took place in updating the Brake Assembly 9550377 from AP-309 to AP-420:

a. Changed Cover and Title pages to new format.

b. Changed Masthead and "disc" to "disk".

c. Added Leading Particulars.

d. Changed rubber parts cleaning solution.

e. Revised Checking procedures and added approved penetrant materials.

f. Revised Repair procedures.

g. Revised Storage Instructions and Illustrated Parts List.

COMPONENT MAINTENANCE MANUAL
BRAKE ASSEMBLY 9550377

INTRODUCTION

This manual is published in accordance with Air Transport Association Specification No. 100 for the guidance of personnel responsible for the overhaul and/or maintenance of the assembly(ies) covered in this publication. The procedures described in this manual may be altered if better and/or more economical equivalent methods can be employed by the individual facilities. However, the alternate procedures must not lessen the performance or efficiency of operation of the assembly, and all torque and specific limits or values contained herein must be strictly observed.

All dimensions and other values are expressed in U.S. units followed, where applicable, by the appropriate SI (International System) metric units in parentheses. All illustration dimensions are in inches with millimeter conversions in parentheses unless otherwise specified. Dimensions of standard tools or parts such as drills, taps, bolts, nuts, etc. where there are no equivalent metric tools or parts for the application, appear in U.S. units. Illustrations are for reference only and are not drawn to scale. Attempt is made to illustrate relationship to adjoining parts in proper proportion.

The following precautions apply to all procedures in this manual:

NOTICE

Any alteration to or substitution of any part contained in any wheel and/or brake affecting those assemblies could result in unit malfunction, or other adverse effects.

If alteration to or substitution of any part contained in any Aircraft Braking Systems' wheel and/or brake affecting those assemblies is necessary, obtain prior written Aircraft Braking Systems' authorization and instruction before performing such alteration or substitution.

AIRCRAFT BRAKING SYSTEMS ASSUMES NO LIABILITY WHATSOEVER, WHETHER CONTRACTURAL, WARRANTY, TORT OR OTHERWISE, FOR ANY UNAUTHORIZED SUBSTITUTION OF OR ALTERATION TO ANY PART CONTAINED IN ANY WHEEL AND/OR BRAKE OR FOR ANY ALTERATION NOT PERFORMED IN ACCORDANCE WITH AIRCRAFT BRAKING SYSTEMS APPROVED PROCEDURES.

While Aircraft Braking Systems represents the information contained in this manual was current at the time of publication of this issue, and verified by comparison to engineering documentation, the user is cautioned that he must inquire of the nearest authorized distributor or dealer of Aircraft Braking Systems' wheels and brakes as to whether a more recent publication is in existence before proceeding with overhaul or maintenance operations. If you cannot locate a dealer or distributor, make your inquiry directly to our Customer Support Department, Aircraft Braking Systems, 1204 Massillon Road, Akron, Ohio 44306-4186.

Users outside the United States and Canada should contact the nearest Aircraft Braking Systems International Field office as listed in this manual or the closest Aircraft Braking Systems' distributor.

The aircraft maintenance manual shall take precedence for the component's interface connections with the functional features as used in the aircraft. This manual may also describe functional features that may or may not be used when installed as a component of a system in the aircraft.

TSO NOTICE

This assembly for commercial transport usage carries a "TSO" marking which identifies it as having been fully laboratory tested and qualified to the applicable Federal Aviation Administration (FAA) regulations. As a commercial transport category assembly, it is also tested and qualified to the specification requirements of the applicable airframe manufacturer and, finally, is certified on the applicable aircraft.

After final certification, any substitution of or alteration to any part and/or any change of process or material is not permitted without complete requalification of this assembly and resubmittal of the test data to the FAA for approval.

The FAA regulations subject Aircraft Braking Systems, the airframe manufacturer and the operator to constant surveillance to assure that proper Quality Assurance material and processing controls are maintained in order to provide replacement parts that are the same quality as the parts originally certified in this assembly.

SAFETY SUMMARY

Adhere to all manufacturer's Warnings and Cautions for all materials specified in this manual. Wear protective clothing (gloves, apron, etc.) approved for the materials and tools being used.

ON-CONDITION MAINTENANCE

Individual operators shall determine the frequency of maintenance. Since each operator has a different set of operating conditions, overhaul frequency will vary. Aircraft Braking Systems recommends that on-condition maintenance be performed.

World Airlines Technical Operations Glossary (WATOG) defines on-condition maintenance as follows:

A primary maintenance process having repetitive inspections or tests to determine the condition of units, systems or portions of structure with regard to continued serviceability (corrective action is taken when required by item condition).

DATA RIGHTS

The unit charge for this manual covers reproduction and handling costs only and does not constitute purchase of the data or design contained herein, nor does it convey to the purchaser any rights, patent or otherwise, to reproduce or manufacture from said data.

DESCRIPTION AND OPERATION

1. Description (Ref. Fig. 1)

A. The single disk brake assembly is used on the main landing gear of the aircraft. The brake disk contains gear teeth at its perimeter for mating with a wheel assembly containing a gear tooth drive ring. Two interchangeable inlet ports are provided on the brake housing. Only one port is used as an inlet (depending on installation position on landing gear), and the other is used as a bleeder port.

B. The brake assembly contains three pistons. Incorporated in each of the three pistons is an automatic adjustment mechanism which controls the clearance between disk and linings when the brake is in the off position, ensuring constant clearance during the life of the linings.

C. The brake pistons are sealed by means of preformed packings compounded for the type of brake fluid used in the brake system.

D. The brake housing is secured to axle torque flange by 12 bolts.

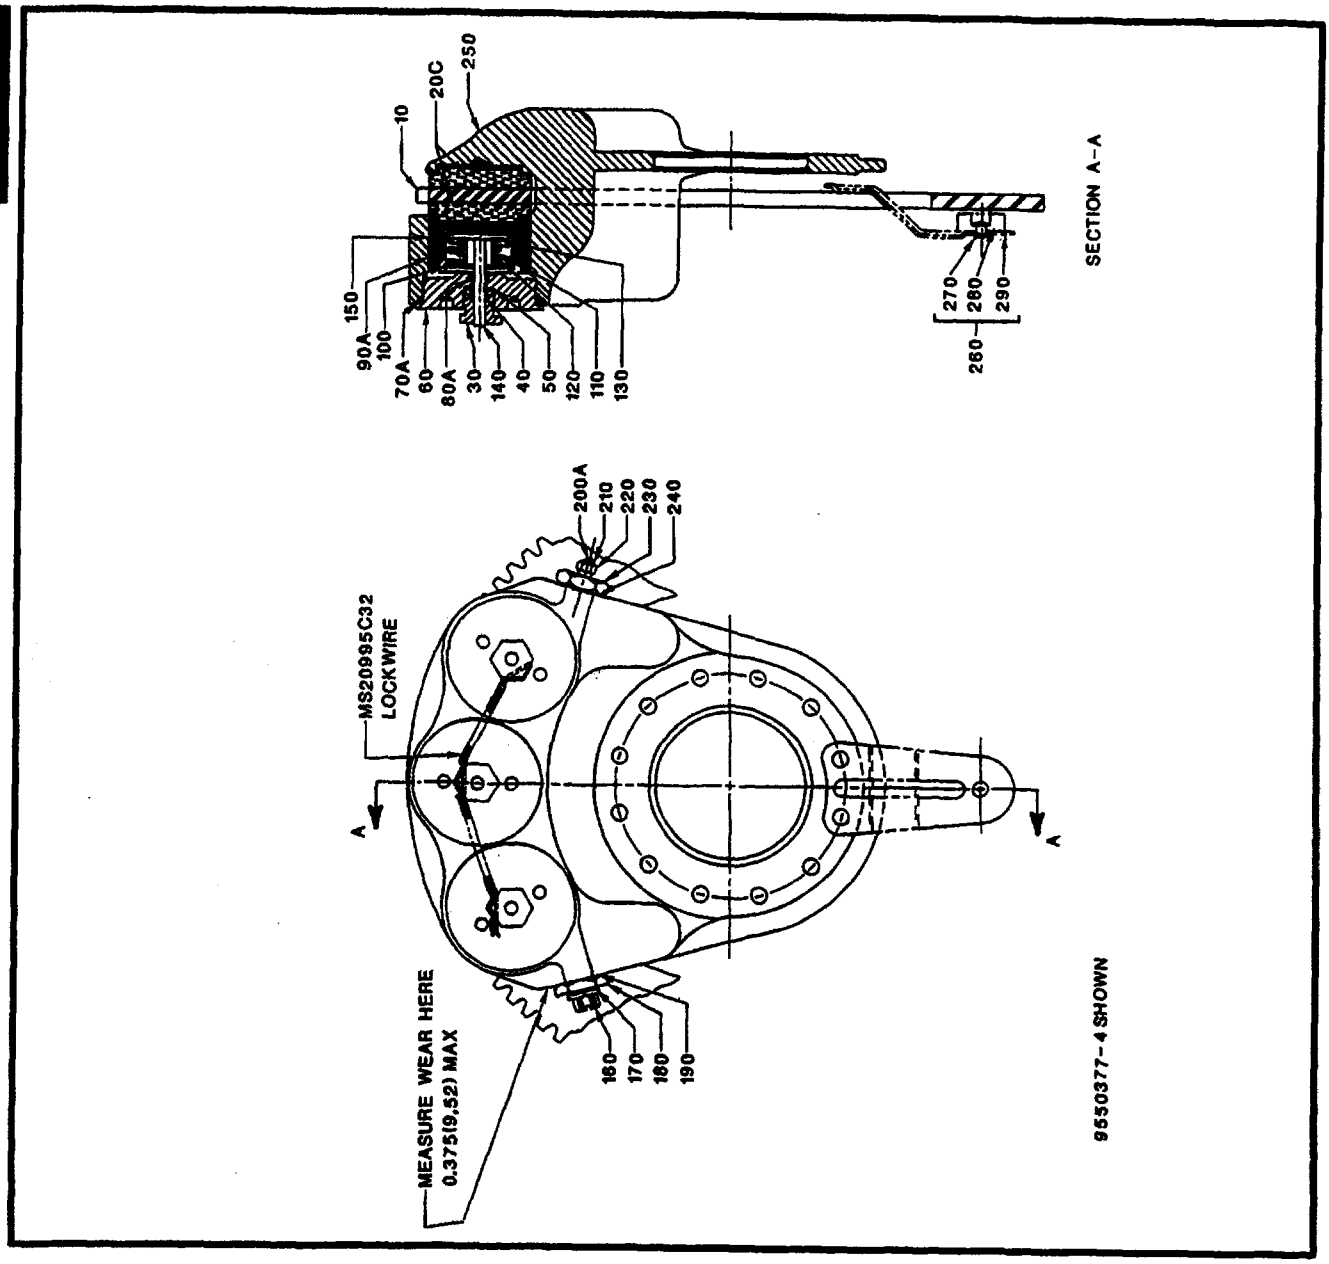
E. At operator's option, an inner and outer disk guide subassembly is provided, but is not furnished unless ordered separately.

2. Operation

A. Single disk brakes operate on the principle of two opposed sections of brake lining separated by an annular disk, which is engaged to rotate with the aircraft wheel. To provide braking action, the linings are pressed against the disk by hydraulic pressure applied against the brake piston.

B. The brake linings are contained in recesses in the piston and anvil section of the brake housing. A throat or groove is provided in the housing for the annular disk to pass through as the wheel rotates.

C. The disk floats on the wheel internal drive ring. This floating action compensates for the movement of the disk when braking pressure is applied. Only the piston side brake lining moves toward the disk, while the anvil side lining remains stationary. As the piston lining presses it, the disk moves until it contacts the anvil lining. The disk then receives equal clamping action on both sides as pressure is increased. Optional disk guides may be installed to minimize sideways movement and cocking of the brake disk.



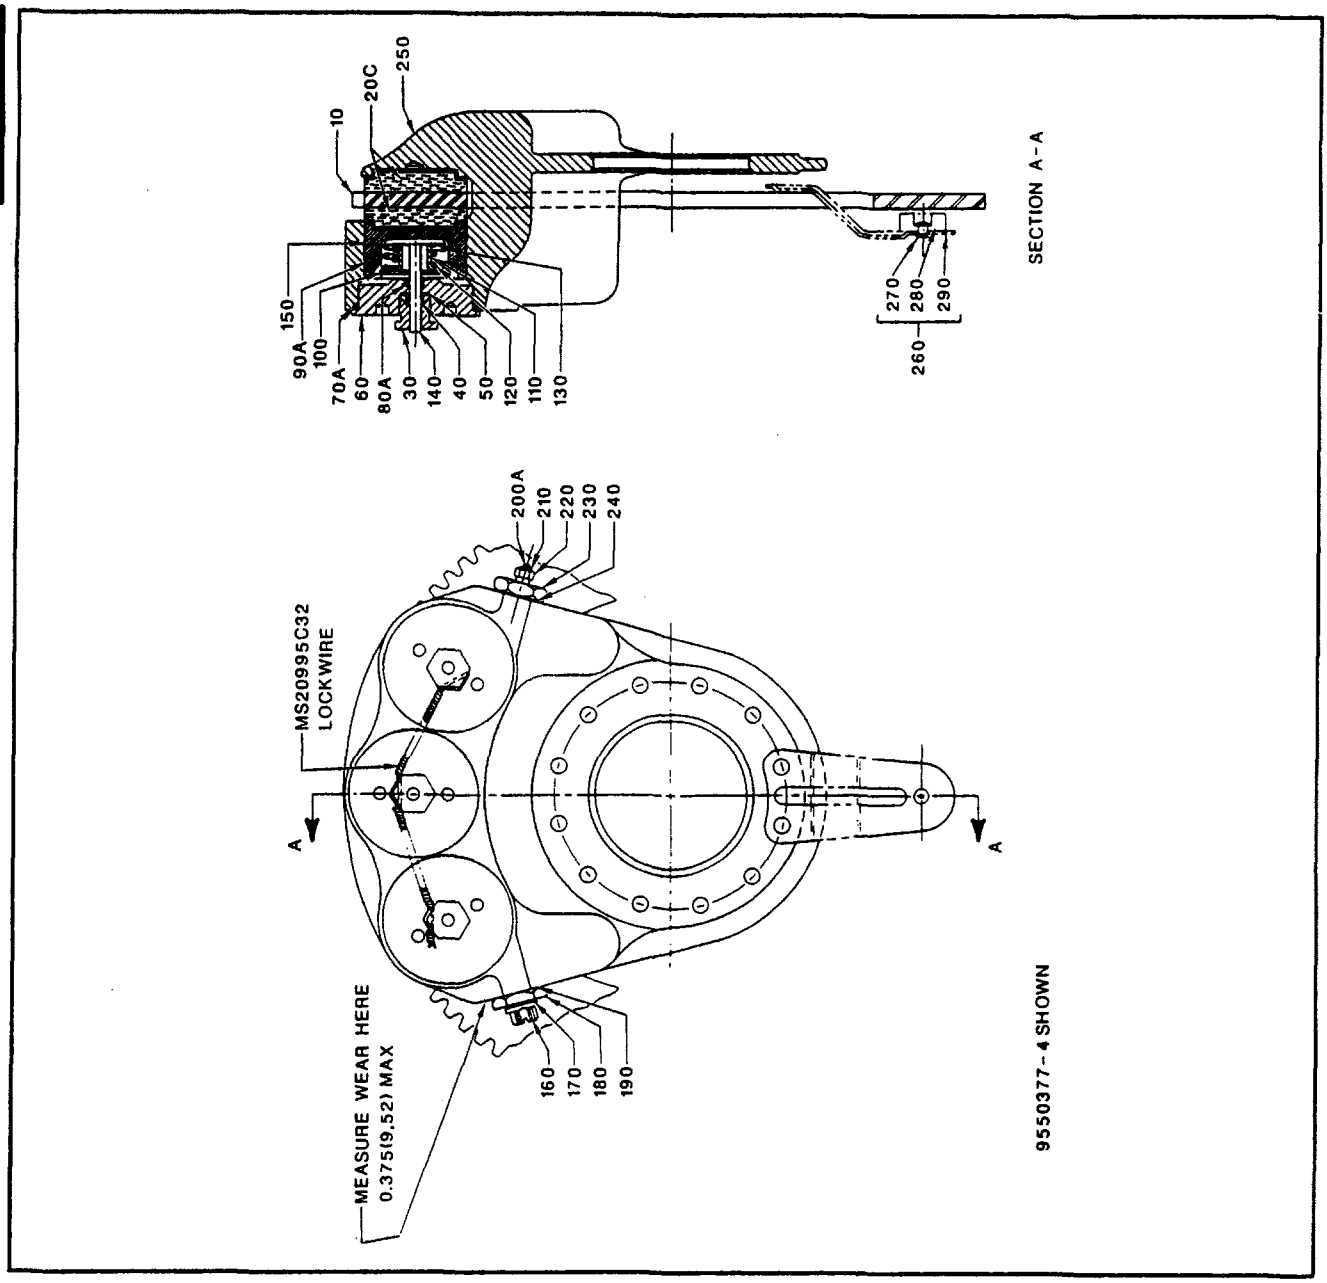
D. The single disk brake is used with a wheel having an aluminum gear tooth drive ring riveted to the drive flange. When rotation of the disk is restrained by the brake unit, the torque forces are transmitted to the wheel through the drive ring.

E. Each brake contains an automatic adjustment mechanism which maintains a constant disk-to-lining clearance throughout the life of the lining, thereby ensuring a drag-free brake.

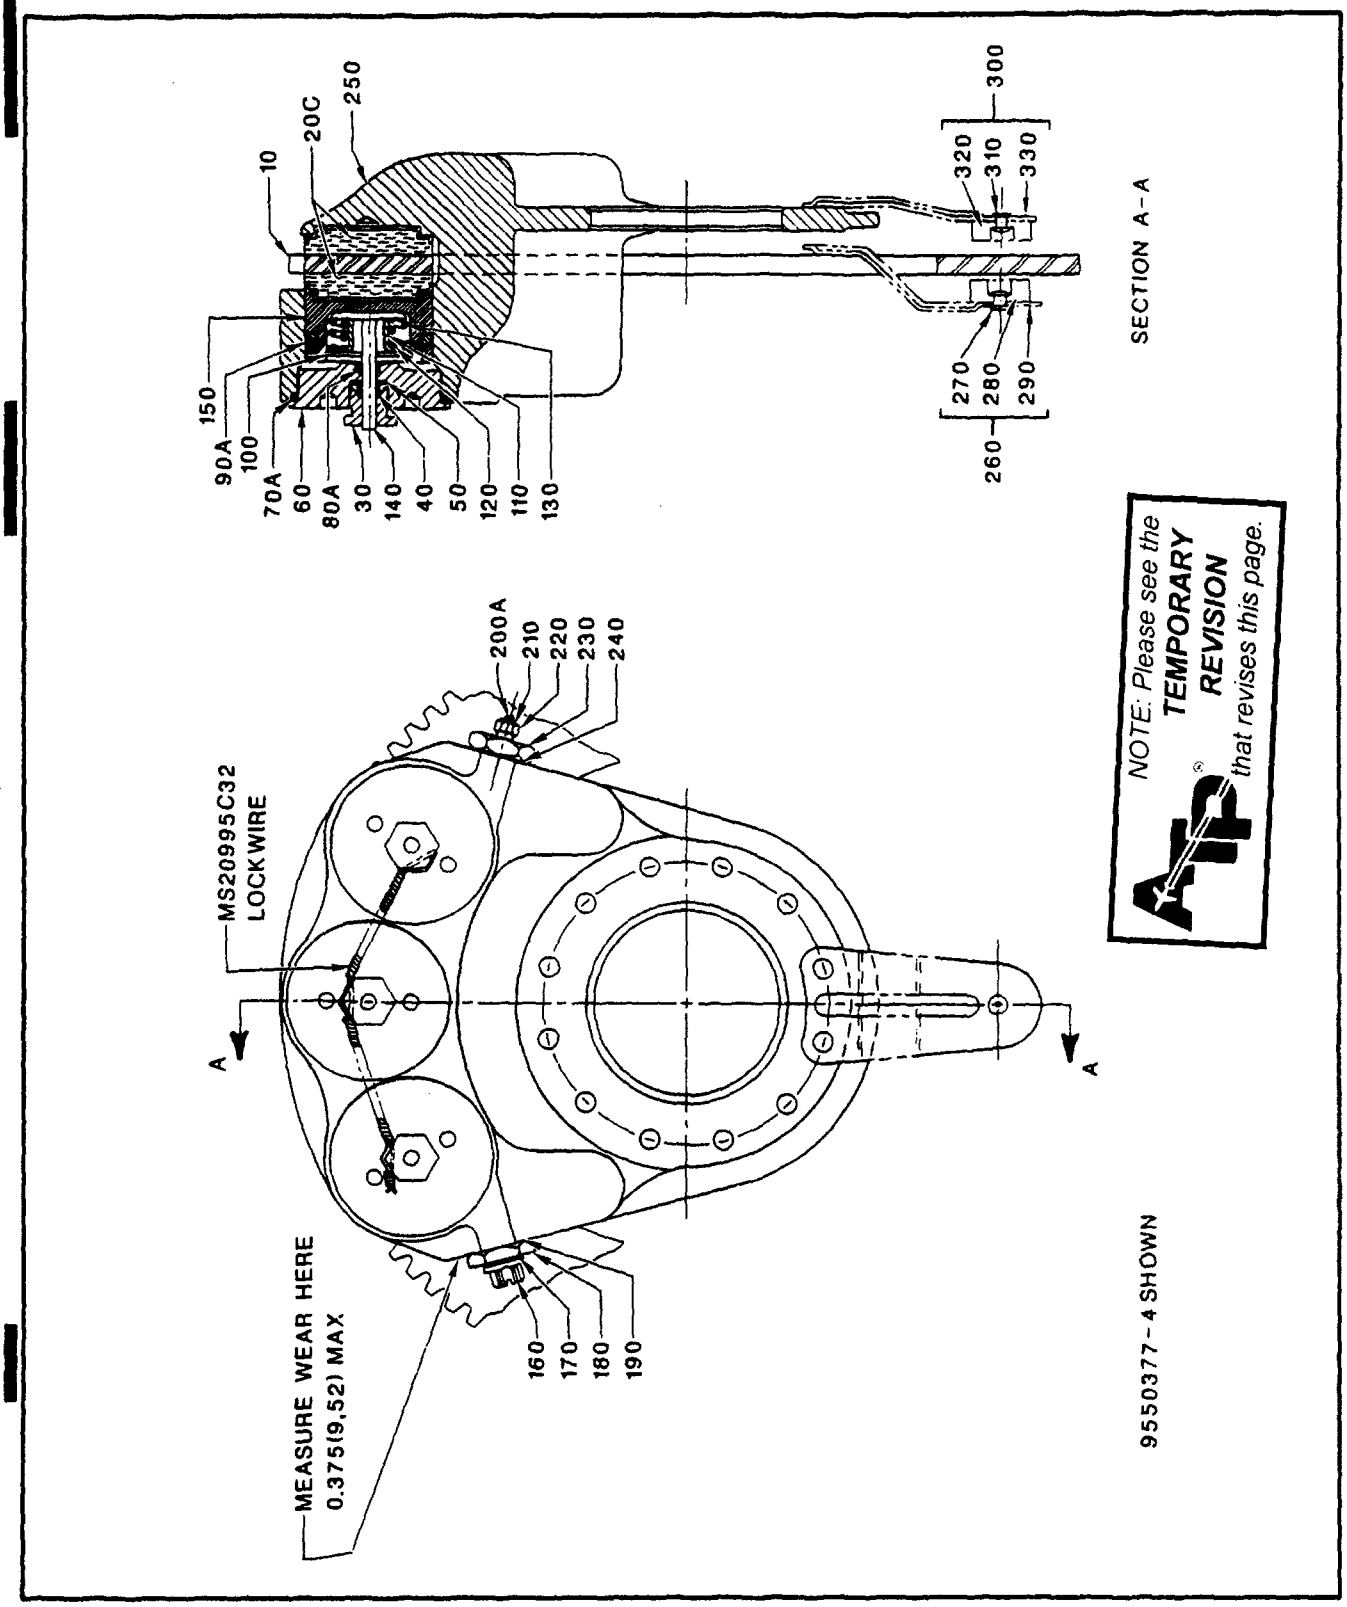
TEMPORARY REVISION NO. 32–6

FILING INSTRUCTIONS: Insert facing page 2 (32–43–23).

DESCRIPTION: Removed items 300, 310, 320 and 330 from Figure 1. This Temporary Revision replaces Temporary Revision No. 32–5, which can be removed.



Brake Assembly
Figure 1



TEMPORARY REVISION NO. 32–5

FILING INSTRUCTIONS: Insert facing page 2 (32–43–23).

DESCRIPTION: Removed items 300, 310, 320 and 330 from Figure 1. This Temporary Revision replaces Temporary Revision No. 32–4, which can be removed.

Brake Assembly

3. Handling Procedures

A. Careful handling of the brake components will assure a long service life and trouble-free operation.

B. Strictly observe torque and Lubtork values specified in this manual. Do not overtighten any bolt, nut or fittting.

C. Handle the brake parts with extreme care. Many failures can be traced to dropping or mishandling the parts during maintenance.

D. The brake should be properly maintained to protect the paint and surface finishes, as exposed surfaces are susceptible to corrosion. Nicks, scratches, and other damage caused by improper handling of the brake during maintenance invite corrosion, which if unattended will lead eventually to fatigue cracks and premature removal from service.

NOTE: Please see the TEMPORARY REVISION that revises this page.

4. Leading Particulars

Weight (approximate)	16.4 pounds (7,44 kg)
(Brake Assembly 9550377-2)	19.1 pounds (8,66 kg)
Brake	Single disk
Hydraulic Fluid	Specification MIL-H-5606
Functional and Clearance Test Pressure	770 psi (53,1 bars)
Operating Clearance at 40 psi (2,76 bars)	
Back Pressure	0.028 inch minimum (0,71 mm)
	0.050 inch maximum (1,27 mm)
Material:	
Brake Housing	Cast Magnesium Alloy
Pistons	Magnesium Alloy
Cylinder Head	Magnesium Alloy
(Brake Assembly 9550377-2)	
Brake Housing	Aluminum Alloy
Pistons	Aluminum Alloy
Cylinder Heads	Aluminum Alloy

5. Brake Differences

A. Brake Assemblies 9550377 and 9550377-1 differ only in the brake linings. Brake Assembly 9550377-1 uses asbestos-free linings.

B. Brake Assemblies 9550377-1 and 9550377-4 differ only in the brake linings and seals. Brake Assembly 9550377-4 uses new, improved asbestos-free linings and "MS" packings.

C. Brake Assembly 9550377-2 differs from 9550377, 9550377-1 and 9550377-4 in that it uses an aluminum brake housing, pistons and cylinder heads rather than magnesium. Brake Assembly 9550377-2 also incorporates a positive brake lining retention feature consisting of buttons machined on the pistons and buttons riveted to the anvil. The asbestos-free brake linings have fastener sockets that mate with the buttons to hold the liners in place.

6. Brake Modification

A. Brake Assembly 9550377

(1) Modification is provided in REPAIR at operator's option to convert Brake Assembly 9550377 to 9550377-1.

(2) This modification provides instructions for replacing asbestos linings with asbestos-free linings and reidentification of brake assemblies.

B. Brake Assembly 9550377-1

(1) Modification is provided in REPIAR, at operator's option, to convert Brake Assembly 9550377-1 to 9550377-4.

(2) This modification provides instructions for replacing asbestos-free linings with new, improved asbestos-free linings and reidentification of brake assemblies.

7. Brake Lining Wear Check on Aircraft

A. Check brake linings while the brake is on the aircraft as follows:

(1) Apply brakes and hold.

B. Measure the distance from the flat of the brake housing (parallel to the disk) to the surface of the brake disk (Ref. Fig. 1), at bleeder or inlet port.

CAUTION: NEVER MIX NEW AND USED BRAKE LININGS. IF NECESSARY TO REUSE WORN LININGS, REINSTALL THEM IN THEIR ORIGINAL POSITION.

LINING SHOULD NOT BE WORN BEYOND THE SPECIFIED 0.375 DIMENSION, OR A BREAKING UP OF LINING COULD OCCUR AND AN EVENTUAL BRAKE LINING LOSS COULD RESULT. REPLACE LINING WHEN THE LINING CUP IS FOUND TO BE DEFORMED AND OUT OF ROUND. ALSO CHECK, AND REPAIR IF NECESSARY, LINING RECESSES IN ACCORDANCE WITH REPAIR.

C. When this dimension reaches 0.375 inch (9,52 mm) or more, the brake linings should be replaced.

TESTING AND FAULT ISOLATION

1. Test Equipment and Materials

NOTE: Equivalent substitutes may be used for items listed.

Hydraulic Test Stand Supplies 0 to 3,000 psi (206,84 bars) pressure gaged to read output pressure to 5 psi (0,345 bars) increments	Commercially available
Hydraulic Fluid (Red Oil) Specification MIL-H-5606	Commercially available

2. Test Setup

A. None required.

3. Operational Test and Fault Isolation Procedures

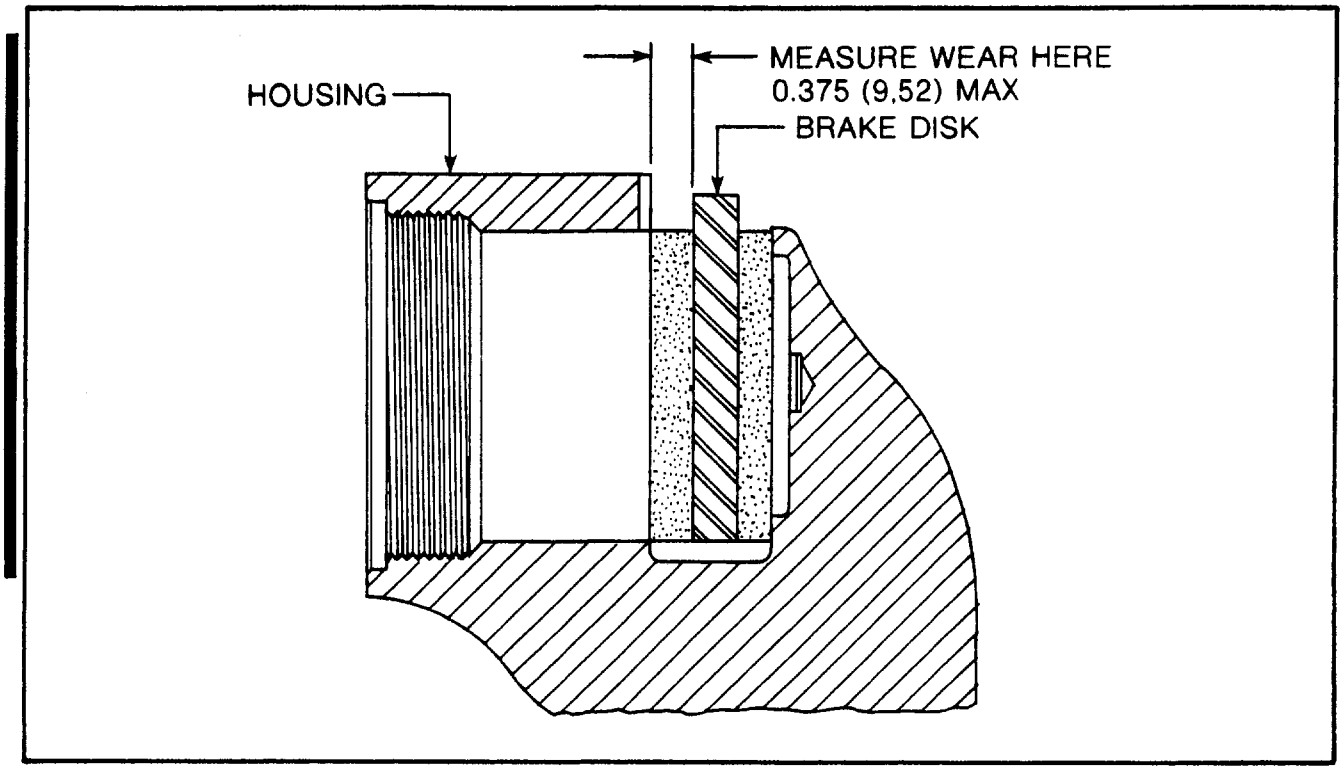
CAUTION: HYDRAULIC TEST STAND MUST CONTAIN RED OIL TO SPECIFICATION MIL-H-5606.

A. Connect brake assembly to a hydraulic test stand capable of applying 770 psi (53,1 bars) hydraulic pressure to brake.

(1) Use brake disk (10) or a spacer of equal thickness between brake linings (20C or 20D).

B. Place brake in upright position with disk (10) in place between linings.

(1) Apply pressure and bleed brake.



(2) Apply 5 psi (0,345 bars) hydraulic pressure at inlet for five minutes. There shall be no measurable leakage.

(3) Apply 770 psi (53,1 bars) hydraulic pressure at inlet for five minutes. There shall be no measurable leakage.

C. Apply and hold pressure for brake lining wear check.

(1) Measure the distance from the flat of the brake housing (parallel to disk) to the surface of the brake disk at inlet or bleeder port as shown in Figure 101.

(2) When this dimension reaches 0.375 inch (9,52 mm) or more, the brake linings should be replaced.

Brake Wear Measurement
Figure 101

D. Adjusting pin slippage test.

(1) Remove disk (10) or spacer from brake assembly.

(2) Fully retract pistons and apply 80 psi (5,52 bars) hydraulic pressure.

(3) After the piston has advanced the amount permitted by the built-in clearance, hold this pressure for 15 seconds. If the required hydraulic pressure is held and there is no further movement of the piston, the pin grip holding force is satisfactory.

NOTE: If pin slippage occurs, the brake shall be rejected and the pin and grip combination replaced.

(4) Reinstall disk (10) or spacer in brake assembly between linings.

E. Apply 770 psi (53,1 bars) pressure and then release brake checking for proper brake release. Repeat three times. The disk (10) should be free to rotate when the brake pressure is released. The hyraulic back pressure should not be greater than 40 psi (2,76 bars).

F. Apply 770 psi (53,1 bars) pressure and release pressure to 40 psi (2,76 bars); then check brake clearance. The brake clearance measured between the lining (20, 20A, 20B, 20C or 20D) and disk (10) should be 0.028 to 0.050 inch (0,71 to 1,27 mm). The hydraulic back pressure should not be greater than 40 psi (2,76 bars).

4. Fault Isolation

A. Fault isolate in accordance with Figure 102.

Trouble	Probable Cause	Correction
Hydraulic fluid leaking from brake	Defective hydraulic connection	Tighten connection or replace fitting.
	Defective preformed packing	Replace preformed packing.
	Piston or cylinder head worn or damaged	Replace piston and/or housing.
Brake not engaging correctly	Air in brake	Bleed brake.
	Brake lining worn out	Overhaul brake.
	Obstruction in hydraulic line or fluid passage	Remove obstruction.
	Pistons sticking	Replace piston O-ring packings.
	Pistons damaged	Replace pistons.
	Cylinder head damaged	Replace cylinder head or brake housing.
	Disk gear defective and disk not moving freely in wheel when brake pressure is released	Replace disk.
Brake not releasing correctly	Obstruction in hydraulic line or fluid passage	Remove obstruction.
	Piston sticking	Replace piston preformed packings.
	Pistons damaged	Replace pistons.
	Cylinder head damaged	Replace cylinder head or brake housing.

Fault Isolation Chart
Figure 102

DISASSEMBLY

1. General (Ref. IPL Fig. 1)

NOTE: See TESTING AND FAULT ISOLATION for operational and test and fault isolation procedures to establish condition of unit and determine extent of disassembly required.

A. Prior to dismounting and disassembling brake, check lining for wear in accordance with the DESCRIPTION AND OPERATION section.

B. Disassemble the brake assembly in accordance with the following instructions.

2. Disassembly Procedures

A. Position brake assembly on a clean work surface.

B. Remove brake disk (10) from brake.

C. Remove brake linings (20B, 20C or 20D).

(1) If it is necessary to reuse linings, the linings should be replaced in the same position.

D. Cut and remove lockwire from self-adjusting pin nuts (30). Remove self-adjusting pin nuts (30).

E. Using a spanner wrench or Cylinder Head Wrench Adapter 43193, remove cylinder heads (60 or 60A).

F. Remove self-adjusting pin grips (40) and steel washers (50).

G. Remove hydraulic preformed packing (70A) and hydraulic preformed packings (80A) from groove in cylinder heads.

H. Remove piston units from brake housing (250).

I. Remove hydraulic preformed packings (90A) from pistons (150 or 150B).

J. Place piston units in arbor press and remove self-adjusting return mechanism as follows:

(1) Fabricate a tool from steel tubing to clear self-adjusting pin (140) and to clear the inside diameter of retaining ring (100).

(2) Place tool over self-adjusting pin (140) and against spring guide (110). Apply pressure to tool with an arbor press until spring force is removed from the retaining ring (100) and hold.

(3) Remove retaining rings (100) with Tru-Arc (or equivalent) pliers.

(4) Carefully release arbor press and remove spring guides (110), brake release springs (120 and 130), and self-adjusting pins (140) from pistons (150).

K. Remove shipping plug (160), if installed, and preformed packing (170).

L. Remove screw thread insert (180) and preformed packing (190) from brake housing (250 or 250A).

M. Complete the disassembly by removing bleeder screw (200), bleeder washer (210), bleeder valve (220), bleeder valve adapter (230) and preformed packing (240).

CLEANING

1. Cleaning Materials

NOTE: Equivalent substitutes may be used for items listed below.

Dry-Cleaning Solution Specification P-D-680 Type I, Stoddard Solvent Type II, 140°F Solvent	Commercially available
Isopropyl Alcohol Specification TT-I-735	Commercially available
Soft Lint-free Cloth	Commercially available
Soft Bristle Brush	Commercially available
Polyplus Plastic Media Screen Size 20/40 (Primary)	Inventive Machine Corporation (I.M.C.) P.O. Box 369 Bolivar, OH 44612
Plastic Reclaimable Abrasive Machine (PRAM)	See SPECIAL TOOLS, FIXTURES AND EQUIPMENT section.
Plastic Media (Dry Stripping Abrasive)	U.S. Technology Corporation A Subsidiary of U.S. Plastic and Chemical Corporation 328 Kennedy Drive Putnam, CT 06260
Paint Removing Solvent (Alternate) Specification MIL-C-19853	Turco Products Division of Purex Corporation 24600 South Main Street P.O. Box 6200 Carson, CA 90749

2. Cleaning Procedures (Ref. IPL Fig. 1)

WARNING: CLEANING SOLVENTS ARE TOXIC AND VOLATILE. USE ONLY IN WELL-VENTILATED AREAS. AVOID PHYSICAL CONTACT WITH SOLVENT AND DO NOT INHALE VAPORS.

CAUTION: A THOROUGH CLEANING OR IMMERSION OF BRAKES MAY CAUSE ENTRAPMENT OF SOLVENT IN PASSAGE HOLES.

A. Clean all metal parts with dry-cleaning solvent, Specification P-D-680. Use a soft bristle brush when necessary.

B. Dry all metal parts thoroughly after cleaning, using filtered and dried compressed air.

NOTE: Ensure foreign materials have been removed from all cavities, threaded holes, pockets and other areas where entrapment might occur.

C. Clean all preformed and O-ring packings or gaskets with isopropyl alcohol, Specification TT-I-735. Dry with a clean, soft cloth.

NOTE: It is recommended new preformed and O-ring packings or gaskets be installed at each brake overhaul.

D. Brake disks (10) may be cleaned with the aid of compressed air and a soft wire or bristle brush.

E. Clean brake linings (20B or 20C) by brushing with a soft bristle brush.

3. Paint Removal Procedures

A. Strip brake housing as follows - Method 1 (Dry Stripping):

WARNING: THE DRY STRIPPING PROCESS IS OPERATOR-SENSITIVE AND ONLY AN EXPERIENCED, TRAINED OPERATOR SHOULD BE PERMITTED TO PERFORM THE PAINT REMOVAL OPERATION IN ACCORDANCE WITH EQUIPMENT MANUFACTURER'S RECOMMENDATIONS.

NOTE: This procedure covers general information of dry stripping process of pneumatic blast removal of paint utrilizing ground plastic particles. The procedure provides suggested control parameters to safely and effectively remove paint from aircraft component parts using the dry stripping process.

Paint must be stripped from parts before inspecting by Zyglo, dye penetrant or eddy-current methods; otherwise, inaccurate readings will result.

(1) Completely disassemble the part to be stripped. Remove all parts from brake housing in accordance with DISASSEMBLY.

(2) Clean the part to be stripped per Cleaning Procedures.

(3) Plug and seal off any threaded holes and piston cavities as required.

(4) Remove paint using the dry stripping procedure in accordance with Figure 401 as follows:

(a) The media dry stripping abrasive is effective only when used with the appropriate equipment. Depending on operator requirements, it is advised that the operator check with these (or other suitable) manufacturers for advice and application information concerning their particular equipment.

(b) Refer to Cleaning Materials for recommended dry stripping abrasive and equipment.

CAUTION: FLUSH MEDIA FROM CAVITIES, THREADED HOLES, POCKETS AND OTHER AREAS WHERE ENTRAPMENT MIGHT OCCUR.

(5) Remove part from solvent and rinse thoroughly, two times, with water heated to a temperature of 160° to 180°F (71° to 82°C).

(6) Dry the part thoroughly with filtered and dried compressed air.

NOTE: After paint stripping, the parts must be re-treated and repainted in accordance with instructions in REPAIR.

B. Strip brake housing as follows - Method II (Wet Stripping):

WARNING: PAINT REMOVAL SOLVENTS ARE TOXIC AND VOLATILE. USE ONLY IN WELL-VENTILATED AREAS. AVOID PHYSICAL CONTACT WITH SOLVENT AND DO NOT INHALE VAPORS.

NOTE: Paint must be stripped from brake assembly before inspecting by Zyglo, dye penetant or eddy-current methods; otherwise, inaccurate readings will result.

(1) Completely disassemble the part to be cleaned to prevent solvent from being entrapped between mating surfaces. Remove all parts from brake housing in accordance with DISASSEMBLY.

(2) Clean the part to be stripped in accordance with Cleaning Procedures.

CAUTION: PARTS MUST BE COMPLETELY IMMERSED IN SOLVENT. CONTACT WITH WATER BLANKET DURING IMMERSION WILL CAUSE SEVERE CORROSION OF THE PART.

(3) Immerse part in paint removing solvent, Specification MIL-C-19853, for a period of 30 minutes to two hours. Immersion time depends upon condition of paint. Carefully follow the manufacturer's instructions for the particular solvent being used.

NOZZLE TYPE/SIZE	NOZZLE PRESSURE	NOZZLE DISTANCE	MEDIA TYPE	ANGLE OF APPROACH
1, 4 BMLV-8 1/2 inch (12,7 mm)	45 - 55 PSI (3,10-3,79 bars) 3	36 - 48 inch (914-1219 mm)	POLYPLUS 20/40	45 - 75°
2, 4 VENTURI 5/16 inch (7,94 mm)	UNDER 30 PSI (2,07 bars) 3	6 - 8 inch (152,4-203,2 mm)	POLYPLUS 20/40	45 - 75°

PHYSICAL REQUIREMENTS OF MEDIA

	POLYEXTRA	POLYPLUS
HARDNESS (MOH SCALE)	3.0 ± .25	3.5 ± .25
SPECIFIC GRAVITY (GMS/CC)	1.15 ± 10%	1.50 ± 10%

NOTES:

1. STAND-OFF, OPEN BLASTING.
2. CLOSED-CYCLE BLASTING (PERFORMED IN PRESSURE BLAST EQUIPMENT CHAMBER).
3. PRESSURE READINGS MUST BE TAKEN AT THE NOZZLE RATHER THAN ESTIMATED FROM REGULATOR GAGE READINGS. RECHECK PRESSURE EVERY FOUR HOURS AND EACH TIME PRESSURE IS CHANGED AT REGULATOR.
4. PROCESS VARIABLES INCLUDE PRESSURE, DISTANCE FROM NOZZLE TO WORK PIECE, ANGLE OF ATTACK AND NOZZLE SIZE. PARAMETERS SELECTED WILL VARY WITH PAINT COATING AGE, TYPE AND NUMBER OF COATINGS, BUT THE FOLLOWING PARAMETERS HAVE SUCCESSFULLY REMOVED VARIOUS COATING TYPES WITH NO EFFECT ON SUBSTRATE.
5. RECOMMENDED PLASTIC MEDIA TYPE AND SIZE IS POLYPLUS 20/40. POLYEXTRA 12/20 OR 20/30 PRODUCES A SMOOTHER FINISH BUT PAINT REMOVAL RATE IS LOWER. TYPE III PLASTIC MEDIA TYPE IS NOT TO BE USED ON THE SUBJECT AIRCRAFT COMPONENTS.

Recommended Dry Stripping Variables
Figure 401

CAUTION: FLUSH SOLVENT FROM CAVITIES, THREADED HOLES, POCKETS AND OTHER AREAS WHERE ENTRAPMENT MIGHT OCCUR.

(4) Remove part from solvent and rinse thoroughly in water heated to a temperature of 160° to 180°F (71° to 82°C).

(5) Dry the part thoroughly with filtered and dried compressed air.

NOTE: After paint stripping, the part must be re-treated and repainted in accordance with instructions in REPAIR.

CHECK

1. Check Materials

NOTE: Equivalent substitutes may be used for items listed below.

Type	Penetrant	Developer	Supplier
Fluorescent	Zyglo ZL-16	Zyglo ZP-13 (wet) optional	Magnaflux Corporation 7310 West Lawrence Street Chicago, IL 60656
	Penetrex ZL-2A with emulsifier ZE-4	Penetrex ZP-4 (dry) or ZP-13 optional	
Red Dye	Spot Check	Spot Check	
	Dy-Chek	Dy-Chek	Turco Products Division of Purex Corporation P.O. Box 6200 Carson, CA 90749
	Met-L-Chek	Met-L-Chek	Met-L-Chek 1639 Euclid Street Santa Monica, CA 90404

2. General (Ref. IPL Fig. 1)

A. Check all components of the brake assembly for wear, cracks, corrosion, structural damage, distortion and thread damage. Replace all parts that show evidence of cracks, excessive wear, severe corrosion, and structural and thread damage. Repair minor scratches and corrosion.

B. Perform the specific checks listed referring to REPAIR for appropriate repair procedures.

3. Brake Disk (10)

A. Check brake disk (10) as follows:

(1) Measure thickness of disk. Disks that have worn to a thickness of 0.360 inch (9,14 mm) or less must be replaced.

(2) Check disk for warpage. Disks that have warped or dished to the extent they cause brake drag can be surface ground and reused if they exceed the minimum thickness of 0.360 inch (9,14 mm) after grinding.

NOTE: It is recommended the disk be reversed in the brake housing at each tire change to minimize dishing.

(3) Replace disks which have shrunk to an outside diameter of 13.025 inches (330,83 mm).

(4) Disks containing heat checks of less than 1.25 inches (31,75 mm) in length that do not extend to within 0.25 inch (6,35 mm) of the inside or outside diameter edge can be continued in service. Check disks with such heat checks at time of each lining change.

4. Brake Lining (20C or 20D)

CAUTION: NEVER MIX NEW AND USED BRAKE LININGS. IF NECESSARY TO REUSE WORN LININGS, INSTALL THEM IN THEIR ORIGINAL POSITION.

A. Measure thickness of brake linings (20C or 20D) at center of lining. Replace linings if worn to a thickness of 0.195 inch (4,95 mm) or less. Always replace both piston and anvil linings.

B. Replace linings when the lining cup is found to be deformed and out of round.

NOTE: The lining cup is designed to wear away with lining.

5. Self-Adjusting Pin Nut (30)

A. Check self-adjusting pin nut (30) for stripped threads or other damage and distortion. Replace defective parts.

6. Self-Adjusting Pin Grip (40) and Steel Washer (50)

A. Check for damage and distortion. Replace any defective parts.

7. Cylinder Head (60)

A. Check cylinder heads for stripped threads or other damage. Replace if damaged.

8. O-Ring Gasket (70), O-Ring Packing (80, 90) and Preformed Packing (70A, 80A, 90A, 170, 190 and 240)

A. Check O-ring gasket, O-ring packing and preformed packings for distortion and wear. It is recommended all gaskets and packings be replaced at each overhaul.

9. Retaining Ring (100) and Spring Guide (110)

A. Check retaining ring and spring guide for structural damage, corrosion and distortion. Replace any defective parts.

10. Brake Release Spring (120 and 130)

A. Check brake release springs as follows:

(1) Measure force required to compress springs.

(2) Replace brake release spring (120) when compression force is less than 60 pounds (267 N) at a height of 0.538 inch (13,66 mm).

(3) Replace brake release spring (130) when compression force is less than 115 pounds (512 N) at a height of 0.538 inch (13,66 mm).

11. Self-Adjusting Pin (140)

A. Check self-adjusting pins (140) for nicks, rough spots, distortion or damage which might injure O-ring packing. Depressions of 0.003 inch (0,076 mm) or less are acceptable. However, raised metal from such nicks should be removed by polishing. If grip holding surfaces of pins are tapered or reduced in diameter, more than 0.0005 inch (0,013 mm) in the operating length, the pins should be replaced.

B. If grip holding surfaces of pins are reduced in diameter in the operating length to 0.245 inch (6,22 mm) or less, the pins should be replaced.

12. Piston (150, 150A, 150B or 150C)

A. Check contacting surfaces of pistons (150, 150A, 150B or 150C) for wear or scratches which might injure preformed packing and cause leaks. Measure piston diameter at three different places. If piston (150 or150B) is worn to a diameter of 2.112 inches (53,64 mm) or less, replace piston. If piston (150A or 150C) is worn to a diameter of 2.161 inches (54,89 mm) or less, replace piston.

13. Protective Plug (160) and Threaded Insert (180)

A. Check protective plug and threaded insert for stripped threads or other damage. Replace if damaged.

14. Bleeder Valve (220) and Bleeder Valve Adapter (230)

A. Check bleeder valve and valve adapter for stripped threads or other damage. Replace defective parts.

15. Brake Housing (250 or 250A)

A. Check brake housing for cracks using a dye-penetrant method. Replace housing if cracked.

NOTE: Pay particular attention to housing throat section.

B. Visually check housing for corrosion and scratches. Blend out minor corrosion and scratches. See REPAIR.

C. Check cylinder wall for damage to threads and packing seat. See REPAIR.

D. Check lining recesses in the anvil section of the brake housing for wear and damage. See REPAIR.

E. Check lining retainer (252) and rivet (251) for security of attachment and damage. See REPAIR.

16. Disk Guide Lining (280 and 320)

A. Check disk guide linings for wear. Replace disk guide lining (280 and 320) when thickness reaches 0.205 inch (5,21 mm) or less. New linings 0.375 inch (9,53 mm) thick should be ground down to 0.325 +0.002, -0.003 inch (8,25 +0.051, -0,076 mm) thick as shown in REPAIR.

17. Disk Guide Bracket (290 and 330)

A. Check disk guide bracket for distortion or damage. Replace damaged parts.

REPAIR

1. Repair Materials

NOTE: Equivalent substitutes may be used for items listed below.

Surface Treat Solution Specification MIL-M-3171, Type VI	Commercially available
Methyl Isobutyl Ketone (MIBK) Specification TT-M-268	Commercially available
Zinc Chromate Primer Specification TT-P-1757	Commercially available
Aluminum Lacquer Specification TT-L-32	Commercially available
Aluminum Topcoat/Primer Combination (FA-10242) Aeroprite	Contact your local distributor of aviation products and supplies.
Aeroprite Reducer TH-89	Contract your local distributor of aviation products and supplies.
Aluminum Oxide Cloth (340 to 400 grit, wet or dry)	Commercially available
Steel Bar No. 1117 Specification QQ-S-633	Commercially available
Cadmium Plating Specification QQ-P-416, Type II, Class 3	Commercially available
Wash Primer Specification MIL-C-8514	Commercially available
Butyl Alcohol Thinner Specification TT-B-846	Commercially available
Ethyl Alcohol Thinner Specification O-E-760, Type III	Commercially available

2. General (Ref. IPL Fig. 1)

A. Repair of the brake assembly is limited to the replacement of worn or damaged parts and to the specific repairs listed in this section. Replace all cracked parts. No attempt should be made to repair cracked, severely corroded or badly damaged parts. Components that cannot be repaired within the limits defined in this section should be replaced.

3. Repair of Brake Housing (250)

CAUTION: REMOVAL OF CORROSION AND SURFACE DAMAGE WILL PREVENT STRESS CONCENTRATIONS. HOWEVER, ANY REMOVAL OF MATERIAL WILL SHORTEN THE LIFE OF THE BRAKE HOUSING. THEREFORE, IT IS RECOMMENDED THAT MATERIAL REMOVED BY BLENDING BE LIMITED TO THE MINIMUM REQUIRED FOR REMOVING CORROSION OR SURFACE DAMAGE.

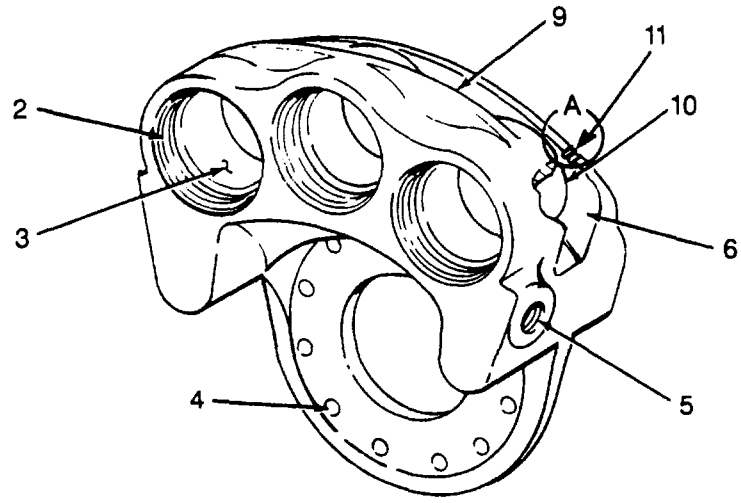
A. Remove corrosion, scratches, nicks and abrasions with aluminum oxide cloth. Remove all corrosion and surface damage on the brake housing according to limits defined in Figure 601. Blend out any damage that might become a source of corrosion or stress cracks. Remove any corrosion from threads with a soft wire brush.

NOTE: Since removal of metal in areas 1, 2, 3 and 7 can shorten the ultimate life of the part, it is recommended that removal in these areas be kept to a minimum.

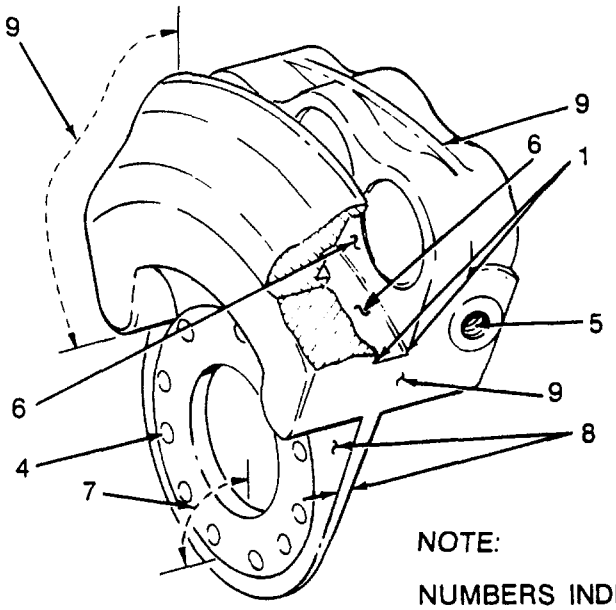
B. Thoroughly clean surface. Treat and repaint reworked areas of housing in accordance with Re-Treating and Repainting.

C. If piston cavity is worn or damage exists beyond the 2.136 inch (54,25 mm) inside diameter, repair piston cavity in accordance with Repair No. 1 - Repair of Piston Cavity for Oversize Piston.

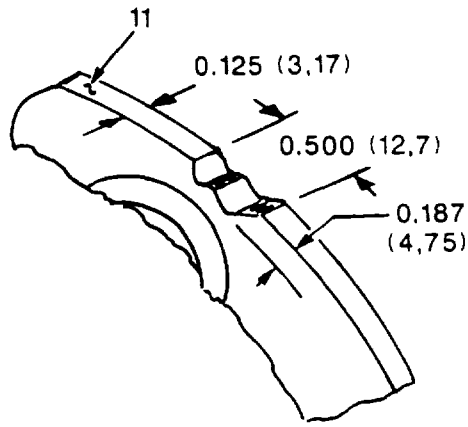
D. If lining recess is worn or damage exceeds limits as shown in Figure 602, repair lining recess in accordance with Repair No. 2 - Repair of Lining Recesses.



E. If mounting bolt holes have conical surface cracks, material distortion or other damage, repair in accordance with Repair No. 3 - Repair of Mounting Bolt Holes.



F. If linings are loose on the anvil side of brake housing, repair in accordance with Repair No. 4 - Repair of Brake Housing for Anvil Lining Retention Repair.

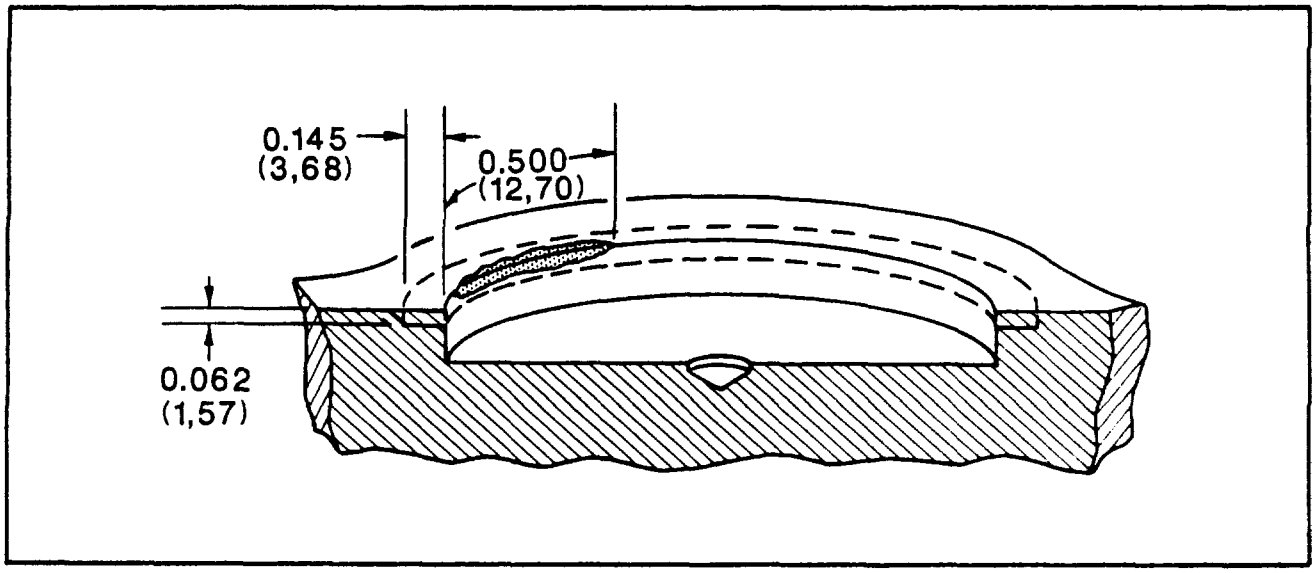


G. At operator's option, the piston cavity may be machined to accept a wiper ring. Repair in accordance with Repair No. 5 - Repair of Brake Housing for Machining Wiper Ring Groove.

H. To eliminate interference between brake disk and magnesium housing during disk installation and removal while brake is on aircraft, repair in accordance with Rework No. 6 - Rework of Brake Housing 9550376 for Removal of Excess Material.

I. If lining retainer on aluminum Pistons 5009128 or 5009408 is damaged, repair in accordance with Repair No. 7 - Repair of Piston Lining Retainer.

DETAIL A



NOTE:

NUMBERS INDICATE INSPECTION AND REWORK AREAS.

Rework Areas for Brake Housing
Figure 601

Key to Figure 601

General:	Repairs are limited in each marked area to the following limits. The material removed by blending is limited to the minimum required for removing corrosion or surface damage. Except where restricted by length or locale when damage depth is less than 0.015 inch (0,381 mm) deep, all blend type repairs should be blended with a depth to width ratio of 1 to 100 in surface width. Where not possible, use as generous a width to depth ratio as practical with the area being repaired.
Area 1:	Carefully check by Zyglo, dye-penetrant or other methods suitable for use with cast magnesium. Replace cracked housings. Grooves or scratches to 0.010 inch (0,254 mm) maximum deep in throat area of brake should be blended and polished out with 340 grit, aluminum oxide cloth.
Area 2:	Check cylinder head cavity threads for damage. If threads are worn or badly damaged, remove brake housing from service.
Area 3:	Polish out minor scratches and/or pits with 360 grit, aluminum oxide cloth. Do not polish beyond 2.136 inches (54,25 mm) inside diameter at any location in the piston cavity.
Area 4:	Rework holes as required to 0.015 inch (0,381 mm) maximum oversize. Do not exceed 0.345 inch (8,767 mm) diameter. Round off sharp edges.
Area 5:	Clean and remove housing and replace if threads are stripped or badly damaged.
Area 6:	Blend out and polish imperfections up to 0.03 inch (0,762 mm) deep. Maximum blending of reworked area limited to 0.50 square inch (12,70 sq. mm).
Area 7:	Blend out imperfections up to 0.03 inch (0,762 mm) deep. In area covered by mounting bolt washers, blend out nicks or scratches up to 0.010 inch (0,254 mm) deep. Maximum blending of reworked area limited to 0.50 square inch (12,70 sq. mm).
Area 8:	Blend out and polish imperfections up to 0.03 inch (0,762 mm) deep. Do not blend opposite surfaces. Maximum blending of reworked area limited to 0.50 square inch (12,70 mm).
Area 9:	Blend out imperfections up to 0.03 inch (0,762 mm) deep. Maximum blending of reworked area limited to 0.50 square inch (12,70 sq. mm).
Area 10:	Blend out imperfections up to 0.062 inch (1,575 mm) deep, 0.145 inch (3,687 mm) wide and 0.500 inch (12,700 mm) long on edge of lining recess as shown in Figure 602. One repair to above limits is permissible per recess.
Area 11:	Blend to remove all sharp edges if damage occurs to the outer radius of the housing anvil. The repair of this damaged or chipped area is limited to a maximum area 0.50 inch (12,70 mm) long by 0.187 inch (4,648 mm) wide by 0.125 inch (3,175 mm) deep (recess bore depth). Replace brake housing if damage has occurred beyond this limit. When lining recess repair is made, the damaged or chipped area at the anvil outer edge may be blended to the insert ring.

Lining Recess Edge Repair Limits
Figure 602

4. Repair of Self-Adjusting Pin (140)

   A. Repair damaged self-adjusting pins as follows:

      (1) Self-adjusting pins with small nicks or imperfections on the seal contacting surfaces of 0.003 inch (0,076 mm) or less in depth are acceptable; however, raised metal from such nicks should be removed by polishing with 400 grit, aluminum oxide cloth.

      (2) If grip holding surfaces of pins are tapered more than 0.0005 inch (0,013 mm), the pins should be replaced.

      (3) Measure diameter of pins at grip holding surface. If diameter is less than 0.245 inch (6,22 mm), replace pins.

5. Replacing Disk Guide Lining

   A. Using a 5/32 (0.156) inch drill, drill out shop head of rivet (270 and 310).

   B. Remove rivet from disk guide bracket (290 and 330) being careful to avoid enlarging the rivet hole.

   C. Grind new disk guide linings (270 or 320) if they are 0.375 inch (9,58 mm) thick to 0.325, +0.002, - 0.008 inch (8,26 + 0,051, -0,203 mm) thick as shown in Figure 603.

   D. Insert new rivet (270 or 310) through lining (280 or 320) and disk guide bracket (320) and form shop head of rivet against disk guide.

   E. Shop head of rivet must have an outside diameter of 80 percent (minimum) of the outside diameter of the manufactured head. Disk guide lining is to be tight under finger pressure.

Disk Guide Lining Rework
Figure 603

6. Re-Treating and Repainting

A. Repaired areas of brake housing and those having paint and treated finish removed, should be re-treated and repainted in accordance with following procedures:

B. Re-Treating

WARNING: CLEANING SOLVENTS ARE TOXIC AND VOLATILE. USE ONLY IN WELL-VENTILATED AREAS. AVOID PHYSICAL CONTACT WITH SOLVENT AND DO NOT INHALE VAPORS.

(1) Thoroughly clean surface to be re-treated and repainted. Clean with hot water or methyl isobutyl ketone, Specification TT-M-268, and dry thoroughly with compressed air.

(2) Re-treat all exposed magnesium surfaces with surface treat solution conforming to Specification MIL-M-3171 in accordance with the manufacturer's instructions. Refer to Repair Materials for recommended solution.

(3) Re-treat all exposed aluminum surfaces with chemical film solution, Specification MIL-C-5541, in accordance with the manufacturer's instructions. Refer to Repair Materials for recommended solution.

C. Repair and touchup painting should be performed as follows:

(1) The part or area requiring touchup painting must be thoroughly clean and free of all contaminants.

(2) Prepare area to be painted (scratches, nicks, chipped paint, etc) by sanding lightly to feather out all edges of adjacent finish, using 320 to 360 grit, wet-or-dry aluminum oxide cloth. Wet sanding is preferred. Avoid removing more primer than absolutely necessary from damaged area.

WARNING: CLEANING SOLVENTS ARE TOXIC AND VOLATILE. USE ONLY IN WELL-VENTILATED AREAS. AVOID PHYSICAL CONTACT WITH SOLVENT AND DO NOT INHALE VAPORS.

(3) Wipe repaired surface with a cloth moistened with methyl isobutyl ketone, Specification TT-M-268, and wipe surface dry with clean cheesecloth. If chemical film solution has been removed, re-treat as required.

CAUTION: IF BARE METAL IS EXPOSED BY SANDING, IT MUST BE RE-TREATED BEFORE APPLYING WASH PRIMER.

(4) Starting with the last intact paint layer, reapply paint coats in accordance with repainting.

NOTE: *The gloss must be removed in the area to be touched up with an* abrasive material, the defective area smoothed and edges feathered. The area must then be cleaned removing all loose and foreign material.

D. Repaint brake housing as follows:

WARNING: CLEANING SOLVENTS ARE TOXIC AND VOLATILE. USE ONLY IN WELL-VENTILATED AREAS. AVOID PHYSICAL CONTACT WITH SOLVENT AND DO NOT INHALE VAPORS.

(1) *Thoroughly clean all surfaces to be treated and/or painted.* Housing subassembly should be vapor degreased or washed with methyl isobutyl ketone, Specification TT-M-268.

(2) Treat all magnesium surfaces of brake subassemblies with chemical film solution conforming to Specification MIL-M-3171, in accordance with manufacturer's instructions. Refer to Repair Materials for recommended solution.

(3) Re-treat all exposed aluminum surfaces with chemical film solution, Specification MIL-C-5541, in accordance with the manufacturer's instructions. Refer to Repair Materials for recommended solution.

CAUTION: DO NOT PAINT INTERIOR OF PISTON CAVITIES, INLET OR BLEEDER OPENINGS.

(4) Mask all threaded holes and hydraulic cavities to avoid getting paint on these surfaces.

E. For magnesium parts only, repaint reworked and treated areas with one coat of wash primer as follows:

(1) Wash primer is supplied in two separate containers; one contains the base primer, the other the acid component. Both must be thoroughly mixed before use.

(2) Mix wash primer, Specification MIL-C-8514 as follows:

(a) The resin component should be well stirred to redisperse any settled pigment. Then add the acid component slowly to the resin while stirring; never add in reverse order. One volume of acid component is always used with four volumes of the resin. Add the water to the alcohol (ethyl), do not reverse this admix procedure. Mix and stir well. Add only enough of the water alcohol mix to the resin mix to reduce the specific gravity to a range of 0.885 to 0.915.

NOTE: If either of the admix procedures are reversed, scrap the material and start over.

(b) Formula to be used when humidity is below 90 percent:

16 ounces (453,6 grams) resin component
4 ounces (113,4 grams) acid component
12 ounces (340,2 grams) ethyl alcohol, Specification O-E-760, Type III
1/2 ounce (14,18 grams) distilled water

Batch life under four hours

(c) Formula to be used when humidity is above 90 percent:

16 ounces (453,6 grams) resin component
4 ounces (113,4 grams) acid component
9 ounces (255,15 grams) ethyl alcohol, Specification O-E-760, Type III
3 ounces (85,05 grams) butyl alcohol, Specification TT-B-846
1/2 ounce (14,18 grams) distilled water

Batch life under two hours

Specific gravity range 0.885 to 0.915.

(3) Application

NOTE: All surfaces should have received anodic or chemical treatment. All surfaces must be clean of all contaminantes by degreasing and/or solvent washing prior to applying the wash primer.

(a) Apply a single wet coat of wash primer to a dry film thickness of approximately 0.0002 to 0.0003 inch (0,005 to 0,007 mm). Do not attempt to obtain a full hiding coat. If such a coating is produced, it should be immediately removed with alcohol and replaced with a properly applied coating.

(b) Air dry one hour minimum to four hours maximum. Subsequent topcoats should be applied as soon as practical after the minimum drying time but no later than four hours after the application of the wash primer. If subsequent primer coats are not applied within the specified time, the parts should be stripped and recoated with wash primer.

F. *Method I (Primary) - Repaint brake housing with two coats of aluminum* topcoat/primer combination as follows:

(1) Surface Preparation

(a) Parts must be clean and have received the surface treatment required. Magnesium parts must have one coat of wash primer before the application of paint.

(2) Mixing

(a) Mix the aluminum topcoat/primer combination until a viscosity of approximately 25 seconds in a No. 2 Zahn cup is obtained.

NOTE: Aluminum topcoat/primer combination should be at the proper viscosity. If required, thinning can be accomplished using *Aeroprite Reducer TH-89.*

(3) Application

(a) Spray one full wet cross coat to a dry film thickness of approximately 0.0004 to 0.0006 inch (0,010 to 0,015 mm).

(b) Air dry for a minimum of 45 minutes before applying a second coat.

(c) Spray a second full cross coat to a dry film thickness of approximately 0.0004 to 0.0006 inch (0,010 to 0,015 mm).

(d) Air dry 45 minutes before handling. Paint will reach full cure in 72 hours.

G. Method II (Alternate) - Repaint brake housing with two coats of zinc chromate primer and two coats of aluminum lacquer as follows:

(1) Surface Preparation

(a) Parts must be clean and have received the surface treatment required and one coat of wash primer before the application of paint.

(2) Apply two coats of zinc chromate primer, Specification TT-P-1757.

NOTE: Do not exceed the recommended thickness for the applied topcoats. If the humidity should drop below 20 percent, primer application should be stopped until steps are taken to raise the percent humidity.

(a) Apply one coat of primer to obtain a dry film thickness of 0.0003 to 0.0004 inch (0,00762 to 0,0102 mm).

(b) After a minimum flash off period of five minutes, apply second coat of primer to obtain a total dry film thickness of 0.0006 to 0.0008 inch (0,015 to 0,020 mm).

(c) Allow the primed surface to dry a minimum of two hours and a maximum of 12 hours before topcoating with aluminum lacquer, Specification TT-L-32.

(3) Apply two coats of aluminum lacquer, Specification TT-L-32.

(a) Spray one full wet cross coat to a dry film thickness of approximately 0.0004 to 0.0006 inch (0,010 to 0,015 mm) over the primer coating.

(b) After a minimum flash off period of five minutes, apply second coat of aluminum lacquer to obtain a total thickness of 0.0008 to 0.0012 inch (0,020 to 0,030 mm).

(c) Air dry 45 minutes before handling. Paint will reach full cure in 24 hours.

7. Modification and/or Rework Brake Assembly 9550377 to Brake Assembly 9550377-1

A. At operator's option, Asbestos Linings 9523331 or Alternate Asbestos Linings 9534896 may be replaced with Asbestos-Free Linings 9523331-1 as follows:

NOTE: Asbestos linings are no longer manufactured. The new asbestos-free linings will be readily identified by their white color.

(1) At the next brake overhaul or next lining replacement, replace Linings 9523331 or 9534896 with Asbestos-free Linings 9523331-1.

(a) Operators are advised that old asbestos linings may be used until stock depletion. The new asbestos-free linings are to be used as a set, they are not to be mixed with the old linings in any one assembly.

(2) Reidentify Brake Assembly 9550377, by metal stamping a "-1" after brake assembly number in 0.12 inch (3,05 mm) characters to read 9550377-1.

NOTE: Where necessary, the part should be suitably supported for stamping.

(3) Metal stamp repair number "5R85-078" in 0.09 inch (2,3 mm) characters adjacent to the assembly number.

NOTE: Where necessary, the part should be suitably supported for stamping.

(4) Re-treat and repaint any displaced metal in accordance with Re-Treating and Repainting.

8. Modification and/or Rework of Brake Assembly 9550377-1 to Brake Assembly 9550377-4

A. At operator's option, Asbetos-Free Linings 9523331-1 may be replaced with new, improved Asbestos-Free Linings 5008993 as follows:

NOTE: The new, improved asbestos-free linings will be readily identified by white paint and part number on the back side.

(1) At the next brake overhaul or next lining replacement, replace Linings 9523331-1 with new, improved Asbestos-free Linings 5008993.

(a) Operators are advised that Linings 9523331-1 may be used until stock depletion. The new, improved asbestos-free linings are to be used as a set, they are not to be mixed with the old linings in any one assembly.

(2) Reidentify Brake Assembly 9550377-1, by metal stamping a "-4" after brake assembly number in 0.12 inch (3,05 mm) characters to read 9550377-4.

NOTE: Where necessary, the part should be suitably supported for stamping.

(3) Metal stamp repair number "5R87-064 " in 0.09 inch (2,3 mm) characters adjacent to the assembly number.

NOTE: Where necessary, the part should be suitably supported for stamping.

(4) Re-treat and repaint any displaced metal in accordance with Re-Treating and Repainting.

9. Replacing Lining Retainer (252) or Rivet (251)

A. Use a 1/8 (0.125) inch drill to drill out rivet (251), being careful to avoid damaging housing.

B. Remove remainder of rivet (251) and lining retainer (252).

C. Install new lining retainer (252) and secure with rivet (251).

REPAIR NO. 1 - REPAIR OF PISTON CAVITY

1. General (Ref. IPL Fig. 1)

   A. This repair is used for the repair of worn or damaged piston cavities in brake housing (250 and 250A).

   B. This repair provides for machining of piston cavity for oversize pistons (150A and 150C).

   C. Use the following procedure to determine when rework is required.

      (1) Remove pistons (150 or 150B) from brake housing and remove preformed packings (90A) from pistons.

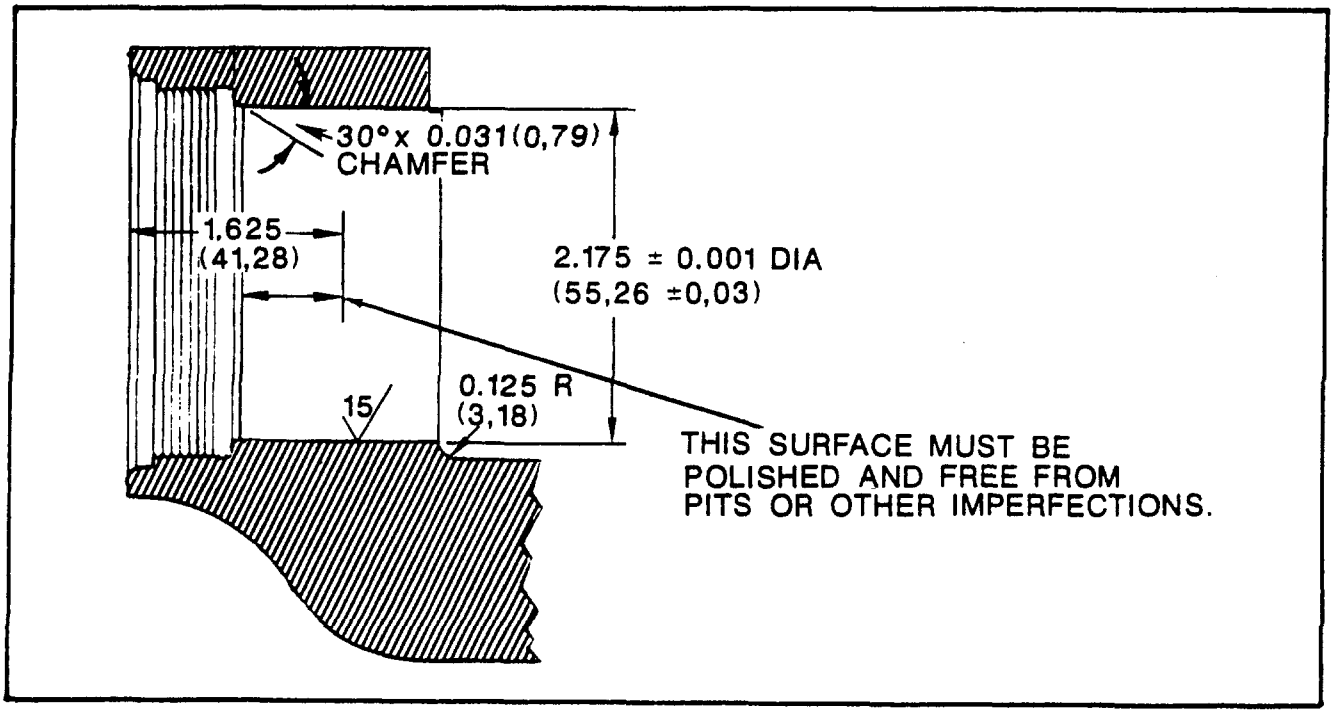
      (2) Place the pistons (150 or 150B) in the piston cavity and check the clearance between pistons and piston cavity walls with a narrow feeler gage. Check clearance at several positions around the pistons. If clearance does not exceed 0.010 inch (0,254 mm), continue unit in service.

      (3) If the clearance is more than 0.010 inch (0,254 mm), remove pistons and proceed as follows:

         (a) Measure diameter of each piston (150 or 150B) at three different places and if worn to a diameter of 2.112 inches (53,64 mm), replace the piston.

         (b) Measure inside diameter of cylinder cavity. If worn to 2.136 inches (54,24 mm) or greater, machine cylinder bore to oversize dimensions in accordance with Piston Cavity Repair.

            NOTE: If cylinder wall diameter has not reached the dimension necessary for rework, it may be possible to obtain a measurement of less than 0.010 inch (0,254 mm) between piston and piston cavity by installing a new piston. By using selective fits, additional service life can often be obtained from the brake housing before rework is required.



2. Piston Cavity Repair (Ref. Repair Fig. 601)

   A. If machining of piston bore is required, proceed as follows:

      (1) Machine cylinder bore to 2.175 ± 0.001 inches (55,26 ± 0,03 mm) diameter.

         NOTE: Concentricity with the cylinder head thread diameter must be maintained.

      (2) Working surface of the piston cavity must be polished free of pits or other imperfections. The recommended surface finish is 15 RHR.

Piston Cavity Rework for Oversize Piston
Figure 601

(3) Treat machined surface of brake housing 9550376 (250) with surface treat solution, Specification MIL-M-3171, Type VI. Treat machined surface of Brake Housing 5009126 (250A) with chemical conversion coating, Specification MIL-C-5541, Alodine 1200.

B. Metal stamp the letter "R" after the brake assembly number on the housing in 0.12 inch (3,05 mm) characters to show the assembly has been reworked for oversize pistons.

C. Use oversize Pistons 9522145 (150A) and standard Preformed Packings MS28775-327 (90A) with reworked Brake Housings 9550376 (250). Use oversize Pistons 5009128 (150B) and standard Preformed Packings MS28775-327 (90A) with reworked Brake Housings 5009126 (250A).

REPAIR NO. 2 - REPAIR OF LINING RECESS

1. General (Ref. IPL Fig. 1)

   A. This repair is used for the repair of worn or damaged lining recesses in brake housing (250 or 250A).

   B. This repair provides for machining of lining recess and installing a locally fabricated ring.

2. Lining Recess Repair (Ref. Repair Fig. 601)

   A. If damage on one side of lining recess is beyond the limits of 0.062 inch (1,57 mm) deep and 0.145 inch (3,68 mm) wide, rework as follows:

      (1) Fabricate a ring from No. 1117 steel bar (Specification QQ-S-633) as shown in Repair Figure 601. Cadmium plate (Specification QQ-P-416, Type II, Class 3) to 0.0002 inch (0,0051 mm) to maximum 0.0003 inch (0,0076 mm).

      CAUTION: MAINTAIN ORIGINAL CENTER POINT OF LINING RECESS.

      (2) Machine lining recess diameter to 2.047 +0.000,-0.001 inches (51,99 +0,000, -0,025 mm) as shown in Repair Figure 601.

      (3) Treat machined surfaces of housing (250) with surface treat solution, Specification MIL-M-3171, Type VI.

      (4) Heat brake housing in an oven to 275°F (135°C).

      (5) Apply one coat of zinc chromate primer, Specification TT-P-1757, to reworked area of housing.

      (6) Insert ring fabricated in step (1), chamfered edge first, into reworked recess of heated housing as shown in Repair Figure 601.

      NOTE: Blend any metal that extends over the edge of the housing to the original housing contour after repair of lining recess.

   B. Metal stamp repair number "5R3-167" on surface shown on Repair Figure 601 in 0.12 inch (3,05 mm) characters.

      (a) Re-Treat and repaint metal stamped areas of brake housing in accordance with Re-Treating and Repainting.

NOTES:

1. MATERIAL - 1117 STEEL BAR, SPECIFICATION QQ-S-633, CADMIUM PLATE PER QQ-P-416, TYPE II, CLASS 3 - THICKNESS OF 0.0002-0.0003 (0,0051-0,0076).
2. METAL STAMP "5R3-167" ON SURFACE SHOWN IN 0.12 (3,05) CHARACTERS.
3. INSERT RING WITH CHAMFERED EDGE INSIDE.

Lining Recess Repair
Figure 601

REPAIR NO. 3 - REPAIR OF MOUNTING BOLT HOLE

1. General (Ref. IPL Fig. 1)

   A. This repair is used for the repair of worn or damaged mounting bolt holes on brake housings (250 and 250A).

   B. This repair provides for machining of mounting bolt holes and installation of locally manufactured bushing.

2. Mounting Bolt Hole Repair (Ref. Repair Fig. 601)

   A. Housing mounting bolt holes which have conical surface cracks, show material distortion or other damage, may be repaired as follows:

      (1) Machine bushing from Steel Rod F.A.O., Type SAE 1113 or equivalent, Specification QQ-S-633, as shown in Repair Figure 601. Cadmium plate (Specification QQ-P-416, Type III, Class 3) to 0.0002 inch (0,0051 mm) to maximum 0.0003 inch (0,0076 mm).

      (2) Machine mounting bolt holes as shown in Repair Figure 601.

      (3) Treat machined surfaces of housing.

      (4) Heat brake housing in an oven to 250°F (121°C) and cool machined bushing.

      (5) Shrink fit bushing into torque flange of brake housing.

   B. Metal stamp repair number "5R2-404" on surface shown on Repair Figure 601 in 0.12 inch (3,05 mm) characters.

Mounting Bolt Hole Repair
Figure 601

REPAIR NO. 4 - REPAIR OF BRAKE HOUSING FOR ANVIL LINING RETENTION REPAIR

1. General (Ref. IPL Fig. 1)

   A. This repair is for the rework of Brake Assemblies 9550377, 9550377-1 and 9550377-4.

   B. This repair provides for the machining of the anvil side of brake housing, and brake lining to accept a fastener to improve brake lining retention.

2. Repair of Brake Housing Anvil and Lining (Ref. Repair Fig. 601)

   A. Disassemble brake assembly completely in accordance with DISASSEMBLY.

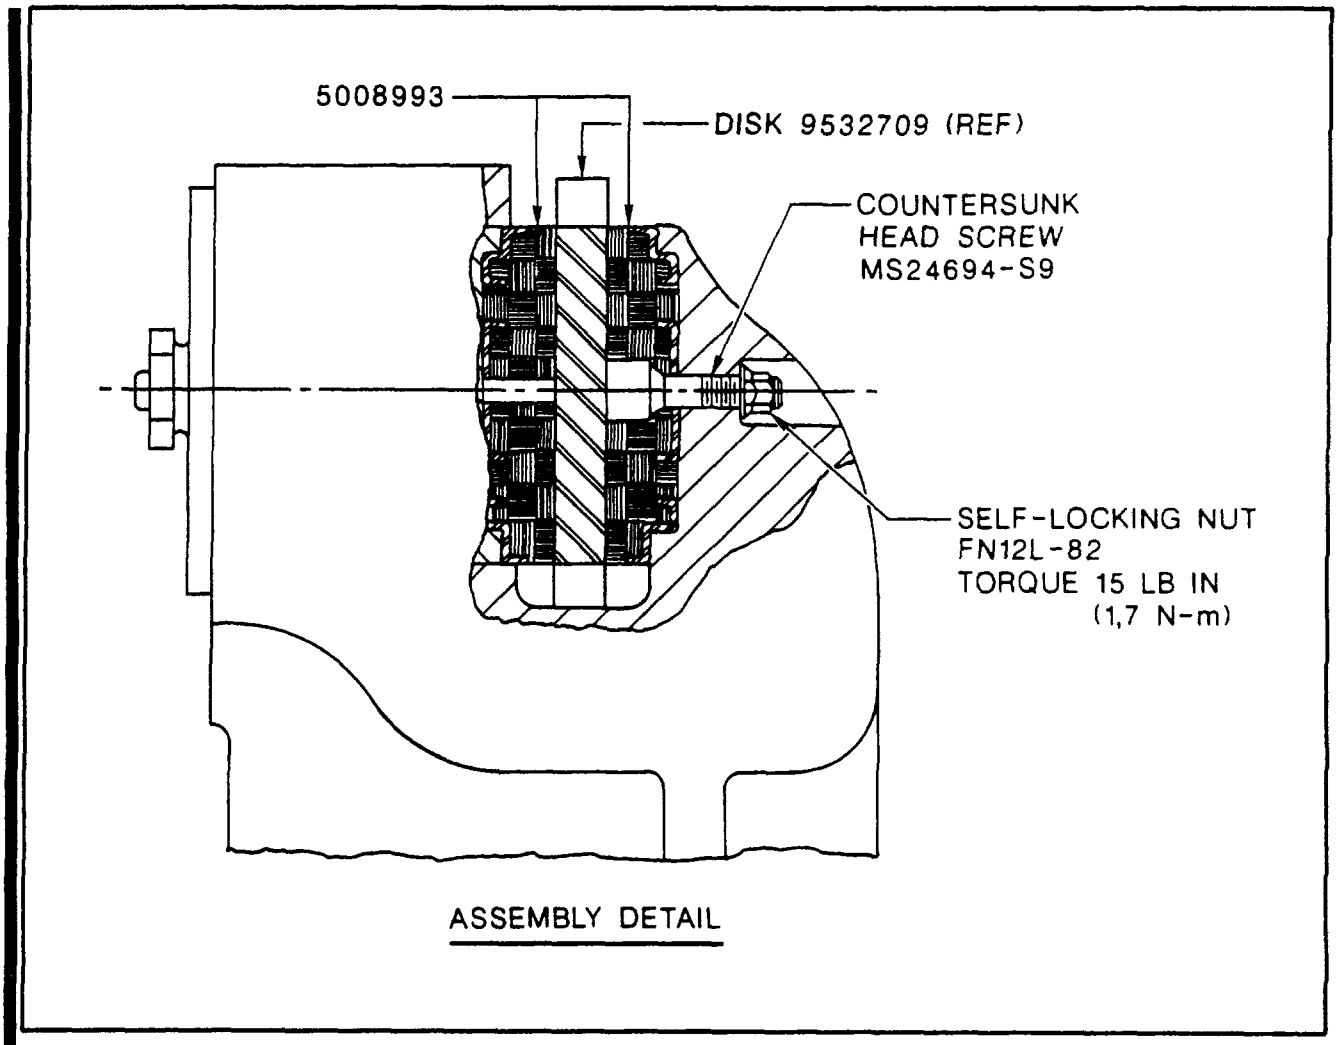
   B. Machine brake housing and brake linings in accordance with Repair Figure 601 and as follows:

      (1) Machine anvil side of brake housing to dimension shown in Repair Figure 601.

      (2) Machine anvil lining only to dimension shown in Repair Figure 601.

      (3) Metal stamp "5R85-015" in 0.12 inch (3,05 mm) characters on surface shown in Repair Figure 601.

      (4) Ink stamp "R" in 0.12 inch (3,05 mm) characters adjacent to brake lining part number.



MACHINING DETAIL
FOR BRAKE HOUSING AND LINING

NOTE:

1. REWORK REQUIRED FOR ANVIL LINING ONLY.
2. METAL STAMP "5R85-015" ON SURFACE SHOWN IN 0.12 (3,05) CHARACTERS.

Anvil Lining Retention Repair
Figure 601 (Sheet 2 of 2)

REPAIR NO. 5 - REPAIR OF BRAKE HOUSING FOR MACHINING WIPER RING GROOVE

1. General (Ref. IPL Fig. 1)

   A. This repair is for Brake Housing 9550376 (250).

   B. This repair provides instructions for machining a groove in the piston cavity to facilitate the installation of a wiper ring which will prevent foreign material from entering the piston cavity.

2. Brake Housing Piston Cavity Rework

   A. Rework piston cavities in Brake Housing 9550376 (250) as follows:

      NOTE: Reworked piston cavities require the installation of a wiper ring at assembly.

      (1) Machine a 2.371 ±0.001 (60,22 mm) diameter groove in each piston cavity and radius as shown in Repair Figure 601.

      (2) Metal stamp "5R86-067" in a 0.12 inch (3,05 mm) characters on surface shown in Repair Figure 601.

      (3) Treat all newly machined surfaces of Brake Housing 9550376 (250) with surface treat solution, Specification MIL-M-3171.

   B. Install appropriate wiper ring for piston bore machined, in accordance with ASSEMBLY AND STORAGE.

      NOTE: Piston cavity for Brake Housing 9550376 requires Wiper Ring 5009211. Piston Cavities bored oversize for Brake Housing 9550376 require Wiper Ring 5009213.

WIPER RING 1	BRAKE HOUSING 2	PISTON 3	PISTON BORE 4
5009211	9550376 (MAG)	511921	2.126 (54,00) DIA
5009213	9550376 (MAG)	9522145 (OVERSIZE)	2.175 (55,25) DIA

BRAKE ASSEMBLY 9550377

REPAIR NO. 6 - REWORK OF BRAKE HOUSING 9550376 FOR REMOVAL OF EXCESS CASTING MATERIAL

1. General (Ref. IPL Fig. 1)

   A. This repair is for Brake Housing 9550376 (250).

   B. This repair provides instructions for grinding off excess material parallel to piston cavity at two (2) places to ease brake disk installation and removal.

2. Rework of Brake Housing (Ref. Repair Fig. 601)

   NOTE: It is recommended this rework and/or repair be accomplished at the next maintenace action at operator's option.

   A. Rework brake housing to remove excess brake housing material as follows (Ref. Repair Fig. 601):

      NOTE: This rework can be performed on aircraft if required.

      (1) Scribe a line parallel to piston housing at a distance of 0.31 + 0.03/-0.06 inch (7,8 + 0,7/-1,52 mm).

      (2) Grind off excess brake housing material on outside lower anvil area of housing as shown in Repair Figure 601 (2 places).

      (3) Metal stamp repair number "5R88-001" in 0.12 inch (3,05 mm) characters in area of removed material after rework.

      (4) Re-treat and repaint reworked area in accordance with Re-Treating and Repainting.

Brake Housing Rework
Figure 601

REPAIR NO. 7 - REPAIR OF PISTON LINING RETAINER

1. General (Ref. IPL Fig. 1)

   A. This repair is for Pistons 5009128 and 5009408 (150B and 150C).

   B. This repair provides instructions for machining off a damaged lining retainer and for machining a hole to install a new lining retainer.

2. Repair of Piston Lining Retainer (Ref. Repair Fig. 601)

   A. Repair damaged piston lining retainer in accordance with Repair Figure 601 and the following instructions.

      (1) Machine off damaged button.

      (2) Machine retaining ring and lining retainer recess according to Repair Figure 601.

      (3) Treat newly machined surface with Alodine 1200 chemical conversion coating, Specification MIL-C-5541.

      (4) Install new Lining Retainer 5009129 and new Retaining Ring 9521958.

   B. Metal stamp repair number "5R87-30" in 0.09 inch (2,29 mm) characters on surface shown in Repair Figure 601.

MACHINING DETAIL

INSTALLATION DETAIL

DETAIL A

1. MACHINE OFF DAMAGED BUTTON.
2. MACHINE HOLE FOR LINING RETAINER AND RETAINING RING ACCORDING TO DETAIL A.
3. TREAT NEWLY MACHINED SURFACES WITH ALODINE 1200 CHEMICAL CONVERSION COATING, SPECIFICATION MIL-C-5541.
4. LINING RETAINER 5009129.
5. RETAINING RING 9521958.
6. METAL STAMP "5R87-30" IN 0.09 (2,29) CHARACTERS ADJACENT TO PART NUMBER. REMOVE DISPLACED METAL TO MAINTAIN FLAT SURFACES.

Repair of Piston Lining Retainer
Figure 601

ASSEMBLY AND STORAGE

1. Assembly and Storage Materials

NOTE: Equivalent substitutes may be used for items listed below.

Pliobond 5001	W. J. Ruscoe and Company 483 Kenmore Boulevard Akron, OH 44301
Lockwire (MS20995C32)	Commerically available
Hydraulic Preservative Fluid Specification MIL-H-6083	Commercially available
Hydraulic Fluid (Red Oil) Specification MIL-H-5606 (Alternate for Hydraulic Preservative Fluid)	Commercially available
Rust Veto 4214	E. F. Houghton and Company Madison and VanBuren Street Valley Forge, PA 19482
Naphtha or Lead-Free Gasoline	Commercially available
Zinc Chromate Primer Specification TT-P-1757	Commercially available

2. General (Ref. IPL Fig. 1)

A. It is recommended that new preformed packings be installed at each overhaul.

B. It is recommended that brake linings be replaced at time of overhaul.

NOTE: Brake linings must be similar and not intermixed with alternate brake linings. Alternate brake linings must be replaced as a set.

3. Assembly Procedures (Ref. IPL Fig. 1)

A. Assemble the brake assembly in accordance with the following procedures:

CAUTION: ASSEMBLE THE BRAKE ON A CLEAN, FLAT SURFACE BEING CAREFUL NOT TO NICK, SCRATCH OR SCUFF THE PAINT OR PROTECTIVE FINISH. ENSURE PROPER PARTS ARE USED FOR EACH BRAKE ASSEMBLY.

B. Install bleeder as follows:

(1) Lubricate preformed packing (240) with a light coat of hydraulic preservative fluid, Specification MIL-H-6083.

(2) Place lubricated preformed packing (240) on bleeder valve adapter (230); then install in brake housing (250 or 250A) bleeder port.

(3) Tighten bleeder valve adapter (230) to a torque value of 30 pound-feet (41 N-m).

(4) Install bleeder valve (220) into bleeder valve adapter (230) and tighten to a torque value of 120 pound-inches (13,6 N-m).

(5) Place bleeder washer (210) on bleeder screw (200) and install in bleeder valve (220).

C. Install inlet as follows:

(1) Lubricate preformed packing (190) with a light coat of hydraulic preservative fluid, Specification MIL-H-6083.

(2) Place lubricated preformed packing (190) on screw threaded insert (180) and install in brake housing (250 or 250A) inlet port.

(3) Tighten screw thread insert (180) to a torque value of 30 pound-feet (41 N-m).

(4) Lubricate preformed packing (170) with a light coat of hydraulic preservative fluid, Specification MIL-H-6083.

(5) Place lubricated preformed packing (170) on protective plug (160) and install in screw thread insert (180).

D. Assemble each of the piston units as follows:

NOTE: If letter "R" has been stamped after brake assembly number on housing, assembly has been reworked for oversize piston.

(1) Place the head of self-adjusting pin (140) into piston (150, 150A, 150B or 150C).

(2) Place brake release spring (130) over pin into piston.

(3) Place brake release spring (120) over self-adjusting pin (140) and inside brake release spring (130).

(4) Place spring guide (110) over self-adjusting pin (140) and on the inside brake release spring (120).

(5) With piston opening up, place retaining ring (100) on top of piston over opening.

(6) Place tool (tubing used in disassembly) over self-adjusting pin (140), inside retaining ring (100) and against spring guide (110).

(7) Place piston unit into arbor press and apply force to tool (tubing), against spring guide (110), compressing the springs just enough to enable the installation of retaining ring (100) into groove of piston. Release arbor press slowly and ensure retaining ring is seated. Remove piston unit from arbor press.

E. Install wiper ring (255 or 256) in brake housing as follows:

NOTE: If "5R86-067" has been stamped on brake housing, piston cavity has been reworked for a wiper ring. Install Wiper Ring 5009211 (255) or wiper ring (256) (oversize) (Ref. Repair No. 5 - Repair of Brake Housing for Machining Wiper Ring Groove.)

(1) Lubricate wiper ring (255 or 256) with hydraulic preservative fluid, Specification MIL-H-6083.

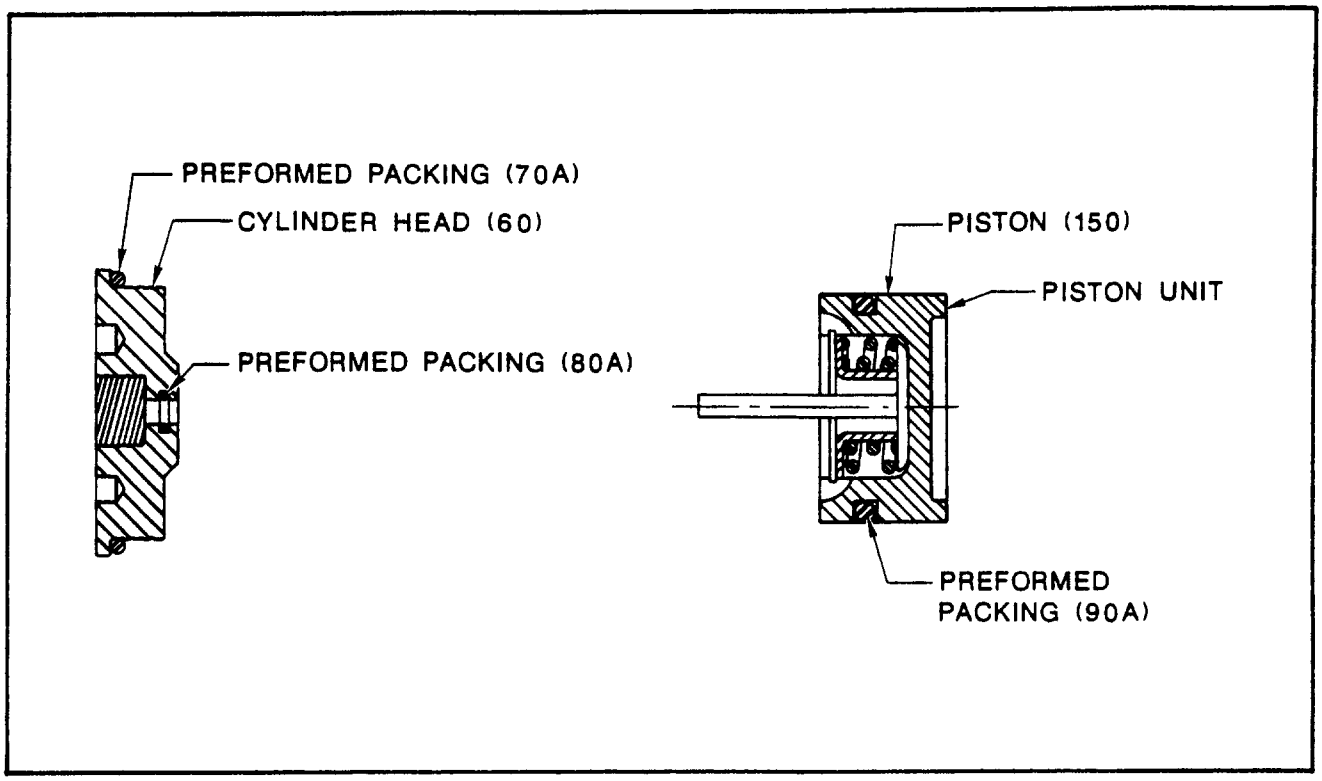
(2) Install lubricated wiper ring (255 or 256) in groove of piston cavity.

F. Install piston units and cylinder head as follows:

(1) Lubricate preformed packings (80A and 90A) and preformed packing (70A) with hydraulic preservative fluid, Specification MIL-H-6083.

(2) Install lubricated preformed packing (90A) in seal groove of piston (150) (Ref. Fig. 701).

(3) Install lubricated preformed packing (80A) and preformed packing (70A) in cylinder head (60 or 60A) (Ref. Fig. 701).



(4) Lubricate contacting surfaces of pistons and piston cavity with light coat of hydraulic preservative fluid, Specification MIL-H-6083.

(5) Install lubricated piston unit with preformed packing (90A) on brake housing (250 or 250A).

(6) Install cylinder head (60 or 60A) with packings (70A and 80A) over self-adjusting pin (140) and thread into position in brake housing (250 or 250A).

(7) Using a spanner wrench on cylinder head wrench adapter, tighten cylinder head to a torque value of 75 pound-feet (102 N-m).

(8) Install steel washer (50) on self-adjusting pin (140).

Preformed Packing Installation
Figure 701

(9) Dip self-adjusting pin grip (40) into clean hydraulic brake fluid, Specification MIL-H-5606 and install on self-adjusting pin (140), large end first.

(10) Install self-adjusting pin nut (30) over self-adjusting pins (140) and screw into cylinder head (60 or 60A) but do not tighten.

(11) Push pistons (150, 150A, 150B or 150C) completely back against cylinder head (140) and tighten self-adjusting pin nuts (30) to a torque value of 25 pound-feet (34 N-m) and back off several times to seat parts and final torque.

(12) Lockwire self-adjusting pin nuts (30) in series, using Lockwire MS20995C32 (Ref. Fig. 1).

G. Install brake linings as follows:

NOTE: If "5R85-015" has been stamped on brake housing, anvil section has been reworked to accept a fastner to improve brake lining retention. Install reworked lining, countersunk head screw (254), and self-locking nut (253). Torque self-locking nut to 15 pound-inches (1,7 N-m). (Ref. Repair No. 4 - Repair of Brake Housing for Anvil Lining Rention Repair.)

(1) For Brake Assemblies 9550377, 9550377-1 and 9550377-4, apply Pliobond 5001 cement to back of brake linings. Use naphtha or lead-free gasoline to remove cement that may accidentally drip on lining wear surface.

(2) For Brake Assembly 9550377-4, install brake lining (20C) in piston and anvil recesses of brake housing.

(3) For Brake Assembly 9550377-2, install brake linings (20D) in piston and anvil recesses of brake housing so that lining retaining cups mate with the lining retainers.

H. Install brake disk (10) into position between brake linings.

I. Test brake assembly in accordance with applicable TESTING AND FAULT ISOLATION instructions.

4. Installation of Disk Guide Bracket Subassembly (260 and 300)

NOTE: Disk guides are installed at operator's option after installation of brake assembly on aircraft.

A. Install disk guide bracket subassembly as follows:

(1) Install disk guide bracket subassembly (260 and 300) using brake mounting bolts in the two adjacent bolt holes in bottom of brake housing. Install disk guide with lining toward brake disk (10) (Ref. Fig. 1).

NOTE: If "5R2-404" has been stamped on brake housing, mounting bolt holes have been reworked oversize. Ensure that locally manufactured bushing is installed (Ref. Repair No. 3 - Repair of Mounting Bolt Hole).

5. Storage Instructions

A. The brake assembly should be stored as follows:

CAUTION: BRAKES EQUIPPED WITH QUICK-DISCONNECT FITTINGS SHOULD HAVE THE FITTINGS PROTECTED DURING SHELF STORAGE BY SUITABLE CAPS OR OTHER MEANS.

(1) The brake assembly should be stored in moisture-barrier material and a sealed corrugated cardboard container, or equivalent.

(2) The brake assembly should be stored in a clean, dry storeroom. The desirable storeroom temperature range is from 50° to 70°F (10° to 21°C). If this temperature range cannot be maintained, temperatures as high as 125°F (+52°C) and as low as -20°F (-29°C) can be tolerated for short periods. Total time above 100°F (38°C) should not exceed three months.

(3) When brake disk is stored separated, insert cardboard between brake linings to hold them in position.

B. Housing and disk:

(1) Housings and disks that are to be stored for an indefinite period should be treated as follows:

(a) Vapor degrease metal parts to remove all oil and residue.

WARNING: RUST INHIBITORS ARE HIGHLY FLAMMABLE AND MUST BE USED ONLY IN AN OPEN OR WELL-VENTILATED AREA. EXERCISE EXTREME CARE.

(b) Immerse parts in Houghton's Rust Veto 4214 or equivalent. Use in the "as-received" condition without dilution. Allow parts to drip and air dry for five minutes. Clean compressed air may be used to speed drying.

(c) Wrap parts in moisture-barrier material and package in a cardboard container.

(d) Prior to placing parts back into service, degrease in a vapor degreaser.

FITS AND CLEARANCES

Item No. (Ref. IPL Fig. 1)	Compressed Length	Minimum Load
120	0.538 inch (13,66 mm)	60 pounds (267 Newtons)
130	0.538 inch (13,66 mm)	115 pounds (512 Newtons)

Spring Values
Figure 801

Item No. (Ref. IPL Fig. 1)	Nomenclature	Replacement Dimension
10	Brake Disk Thickness (minimum) Outside diameter (minimum)	 0.360 inch (9,14 mm) 13,025 inches (330,83 mm)
20B, 20C or 20D	Brake Lining (Thickness)	 0.195 inch (4,95 mm)
140	Self-Adjusting Pin (Diameter at grip holding surface)	 0.245 inch (6,22 mm)
150 or 150B	Piston (Diameter)	 2.112 inches (53,64 mm)
150A or 150C	Piston (Diameter)	2.161 inches (54,89 mm)
280 or 320	Disk Guide Linings (Thickness)	0.205 inch (5,21 mm)

Wear Tolerances
Figure 802

Item No. (Ref. IPL Fig. 1)	Nomenclature	Torque Value
30	Self-Adjusting Pin Nuts	25 pound-feet (34 N-m)
60 or 60A	Cylinder Head	75 pound-feet (102 N-m)
180	Screw Thread Insert	30 pound-feet (41 N-m)
220	Bleeder Valve	120 pound-inches (13,6 N-m)
230	Bleeder Valve Adapter	30 pound-feet (41 N-m)

Torque Values

ILLUSTRATED PARTS LIST

1. Introduction

A. General

(1) The Illustrated Parts List (IPL) section illustrates and lists the procurable parts of the assembly(ies) in this publication.

B. Parts List

(1) IPL Figure 1 is an exploded view of assembly(ies) covered by the parts list.

(2) Components in the parts list are listed in order of disassembly.

(3) The Figure and Item column provides the cross reference between the parts list and the associated IPL Figure 1.

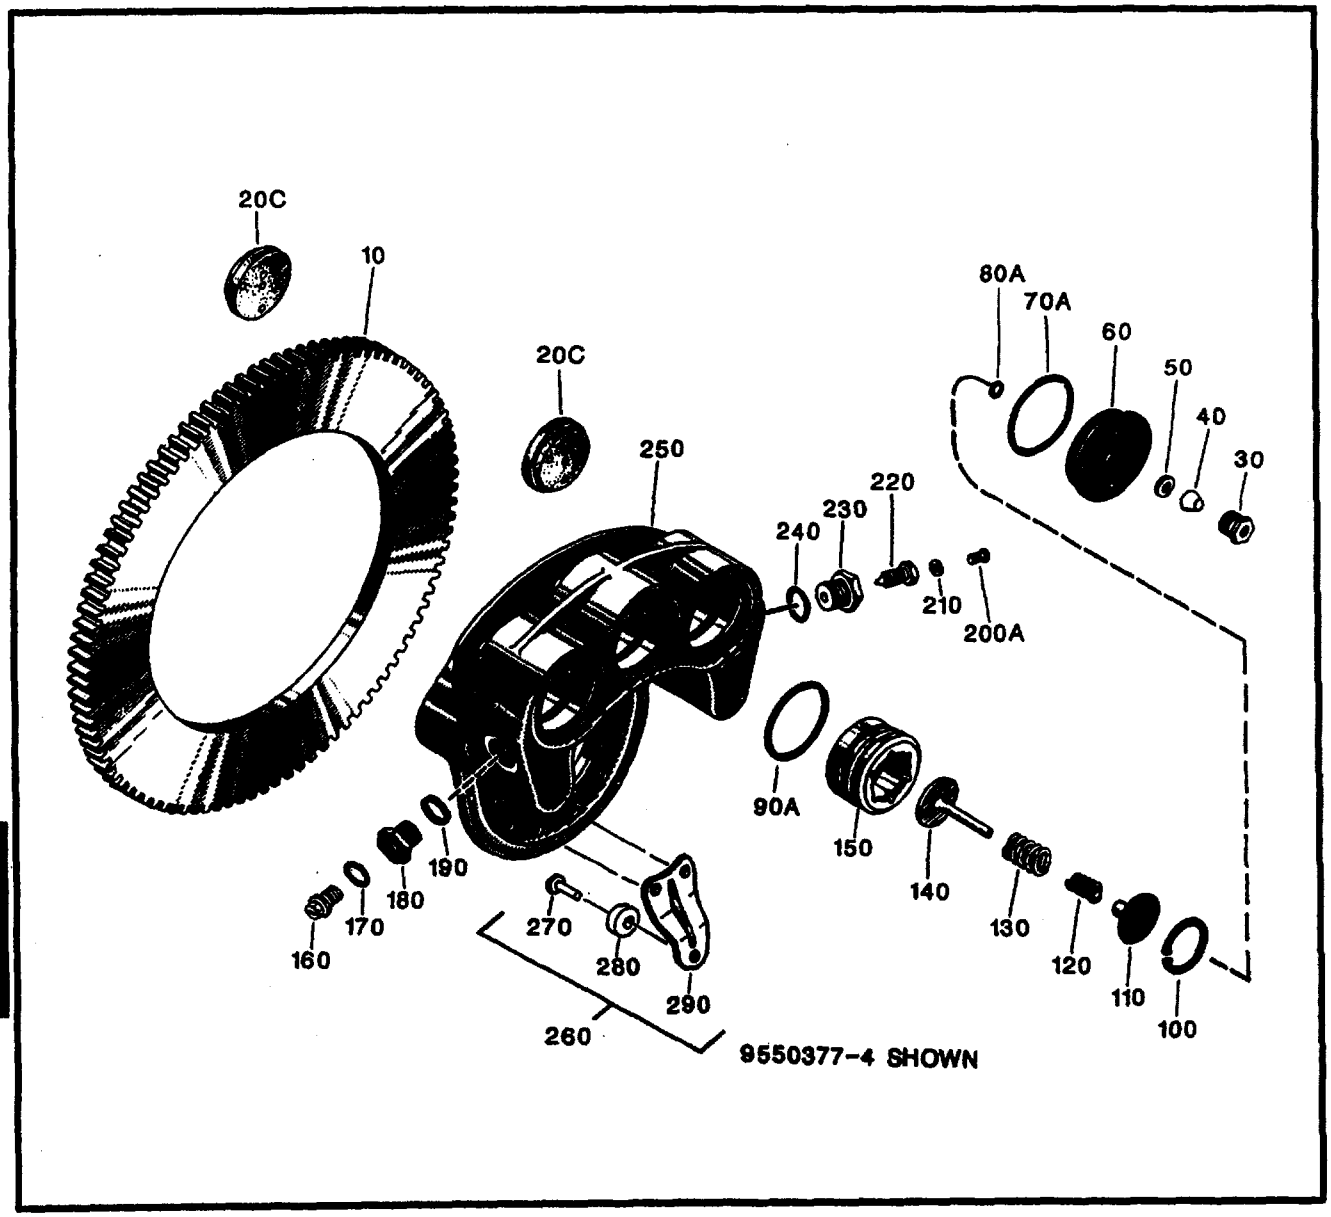
(4) The Part Number column gives the part number of the item, which is stamped on the part when practical. This number should be used when ordering parts.

(5) The Airline Stock Number column is provided for the convenience of the operator to enter individual part numbers.

(6) The Nomenclature column gives the basic noun name of each part, together with any descriptive or dimensional information and specifications required to identify the part listed. Parts are indented under the numbered sub-column heading showing the relationship of the parts to their subassemblies and to the assembly. When an alternate part or repair part exists for the recommended part, it is indicated in parentheses following the part nomenclature. A federal supply code number is given for all vendor-supplied items.

(7) The Effect Code column shall establish parts relationship with units or assemblies which are essentially the same but have minor variations. These units or assemblies are the lead items. These units or assemblies shall be assigned reference letters such as A, B, C, D, etc. Parts which are not common to all configurations, but are associated with one or more of the coded lead items, shall carry the letter or letters assigned to the lead item with which it is associated. If a part is common to all lead items, the Effect Code column shall be blank.

(8) The Units Per Assembly column gives the number of parts required for each assembly or subassembly.



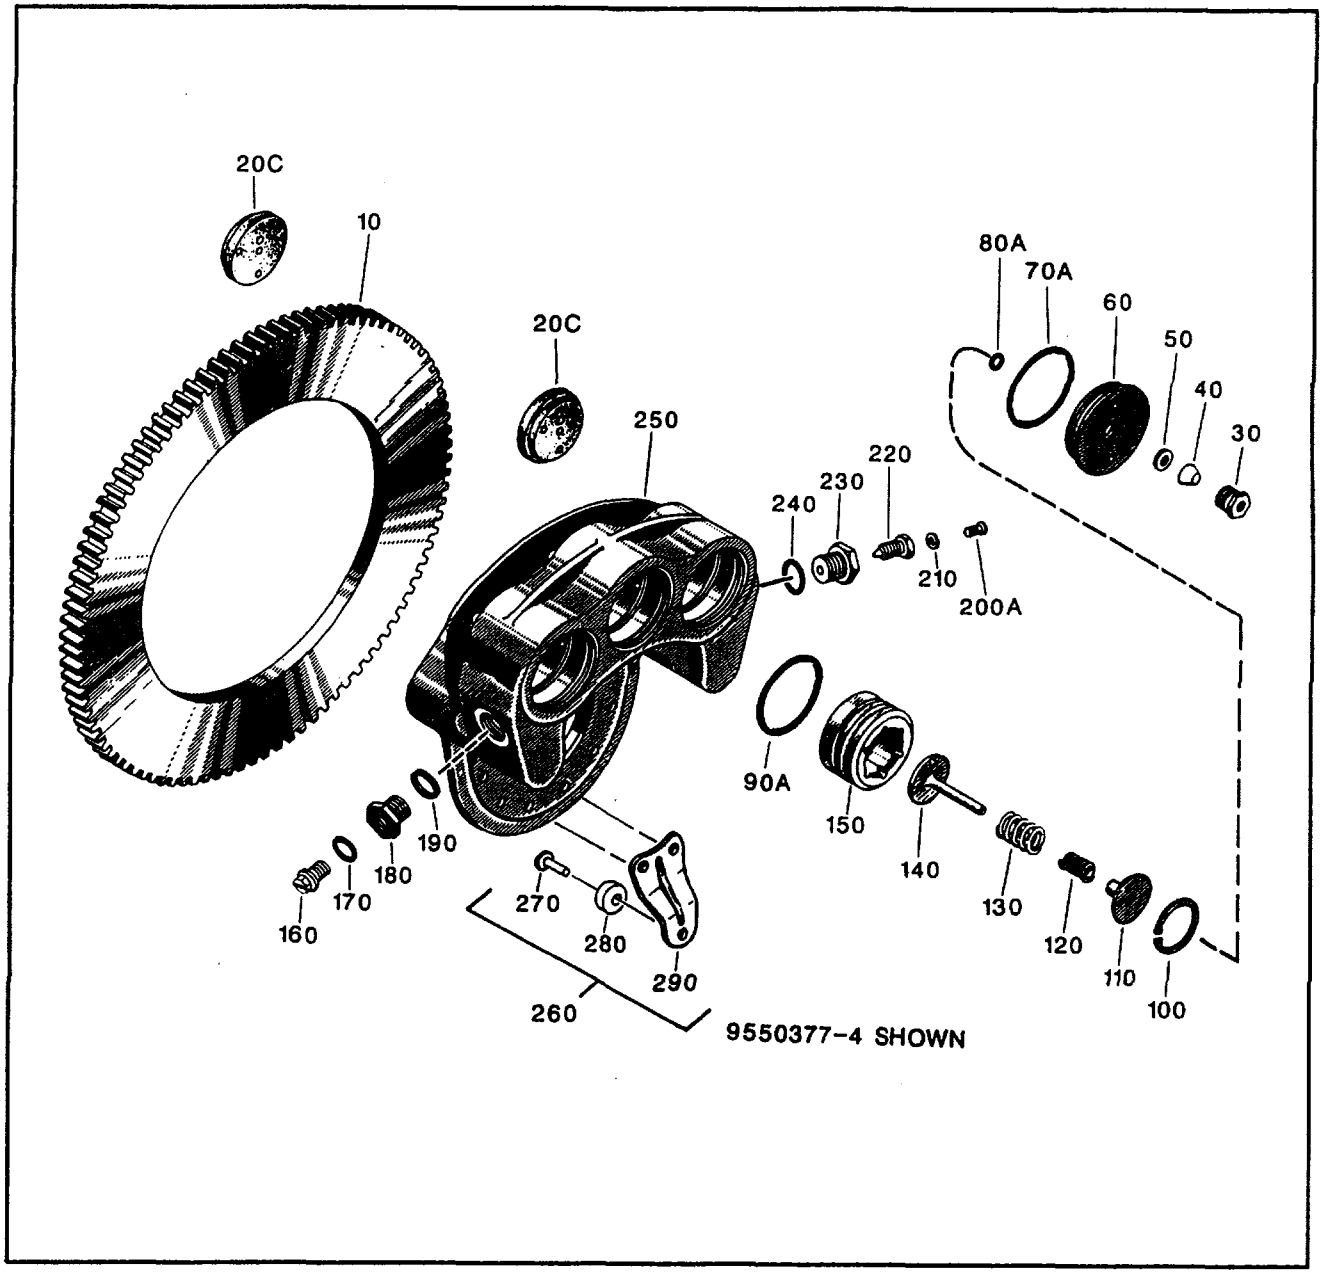
C. Federal Supply Codes for Manufacturers

(1) A list of vendor codes with names and addresses is provided.

TEMPORARY REVISION NO. 32–6

FILING INSTRUCTIONS: Insert facing page 1002 (32–43–23).

DESCRIPTION: Removed items 300, 310, 320 and 330 from IPL Figure 1. This Temporary Revision replaces Temporary Revision No. 32–5, which can be removed.



Brake Assembly

TEMPORARY REVISION NO. 32–6

FILING INSTRUCTIONS: Insert facing page 1003 (32–43–23).

DESCRIPTION: Corrected "Order –4" to "Order –2" for items 1 and 1A and added it to item 1D and added items 20D and 20E as alternates for item 20C. Also, changed item 1B, 20D, 150, 150A, 150B and 150C nomenclature to tell which items are aluminum and which items are magnesium.

INTRODUCTION

This manual contains instructions for the overhaul of the De Havilland Power Brake Control Assembly Part Nos. C6HF1036 and C6HF1037.

POWER BRAKE VALVE ASSEMBLY PART NO. C6HF1036 AND C6HF1037

1. Description and Operation

A. Description

The power brake valve assembly (Figure 1), consists of a cast aluminum body containing a lever-operated floating piston and a spring-loaded inlet/outlet poppet valve. The valve body has three ports; inlet pressure, brake pressure, and return.

B. Operation

Deflection of the splined lever is transmitted to the valve piston, and piston movement momentarily opens the pressure inlet valve to the brake pressure port. Pressure build-up in the brake pressure port is sensed by the valve piston, which yields a predetermined amount closing the inlet valve. Release of the splined lever allows the valve piston to withdraw under hydraulic pressure load and in so doing opens the brake pressure port to return, releasing any residual pressure.

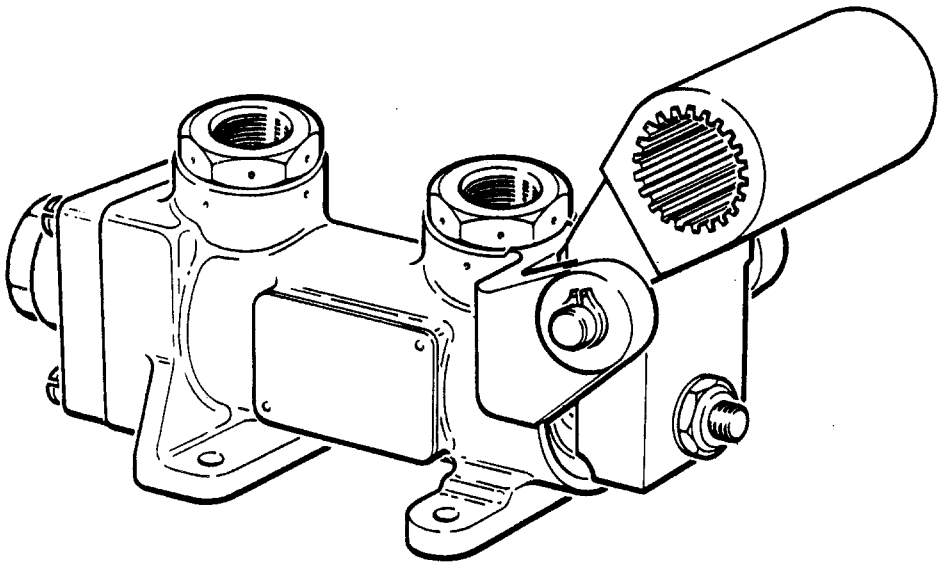
C. Data

Hydraulic Fluid	MIL-H-5606
Operating Pressure	3000 psig
Proof Pressure	4000 psig
Brake Port Pressure	1000 + 50 psig - 0
Mounting Holes	0.256 to 0.261 inch diameter
Weight (nominal)	2.5 pounds

2. Disassembly

A. Disassemble Power Brake Valve (Figure 3)

(1) Remove two retainer rings (1), withdraw pin (2), and slide splined lever (7) complete with nut (3), washer (4), adjusting screw (5), and screw locking insert (6) from valve body (29), then remove rod (8).



(2) Remove nut (3), washer (4), and unscrew adjusting screw (5) from splined lever (7). Remove screw locking insert (6) from splined lever.

(3) Remove bushing (9) and gasket (10) from end (12). Cut and remove lockwire from four screws (11), remove screws and separate end (12) from valve body (29).

(4) Pull spacer (13), packing (14), and stake assembly (15) from valve body (29).

(5) Disassemble stake assembly (15) as follows:

(a) Depress retainer (18), drill out pin (16), and slide poppet (17), retainer (18), and spring (19) in order from valve (20).

Power Brake Valve Assembly

Figure 1

(b) Remove valve (20) from seat (21).

(6) Pull spring (22) and piston (23) with two packings (24) from valve body (29). Remove packings (24) from grooves of piston (23).

(7) Remove bushing (25), gasket (26), bushing (27), and gasket (28) from ports on valve body (29).

3. Cleaning

A. General

(1) Clean component parts by washing or spraying with a dry-cleaning solvent.

(2) Dry with moisture-free compressed air or a lint-free cloth.

4. Inspection/Check

A. General

(1) *Inspect all threads for damage and deformity.*

(2) Under a strong light and preferably under magnification, inspect all parts for nicks, scores, scratches, or excessive wear that might cause improper operation of the valve.

(3) Refer to Table 1 for original tolerances and service limits. Replace parts worn in excess of service limits. Replace all defective parts not listed in table.

B. Detail Parts (Figure 3)

(1) Carry out a magnetic particle inspection of pin (2), rod (8), and seat (21).

(2) Check adjusting screw (5) head interior for excessive wear. Rod (8) should slide perfectly into head of adjusting screw.

(3) Carefully inspect seating surfaces of seat (21), valve (20), and poppet (17) for nicks, scoring, or sharp and smooth corners.

(4) Inspect piston (23) for distortion, nicks, cracks, or excessive wear and roughness at groove seating of packings (24). Seat must be round within 0.005 inch with sharp edges.

(5) Inspect valve body (29) for cracks, scoring, or pitted surfaces in area of packings, and other apparent defects. All passages must be free of restriction.

5. Repair

A. General

(1) Except for minor scratches that can be polished out with crocus cloth, Federal Specification P-C-458, repair of detail parts is not practical. Replace all parts which fail to meet inspection requirements.

B. Detail Parts (Figure 3)

(1) Install new packings (14) and (24), gaskets (10), (26) and (28), screw locking insert (6), and pin (16) at each overhaul of the power brake valve.

(2) Remove roughness of sealing areas in contact with packings using No. 600 emery paper. If a satisfactory finish cannot be obtained, replace the damaged part.

Table 1

Original Tolerances and Service Limits

FIGURE 3 ITEM NO.	NAME	DISCREPANCY LOCATION	ORIGINAL DIMENSION (INCHES)	SERVICE LIMIT (INCHES)	DISPOSITION
2	Pin	OD	0.3125 - 0.3115	0.311	Replace
7	Splined Lever	Pin Hole Diameter	0.3125 - 0.3134	0.3143	Replace
29	Valve Body	Pin Hole Diameter	0.313 - 0.315	0.317	Replace

6. Assembly

List of Materials

MATERIAL	SPECIFICATION
Oil	MIL-H-6083

A. Assemble Power Brake Valve (Figure 3)

(1) Install gasket (28), bushing (27), gasket (26) and bushing (25) to ports on valve body (29).

(2) On assembly, lubricate all internal metal parts using preservative oil MIL-H-6083. Install two packings (24) to grooves on piston (23), then position piston and spring (22) in valve body (29).

(3) Assemble stake assembly (15) as follows:

(a) Assemble poppet (17) to seat (21). Slide spring (19) and retainer (18) over end of poppet, and screw valve (20) onto end of poppet.

(b) Depress retainer (18) and install pin (16). Stake retainer in place in area next to ends of pin with two 0.06-inch diameter stakes from 0.010 to 0.020 inch deep.

(4) Position stake assembly (15) in valve body (29), making certain that spring (22) seats properly against shoulders of retainer (18).

(5) Insert packing (14) and spacer (13) in valve body (29). Position end (12) and secure using four screws (11). Do not lockwire screws until completion of test (see Testing). Install gasket (10) and bushing (9) on end (12).

(6) Install screw locking insert (6) in splined lever (7). Thread adjusting screw (5) into splined lever, and temporarily install washer (4) and nut (3). Do not secure washer and nut on adjusting screw. (See Testing).

(7) Position rod (8) and assembled splined lever (7) in valve body (29), and insert pin (2). Secure pin using two retainer rings (1).

7. Fits and Clearances

See Table 1.

8. Testing (Figure 2)

List of Materials

MATERIAL	SPECIFICATION
Red Lacquer	TT-L-32

A. General

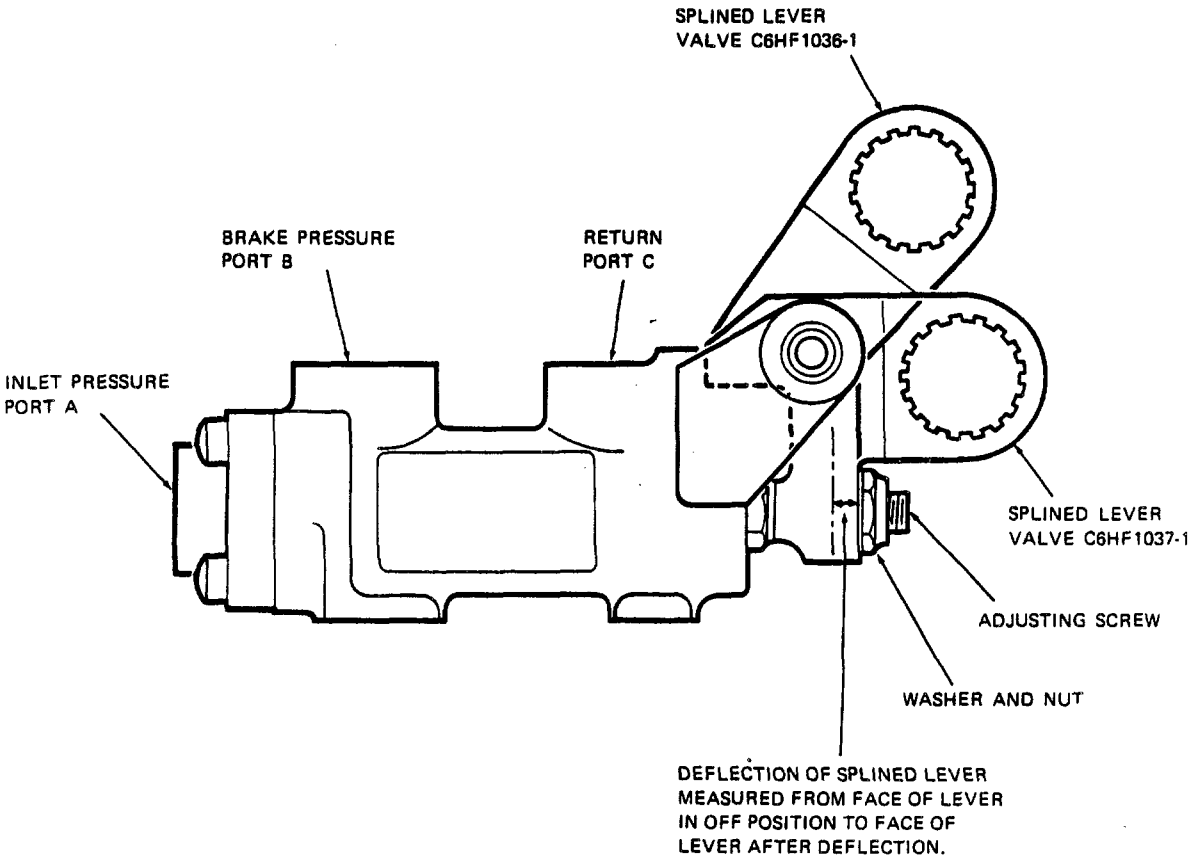
(1) The hydraulic test rig must be capable of supplying and maintaining the pressures required by the test procedures in Table 2.

(2) Clean hydraulic fluid MIL-H-5606 or MIL-H-6083 must be used as the test medium (at room temperature).

CAUTION: DO NOT DRY CYCLE VALVE. CYCLING MAY OCCUR ONLY WHEN UNDER PRESSURE AND LUBRICATED WITH HYDRAULIC FLUID.

(3) Bleed all air from valve prior to testing.

B. Test Set-up



(1) Connect supply to inlet pressure port ("A"). Turn adjusting screw until fluid flows from brake pressure port ("B"). Regulate screw until flow stops. Turn an additional 1/2 to 3/4 turn, and lock adjusting screw with washer and nut.

(2) Witness-mark setting of adjusting screw with red lacquer TT-L-32.

C. Proof Pressure, Function and Leakage Tests

(1) Test power brake valve in the sequence designated in Table 2.

(2) On completion of testing, lockwire four screws securing end to valve body.

Testing - Power Brake Valve

Figure 2

Table 2

Test Requirements

TEST NO.	TEST PORT	PRESS. P.S.I.	PORT PLUGGED	TEST TIME	REMARKS
1	A	2250	None	2 Minutes	Lever in OFF position. There must be no leakage, permanent set or deformation.
2	A and C	1000	B	2 Minutes	Deflect splined lever 0.125 in. before applying pressure. There must be no external leakage or permanent set.
3	A	1000	B	5 Minutes	Splined lever in OFF position. Leakage at port C shall not exceed 20 drops in the last 4 minutes of 5 minute test.
4	Couple up a high pressure gage to port B. With 1000 psi at port A and splined lever initially relaxed, progressively deflect splined lever until pressure at port B increases to 800 psi. Hold at this pressure for 5 minutes; check that pressure at port B does not creep more than 10% of initial pressure and that leakage at port C does not exceed 20 drops in last 4 minutes of test. Release splined lever and note that pressure at port B immediately drops to zero.				

9. Trouble Shooting (Figure 3)

TROUBLE	PROBABLE DAUSE	CORRECTION
Internal leakage.	Incorrect setting of adjusting screw.	Refer to Testing, Set adjusting screw and test.
	Nicks or scores on seating surfaces of poppet (17) seat (21), or valve (20).	Remove stake assembly (15). Clean and inspect for excessive wear, nicks or scores. Replace suspect parts, reassemble and test.
External leakage at end (12).	Sealing of packing (14).	Remove packing, Inspect for roughness on valve body in area of packing. Install new packing, reassemble and test.

9. Trouble Shooting (Figure 3) (Cont'd)

TROUBLE	PROBABLE CAUSE	CORRECTION
External leakage at adjusting screw (5).	Sealing of packing (24) on piston (23).	Remove packing. Inspect groove on piston. Inspect for roughness on valve body in area of packing. Install new packing, reassemble and test.

10. Storage Instructions

A. Preparation

(1) Cap inlet pressure, brake pressure and return ports.

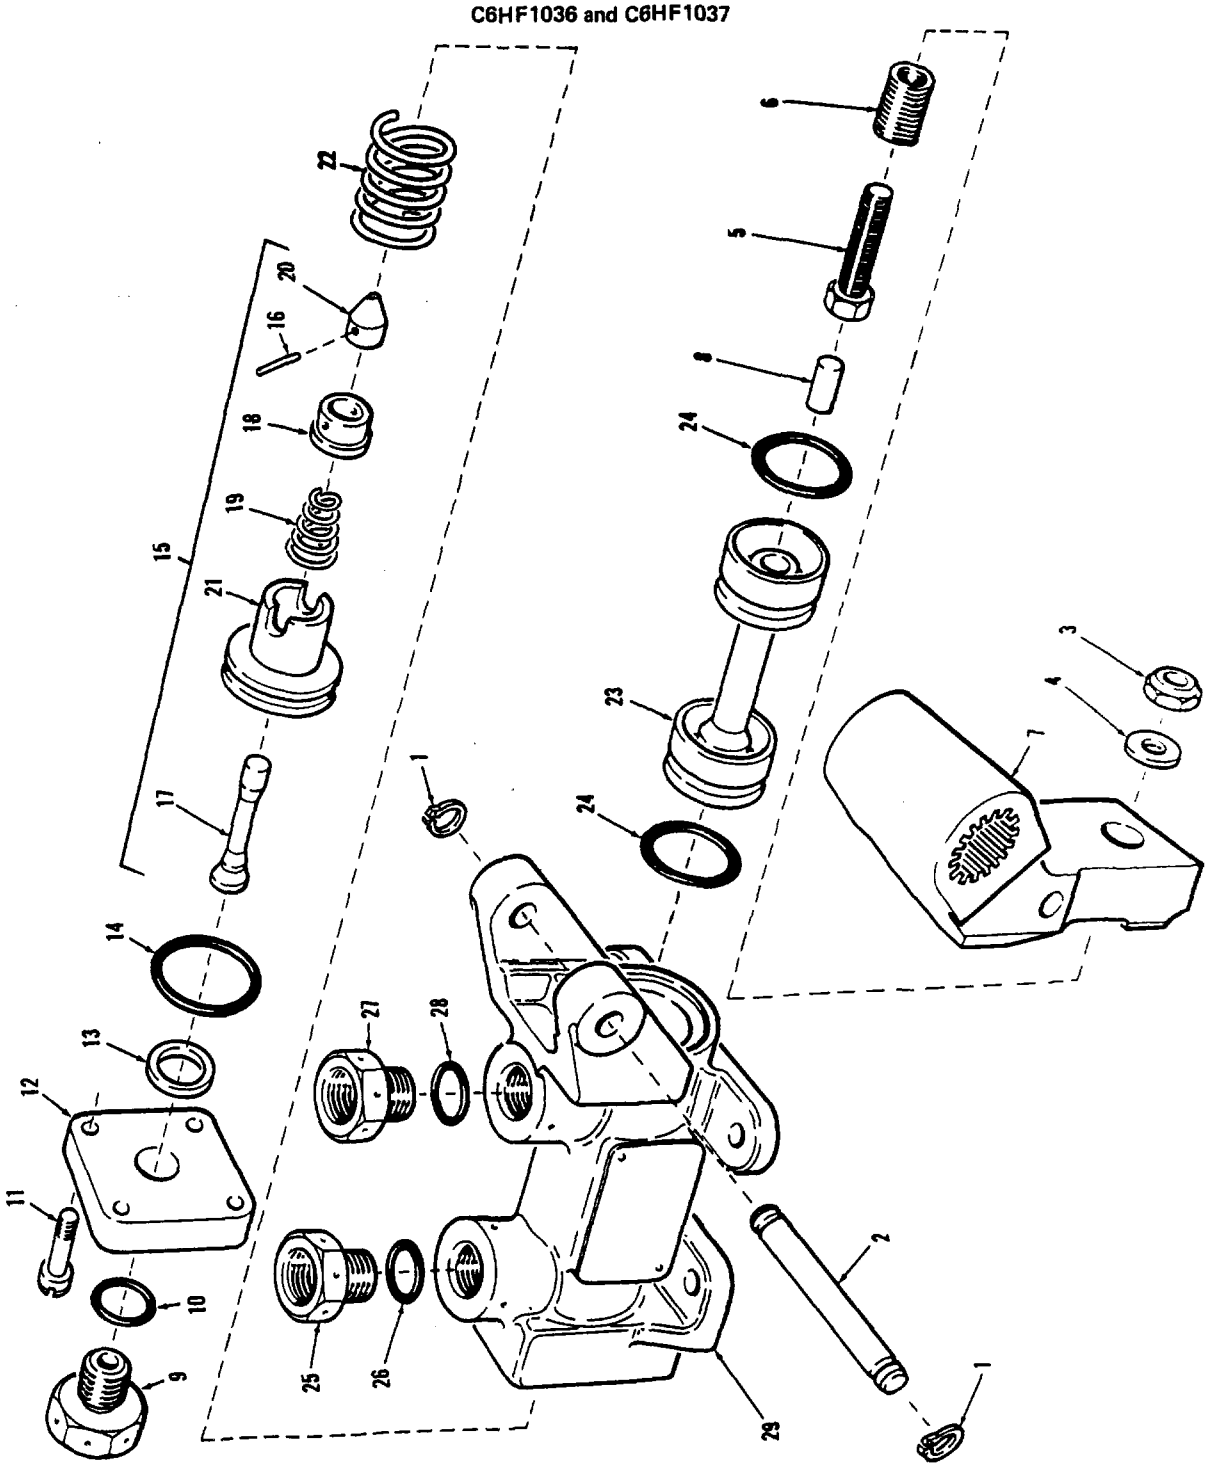
(2) Clean power brake valve with a clean dry cloth.

(3) Enclose unit in a polyethylene bag.

(4) Affix label, giving following information:

(a) Part and serial numbers.

(b) Date of overhaul.



(c) Inspection.

11. Special Tools

Hydraulic test rig capable of supplying and maintaining pressure of 2250 psi.

High pressure gage 0 to 1500 psi.

Tool capable of progressively deflecting the splined lever.

Exploded View - Power Brake Valve

NOSE GEAR LEG ASSEMBLY - HEROUX PART NOS. 71-100-1, -3, -5, -7, -9, -9B, -11, -11B, -15, -17, -19, -21, -23, -25, -27, -29, -31, -33 AND -35

DESCRIPTION AND OPERATION

1. General (Figure 1)

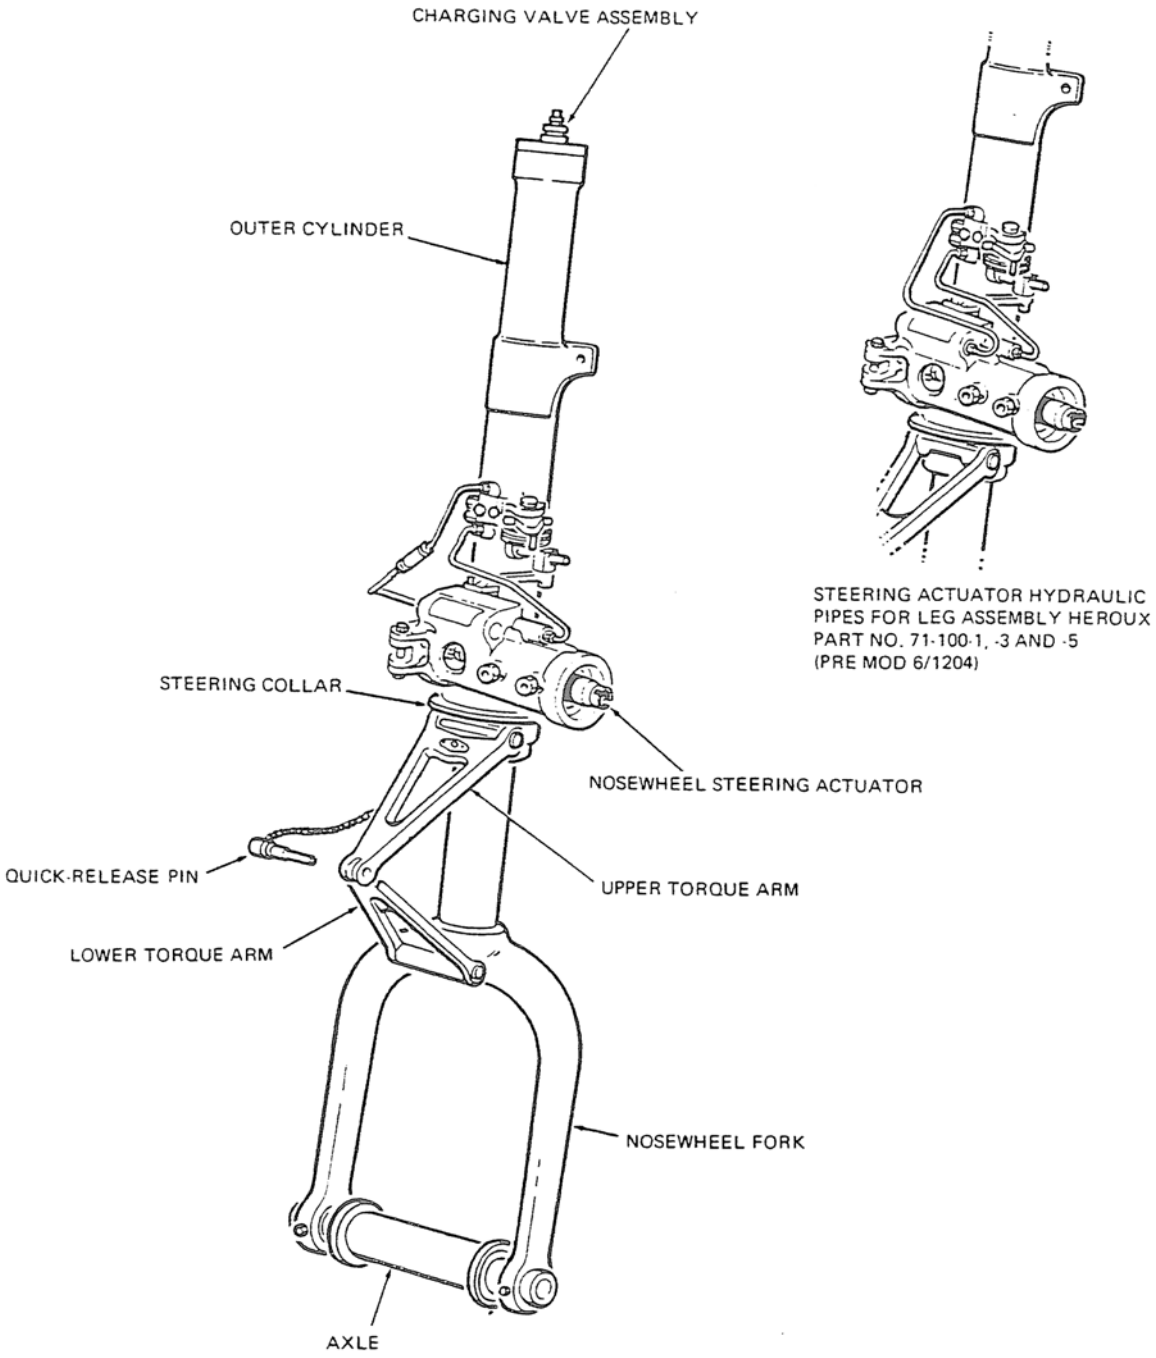
The nose gear leg assembly consists of a shock strut assembly, and a steering actuator and links sub-assembly.

The shock strut assembly is an oleo pneumatic type, and consists of an outer cylinder, piston assembly, steering collar, nose wheel fork, axle, and upper and lower torque arms. The oil and air is contained within the outer cylinder and the inner cylinder of the piston assembly. The piston assembly telescopes into the outer cylinder, which forms the main structure of the shock strut assembly and provides the mounting for the steering actuator. The links sub-assembly connects the steering actuator with the steering collar which transmits steering selection through the upper and lower torque arms to the nose wheel fork and axle. The nose wheel fork is secured to the lower end of the piston assembly. When subjected to loads, the compression and extension of the shock strut is dampened by restricting the flow of oil and air between the outer cylinder and the inner cylinder of the piston assembly. The oil and air charging valve is located at the top of the shock strut assembly.

The steering actuator and links sub-assembly is descibed in 32-50-11, NOSE WHEEL STEERING ACTUATOR AND LINKS SUB-ASSEMBLY.

2. Data

A. General



Oil Type - Hydraulic Fluid MIL-H-5606
Air Pressure - 91± 4 psi with shock strut fully extended.

Nose Gear Leg Assembly

Figure 1

B. Configuration

Refer to Table 1 for buildup of main components comprising the nose gear leg assembly.

C. Shimmy Damper Installation

Certain shock strut assemblies have a special shimmy damper installation at the steering collar. Tables 2 through 5A list the additional parts required, together with any superseded parts, for this installation, which will be embodied under the following circumstances:

(a) When wheel skis are installed (Mod S.O.O. 6001).

(b) When intermediate flotation gear (15.00 x 12.00 tires) is installed (Mod S.O.O. 6048).

(c) As a special order option (Mod S.O.O. 6149)

NOTE: Mod S.O.O. 6149 is up-dated by Mod 6/1321 to improve shimmy damping.

Modification 6/1554 introduces the shimmy damper installation as basic and it equivalent to S.O.O. 6149 and Mod 6/1321.

D. Interchangeability

It is permitted to interchange the main components comprising the nose gear leg assembly (refer to Table 1 for production standard configuration). For example, the steering actuator and links sub-assembly Part No. 71-190-9 can be fitted to shock strut assembly Part No. 71-300-1, 71-300-3 and 71-300-5. When interchanged, note that the overhaul instructions and any spare parts required are as detailed for the appropriate main component.

E. To Upgrade Shock Strut Assembly During Overhaul

For operators wishing to upgrade shock strut assemblies, Part No. 71-300-3, 71-300-5, 71-300-7 or 71-300-9 to the standard of Part No. 71-300-11 during overhaul. Tables 6, 7, 8 and 8A are provided to list new parts required and parts superseded. Tables 8B, 8C, 8D, 8E and 8F are provided to upgrade shock strut assemblies, Part No. 71-300-11, 71-300-15, 71-300-17, 71-300-19, 71-300-21 or 71-300-23 to the latest standard of Part No. 71-300-25.

If upgrading, use assembly procedures provided for shock strut assemblies Part No. 71-300-11 or Part No. 71-300-15 through 71-300-25, as applicable. It is not recommended that operators upgrade shock strut assembly Part No. 71-300-1 to a later standard.

G. To upgrade steering actuator and links sub-assembly during overhaul, refer to 32-50-11, NOSE WHEEL STEERING ACTUATOR AND LINKS SUB-ASSEMBLY.

DISASSEMBLY

1. Procedures

A. Separate Shock Strut Assembly and Steering Actuator and Links Sub-Assembly (Figure 101)

(1) Disconnect hydraulic return pipe at top swivel fitting (16), and hydraulic pressure pipe at bottom swivel fitting (15) on leg assembly.

(2) Remove cotter pin (11) and nut (12) securing actuator lever assembly (8) to stud (10) on steering collar (9).

(3) Support steering actuator (6), and remove cotter pin (3), nut (14) and washer (13) from bolt (5) attaching actuator to shock strut assembly. Turn leg to obtain clearance from steering collar and upper torque arm (7), and withdraw bolt (5). Turn leg assembly fully to right, disengage pivot (2) and slider (1) from steering lever (4), and lift actuator clear of stud on steering collar. (For further breakdown of steering actuator and link sub-assembly, refer to 32-50-11 NOSE WHEEL STEERING ACTUATOR AND LINKS SUB-ASSEMBLY).

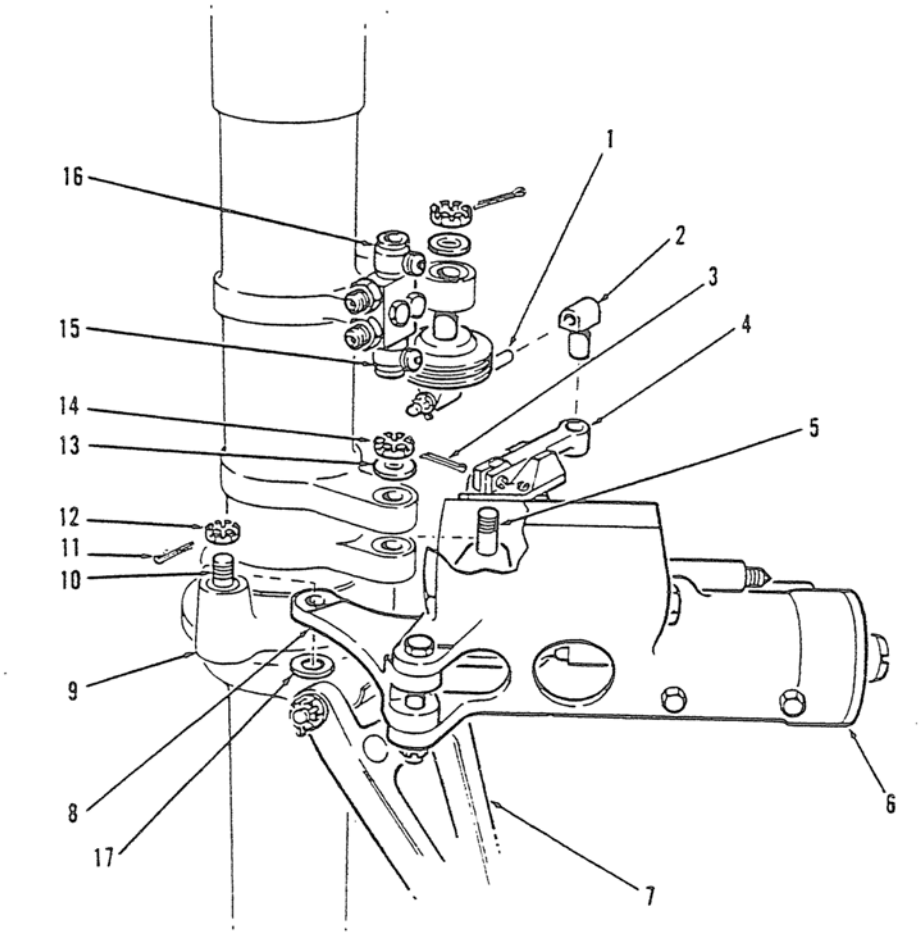
(4) Temporarily install nut (12) to stud (10), and bolt (5), washer (13) and nut (14) to lugs on leg assembly. When DH Mod 6/1622 is embodied, ensure that washer (17) is located on stud (10) adjacent to steering collar (9).

B. Disassemble Nose Gear Shock Strut, Part No. 71-300-1 and 71-300-3 (Figure 1101)

WARNING: DO NOT ATTEMPT TO DISASSEMBLE SHOCK STRUT OR REMOVE AIR CHARGING VALVE BEFORE RELEASING ALL AIR PRESSURE THROUGH AIR CHARGING VALVE. FAILURE TO DO SO COULD RESULT IN SERIOUS INJURY OR POSSIBLE LOSS OF LIFE.

(1) Remove air charging valve cap (2). Unscrew nut of air charging valve (1) counterclockwise (approximately one turn) to slowly release air pressure.

WARNING: DO NOT ATTEMPT TO FURTHER LOOSEN OR BACK OFF 3/4 INCH HEXAGON STEM ASSEMBLY BEFORE ENSURING THAT ALL AIR PRESSURE IS RELEASED FROM THE SHOCK STRUT ASSEMBLY.



(2) Remove air charging valve (1).

(3) Remove set-screw (3) securing end cap sub-assembly to outer cylinder. Unscrew and remove end cap sub-assembly from outer cylinder. Turn shock strut upside down and drain off hydraulic fluid.

NOTE: Strain fluid through a suitable fine mesh strainer. Pay particular attention to any foreign matter removed from the fluid (refer to INSPECTION/CHECK) and reject fluid for further use in nose gear shock strut.

(4) Remove O-ring (4) from end cap sub-assembly.

(5) Cut lockwire and remove machine screw (6) securing nut (7) of end cap sub-assembly. Unscrew nut (7) using special tool T-188, and remove end cap (8) from support tube (9). Remove O-ring (10) from upper end of support tube.

Steering Actuator Mounting on Nose Gear Shock Strut

Figure 101

(6) At lower end of support tube, remove pellet (11) covering set-screw (12), loosen set-screw and remove guide bearing (13), damping plate (14) and place orifice (15) from support tube.

NOTE: Do not remove slipper ring (17) unless it is defective. A split ring is fitted under slipper ring only where guide bearing has a corresponding groove.

(7) Disengage upper and lower torque arms by removing quick-release pin (18). Remove chain (19) securing quick-release pin to upper torque arm.

(8) Push piston assembly into outer cylinder, and remove lockring (21) from shoulder nut (22) at top of piston assembly. Remove shoulder nut using special tool T-190, and withdraw piston assembly with fork from outer cylinder, dislodging flapper (23), flapper spacer (24), floating piston (25) and rubber bumper (26) of piston assembly. Remove shoulder (27) from piston tube (28). Remove two back-up rings (29), O-ring (30), two back-up rings (31) and O-ring (32) from floating piston (25).

(9) Cut lockwire, and remove set-screw (33) and washer (34) from locknut (35) securing fork to piston tube. Unscrew locknut (35) using special tool T-187, remove cartridge assembly and withdraw piston tube from fork.

(10) Remove O-ring (36) from cartridge assembly. Cut lockwire, and remove plug (38) and packing (39) from cylinder (40) of cartridge assembly.

(11) Remove dowel (42) and withdraw bushing (43) from fork (41).

(12) Remove cotter pin (44), nut (45), washer (46) and bolt (47), and remove lower torque arm assembly from fork. Remove four screws (49), two thrust washers (50), two dust rings (51) and bushing (52) from lower torque arm (53). Remove two pins (54), two thrust washers (55), two dust rings (56) and two bushings (57) from fork.

(13) On shock strut assembly Part No. 71-300-1 only: remove two nuts (58) and two bolts (60) attaching axle and two towing spools to fork, and withdraw two towing spools (61); remove cotter pin securing retaining nut (63) to adjustment spacer (64) and withdraw axle (67) from spacer (66), adjustment spacer, retaining nut and fork; remove two flanged bushings (68) from lugs on fork.

(14) On shock strut assembly Part No. 71-300-3 only: remove two nuts (58), two washers (59), and two bolts (60) attaching axle and two towing spools to fork, and withdraw two towing spools (61); cut lockwire and loosen setting screws (62) securing retaining nut (63) to adjustment spacer (64), and remove lockring (65) from spacer (66); withdraw axle (67) from spacer, adjustment spacer, retaining nut and fork. Remove four bushes (68) from lugs on fork.

(15) Remove set-screw (69) securing locknut (70) to lower end of outer cylinder, and remove locknut using special tool T-191. Remove washer (71), scraper (72), bearing retainer (73) and bearing (74) from outer cylinder.

(16) Cut lockwire and remove two machine screws (75) and two lockring nuts (76) from cylinder nut (77) securing steering collar assembly to outer cylinder. Remove cylinder nut (77), thrust washer (78), steering collar assembly complete with upper torque arm assembly, and journal bearing (79) from outer cylinder.

NOTE: Refer to DESCRIPTION AND OPERATION, Tables 2 and 3 for variations due to special shimmy damper installation.

(17) Remove screws (99) and cover (100) from steering collar assembly. Remove cotter pin (80), nut (81) and washer (82) from bolt (83) attaching upper torque arm assembly to steering collar. Hold upper torque arm to its uppermost position, and using a screwdriver, carefully pry off cam (84) from bolt (83). Withdraw bolt and remove spring (85) and upper torque arm assembly.

(18) Remove nuts (87), washers (88), screws (89), spring retainer (90), spring (91) and latch pin (92) from upper torque arm (93).

NOTE: Do not remove two bushings (94) from upper torque arm unless they are defective and have to be replaced (refer to FITS AND CLEARANCES).

(19) Remove two pins (95), two thrust washers (96) and two dust rings (97) from steering collar assembly.

(20) Remove spring pin (101), and stud (102) with locknut (104) from steering collar (107).

NOTE: Do not remove bushing (105) or two bushings (106) from steering collar (107) unless they are defective and have to be replaced (refer to FITS AND CLEARANCES).

Cotter pin (103) securing locknut (104) to stud (102) is removed on separation of steering actuator and shock strut assemblies.

(21) Cut lockwire and remove two bolts (108) attaching swivel fitting assembly to outer cylinder. Remove two unions (110) and two packings (111) fro swivel fitting assembly. Remove spring pin (112), collar (113), swivel (114), two back-up rings (115) and two O-rings (116) from each end of swivel bolt (117).

(22) Remove cotter pin (118), nut (119), washer (120), washer (121) and withdraw pulley shaft (122) from outer cylinder. Remove cotter pin (123), nut (124) and washer (125) from slider (126), and remove slider with pivot (127) and bushing (128) from pulley shaft.

(23) Remove set-screw (129) securing cable guard assembly, loosen two nuts (131) from two screws (132), and remove both halves of cable guard (133) with guard pins (134) from outer cylinder.

(24) Remove two pins (135), two thrust washers (136) and bushing (137) from outer cylinder.

(25) Remove nut (139), washer (140), two washers (141) and bolt (142), and remove two pins (143), two bushings (144) and spacer (145) from outer cylinder (146).

NOTE: Cotter pin (138) securing nut (139) to bolt 9142) is removed on separation of steering actuator and shock strut assembly.

C. Disassemble Nose Gear Shock Strut Part No. 71-300-5 and -7 (Figure 1102)

<u>WARNING</u>: DO NOT ATTEMPT TO DISASSEMBLE SHOCK STRUT OR REMOVE AIR CHARGING VALVE BEFORE RELEASING ALL AIR PRESSURE THROUGH AIR CHARGING VALVE. FAILURE TO DO SO COULD RESULT IN SERIOUS INJURY OR POSSIBLE LOSS OF LIFE.

(1) Release air pressure, remove air charging valve, disassemble end cap sub-assembly and drain off hydraulic fluid as detailed in Paragraph 1.B., steps (1) through (6).

(2) Disengage upper and lower torque arms, disassemble piston assembly and remove cartridge assembly as detailed in Paragraph 1.B., steps (7) through (9).

(3) Disassemble cartridge assembly for shock strut assembly Part No. 71-300-5 only, as follows:

(a) Refer to Figure 1101, and remove O-ring (36) from cartridge assembly. Cut lockwire, and remove plug (38) and packing (39) from cylinder (40) of cartridge assembly.

(4) Disassemble cartridge assembly for shock strut assembly Part no. 71-300-7 only, as follows:

(a) Remove O-ring (36) and back-up ring (37) from cap plug (39) of cartridge assembly.

NOTE: Do not remove cap plug (39) from cylinder (41) of cartridge assembly unless it is defective and has to be replaced (refer to FITS AND CLEARANCES).

(5) Remove dowel (43) and withdraw bushing (44) from fork (42).

(6) Remove cotter pin (45), nut (46), washer (47) and bolt (48), and remove lower torque arm assembly from fork. Remove four screws (50), two thrust washers (51), two dust rings (52) and bushing (53) from lower torque arm (54). Remove two pins (55), two thrust washers (56), two dust rings (57) and two bushings (58) from fork.

(7) Remove two nuts (59), two washers (60), and two bolts (61) attaching axle and two towing spools to fork, and withdraw two towing spools (62); cut lockwire and loosen setting screws (63) securing retaining nut (64) to adjustment spacer (65), and remove lockring (66) from spacer (67); withdraw axle (68) from spacer, adjustment spacer, retaining nut and fork. Remove four bushes (69) from lugs on fork.

(8) Remove set-screw (70) securing locknut (71) to lower end of outer cylinder, and remove locknut using special tool T-191. Remove washer (72), scraper (73), bearing retainer (74) and bearing (75).

NOTE: Do not remove sleeve (76) of outer cylinder unless it is defective and has to be replaced (refer to FITS AND CLEARANCES).

(9) Remove nut (77), washer (78), screw (79), two blocks (80), locking clip (81) and locking key (82) at cylinder nut (83) securing steering collar assembly to outer cylinder. Remove cylinder nut (83), thrust washer (84), steering collar assembly complete with upper torque arm assembly, bushing (85) and two thrust washers (86) from outer cylinder.

NOTE: Refer to DESCRIPTION AND OPERATION, Tables 4 and 5 for variations due to special shimmy damper installation.

(10) Remove screws (106) and cover (107) from steering collar assembly. Remove cotter pin (87), nut (88) and washer (89) from bolt (90) attaching upper torque arm assembly to steering collar. Hold upper torque arm to its uppermost position, and using a screwdriver, carefully pry off cam (91) from bolt (90). Withdraw bolt and remove spring (92)and upper torque arm assembly.

(11) Remove nuts (94), washers (95), screws (96), spring retainer (97), spring (98) and latch pin (99) from upper torque arm (100).

NOTE: Do not remove two bushings (101) from upper torque arm unless they are defective and have to be replaced (refer to FITS AND CLEARANCES).

(12) Remove two pins (102), two thrust washers (103) and two dust rings (104) from steering collar assembly.

(13) Remove spring pin (108) and stud (109) with locknut (111) from steering collar assembly.

NOTE: Do not remove bushings (112), two bushings (113), bearing (114) from steering collar (115) unless they are defective and have to be replaced (refer to FITS AND CLEARANCES).

Cotter pin (110) securing locknut (111) to stud (109) is removed on separation of steering actuator and shock strut assemblies.

(14) Cut lockwire and remove two bolts (116) attaching swivel fitting assembly to outer cylinder. Remove two unions (118) and two packings (119) from swivel fitting assembly. Remove spring pin (120), collar (121), swivel (122), two back-up rings (123), and two O-rings (124) from each end of swivel bolt (125).

(15) Remove cotter pin (126), nut (127), washer (128), washer (129), and withdraw pulley shaft (130) from outer cylinder. Remove cotter pin (131), nut (132) and washer (133) from slider (134), and remove slider with pivot (135) and bushing (136) from pulley shaft.

(16) Remove set-screw (137) securing cable guard assembly, loosen two nuts (139) from two screws (140), and remove both halves of cable guard (141) with guard pins (142) from outer cylinder.

(17) Remove two pins (143), two thrust washers (144) and bushing (145) from outer cylinder.

(18) Remove nut (147), washer (148), two pins (151), two washers (149) and bolt (150), and remove two bushings (152) and spacer (153) from outer cylinder (154).

NOTE: Cotter pin (146) securing nut (147) to bolt (150) is removed on separation of steering actuator and shock strut assembly.

D. Disassemble Nose Gear Shock Strut Part No. 71-300-9 and 71-300-11 (Figure 1103)

WARNING: DO NOT ATTEMPT TO DISASSEMBLE SHOCK STRUT OR REMOVE AIR CHARGING VALVE BEFORE RELEASING ALL AIR PRESSURE THROUGH AIR CHARGING VALVE. FAILURE TO DO SO COULD RESULT IN SERIOUS INJURY OR POSSIBLE LOSS OF LIFE.

(1) Remove air charging valve cap (2). Unscrew nut of air charging valve (1) couter clockwise (approximately one turn) to slowly release air pressure.

WARNING: DO NOT ATTEMPT TO FURTHER LOOSEN OR BACK OFF 3/4 INCH HEXAGON STEM ASSEMBLY BEFORE ENSURING THAT ALL AIR PRESSURE IS RELEASED FROM THE SHOCK STRUT ASSEMBLY.

(2) Remove air charging valve (1).

(3) Remove set-screw (3) securing end cap sub-assembly to outer cylinder. Unscrew and remove end cap sub-assembly from outer cylinder. Turn shock strut upside down and drain off hydraulic fluid.

NOTE: Strain fluid through a suitable fine mesh strainer. Pay particular attention to any foreign matter removed from the fluid (refer to INSPECTION/CHECK) and reject fluid for further use in nose gear shock strut.

(4) Remove O-ring (4) from end cap sub-assembly.

(5) Cut lockwire and remove machine screw (6) securing nut (7) of end cap sub-assembly. Unscrew nut (7) using special tool T-188, and remove end cap (8) from support tube (9). Remove O-ring (11) from upper end of support tube.

NOTE: The shoulder in support tube (9) is a shrink fit and will not be removed.

(6) At lower end of support tube, remove pellet (12) covering set-screw (13), loosen set-screw and remove guide bearing (14), damping plate (15) and plate orifice (16) from support tube.

NOTE: Do not remove slipper ring (18) unless it is defective. A split ring is fitted under slipper ring only where guide bearing has a corresponding groove.

(7) Disengage upper and lower torque arms by removing quick-release pin (19). Remove chain (20) securing quick-release pin to upper torque arm.

(8) On shock strut assembly Part No. 71-300-9 only: push piston assembly into outer cylinder and remove lockring (22) from shoulder nut (23) at top of piston assembly. Remove shoulder nut using special tool T-190, and withdraw piston assembly with for from outer cylinder, dislodging flapper (24), flapper spacer (25), floating piston (28) and bumper (29) of piston assembly. Remove shoulder (30) from piston tube (31). Remove rings (32) and (33), and bearings (26) and (27) from floating piston (28).

NOTE: The two bearings (27) each consist of two halves. The halves are matched and must be retained as sets.

(9) On shock strut assembly Part No. 71-300-11 only: push piston assembly into outer cylinder, and remove lock ring (22) from shoulder nut (23) at top of piston assembly. Remove shoulder nut using special tool T-190, and withdraw piston assembly with fork from outer cylinder, dislodging flapper spacer (25), floating piston (28) and bumper (29) of piston assembly. Remove shoulder (30) from piston tube (31). Remove rings (32) and (33) from floating piston (28).

(10) Remove cotter pin (38), nut (39), washer (40) and lock bolt (41). Unscrew locknut (34) using special tool T-187, and remove nut with washer (35) and shim (36).

(11) Remove diaphragm (37) and cartridge assembly, and withdraw piston tube (31) from fork (55). Remove O-ring (42) and back-up ring (43) from cap plug (45) of cartridge assembly.

NOTE: Do not remove cap plug (45) from cylinder (46) of cartridge assembly unless it is defective and has to be replaced (refer to FITS AND CLEARANCES).

(12) Withdraw bushing (53) from fork (55). Remove lubricator (54) if defective.

NOTE: Remove bushings (48) and (49) only if defective (refer to FITS AND CLEARANCES).

(13) Remove cotter pin (56), nut (57), washer (58) and bolt (59), and remove lower torque arm assembly from fork. Remove bushings (61) and dust ring (62) from torque arm (64). Remove lubricator (63) if defective remove two dust rings (66) from fork (55).

NOTE: Do not remove bushings (50) from fork (55) unless they are defective and have to be replaced (refer to FITS AND CLEARANCES). If bushings are removed, there may be shims under the bushing flanges; these shims will have been installed during a previous repair (refer to REPAIR). Similarly shims may be installed under the flanges of bushings (61) if these bushings have been previously installed by Mod 6/1377. In both cases make carefully note of shim position for subsequent installation.

(14) Remove two nuts (67), two washers (68) and two bolts (69) attaching axle and two towing spools to fork, and withdraw two towing spools (70); cut lockwire and loosen setting screws (71) securing retaining nut (72) to adjustment spacer (73), and remove lockring (74) from spacer (75); withdraw axle (76) from spacer, adjustment spacer, retaining nut and fork. Remove four bushes (52) from lugs on fork.

(15) Remove set-screw (77) securing locknut (78) to lower end of outer cylinder, and remove locknut using special tool T-191. Remove washer (79), scraper (80), bearing retainer (81), and bearing (82).

NOTE: Do not remove sleeve (83) from outer cylinder unless it is defective and has to be replaced (refer to FITS AND CLEARANCES).

(16) Remove nut (84), washer (85), screw (86), two blocks (87), locking clip (88) and locking key (89) at cylinder nut (90) securing steering collar assembly to outer cylinder. Remove cylinder nut (90), thrust washer (91), steering collar assembly complete with upper torque arm assembly, bushing (92) and two thrust washers (93) from outer cylinder.

NOTE: Refer to DESCRIPTION AND OPERATION, Tables 4 and 5 from variations due to special shimmy damper installation.

(17) Remove screws (111) and cover (112) from steering collar assembly. Remove cotter pin (94), nut (95) and washer (96) from bolt (97) attaching upper torque arm assembly to steering collar. Hold upper torque arm to its uppermost position, and using a screwdriver, carefully pry off cam (98) from bolt (97). Withdraw bolt and remove spring (99) and upper torque arm assembly. Remove two dust rings (109) from steering collar assembly.

(18) Remove nuts (101), washers (102), screws (103), spring retainer (104), spring (105) and latch pin (106) from upper torque arm (107).

NOTE: Do not remove two bushings (108) from upper torque arm unless they are defective and have to be replaced (refer to FITS AND CLEARANCES).

(19) Remove spring pin (113) and stud (114) with locknut (116) from steering collar assembly.

NOTE: Do not remove bushing (117), two bushings (119), bearing (118) or lubricator (120) from steering collar (121) unless they are defective and have to be replaced (refer to FITS

AND CLEARANCES). If bushings (119) are removed, there may be shims under the bushing flanges. These shims were installed during a previous repair (refer to REPAIR), and shim positions should be recorded for subsequent re-installation.

Cotter pin (115) securing locknut (116) to stud (114) is removed on separation of steering actuator and shock strut assemblies.

(20) Cut lockwire and remove two bolts (122) attaching swivel fitting assembly to outer cylinder. Remove two unions (124) and two packings (125) from swivel fitting assembly. Remove spring pin (126), collar (127), swivel (128), two back-up rings (129), and two O-rings (130) from each end of swivel bolt (131).

(21) Remove cotter pin (132), nut (133), washer (134), washer (135), and withdraw pulley shaft (136) from outer cylinder. Remove cotter pin (137), nut (138) and washer (139) from slider (140), and remove slider with pivot (141) and bushing (142) from pulley shaft.

(22) Remove set-screw (143) securing cable guard assembly. Slacken two nuts (145) from screws (146) and remove both halves of cable guard (147) with guard pins (148) from outer cylinder.

(23) Remove two pins (149), two thrust washers (150) and bushing (151) from outer cylinder.

(24) Remove nut (153), washer (154), two pins (157), two washers (155) and bolt (156), and remove two bushings (158) and spacer (159) from outer cylinder (160).

NOTE: Cotter pin (152) securing nut (153) to bolt (156) is removed on separation of steering actuator and shock strut assembly.

E. Disassemble Nose Gear Shock Strut Part No. 71-300-15 through 71-300-33 (Figure 1104)

WARNING: DO NOT ATTEMPT TO DISASSEMBLE SHOCK STRUT OR REMOVE AIR CHARGING VALVE BEFORE RELEASING ALL AIR PRESSURE THROUGH AIR CHARGING VALVE. FAILURE TO DO SO COULD RESULT IN SERIOUS INJURY OR POSSIBLE LOSS OF LIFE.

(1) Remove air charging valve cap (2). Unscrew nut of air charging valve (1) counterclockwise (approximately one turn) to slowly release air pressure.

WARNING: DO NOT ATTEMPT TO FURTHER LOOSEN OR BACK OFF 3/4 INCH HEXAGON STEM ASSEMBLY BEFORE ENSURING THAT ALL AIR PRESSURE IS RELEASED FROM THE SHOCK STRUT ASSEMBLY.

(2) Remove air charging valve (1).

(3) Remove set-screw (3) securing end cap sub-assembly to outer cylinder. Unscrew and remove end cap sub-assembly from outer cylinder. Turn shock strut upside down and drain off hydraulic fluid.

NOTE: Strain fluid through a suitable fine mesh strainer. Pay particular attention to any foreign matter removed from the fluid (refer to INSPECTION/CHECK) and reject fluid for further use in nose gear shock strut.

(4) Remove O-ring (4) from end cap sub-assembly.

(5) Cut lockwire and remove machine screw (6) securing nut (7) of end cap sub-assembly. Unscrew nut (7) using special tool T-188, and remove end cap (8) from support tube (9). Remove O-ring (11) from upper end of support tube.

NOTE: The shoulder in support tube (9) is a shrink fit and is not removed.

(6) At lower end of support tube, remove pellet (12) covering set-screw (13), loosen set-screw and remove guide bearing (14), damping plate (15) and plate orifice (16) from support tube.

NOTE: Do not remove slipper ring (18) unless it is defective. A split ring is fitted under slipper ring only where guide bearing has a corresponding groove.

(7) Disengage upper and lower torque arms by removing quick-release pin (19). Remove chain (20) securing quick-release pin to upper torque arm.

(8) On shock strut assembly Part No. 71-300-15 and -17 only: Push piston rod and fork assembly into outer cylinder, and remove lockring (23) from shoulder nut (24) at top of piston assembly. Remove shoulder nut using special tool T-190, and withdraw piston assembly with fork from outer cylinder, dislodging flapper spacer (26), floating piston (27) and bumper (29) of piston assembly. Remove shoulder (30) from piston tube (31). Remove piston and bumper from outer cylinder and remove rings (32) and (34) from floating piston (27).

(9) On shock strut assemblies Part No. 71-300-19, -21, -23, and -25 only: Push piston rod and fork sub-assembly into outer cylinder and remove lockring (23) from shoulder nut (25). Remove shoulder nut using special tool T-190 and withdraw piston rod and fork sub-assembly from outer cylinder, dislodging floating piston (28) and bumper (29) of piston assembly. Remove shoulder (30) from piston tube (31). Remove piston and bumper from cylinder and remove rings (33) and (35) from piston.

(10) On shock strut assemblies Part No. 71-300-27, -29, -31 and -33 only: Push piston rod and fork sub-assembly into outer cylinder and remove cotter pin (23A) and locking screw (23B) from shoulder nut (25A). Remove shoulder nut using special tool T-190 and withdraw piston rod and fork sub-assembly from outer cylinder, dislodging floating piston (28) and bumper (29) of piston assembly. Remove shoulder (30) from piston tube (31). Remove piston and bumper from cylinder and remove rings (33) and (35) from piston.

(11) On shock strut assemblies Part No. 71-300-15 through -23 only: Remove cotter pin (40), nut (41), washer (42) and lockbolt (43). Unscrew locknut (36) using special tool T-187 and remove locknut with washer (37) and shim (38).

(12) On shock strut assemblies Part No. 71-300-25, -27, -29, -31 and -33 only: Gain access through hole in locknut (36A) and remove self-locking nuts (41A), washer (176) and profile washer (42A) securing lockbolts (43A). Remove lockbolts. Unscrew locknut (36A) using special tool T-187 and remove locknut with washer (37) and shim (38).

(13) Remove diaphragm (39) and cartridge assembly, and withdraw piston tube (31) from fork (56). Remove O-ring (44) and back-up ring (45) from cap plug (47) of cartridge assembly.

NOTE: Do not remove cap plug (47) from cylinder (48) of cartridge assembly unless it is defective and has to be replaced (refer to FITS AND CLEARANCES).

(14) Withdraw bushings (54) from fork (56). Remove lubricator (55) if defective.

NOTE: On shock strut assemblies Part No. 71-300-15 through -23 only: Remove bushing (49) and (50) only if defective (refer to FITS AND CLEARANCES). On shock strut assemblies Part No. 71-300-25, -27, -29, -31 and -33, bushings (49) and (50) are replaced by two bushings (49A).

(15) Remove cotter pin (57), nut (58), washer (59) and bolt (60), and remove lower torque arm assembly from fork. Remove bushings (61) and dust ring (62) from torque arm (65). Remove lubricator (64) if defective. Remove two dust rings (66) from fork (56).

NOTE: Do not remove bushings (52) from fork (56) unless they are defective and have to be replaced (refer to FITS AND CLEARANCES). If bushings are removed, there may be shims (172) under the bushing flanges; these shims were installed during a previous repair (refer to REPAIR). Similarly, shims may be installed under the flanges of bushings (61). In both cases, record shim positions for subsequent re-installation.

(16) Remove two nuts (67), two washers (68) and two bolts (69) attaching axle and two towing spools to fork, and withdraw two towing spools (70); cut lockwire and loosen setting screws (71) securing retaining nut (72) to adjustment spacer (73), and remove lockring (74) from spacer (75); withdraw axle (76) from spacer, adjustment spacer, retaining nut and fork. Remove four bushings (53) from lugs on fork.

(17) On shock strut assemblies Part No. 71-300-15, -17 and -19 only: Remove set-screw (77) securing locknut (79) to lower end of outer cylinder, and remove locknut using special tool T-191. Remove washer (80), scraper (82), bearing retainer (83), and bearing assembly (85). Remove sleeve from bearing assembly.

(18) On shock strut assemblies Part No. 71-300-21, -23, -25, -27, -29, -31 and -33 only: Remove set-screw (77), securing locknut (78) to lower end of outer cylinder, using special tool T-191. Remove scraper (81) and bearing (84).

(19) On shock strut assembly Part No. 71-300-15 only: Remove nut (86), washer (87), screw (88), two blocks (89), locking clip (90) and locking key (91) at cylinder nut (92), locating steering collar assembly on outer cylinder. Remove cylinder nut (92), thrust washer (93), steering collar assembly complete with upper torque arm assembly bushing (98) and two thrust washers (94) from outer cylinder.

NOTE: Refer to DESCRIPTION AND OPERATION, Table 5A for variations due to special shimmy damper installation on shock strut assembly Part No. 71-300-15 only.

(20) On shock strut assemblies Part No. 71-300-17, -19, -21, -23, -25, -27, -29, -31 and -33 only: Remove nut (86), washer (87), screw (88), two blocks (89), locking clip (90) and locking key (91) at cylinder nut (92), locating steering collar on outer cylinder. Remove cylinder nut (92), shim washer (96) thrust ring (95) and slide steering collar complete with bonded item thrust washer (130) and wear washer (129) and attached upper torque arm and bushing (98) from outer cylinder.

(21) Remove screws (117) and cover (118) from steering collar assembly. Remove cotter pin (99), nut (100) and washer (101) from bolt (102) attaching upper torque arm assembly to steering collar. Hold upper torque arm to its uppermost position, and using a screwdriver, carefully pry off cam (103) from bolt (102). Withdraw bolt and remove spring (104) and upper torque arm assembly. Remove two dust rings (114) from steering collar assembly.

(22) Remove nuts (106), washers (107), screws (108), spring retainer (109), spring (110) and latch pin (111) from upper torque arm (112).

NOTE: Do not remove two bushings (113) from upper torque arm unless they are defective and have to be replaced (refer to FITS AND CLEARANCES).

(23) On shock strut assemblies Part No. 71-300-15 through -23 only: Remove spring pin (119) and stud (120) with locknut (122) from steering collar assembly.

NOTE: 1. On shock strut assembly Part No. 71-300-15 only: Do not remove bushing (123), two bushings (126), bearing (124) or lubricator (127) from steering collar (128) unless they are unserviceable and have to be replaced (refer to FITS AND CLEARANCES). If bushings (126) are removed, there may be shims under the bushing flanges. These shims were installed during a previous repair (refer to REPAIR) and shim positions should be recorded for subsequent re-installation.

2. On shock strut assemblies Part No. 71-300-17, -19, -21, -23, -25, -27, -29, -31 and -33 only: Do not remove bushing (123), two bushings (126), bearing (125), lubricator (127) and bonded items, wear washer (129) and thrust washer (130) from steering collar (128) unless unserviceable (refer to FITS AND CLEARANCES). If bushings (126) are removed, there may be shims under bushings flanges. These shims were installed during previous repair (refer to REPAIR). Shim positions should be recorded for use in subsequent re-installation.

3. Cotter pin (121) securing locknut (122) to stud (120) was removed during separation of steering actuator and shock strut assembly.

(24) On shock strut assemblies Part No. 71-300-25, -27, -29, -31 and -33: Remove spring pin (119) and stud (120) with washer (123A) and locknut (122) from steering collar. Carry out requirements of NOTE following step (23), as applicable.

(25) Cut lockwire and remove two bolts (131) attaching swivel fitting assembly to outer cylinder. Remove two unions (133) and two packings (134) from swivel fitting assembly. Remove spring pin (135), collar (136), swivel (137), two back-up rings (138) and two O-rings (139) from each end of swivel bolt (140).

(26) Remove cotter pin (141), nut (142), washer (143), washer (144) and withdraw pulley shaft (145) from outer cylinder. Remove cotter pin (146), nut (147) and washer (148) from slider (140), and remove slider with pivot (150) and bushing (151) from pulley shaft.

(27) Remove two pins (158), two thrust washers (159) and bushing (160) from outer cylinder.

(28) Remove set-screw (152) securing cable guard assembly. Remove two nuts (154) from two screws (155) and remove both halves of cable guard (156) with guard pins (157) from outer cylinder.

(29) Remove nut (162), washer (163), two pins (166), two washers (164) and bolt (165), and remove two bushings (167) and spacer (168) from outer cylinder (170).

NOTE: Cotter pin (161) securing nut (162) to bolt (165) is removed on separation of steering actuator and shock strut assembly.

(30) Remove sleeve (171) from outer cylinder (170).

NOTE: Do not attempt to remove bonded item, friction disc (97) from outer cylinder unless it is unserviceable (refer to FITS AND CLEARANCES).

(31) Do not remove name and instruction label (173) on Modification plate (174).

THIS PAGE INTENTIONALLY LEFT BLANK

CLEANING

1. Procedures

   A. General

      (1) Clean components by washing or spraying with a dry cleaning solvent (refer to Table 201).

      WARNING: USE SOLVENT IN A WELL-VENTILATED AREA AND AVOID BREATHING FUMES. AVOID SKIN CONTACT AND KEEP AWAY FROM FLAME.

      (2) Dry with moisture-free compressed air or a lint-free cloth.

Table 201

Cleaning Materials and Compounds

MATERIAL	SPECIFICATION OR MANUFACTURER
Solvent	P-D-680

THIS PAGE INTENTIONALLY LEFT BLANK

INSPECTION/CHECK

1. Procedures

   A. General

      (1) Examine any foreign matter found on draining the hydraulic fluid from the shock strut assembly (refer to DISASSEMBLY). Pay particular attention to any metal particles, and determine the source during the inspection procedure.

      (2) Carry out a magnetic particle inspection of all magnetic metal components, where practicable.

      (3) Inspect non-magnetic metal components using the fluorescent penetrant method, or an approved dye penetrant method.

      (4) Inspect all parts visually for signs of fatigue and cracks, and for damage such as galls, scores, scratches, excessive wear and corrosion.

      (5) Inspect threaded parts for damaged, stripped or crossed threads.

      (6) Check all holes, internal and external diameters for wear, concentricity, and taper. Refer to FITS AND CLEARANCES, Table 601, for original tolerances and service limits. Repair or replace parts worn in excess of service limits.

      (7) Inspect dry film lubrication on lugs of upper and lower torque arms, torque arm repair bushings and wear plates for adhesion to parent metal, scuffing and scoring.

THIS PAGE INTENTIONALLY LEFT BLANK

REPAIR

1. Procedures

A. General

(1) Replace all defective parts not listed in FITS AND CLEARANCES, Table 601.

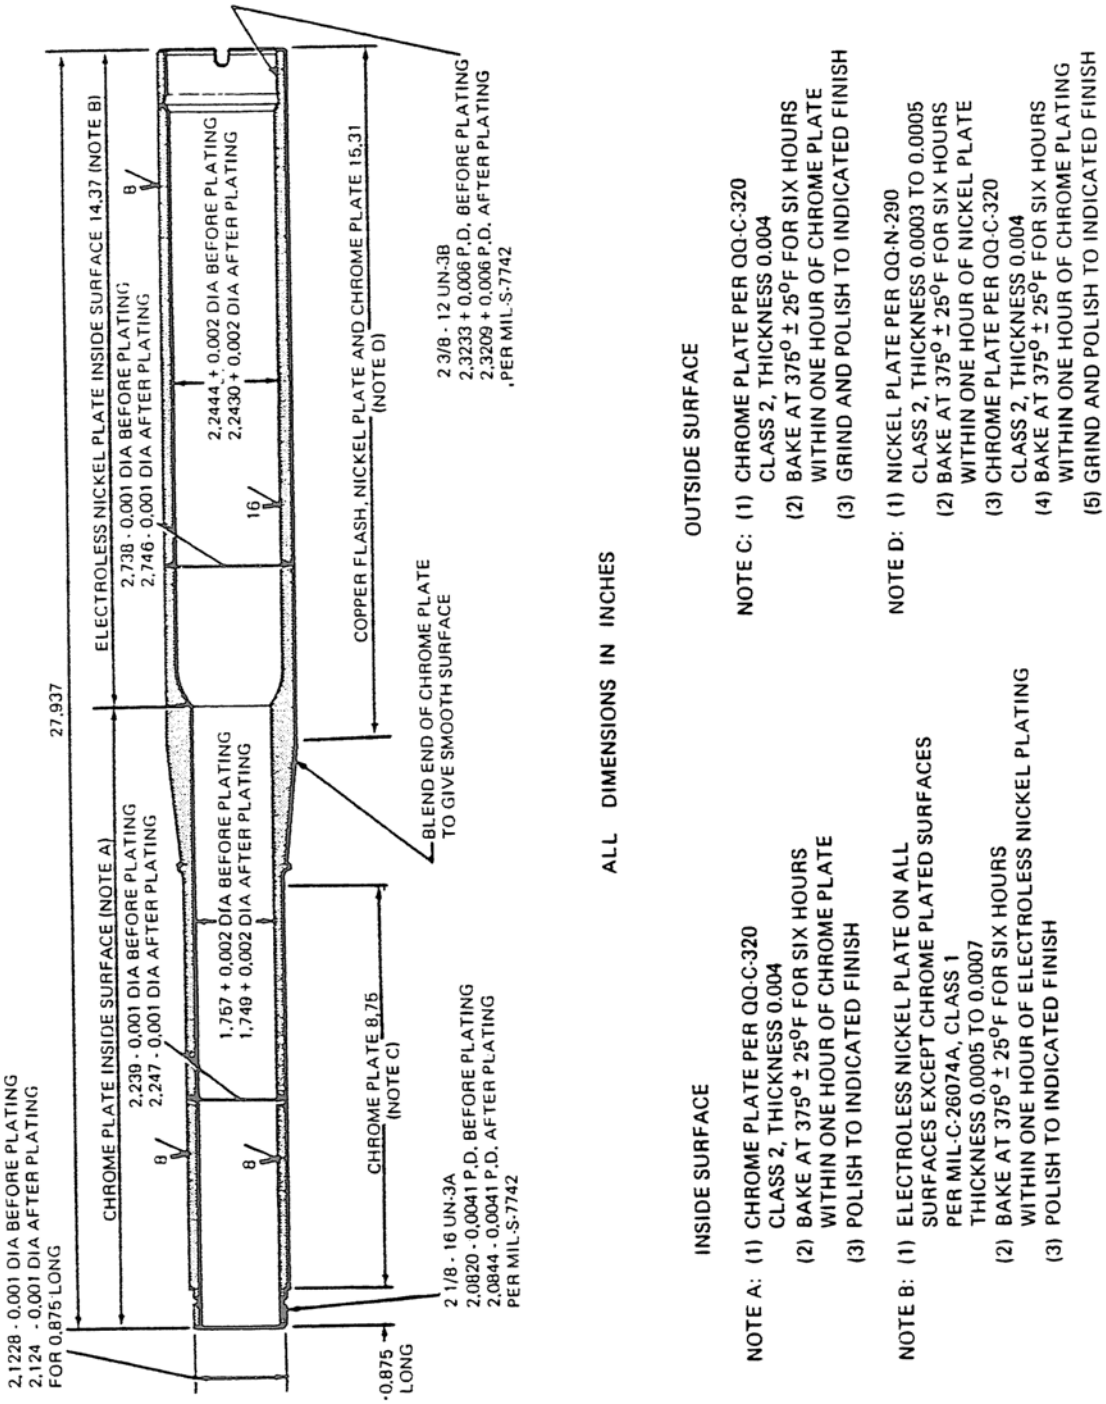
(2) When anodized parts have had protective treatment damaged or removed, apply a protective coating of Alodine solution 1200S (refer to Table 401) to the affected area(s) or reanodize the part.

(3) Replace standard parts such as cotter pins, spring pins, washers, nuts, bolts or screws, lockrings, packing or O-rings, back-up rings and springs at each overhaul.

(4) Where indicated in FITS AND CLEARANCES, Table 601, parts may be repaired by hard chrome plating or hard anodizing the affected surface, then grinding or honing the surface to the original dimension shown in the table. Where parts were originally chrome plated, strip the original plating before repair. Parts not previously plated should be ground to the minimum necessary to produce a smooth surface before plating the part.

(5) Dry film lubricant on lugs of upper and lower torque arms, or repair bushings (refer to paragraph C.) must be repaired or stripped and re-processed (refer to paragraph H.).

B. Replating Piston Tube



(1) When replating of piston tube (index No. (28), Figure 1101 or 1102, index No (31), Figures 1103 and 1104 is necessary, refer to Figure 401 for chrome plating and electroless nickel plating areas, and dimensions of inside and outside surfaces.

NOTE: When a piston tube fails to meet inspection requirements and cannot be replaced, piston tubes 71-141-7 and 71-141-9 are interchangeable, and can be fitted to shock strut assemblies Part No. 71-300-1 through -11 and 71-300-15 through -27.

C. Repair Upper and Lower Torque Arms with Worn Inner Faces

A torque arm (Part No. 71-102 or 71-163) or torque link (Part No. 71-338) with worn inner faces can be repaired as follows:

(1) Rework torque arm inner faces and holes to dimensions shown in Figures 402.

(2) Apply protective coating of Alodine solution 1200S (refer to Table 401) to bare metal surfaces.

(3) Machine two bushings to dimensions shown in Figure 402. Use 17-4PH Corrosion Resistant Steel, Condition H-1150.

(4) Coat bushings with zinc chromate primer (refer to Table 401) and press bushings into position with flanges against torque arm inner faces.

(5) Line ream bushing holes to 0.3750 + 0.0006 inch diameter.

(6) Apply dry film lubricant to outer face of bushings in areas of contact with bushings in shock strut boss (refer to Table 401).

D. Repair Upper and Lower Torque Arms with Damaged Anti-rotation Shoulders

A torque arm (Part No. 71-102 or 71-163) or torque link (Part No. 71-338) with damaged anti-rotation shoulders can be repaired as follows:

(1) Manufacture stop plate as shown in Figure 403.

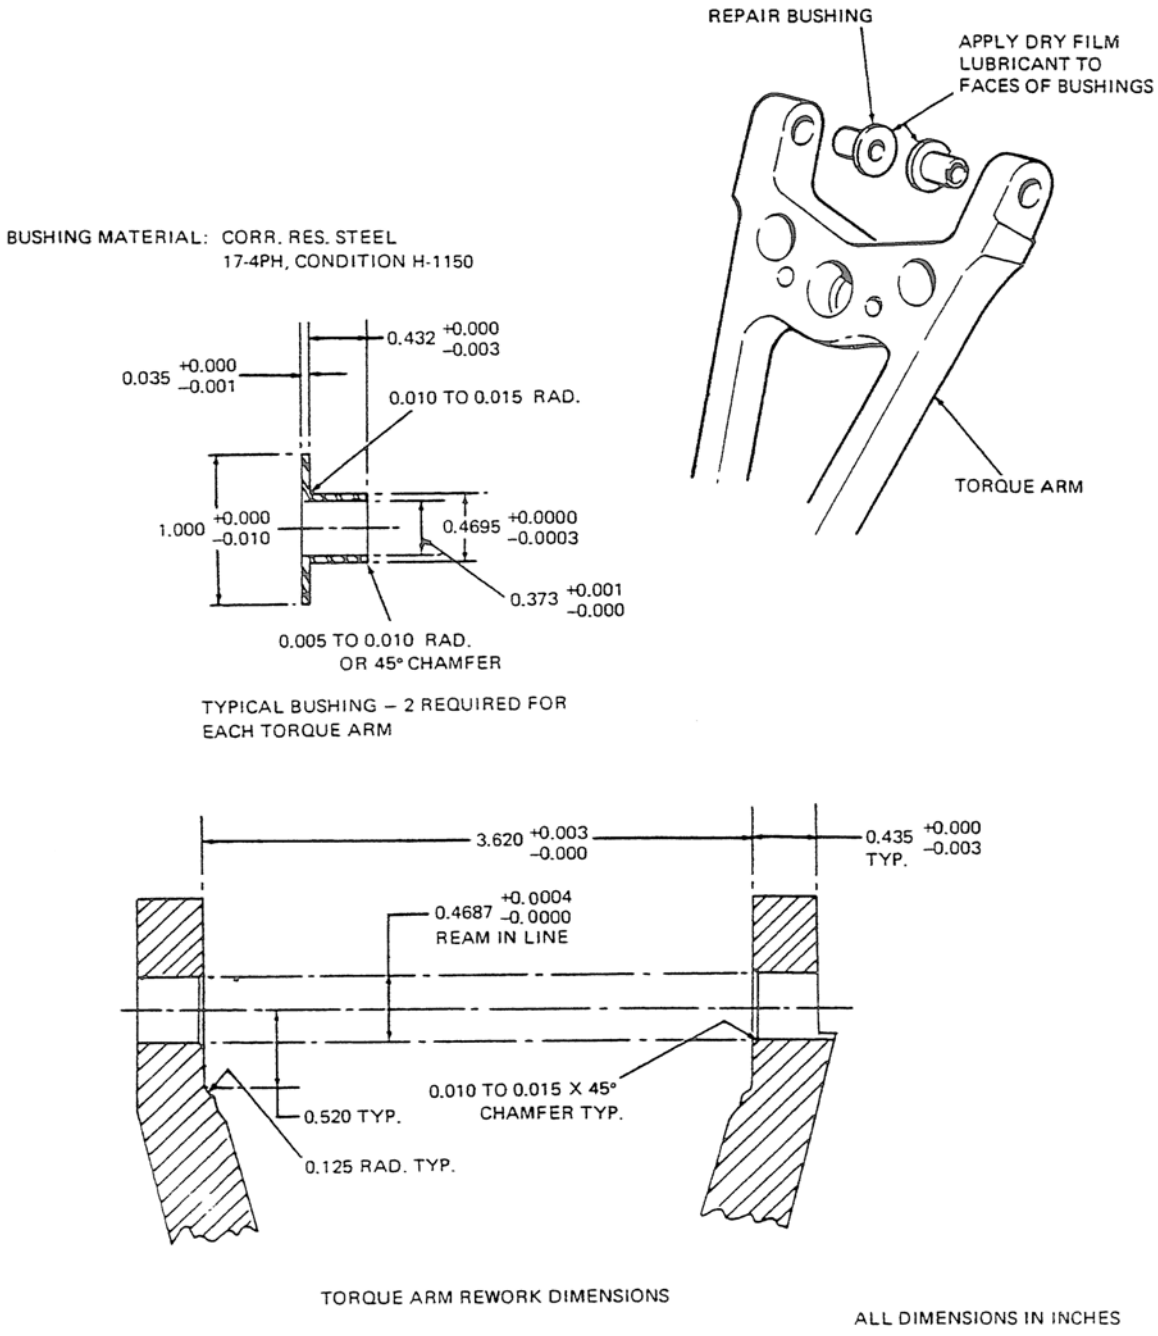
(2) Machine off existing shoulder until thickness of torque arm lug is 0.510 - 0.005 inch. Refer to Figure 403. Apply protective coating of Alodine solution 1200S (refer to Table 401) to bare metal surfaces.

(3) Clamp stop plate to torque arm in location shown in Figure 403. Using stop plate as template, drill holes in torque arms using a No. 29 drill and tap 8-32UNC-3B.

(4) Coat contact face of stop plate with zinc chromate primer (refer to Table 401) and secure stop plate to torque arm with two MS24677-15 screws.

(5) Wirelock screws using MS20995C32 lockwire.

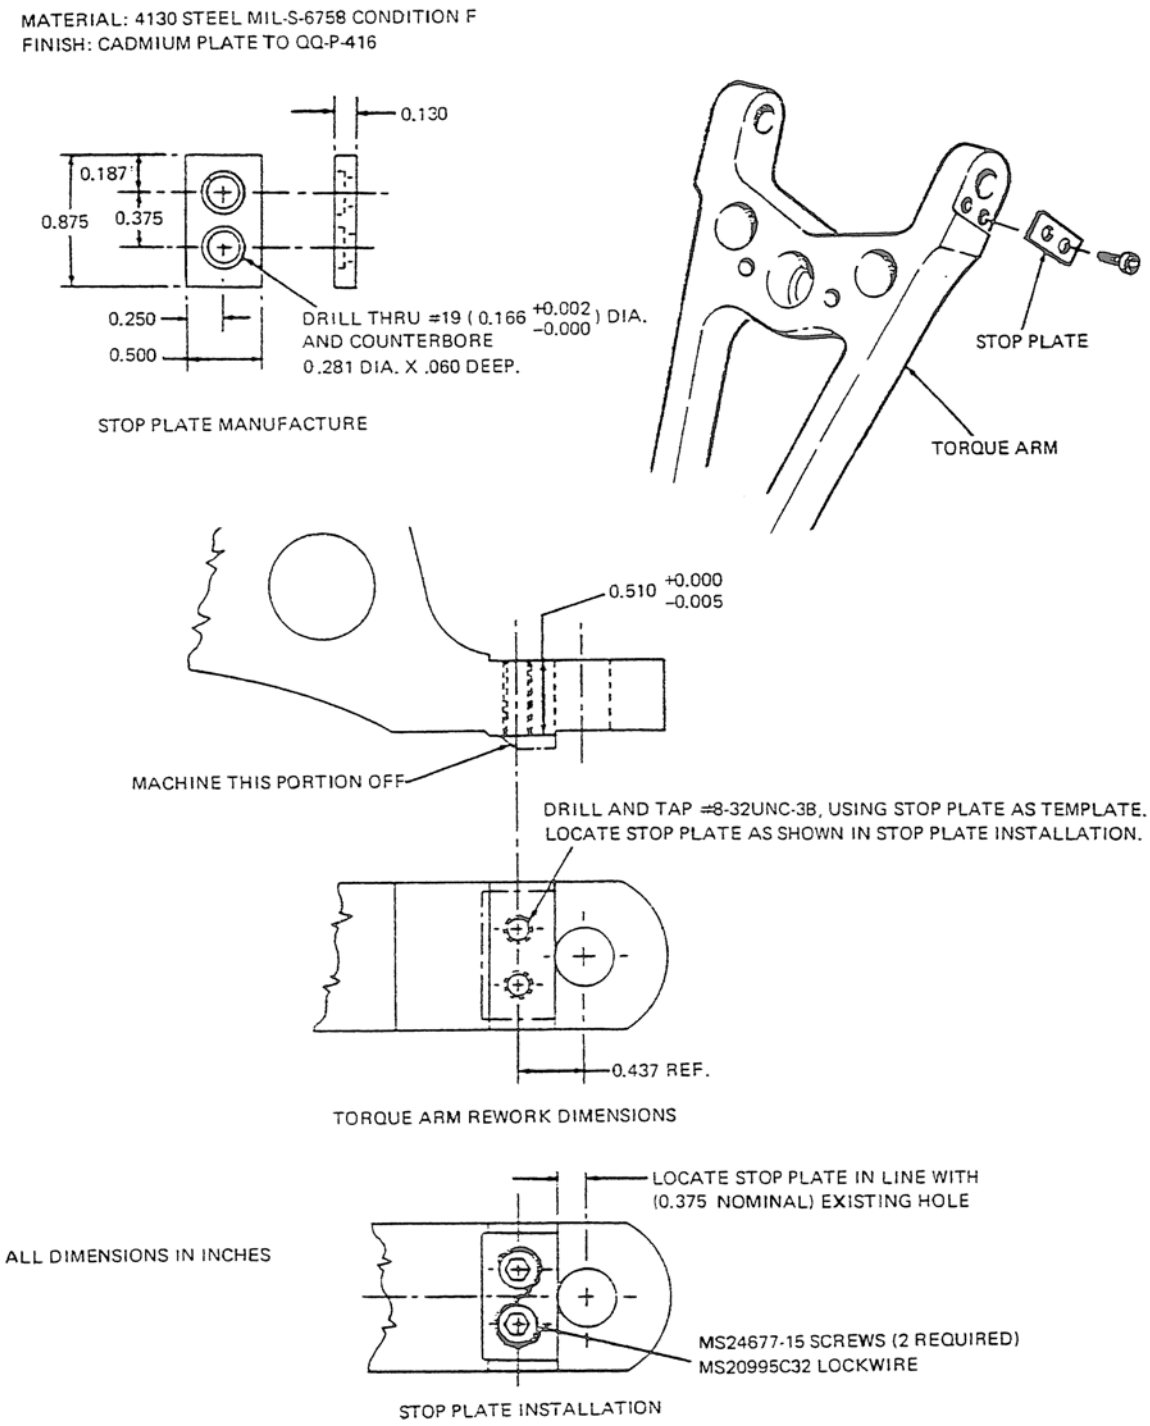
E. Repair Steering Collar Assembly or Fork Sub-assembly at Torque Arm Lugs



Wear at torque arm lugs of steering collar assembly (Part No. 71-177) or fork assembly (Part No. 71-108) may be required as follows:

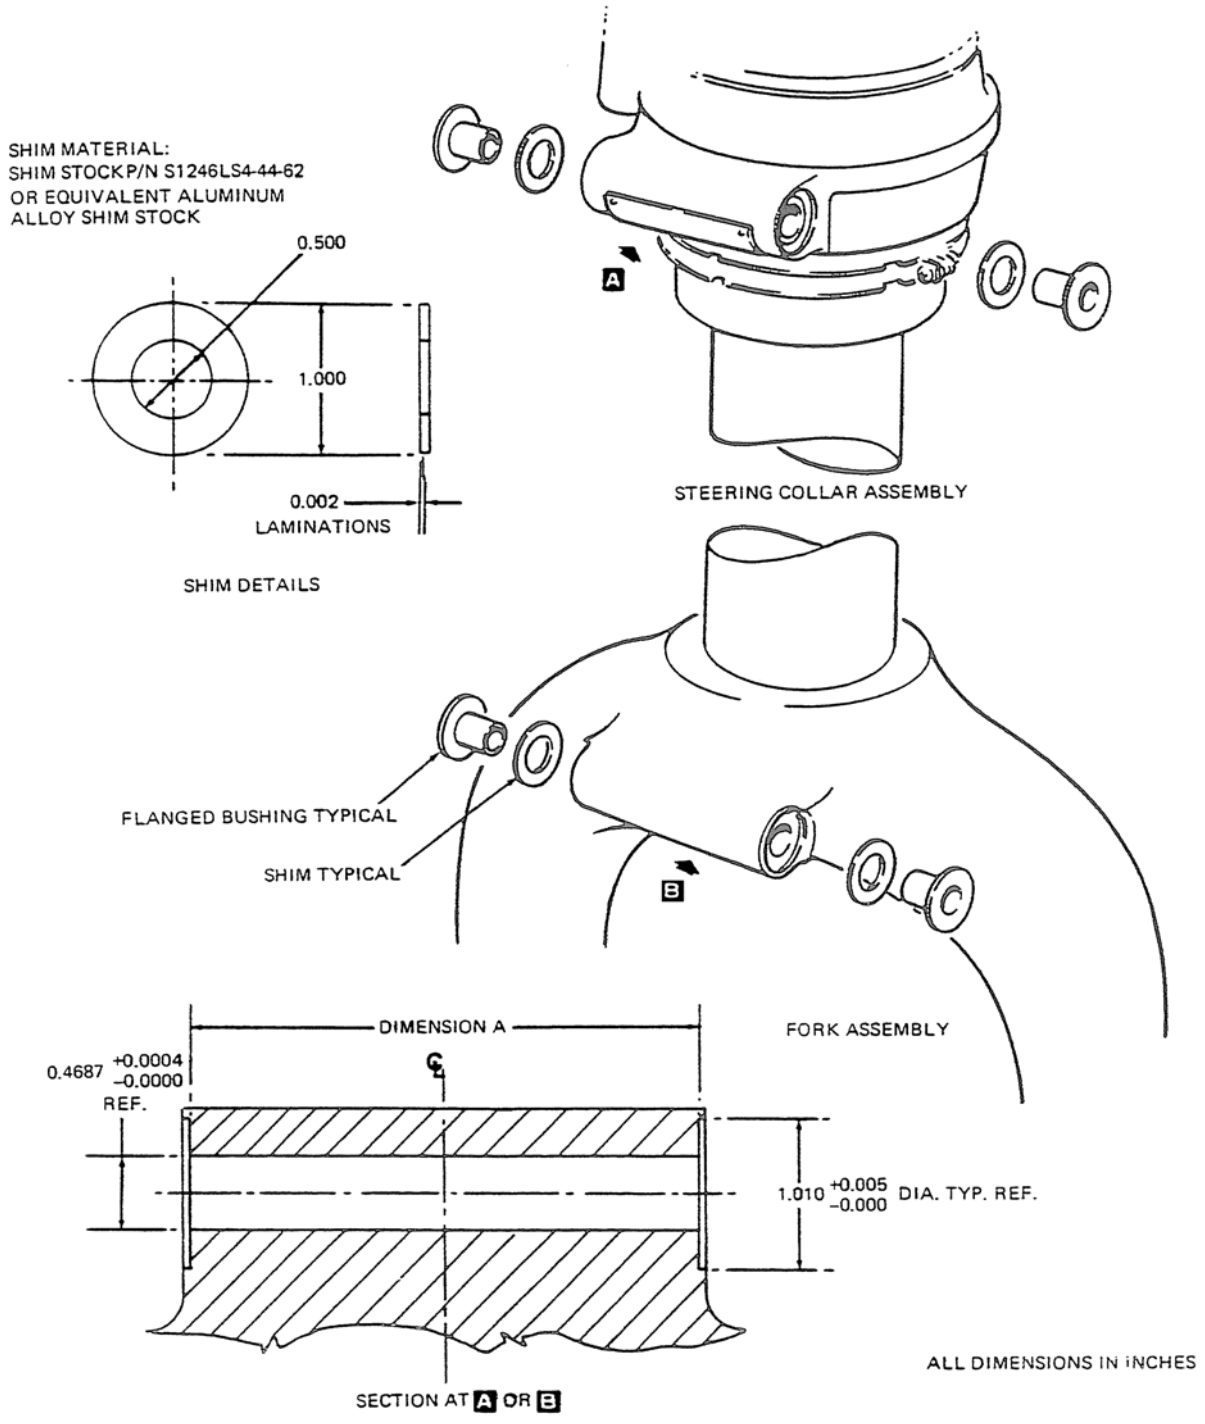
(1) If still installed, remove flanged bushings (Part No. 71-305-9).

(2) Clean up spotface of torque arm lug to a maximum increase in depth of 0.030 inch. Note depth increases.



(3) Apply protective coating of Alodine solution 1200S (refer to Table 401) to bare metal surfaces.

(4) Record face-to-face dimension as shown in Figure 404 (dimension A).



Repair to Torque Arms with Worn Inner Faces

Figure 402

Repair to Torque Arms with Damaged Anti-rotation Shoulders

Figure 403

Repair to Torque Arm Lugs on Steering Collar Assembly or Fork Sub-assembly

Figure 404

(5) Machine shims from shim stock Part No. S1246LS4-44-62 (or equivalent aluminum alloy shim stock) as shown in Figure 404.

(6) Determine shims required to give face-to-face dimension of 3.424 - 0.002 inches equally disposed about the centerline.

(7) Assemble shims against bushing (Part No. 71-305-9) flanges and install bushings.

F. Repair Upper Torque Arm Forked Lugs (Figure 405)

(1) Remove bushings (Part No. 71-164) if installed in torque arm.

(2) Spotface inside surfaces of lug 1.000 + 0.005 inch diameter to a width of 0.570 + 0.005 inch. New width must be equal about centerline of torque arm.

(3) Machine circular groove 0.030 inch deep with 0.030 radius around OD of spotface. Grind 0.060 inch radii (to relieve sharp edges left by spotfacing) to dimensions shown.

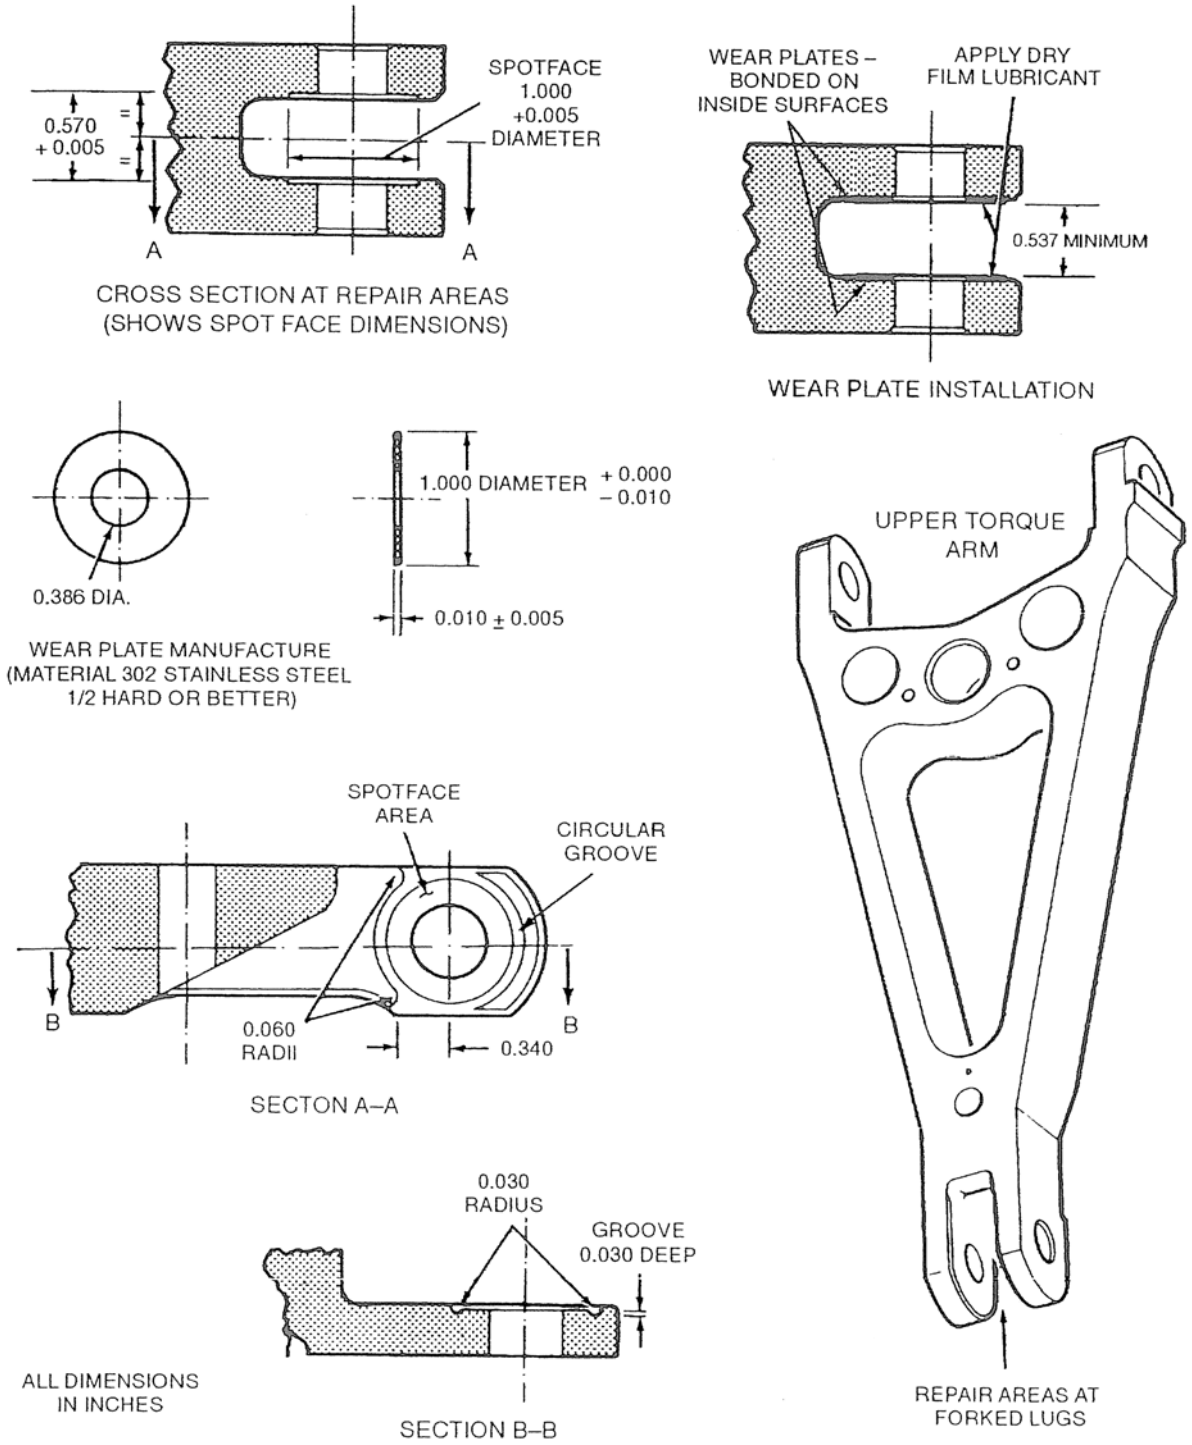
(4) Manufacture two wear plates from 302 stainless steel plate, 1/2 hard or better, to dimensions shown.

(5) Scuff sand spotfaced areas on torque arm and one side of each wear plate, using Scotch Brite pad or aluminum emery paper No. 300. Clean scuffed areas with methyl-ethyl-ketone or acetone.

(6) Observe safety precautions. Prepare and apply Scotch Weld Adhesive EC1751 B/A in accordance with the manufacturer's instructions to scuffed surfaces of torque arm and wear plates. Position wear plates on inner surfaces of lugs, mating adhesive surfaces and aligning hole in plate with corresponding hole in lug. Clamp plates in position and ensure that width between inside surfaces of installed wear plates is not less than 0.537 inch.

(7) Permit bonded areas to cure for 24 hours at room temperature (approximately 70ºF) before removing clamps.

NOTE: Scotch Weld is considered cured when surface of adhesive resists fingernail penetration.



(8) Reinstall bushings on torque arm lugs (if removed) and ensure correct fit (refer to FITS AND CLEARANCES).

(9) Apply dry film lubricant to wear plates in areas of contact with bushings in lower torque arm.

(10) Assemble torque arm to shock strut. Use shims 71-311-9 as necessary to obtain correct fit at joint formed when connecting upper and lower torque arms (refer to ASSEMBLY).

G. Replace Shimmy Damper Bonded Parts (Shock Strut Assemblies 71-300-17 to 71-300-29)

Shock strut shimmy damper bonded parts, thrust washer (Part No. 71-018-5) and friction disc (Part No. 71-323-1), can be replaced as follows:

Repair to Upper Torque Arm with wear at Fork-end Lugs

Figure 405

(1) Remove thrust washer or friction disc (as required) by machining, taking care not to remove metal from steering collar when machining thrust washer, or outer cylinder when machining friction disc.

(2) Scuff and machined areas to remove any residual bonding material, using Scotch Brite pad or aluminum emery paper No. 300. Similarly, scuff sand one side of friction disc or backing side of thrust washer bearing material.

(3) Clean scuffed areas with methyl-ethyl-ketone or acetone.

(4) Observe any safety precautions, prepare and apply Scotch Weld adhesive EC1752 B/A in accordance with adhesive manufacturer's instructions to scuffed areas of parent component and part being bonded.

(5) Position items for bonding as follows:

(a) Position thrust washer concentrically on steering collar, mating adhesive side of washer with adhesive on collar and clamp securely.

OR

(b) Position friction disc on outer cylinder, mating adhesive side of disc with adhesive on cylinder and clamp securely.

(6) Leave clamps in position during curing period of 24 hours at room temperature (approximately 70ºF).

H. Repair Dry Film Lubricant (Molykote 106 or Electrofilm No. 1000)

CAUTION: MATERIALS AND SOLVENTS USED DURING REPAIR OR REPLACEMENT OF DRY FILM LUBRICANT ARE HIGHLY TOXIC AND ARE FLAMMABLE. WORK MUST TAKE PLACE IN A WELL VENTILATED AREA, FACE MASK SHOULD BE WORN AND FIRE PRECAUTIONS TAKEN.

Dry film lubricant (Molykote 106 or Electrofilm No. 1000) on lug faces of upper torque arm (Part No. 71-102), lower torque arm (Part No. 71-163 or 71-338, repair bushings (refer to paragraph C.), and repair plates (refer to paragraph F.), may be repaired as follows:

(1) Lightly scuffed or scored surfaces:

(a) Wash surface of dry film lubricant with methyl-ethyl-ketone or trichlor-ethylene. Ensure adhesion of lubricant to parent metal.

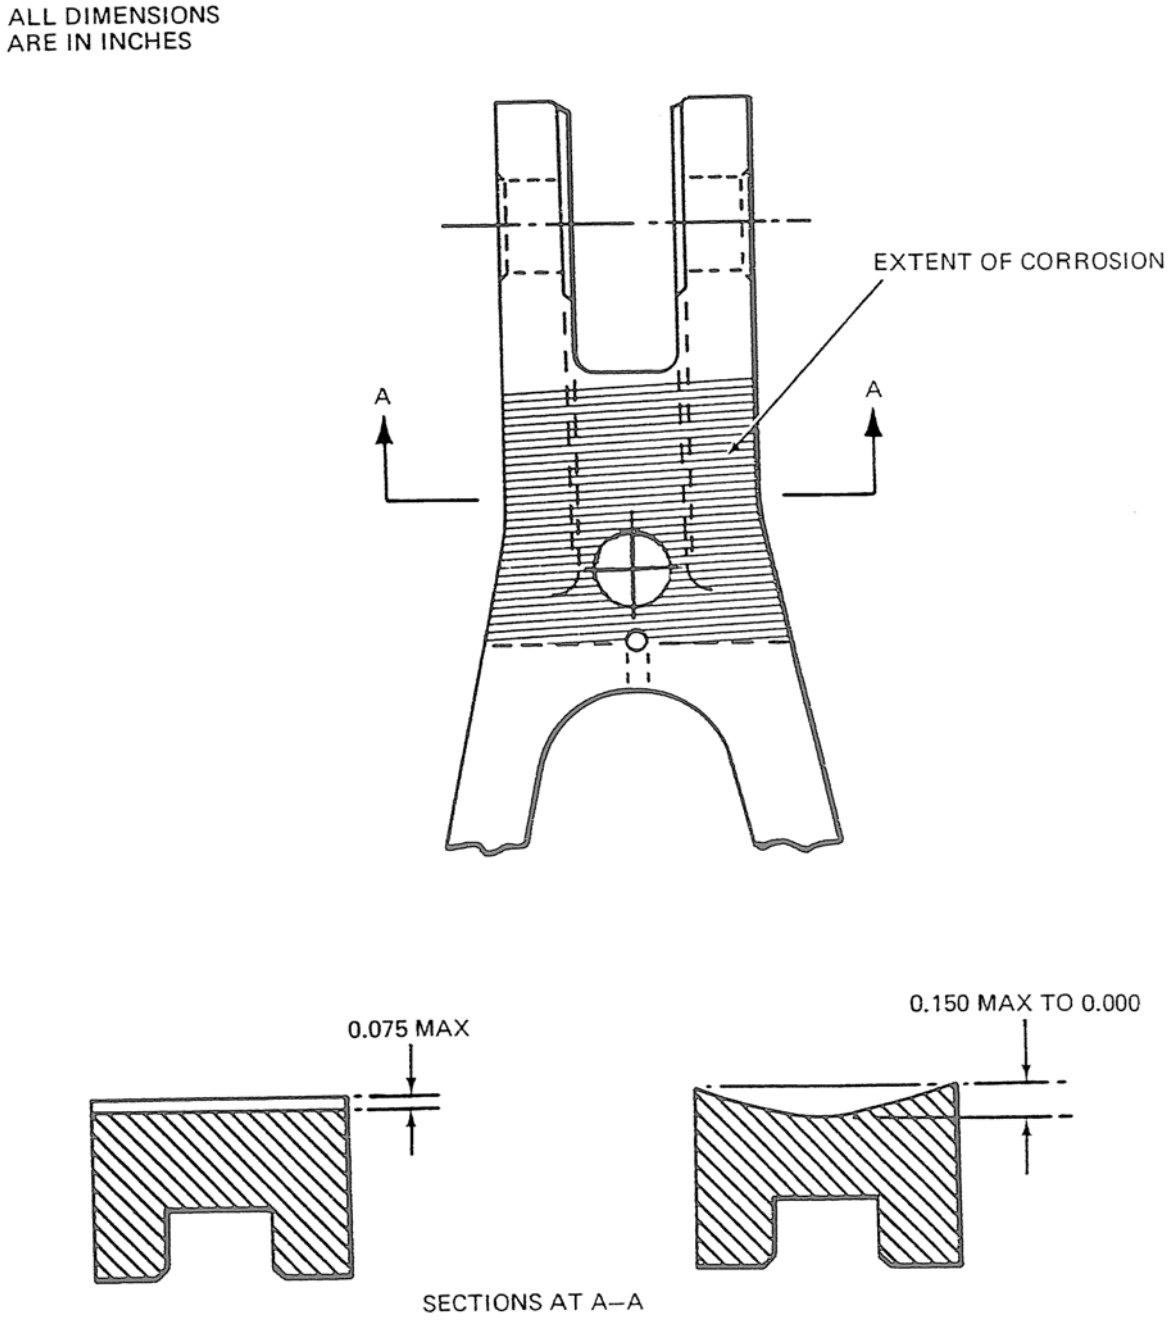
(b) Repair scuffed or scored areas by spraying or by hand application of Molykote 321. Prepare and apply Molykote in accordance with manufacturer's instructions. Apply sufficient new film to effect repair, final thickness not to exceed that of original coating (0.0002 to 0.0004 inch).

(c) Allow repair to air dry for five minutes at room temperature (approximately 70ºF).

NOTE: Molykote coating when dry, must be dull and gray-black in color, with smooth, even finish. Slight variations in color are acceptable. Glossy coatings or coating which appears brown, yellow or green must be replaced (refer to step (d)).

(d) Strip air-dried (cured) Molykote 321 coating by rubbing area with a lint-free cloth soaked in methyl-ethyl-ketone. Repeat steps (b) and (c).

(2) Detached or excessively damaged areas of dry film lubricant may be repaired by stripping original film of lubricant. The lubricant may be replaced to Specification MIL-L-46010, providing wear to the parent material is within limits (refer to FITS AND CLEARANCES).



I. Repair of Upper Torque Arm to Remove Corrosion

Corrosion of upper torque arm may be repaired as follows:

(1) Clean up face of torque arm as shown in Figure 406, to a maximum depth of 0.075 inch over entire face, or, up to a maximum depth of 0.150 inch, tapered to 0.000 at edges of torque arm.

(2) Apply protective coating of Alodine solution 1200S (refer to Table 401), to bare metal surfaces.

(3) Paint repaired surfaces with epoxy zinc chromate primer (refer to Table 401).

Repair of Upper Torque Arm to Remove Corrosion

Figure 406

THIS PAGE INTENTIONALLY LEFT BLANK

ASSEMBLY

1. Procedures

A. Assemble Nose Gear Shock Strut, Part No. 71-300-1 and 71-300-3 (Figure 1101)

(1) Install two bushings (144), with spacer (145) between bushings, to outer cylinder. Secure two washers (141) with two pins (143). Temporarily attach bolt (142), washer (140) and nut (139).

(2) Position cable guard assembly and secure with set-screw (129). Tighten two nuts (131) on two screws (132) to secure both halves of cable guard (133) with guard pins (134) to outer cylinder.

(3) Position bushing (137), two thrust washers (136), and secure in outer cylinder with two pins (135). Assemble slider (126) with pivot (127) and bushing (128) to pulley shaft (122), and secure with washer (125) and nut (124). Torque nut (124) to 6 pounds-feet and install cotter pin (123). Position pulley shaft on outer cylinder, and secure with washer (121), washer (120), and nut (119). Finger tighten nut (119), then tighten to next slot and install cotter pin (118). Check pulley shaft for freedom of movement.

(4) Coat O-rings (116) with grease G. E. Versilube G300 and install two O-rings (116), two back-up rings (115), swivel (114), collar (113) and spring pin (112) at both ends of swivel bolt (117). Install two packings (111) and two unions (110) to swivel bolt. Position swivel fitting assembly on outer cylinder, ensuring that end with engraved marking RET is towards the top of outer cylinder, and secure with two bolts (108). Lockwire bolts (108) using MS20995-C20.

(5) If removed for replacement of defective parts, install two bushing (106) and bushing (105) to steering collar (107). Bushings must be a press fit in steering collar (refer to FITS AND CLEARANCES). Install stud (102) to steering collar and secure with spring pin (101). Temporarily thread locknut (104) to stud. Install two dust rings (97), two thrust washers (96) and two pins (95) to steering collar.

NOTE: If a new stud (102) o steering collar (107) is fitted, drill 0.125 to 0.129 inch diameter hole for spring pin (101) through steering collar and/or stud using hole in steering collar as pilot. Round off end of hole with 0.005 to 0.010 inch radius. Drill hole for cotter pin (103) through stud after assembly to steering collar: measure a dimension of 0.938 to 0.943 inch along stud from face of steering collar, and use a 3/32 inch diameter drill.

Emery Cloth No. 60	P-C-451
Lockwire, Corrosion Resistant	MS20995C20
Lockwire, Corrosion Resistant	MS20995C32

Table 501
Assembly Materials and Compounds

MATERIAL	SPECIFICATION OR MANUFACTURER
Machine Oil	3-GP-335a or MIL-L-7870A
Primer, Epoxy Chromate	B. B. Chemicals Co.

(6) If removed for replacement of defective parts, install two bushings (94) in upper torque arm (93). Bushings must be a press fit in upper torque arm (refer to FITS AND CLEARANCES). Lubricate latch pin (92) and spring (91) with grease MIL-G-23827. Position latch pin (92), spring (91) and spring retainer (90), and secure to upper torque arm with screws (89), washers (88) and nuts (87).

(7) Position upper torque arm assembly on steering collar assembly, and install bolt (83) with spring (85). Hold upper torque arm to its uppermost position, compress spring (85) to allow cam (84) to readily slide on over the flats of bolt (83). Secure bolt with washer (82) and nut (81). Finger tighten nut (81), then tighten to next slot and install cotter pin (80). Depress torque arm, then release. Check that torque arm returns upwards under spring tension. Position cover (100) on steering collar assembly and secure with screws (99).

(8) Position journal bearing (79) in steering collar, and assemble steering collar assembly with upper torque arm assembly on outer cylinder. Ensure thrust washer (78) is tight on shoulder and install cylinder nut (77). Tighten cylinder nut to 30 pounds-feet, then back off to next slot and check steering collar for freedom of movement. Lock cylinder nut with two locking nuts (76) and two machine screws (75). Torque machine screws (75) to 4 pounds-feet, and lockwire with MS20995C32.

NOTE: Refer to DESCRIPTION AND OPERATION, Table 2 and 3 for variations due to special shimmy damper installation.

(9) Install bearing (74) in bore of outer cylinder.

(10) On shock strut assembly, Part No. 71-300-1 only: Install two flanged bushings (68) to lugs on fork, with flange of each bushing on inner face of lug; coat inside of axle with Compound Type 1, MIL-C-16173 (Shell H927); install axle (67), spacer (66), adjustment spacer (64), retaining nut (63), two towing spools (61), and secure to fork with two bolts (60) and two nuts (58); thread retaining nut onto adjustment spacer, and temporarily install cotter pin (62).

(11) On shock strut assembly, Part No. 71-300-3 only: Install four bushings (68) to lugs on fork; coat inside of axle with Compound Type 1, MIL-C-16173 (Shell H927); install axle (67), spacer (66), adjustment spacer (64), retaining nut (63), two towing spools (61), and secure to fork with two bolts (60), two washers (59) and two nuts (58); install lockring (65) securing spacer (66) to axle; thread retaining nut onto adjustment spacer, and temporarily secure with setting screws (62).

(12) Install two bushings (57), two dust rings (56), two thrust washer (55) and two pins (54) to fork. Install bushing (52), two dust rings (51), two thrust washers (50) to lower torque arm (53), and secure with four screws (49). Position lower torque arm assembly on fork, and secure with bolt (47), washer (46) and nut (45). Finger tighten nut (45), then tighten to next slot and install cotter pin (44). Check lower torque arm for freedom of movement.

(13) Install bushing (43) and dowel (42) to fork (41). Retain dowel (42) by peening.

NOTE: Do not insert dowel (42) too far below surface of fork or fouling may occur when installing locknut (35).

(14) Coat packing (39) and O-ring (36) with grease, G. E. Versilube G300; install packing (39) and plug (38) to cylinder (40) of cartridge assembly. Tighten plug and lockwire using MS20995C32. Install O-ring (36) to cartridge assembly.

(15) Position piston tube (28) in fork and ensure that slot engages dowel (42). Install cartridge assembly within piston tube, lubricate contact surface of fork (for locknut (35)) with machine oil, and secure piston tube to fork with locknut (35), using special tool T-187. Torque locknut (35) to 400 pounds-feet and install washer (34) and set-screw (33). Torque set-screw (33) to 1 pound-feet, and lockwire using MS20995C32.

NOTE: If new fork is being installed, drill hole in fork (0.125 + 0.010 inch diameter and 0.20 inch deep) for set-screw (33), after torquing locknut (35).

(16) Lubricate scraper (72) with grease, Specification MIL-G-81322 or equivalent. Position locknut (70), washer (71), scraper (72) and bearing retainer (73) (correctly oriented for assembly into outer cylinder) on piston tube of piston tube and fork sub-assembly.

(17) Install shoulder (27) on piston tube (28). Coat internal surfaces of outer cylinder and bearing (74) with hydraulic fluid, Specification MIL-H-5606 and slide piston tube of piston tube and fork assembly through journal bearing (refer to step (9)) and into bore of outer cylinder.

(18) Slide bearing retainer (73), scraper (72), washer (71) into outer cylinder bore to contact journal bearing. Install locknut (70) and torque to approximately 2 pounds-feet, using special tool T-191, to align set-screw hole in outer cylinder with hole in locknut. Install set-screw (69), tighten to a snug fit, then file flat to contour of outer cylinder.

NOTE: If replacement locknut is installed, torque locknut at assembly to 2 pounds-feet. Drill through locknut 9/64 (0.140 + 0.005) inch diameter, using smaller diameter of set-screw hole in outer cylinder at pilot hole. Install set-screw (refer to step (18)).

(19) Position rubber bumper (26) on piston tube. Coat O-rings (32) and (30) with grease, G. E. Versilube G300, and install O-ring (32), two back-up rings (31), O-ring (30) and two back-up rings (29) to floating piston (25). Position floating piston (25), flapper spacer (24) and flapper (23) on piston tube, and install shoulder nut (22) using special tool T-190. Torque shoulder nut (22) to approximately 20 pounds-feet, to align slot in shoulder nut with existing hole in piston tube. Install lockring (21).

NOTE: If replacement piston tube is installed, torque shoulder nut (22) to 20 pounds-feet, then drill through piston tube 3/32 (0.093) inch diameter, using a slot in nut as pilot.

(20) Install chain (19) and quick-release pin (18) to upper torque arm assembly. Engage quick-release pin in upper and lower torque arms.

(21) If slipper ring (17) has been removed from guide bearing (13), a new slipper ring can be fitted after submerging in boiling water. Where guide bearing has a corresponding groove, install split ring before application of slipper ring. Position orifice plate (15), damping plate (14) and guide bearing (13) on lower end of support tube (9), and secure with set-screw (12). Press fit pellet (11) to cover set-screw, and smooth edge of pellet using No. 60 emery cloth.

(22) Coat O-rings (10) and (4) with grease, G. E. Versilube G300. Install O-ring (10) in groove at upper end of support tube (9). Position end cap (8) and secure with nut (7), using special tool T-188. Tighten nut to align threaded hole in end cap with hole in nut, then install machine screw (6). Install O-ring (4) in groove in end cap sub-assembly. Screw end cap sub-assembly into outer cylinder, using special tool T-188 engaged with nut (7) and torque to 20 pounds-feet. Install set-screw (3) and torque to 2 pounds-feet. Lockwire machine screw (6) to nut (7) using MS20995C32.

(23) Install air charging valve (1) and valve cap (2) to end cap sub-assembly except when shock strut assembly is to be immediately filled with hydraulic fluid (refer to TESTING).

B. Assemble Nose Gear Shock Strut, Part No. 71-300-5 and 71-300-7 (Figure 1102)

(1) Install two bushings (152), with spacer (153) between bushings, to outer cylinder (154). Secure two washers (149) with two pins (151). Temporarily attach bolt (150), washer (148) and nut (147).

(2) Position cable guard assembly and secure with set-screw (137). Tighten two nuts (139) on two screws (140) to secure both halves of cable guard (141) with guard pins (142) to outer cylinder.

(3) Position bushing (145), two thrust washers (144), and secure in outer cylinder with two pins (143). Assemble slider (134) with pivot (135) and bushing (136) to pulley shaft (130), and secure with washer (133) and nut (132). Torque nut (132) to 6 pounds-feet and install cotter pin (131). Position pulley shaft on outer cylinder and secure with washer (129), washer (128) and nut (127). Finger tighten nut (127), then tighten to next slot and install cotter pin (126). Check pulley shaft for freedom of movement.

(4) Coat O-rings (124) with grease, G. E. Versilube G300, and install two O-rings (124) two back-up rings (123), swivel (122), collar (121) and spring pin (120) at both ends of swivel bolt (125). Install two packings (119) and two unions (118) to swivel bolt. Position swivel fitting assembly on outer cylinder, ensuring that end with engraved marking RET is towards the top of outer cylinder, and secure with two bolts (116). Lockwire bolts (116) using MS20995C20.

(5) If removed for replacement of defective parts, install bearing (114), two bushings (113) and bushing (112) to steering collar (115). Bearing and bushings must be a press fit in steering collar (refer to FITS AND CLEARANCES). Install stud (109) to steering collar and secure with spring pin (108). Temporarily thread locknut (111) to stud. Install two dust rings (104), two thrust washer (103) and two pins (102) to steering collar.

NOTE: If a new stud (109) or steering collar (115) is fitted, drill 0.125 to 0.129 inch diameter hole for spring pin (108) through steering collar and/or stud using hole in steering collar as pilot. Round off ends of hole with 0.005 to 0.010 inch radius. Drill hole for cotter pin (110) through stud after assembly to steering collar; measure a dimension of 0.938 to 0.943 inch along stud from face of steering collar, and use a 3/32 inch diameter drill.

(6) If removed for replacement of defective parts, install two bushings (101) in upper torque arm (100). Bushings must be a press fit in upper torque arm (refer to FITS AND CLEARANCES). Lubricate latch pin (99) and spring (98) with grease MIL-G-23827. Position latch pin (99), spring (98) and spring retainer (97), and secure to upper torque arm with screws (96), washers (95) and nuts (94).

(7) Position upper torque arm assembly on steering collar assembly and install bolt (90) with spring (92). Hold upper torque arm to its uppermost position, compress spring (92) to allow cam (91) to readily slide on over the flats of bolt (90). Secure bolt with washer (89) and nut (88). Finger tighten nut (88), then tighten to next slot and install cotter pin (87). Depress upper torque arm, then release and check that arm returns upward by spring action. Position cover (107) on steering collar assembly and secure with screws (106).

(8) Position two thrust washers (86), bushing (85) and steering collar assembly, complete with upper torque arm assembly on outer cylinder. Ensure thrust washer (84) is tight on shoulder and install cylinder nut (83). Tighten cylinder nut to 30 pounds-feet, then back off to next slot and check steering collar for freedom of movement. Lock cylinder nut with locking key (82), locking clip (81), two blocks (80), screw (79), washer (78) and nut (77).

NOTE: Refer to DESCRIPTION AND OEPRATION, Tables 4 and 5 for variations due to special shimmy damper installation.

(9) Install journal bearing assembly consisting of bearing (75) and sleeve (76) in bore of outer cylinder (154).

(10) Install four bushings (69) to lugs on fork; coat inside of axle with Compound Type 1, MIL-C-16173 (Shell H927); install axle (68), spacer (67), adjustment spacer (65), retaining nut (64), two towing spools (62) and secure to fork with two bolts (61), two washers (60) and two nuts (59); install lockring (66) securing spacer (67) to axle; thread retaining nut onto adjustment spacer, and temporarily secure with setting screws (63).

(11) Install two bushings (58), two dust rings (57), two thrust washer (56) and two pins (55) to fork. Install bushing (53), two dust rings (52), two thrust washers (51) to lower torque arm (54), and secure with four screws (50). Position lower torque arm assembly on fork, and secure with bolt (48), washer (47) and nut (46). Finger tighten nut (46), then tighten to next slot and install cotter pin (45). Check lower torque arm for freedom of movement.

(12) Install bushing (44) and dowel (43) to fork (42). Retain dowel (43) by peening.

NOTE: Do not insert dowel (43) too far below surface of fork or fouling may occur when installing locknut (35).

(13) Assemble cartridge assembly for shock strut assembly Part No. 71-300-5 only, as detailed in Paragraph 1.A., step (14), and refer to Figure 1101.

(14) Assemble cartridge assembly for shock strut assembly Part No. 71-300-7 only, as follows:

(a) If removed for replacement of defective part, install cap plug (39) to cylinder (41). Cap plug must be a press fit in cylinder (refer to FITS AND CLEARANCES).

(b) Coat O-ring (36) with grease, G. E. Versilube G300, and install with back-up ring (37) to cap plug (39) of cartridge assembly.

(15) Position piston tube (28) in fork, and ensure that slot engages dowel (43). Install cartridge assembly within piston tube, lubricate contact surface of fork (for locknut (35)) with machine oil, and secure piston tube to fork with locknut (35) using special tool T-187. Torque locknut (35) to 400 pounds-feet, and install washer (34) and set-screw (33). Torque set-screw (33) to 1 pound-feet, and lockwire using MS20995C32.

NOTE: If new fork is being installed, drill hole in fork (0.125 + 0.010 inch diameter and 0.20 inch deep) for set-screw (33), after torquing locknut (35).

(16) Lubricate scraper (73) with grease, Specification MIL-G-81322 or equivalent. Position locknut (71), washer (72), scraper (73) and bearing retainer (74) (correctly oriented for assembly in outer cylinder) on piston ube of piston tube and fork sub-assembly.

(17) Install shoulder (27) on piston tube (28). Coat bores of outer cylinder and journal bearing assembly (refer to step (9)) with hydraulic fluid, Specification MIL-H-5606 and slide piston tube of piston tube and fork assembly through journal bearing and into bore of outer cylinder.

(18) Slide bearing retainer (74), scraper (73), and washer (72) into bore of outer cylinder to contact journal bearing. Install locknut (71) and torque to approximately 2 pounds-feet using special tool T-191, to align set-screw hole in outer cylinder with hole in locknut. Install set-screw (70), tighten to a snug fit and file flat to contour of outer cylinder.

NOTE: If replacement locknut is installed, torque locknut at assembly to 2 pounds-feet. Drill through locknut 9/64 (0.140 + 0.005) inch diameter, using smaller diameter of set-screw hole to outer cylinder as pilot hole. Install set-screw (refer to step (18)).

(19) Position rubber bumper (26) on piston tube. Coat O-rings (32) and (30) with grease G.E. Versilube G300, and install O-ring (32), two back-up rings (31), O-ring (30) and two back-up rings (29) to floating piston (25). Position floating piston (25) flapper spacer (24) and flapper 923) on piston tube, and install shoulder nut (22) using special tool T-190. Torque shoulder nut (22) to approximately 20 pounds-feet, to align slot in shoulder nut with existing hole in piston tube. Install locking (20).

NOTE: If replacement piston tube is installed, torque shoulder nut (22) to 20 pounds-feet and drill through piston tube 3/32 (0.093) inch diameter using slot in shoulder nut as pilot.

(20) Install chain (19) and quick-release pin (18) to upper torque arm assembly. Engage quick-release pin in upper and lower torque arms.

(21) If slipper ring (17) has been removed from guide bearing (13), a new slipper ring can be fitted after submerging in boiling water. Where guide bearing has a corresponding groove, install split ring before installation of slipper ring. Position orifice plate (15), damping plate (14) and guide bearing (13) on lower end of support tube (9), and secure with set-screw (12). Press fit pellet (11) to cover set-screw, and smooth edge of pellet using No. 60 emery cloth.

(22) Coat O-rings (10) and (4) with grease, G. E. Versilube G300. Install O-ring (10) in groove at upper end of support tube (9). Position end cap (8) on support tube and secure with nut (7), using special tool T-188. Tighten nut to align threaded hole in end cap with hole in nut. Install O-ring (4) in groove in end cap sub-assembly. Screw sub-assembly into outer cylinder, using special tool T-188 on nut (7) and torque to approximately 20 pounds-feet. Install set-screw (3) and torque to 2 pounds-feet. Lockwire machine screw (6) to nut (7) using MS20995C32.

(23) Install air charging valve (1) and valve cap (2) to end cap sub-assembly except when shock strut assembly is to be immediately filled with hydraulic fluid (refer to TESTING).

C. Assembly Nose Gear Shock Strut, Part No. 71-300-9 and 71-300-11 (Figure 1103)

(1) Install two bushings (158) with spacer (159) between bushings, to outer cylinder (160). Secure two washers (155) with two pins (157). Temporarily attach bolt (156) washer (154) and nut (153).

(2) Position cable guard assembly and secure with set-screw (143). Tighten two nuts (145) to secure both halves of cable guard (147) with guard pins (148) to outer cylinder.

(3) Position bushing (151), two thrust washers (150), and secure in outer cylinder with two pins (149). Assemble slider (140) with pivot (141) and bushing (142) to pulley shaft (136), and secure with washer (139) and nut (138). Torque nut (138) to 6 pounds-feet and install cotter pin (137). Position pulley shaft on outer cylinder, and secure with washer (135), washer (134) and nut (133). Finger tighten nut (133) then tighten to next slot and install cotter pin (132). Check pulley shaft for freedom of movement.

(4) Coat O-rings (130) with grease, G. E. Versilube G300, and install two O-rings, two back-up rings (129), swivel (128), collar (127) and spring pin (126) at both ends of swivel bolt (131). Install two packings (125) and two unions (124) to swivel bolt. Position swivel fitting assembly on outer cylinder, ensuring that end with engraved marking RET is towards the top of outer cylinder, and secure with two bolts (122). Lockwire bolts (122) using MS20995C20.

(5) If removed for replacement of defective parts, install bearing (118), two bushings (119), and bushing (117) and lubricator (120) to steering collar (121). Bearing and bushings must be a press fit in steering collar (refer to FITS AND CLEARANCES).

NOTE: If steering collar assembly has been repaired, shims may be required under flanges of bushings (119) (refer to DISASSEMBLY).

After installation, line ream bushings (119) to 0.375 + 0.005 inch diameter.

(6) Install stud (114) to steering collar and secure with spring (113). Temporarily thread locknut (116) to stud.

NOTE: If a new stud (114) or steering collar (121) is fitted, drill 0.125 to 0.129 inch diameter hole for spring pin (113) through steering collar and/or stud using hole in steering collar as pilot. Round off ends of hole with 0.005 to 0.010 inch radius. Drill hole for cotter pin (115) through stud after assembly to steering collar; measure a dimension of 0.098 to 0.943 inch along stud from face of steering collar, and use a 3/32 inch diameter drill.

(7) If removed for replacement of defective parts, install two bushings (108) in upper torque arm (107). Bushings must be a press fit in upper torque arm (refer to FITS AND CLEARANCES). Lubricate latch pin (106), spring (105) and spring retainer (104), and secure to upper torque arm with screws (103), washers (102) and nuts (101).

(8) Position two dust rings (109) at bushings (119) on steering collar assembly. Position upper torque arm assembly on steering collar assembly and install bolt (97) with spring (99). Hold upper torque arm to its uppermost position, compress spring (99) to allow cam (98) to readily slide on over the flats of bolt (97). Secure bolt with washer (96) and nut (95). Finger tighten nut (95), then tighten to next slot and install cotter pin (94). Depress upper torque arm, then release. Check that torque arm is returned upwards by spring action. Position cover (112) on steering collar assembly and secure with screws (111).

(9) Position two thrust washers (93), bushings (92) and steering collar assembly, complete with upper torque arm assembly on outer cylinder. Ensure thrust washer (91) is tight on shoulder and install cylinder nut (90). Tighten cylinder nut to 30 pounds-feet, then back off to next slot and check steering collar for freedom of movement. Lock cylinder nut with locking key (89), locking clip (88), two blocks (87), screw (86), washer (85) and nut (84).

NOTE: Refer to DESCRIPTION AND OPERATINON, Tables 4, 5 and 5A for variations due to special shimmy damper installation.

(10) Install journal bearing assembly, consisting of bearing (82) and sleeve (83) in bore of outer cylinder.

(11) Install four bushings (52) to lugs on fork; coat inside of axle with Compound Type 1, MIL-C-16173 (Shell H927); install axle (76), spacer (75), adjustment spacer (73), retaining nut (72), two towing spools (70), and secure to fork with two bots (69), two washers (68) and two nuts (67); install lockring (74) securing spacer (75) to axle; thread retaining nut onto adjustment spacer, and temporarily secure with setting screws (71).

(12) If removed for replacement of defective parts, install lubricator (54) and two bushings (50) to fork (55). Install two dust rings (66).

NOTE: If fork assembly (55) has been repaired, shims may be required under flanges of bushings (50) (refer to DISASSEMBLY).

After installation, line ream bushings (50) to 0.375 + 0.0005 inch diameter.

(13) Install two dust rings (62) and two bushings (61) to lower torque arm (64). If removed for replacement of defective part, install lubricator (63). Position lower torque arm assembly on fork, and secure with bolt (59), washer (58) and nut (57). Finger tighten nut (57), then tighten to next slot and install cotter pin (56). Check lower torque arm for freedom of movement.

NOTE: Bushings (61) installed as part of Mod 6/1377 may require shims (Part No. 71-311-9) under the flanges of the bushings (refer to DISASSEMBLY) to maintain 0.001 inch maximum interference fit to 0.002 inch maximum clearance at joint between upper and lower torque arms.

(14) Assemble cartridge assembly as follows:

(a) If removed for replacement of defective part, install cap plug (45) to cylinder (46). Cap plug must be a press fit in cylinder (refer to FITS AND CLEARANCES).

(b) Coat O-ring (42) with grease, G. E. Versilube G300, and install with back-up ring (43) to cap plug (45) of cartridge assembly.

(15) If removed for replacement of defective parts, coat bushings (48) and (49) with epoxy chromate primer and install to fork while primer is still wet. Install bushing (53) aligning holes in bushings (53), (48) and (49).

(16) Position piston tube (31) in fork, aligning slot with holes in bushings. Install cartridge assembly within piston tube and insert diaphragm (37). Lubricate surface of fork to be contacted by locknut (34) with machine oil and install shim (36), washer (35), and locknut (34) to piston tube (31).

NOTE: To maintain alignment between piston tube and bushings during following locknut tightening procedure, it is recommended that a headed pin, 0.25 inch dia and approximately 0.625 inch in length be inserted through bushing (49), bushing (53) and slot in piston tube (31).

(17) Using special tool T-187, torque locknut (34) to 400 pounds-feet. If the elongated hole in the locknut is visible through the bushing (48), increase torque until holes in locknut and bushing align.

NOTE: If hole in locknut is not visible through bushing (48) after initial torque loading, reduce thickness of shim (36) as necessary and repeat tightening procedure.

(18) Remove alignment pin (refer to step (16)) if fitted.

(19) Coat bores of bushing (48) an (49), lockbolt (41) and washer (40) with epoxy chromate primer and install in fork while primer is still wet. Lock nut (39) with cotter pin (38).

(20) Position locknut (78), washer (79), scraper (80) and bearing retainer (81) (correctly oriented for assembly in outer cylinder) on piston tube (31) of piston tube and fork sub-assembly.

NOTE: On shock strut assembly 71-300-9, lubricate scraper (80) with grease, Specification MIL-G-81322 or equivalent, prior to assembly.

(21) Install shoulder (30) to piston tube (31) of piston tube and fork assembly. Coat internal surfaces of outer cylinder and journal bearing previously installed (refer to step (10)), with hydraulic fluid MIL-H-5606 and slide piston tube of piston tube and fork assembly through journal bearing into bore of outer cylinder.

(22) Position bearing retainer (81), scraper (80) and washer (79) in bore of outer cylinder adjacent to journal bearing. Install locknut (78) and using special tool T-191, torque locknut to approximately 2 pounds-feet to align set-screw hole in outer cylinder with hole in locknut. Install set-screw (77), tighten to a snug fit and file flat to contour of outer cylinder.

NOTE: If replacement locknut is installed, torque locknut at assembly to 2 pounds-feet, then drill through locknut 9/64 (0.140 + 0.0005) inch diameter, using smaller diameter of set-screw hole in outer cylinder as pilot hole. Install set-screw (77) (refer to step 22)).

(23) On shock strut assembly Part No. 71-300-9 only: Install ring (32) and ring (33) in floating piston (28). Ensure that bearing halves (27) are a matched set, then position bearing halves in floating piston. Position floating piston sub-assembly, flapper spacer (25) and flapper (24) on piston tube. Install shoulder nut (23) using special tool T-190. Torque shoulder nut to approximately 20 pounds-feet to align slot in shoulder nut with existing hole in piston tube. Install lockring (22) through nut and piston tube.

(24) On shock strut assembly Part No. 71-300-11 only: Install ring (32) and ring (33) to floating piston (28). Position floating piston (28) and flapper spacer (25) on piston tube, and install shoulder nut (23) using special tool T-190. Torque shoulder nut (23) to approximately 20 pounds-feet to align slot in shoulder nut with existing hole in piston tube. Install lockring (22) through nut and piston tube.

NOTE: When installing rings (32) and (33), ensure the radii of back-up portions face radii of main ring.

If replacement piston tube is installed (refer to steps (23) and (24)), torque shoulder nut to 20 pounds-feet and drill through piston tube 3/32 (0.093) inch diameter, using a slot in shoulder nut as pilot.

(25) Install chain (20) and quick-release pin (19) to upper torque arm assembly. Engage quick-release pin in upper and lower torque arms. Shim bushings (61) with shims Part No. 71-311-9 if necessary to obtain a 0.001 inch interference fit to 0.002 inch maximum clearance at joint formed by upper and lower torque arm.

(26) If slipper ring (18) has been removed from guide bearing (14), a new slipper ring can be fitted after submerging in boiling water. Where guide bearing has a corresponding groove, install split ring before installation of slipper ring. Position orifice plate (16), damping plate (15) and guide bearing (14) on lower end of support tube (9) and secure with set-screw (13). Press fit pellet (12) to cover set-screw, and smooth edge of pellet using No. 60 emery cloth.

(27) Coat O-rings (11) and (4) with grease G. E. Versilube G300 and install O-ring (11) in groove at upper end of support tube (9). Position end cap (8) and secure with nut (7), using special tool T-188. Tighten nut (7) to align threaded hole in end cap with hole in nut and install machine screw (6). Install O-ring (4) in groove in end cap. Screw end cap sub-assembly to outer cylinder, and torque to approximately 20 pounds-feet, engaging special tool T-180 with nut (7). Install set-screw (3) and torque to 2 pounds-feet. Lockwire machine screw (6) to nut (7) using MS20995C32.

(28) Install air charging valve (1) and valve cap (2) to end cap sub-assembly except when shock strut assembly is to be immediately filled with hydraulic fluid (refer to TESTING).

(29) Lubricate upper and lower torque arms through lubricators (54), (63) and (120) using grease MIL-G-81322.

D. Assemble Nose Gear Shock Struts, Part No. 71-300-15, -17, -19, -21, -23, -25, -27, -29, -31 and -33 (Figure 1104)

CAUTION: FIT BETWEEN OUTER CYLINDER BORE AND CYLINDER SLEEVE IS CLOSE TOLERANCE. CARE SHOULD BE EXERCISED TO ENSURE 'IN-LINE' ASSEMBLY.

(1) Apply an even coating of silicone grease, Specification MIL-I-8660 or equivalent to outer surface of sleeve (171) and bore of cylinder (170) in area of contact with sleeve. Assemble sleeve into cylinder, using firm hand pressure. Remove excess silicone grease from cylinder bore and external surfaces with trichlorethylene.

(2) Install two bushings (167), with spacer (168) between bushings, to outer cylinder. Secure two washers (164) with two pins (166). Temporarily attach bolt (165), washer (163) and nut (162).

(3) Position cable guard assembly and secure with set-screw (152). Tighten two nuts (154) to secure both halves of cable guard (156) with guard pins (157) to outer cylinder.

(4) Position bushing (160), two thrust washers (159), and secure in outer cylinder with two pins (158). Assemble slider (149) with pivot (150) and bushing (151) to pulley shaft (145), and secure with washer (148) and nut (147). Torque nut (147) to 6 pounds-feet and install cotter pin (146). Position pulley shaft on outer cylinder, and secure with washer (144), washer (143) and nut (142). Finger tighten nut (142), then tighten to next slot and install cotter pin (141). Check pulley shaft for freedom of movement.

(5) Coat O-rings (139) with grease, G. E. Versilube G300, and install two O-rings, two back-up rings (138), swivel (137), collar (136) and spring pin (135) at both ends of swivel bolt (140). Install two packings (134) and two unions (133) to swivel bolt. Position swivel fitting assembly on outer cylinder, ensuring that end with engraved marking RET is towards the top of outer cylinder, and secure with two bolts (131). Lockwire bolts (131) using MS20995C20.

(6) On shock strut assembly Part No. 71-300-15 only: Install the following parts if removed for replacement of defective parts: bearing (124), two bushings (126), bushing (123) and two lubricators (127) to steering collar (128). Bearing and bushings must be press fit in steering collar (refer to FITS AND CLEARANCES).

(7) On shock strut assembly Part No. 71-300-17, -19, -21, -23, -25, -27, -29, -31 and -33 only: Install the following parts if removed for replacement of defective parts: bearing (125), two bushings (126), bushing (123) and two lubricators (127) to steering collar (128). Bearing and bushings must be press fit in steering collar (refer to FITS AND CLEARANCES).

NOTE: If a new stud (120) or steering collar (128) is fitted, drill 0.125 to 0.129 inch diameter hole for spring pin (119) through steering collar and/or stud using hole in steering collar as pilot. Round off ends of hole with 0.005 to 0.010 inch radius. Drill hole for cotter pin (121) through stud after assembly to steering collar; measure a dimension of 0.938 to 0.943 inch along stud fro face of steering collar, and use a 3/32 inch dia drill.

After installation, line bushings (126) to 0.375 + 0.0005 inch diameter.

(8) On shock strut assembly Part No. 71-300-15, -17, -19, -21 and -23 only: Install stud (120) to steering collar and secure with spring pin (119). Temporarily thread locknut (122) to stud.

NOTE: If a new stud (120) or steering collar (128) is fitted, drill 0.125 to 0.129 inch diameter hole for spring pin (119) through steering collar and/or stud using hole in steering collar as pilot. Round off ends of hole with 0.005 to 0.010 inch radius. Drill hole for cotter pin (121) through stud after assembly to steering collar; measure a dimension of 0.938 to 0.943 inch along stud fro face of steering collar, and use a 3/32 inch dia drill.

(9) On shock strut assemblies Part No. 71-300-25, -27, -29, -31 and -33 only: Install stud (120) to steering collar and secure with spring pin (119). Position washer (123A) on stud, then temporarily thread locknut (122) to stud. Observe requirements in NOTE following step (8).

(10) If removed for replacement of defective parts, install two bushings (113) in upper torque arms (112). Bushings must be a press fit in upper torque arm (refer to FITS AND CLEARANCES). Lubricate latch pin (111), spring (110) and spring retainer (109), and secure upper torque arm with screws (108), washers (107) and nuts (106).

(11) Position two dust rings (114) at bushings (126) on steering collar assembly. Position upper torque arm assembly on steering collar assembly and install bolt (102) with spring (104). Hold upper torque arm to its uppermost position, compress spring (104), to allow cam (103) to readily slide on over the flats of bolt (102). Secure bolt with washer (101) and nut (100). Finger tighten nut (100), then tighten to next slot and install cotter pin (99). Depress upper torque arm, then release. Check that arm returns upward due to spring action.

(12) On shock strut assembly No. 71-300-15 only: Position two thrust washers (94), bushing (98) and steering collar assembly, complete with upper torque arm assembly on outer cylinder. Ensure thrust washer (93) is tight on shoulder and install cylinder nut (92). Tighten cylinder nut to 30 pounds-feet, then back off to next slot and check steering collar for freedom of movement. Lock cylinder nut with locking key (91), locking clip (90), two blocks (89), screw (88), washer (87) and nut (86).

NOTE: Refer to DESCRIPTION AND OPERATION, Table 5A for variations due to special shimmy damper installation on shock strut assembly 71-300-15 only.

(13) On shock strut assemblies Part No. 71-300-17, -19, -21, -23, -25, -27, -29, -31 and -33 only: Ensure that mating surfaces of wear washer (129) (bonded to steering collar) and friction disc (97) (bonded to outer cylinder) are clean and dry, then position bushing (98) and steering assembly complete with upper torque arm on outer cylinder. Position thrust ring (95), and shim washer (96) on outer cylinder and install cylinder nut (92) finger tight. With spring balance attached to stud (120) (which is located three inches from center of shock strut), check that force required to rotate steering collar is less that 20 pounds. Adjust steering collar to provide shimmy damping as follows:

(a) Tighten cylinder nut (92) until force required to rotate steering collar, after 10 cycles, is 50 to 70 pounds at end of extended upper torque link.

(b) Note relative position of nut slot and cylinder keyway, back off nut and peel off one or two laminations of shim washer (96) as required to align nearest slot and keyway. Maximum misalignment: 10º equals 3 shim laminations of 0.002 inch.

(c) Tighten cylinder nut and lock with locking key (91), locking clip (90), two blocks (89), screw (88), washer (87) and nut (86).

(14) On shock strut assembly Part No. 71-300-15, -17 and -19 only: Install journal bearing sub-assembly (85) (consisting of bearing (85A) and sleeve (85B) in bore of outer cylinder.

(15) On shock strut assembly Part No. 71-300-21, -23, -25, -27, -29, -31 and -33 only: Install journal bearing (84) in bore of outer cylinder.

(16) Install four bushings (53) to lug on fork. Coat inside of axle (76) with Compound Type 1, MIL-C-16173 (Shell H927). Install axle, spacer (75), adjustment spacer (73), retaining nut (72), two towing spools (70) and secure to fork with two bolts (69), two washers (68) and two nuts (67); install lockring (74), securing spacer (75) to axle; thread retaining nut onto adjustment spacer, and temporarily secure with setting screws (71).

(17) If removed for replacement of defective parts, install lubricator (55) and two bushings (52) to fork (56). Install two dust rings (66).

NOTE: If fork assembly (56) has been repaired, shims may be required under flanges of bushings (52) (refer to DISASSEMBLY).

After installation, line ream bushings (52) to 0.375 + 0.0005 inch diameter.

(18) Install two dust rings (62) and two bushing (61) to lower torque arm (65). If removed for replacement of defective part, install lubricator (64). Position lower torque arm assembly on fork, and secure with bolt (60), washer (59) and nut (58). Finger tighten nut (58), then tighten to next slot and install cotter pin (57). Check lower torque arm for freedom of movement.

NOTE: Bushings (61) may require shims (172) under the flanges of the bushings (refer to step (35)).

(19) Assemble cartridge assembly as follows:

(a) If removed for replacement of defective part, install cap plug (47) to cylinder (48). Cap plug must be a press fit in cylinder (refer to FITS AND CLEARANCES).

(b) Coat O-ring (44) with grease, G. E. Versilube G300, and install with back-up ring (45) to cap plug (47) of cartridge assembly.

(20) On shock strut assembly Part No. 71-300-15, -17, -19, -21 and -23 only: (if removed for replacement of defective parts). Coat bushings (49) and (50) with epoxy chromate primer and install to fork while primer is still wet. Install bushing0 (54), aligning holes in bushings (54), (49) and (50).

(21) On shock strut assemblies Part No. 71-300-25, -27, -29, -31 and -33 only: (if removed for replacement of defective parts). Coat two bushings (49A) with epoxy chromate primer and install to fork while primer is still wet. Install bushing (54), aligning holes in bushings (54) and (49A).

(22) On shock strut assembly Part No. 71-300-15, -17, -19, -21 and -23 only: Position piston tube (31) in fork, aligning slot with holes in bushings. Install cartridge assembly within piston tube and insert diaphragm (39). Lubricate surface of fork to be contacted by locknut (36), with machine oil and install shim (38), washer (37) and locknut 936) to piston tube (31).

NOTE: To maintain alignment between piston tube and bushings during following locknut tightening procedure (step 23)), it is recommended that a headed pin, 0.25 inch dia and approximately 0.625 inch in length be inserted through bushing (50), bushing (54) and slot in piston tube (31).

(23) On shock strut assembly Part No. 71-300-15, -17, -19, -21 and -23 only: Use special tool T-187 to torque locknut (36) to 400 pounds-feet. If the elongated hole in the locknut is visible through the bushing (49), increase torque until holes in locknut and bushing align.

NOTE: If hole in locknut is not visible through bushing (49) after initial torque loading, reduce thickness of shim (38) as necessary and repeat tightening procedures.

(24) On shock strut assemblies 71-300-25, -27, -29, -31 and -33 only: Position piston tube (31) in fork, aligning slot with holes in bushings. Install cartridge assembly with piston tube and insert diaphragm (39). Lubricate surface of fork to be contacted by locknut (36A) with machine oil and install shim (38), washer (37) and locknut (36A) to piston tube (31).

NOTE: To maintain alignment between piston tube and bushings during following locknut tightening procedure, it is recommended that a headed pin, 0.25 inch dia and approximately 0.625 inch in length be inserted through one bushing (49A), bushing (54) and slot in piston tube (31).

(25) On shock strut assemblies 71-300-25, -27, -29, -31 and -33 only: Use special tool T-187 to torque locknut (36A) to 400 pounds-feet. Align two holes 180º apart in locknut with holes in bushing (54), bushing (49A) and slot in piston tube (31).

(26) On shock strut assembly Part No. 71-300-15, -17, -19, -21 and -23 only: Remove alignment pin if fitted (refer to step (22)). Coat bores of bushing (49) and (50), lockbolt (43) and washer (42) with epoxy chromate primer and install in fork while primer is still wet. Lock nut (41) with cotter pin (40).

(27) On shock strut assemblies 71-300-25, -27, -29, -31 and -33 only: Remove alignment pin if fitted (refer to step (24)), coat bores of bushings (49A), lockbolts (43A) and washer (42A) with epoxy chromate primer and install fork while primer is still wet, and install one lockbolt in each bushing (49A). Insert washers (42A), washers (176) and self-locking nuts (41A) through square hole in locknut (36A) to engage threads on lockbolts (43A). Tighten nuts (41A).

(28) On shock strut assembly Part No. 71-300-15, -17 and -19 only: Position locknut (79), washer (80), scraper (82), and bearing retainer (83) (correctly oriented for assembly into outer cylinder) over piston tube (31) of piston tube and fork sub-assembly.

(29) On shock strut assemblies 71-300-21, -23, -25, -27, -29, -31 and -33 only: Lubricate scraper (81) with grease, Specifications MIL-G-81322 or equivalent. Position locknut (78) and scraper (81) (correctly oriented for assembly in outer cylinder) over piston tube (31) of piston tube and fork sub-assembly.

(30) Coat internal surfaces of outer cylinder sleeve (171) and journal bearing (84) or (85), as applicable (refer to steps (14) and (15)), with hydraulic fluid MIL-H-5606.

(31) Install shoulder (30) to piston tube (31) of piston tube and fork sub-assembly. Slide piston tube of piston tube and fork sub-assembly through journal bearing into outer cylinder. Position bumper (29) on piston tube.

(32) Slide locknut (79) or (78), as applicable and items assembled over piston tube in step (28) or (29) upwards into cylinder bore to contact journal bearing. Install locknut using special tool T-191 and torque to approximately 2 pounds-feet to align set-screw hole in outer cylinder with hole in locknut. Install set-screw (77) to a snug fit and file it flat to contour of outer cylinder.

NOTE: If replacement locknut (78) or (79) is installed, torque locknut at assembly to 2 pounds-feet. Drill through locknut 9/64 (0.140 + 0.005) inch diameter, using smaller diameter of set-screw hole in outer cylinder as pilot hole. Install set-screw (refer to step (32)).

(33) On shock strut assembly Part No. 71-300-15 and -17 only: Install rings (32) and (34) in grooves in floating piston (27) (refer to NOTE following). Position piston and flapper spacer (26) on piston tube (31) and install shoulder nut (24), using special tool T-190. Torque shoulder nut to approximately 20 pounds-feet to align nearest slot in nut with existing hole in piston tube. Install lockring (23).

NOTE: When installing rings (32) and (34) or rings (33) and (35) (step 34) into floating piston, ensure that radii of back-up rings face radii at root of main T-ring.

(34) On shock strut assembly Part No. 71-300-19, -21, -23 and -25 only: Install rings (33) and (35) into grooves in floating piston (28) (refer to NOTE in step (33)). Position piston on piston tube (31). Assemble locking (23) on nut (25); check that it is correctly seated in groove and outer diameter of lockring does not exceed 2.550 inches. (Discard lockring that does not meet this requirement). Lift lockring tongue from 0.093 inch diameter hole and hole pre-positioned in 0.37 inch sot. Install nut, using special tool T-190. Torque nut to approximately 20 pounds-feet, to align nearest slot in nut with existing hole in piston tube. Seat lockring tongue in 0.093 inch diameter hole to secure nut. Check that lockring is seated correctly.

NOTE: If replacement piston tube (31) is installed, torque shoulder nut (24) (step (33)) or shoulder nut (25) (step (34)) to 20 pounds-feet and drill through piston tube 3/32 (0.093) inch diameter using slot in nut as pilot.

(35) On shock strut assembly 71-300-27, -29, -31 and -33 only: Install rings (33) and (35) into grooves in floating piston (28) (refer to NOTE in step (33)). Position piston on piston tube (31); install shoulder nut (25A) using special tool T-190 and torque to approximately 20 pounds-feet, and align locking holes. Install lockring screw (23B) and align hole in head of screw with groove in nut. Secure locking screw with cotter pin (23A).

CAUTION: COTTER PIN (23A) MUST NOT PROTRUDE FROM GROOVE.

NOTE: If replacement piston tube (31) is installed, torque shoulder nut (25A) to 20 pound-feet using special tool T-190. Using hole in nut, drill #29 (0.136 inch dia) hole through piston tube (31). Remove nut and tap hole in piston to #8-32 UNC-2B. Deburr parts.

(36) Install chain (20) and quick-release pin (19) to upper torque arm assembly. Engage quick-release pin in upper and lower torque arms. Shim bushings (61) with equal thickness of shim (172) to obtain 0.001 inch maximum interference fit to 0.002 inch maximum clearance at joint formed by the mating lugs of the upper and lower torque arms.

(37) If slipper ring (18) has been removed from guide bearing (14), a new slipper ring can be fitted after submerging in boiling water. Where guide bearing has a corresponding groove, install split ring before installation of slipper ring. Position orifice plate (16), damping plate (15) and guide bearing (14) on lower end of support tube (9), and secure with set-screw (13). Press fit pellet (12) to cover set-screw, and smooth edge of pellet using No. 60 emery cloth.

(38) Coat O-rings (11) and (4) with grease, G. E. Versilube G300 and install O-ring (11) in groove at upper end of support tube (9). Position end cap (8) and secure with nut (7), using special tool Y-188. Tighten nut (7) to align threaded hole in end cap with hole in nut and install machine screw (6). Install O-ring (4) in groove in end cap. Screw end cap sub-assembly into outer cylinder and torque to 20 pounds-feet, using special tool T-188, engaged on nut (7). Install set-screw (3) and torque to 2 pounds-feet. Lockwire machine screw (6) to nut (7) using wire MS20995C32.

(39) Install air charging valve (1) and valve cap (2) to end cap sub-assembly except when shock strut assembly is to be immediately filled with hydraulic fluid (refer to TESTING).

(40) Lubricate upper and lower torque arms through lubricators (55), (64) and (127) using grease MIL-G-81322.

E. Assemble Shock Strut Assembly and Steering Actuator and Links Sub-assembly (Figure 101)

(1) Remove temporarily attached nut (12) from stud (10) and nut (14), washer (13) and bolt (5) from lugs on outer cylinder of shock strut assembly.

NOTE: When DH Mod 6/1622 is embodied, ensure that washer (17) is located on stud (10) between steering collar (19) and actuator lever assembly (8).

(2) Position and support steering actuator (6) at leg assembly, locate actuator lever (8) on stud (10) of steering collar (9), and engage pivot (2) on slider (1) with steering lever (4). Align actuator with lugs on outer cylinder and insert bolt (5). Secure bolt with washer (13) and nut (14). Finger tighten nut (14), then tighten to next slot and install cotter pin (3). Use cotter pin Part No. MS24665-300.

(3) Install nut (12) to stud (10). Torque nut to 20 pounds-feet and install cotter pin (11). Use cotter pin Part No. MS24665-231.

(4) Remove lock key from jam nut on piston rod end. Loosen jam nut using special tool T-194.

(5) Turn leg assembly fully to right (clockwise). Turn piston to adjust rod end so that with piston firmly against internal stop, a minimum clearance of 0.010 inch and a maximum clearance of 0.020 inch is obtained between actuator lever (8) and outer cylinder of the shock strut. Tighten jam nut on piston rod end using special tool T-194. Install lock key, and lockwire using MS20995C20.

(6) Turn leg assembly fully to left (counterclockwise). Check that with piston firmly against internal stop (end cap on manifold), a minimum clearance of 0.010 inch and a maximum clearance of 0.020 inch is obtained between stud lug on steering collar and lugs on outer cylinder. If necessary, cut lockwire, remove lock key and nut from end cap, and adjust end cap using special tool T-186 to obtain clearance. Finger tighten nut on end cap, install lock key and lockwire using MS20995C20.

(7) Connect hydraulic return pipe to top swivel fitting, and hydraulic pressure pipe to bottom swivel fitting on shock strut assembly.

FITS AND CLEARANCES

1. Original Dimensions and Service Limits

   A. Refer to Table 601 for original dimensions, service limits, and disposition of parts failing to meet inspection requirements.

TESTING

1. Procedures

   A. General

      The following tests must be carried out using hydraulic fluid MIL-H-5606.

      (1) Place assembly in a vertical position. Remove valve cap, and release air slowly.

      (2) Remove air charging valve and slowly compress the strut fully to expel oil (fork to contact cylinder).

         NOTE: If no oil is expelled, strut is almost empty. Add approximately 10 fluid ounces (300 cubic centimeters) of hydraulic fluid, while extending strut. Repeat step (2).

      (3) Extend strut fully permitting strut to suck air, then compress strut fully to expel additional oil.

      (4) Repeat step (3) five times and until no additional oil is discharged.

      (5) Add 25 fluid ounces (725 cubic centimeters) of oil while slowly extending strut.

      (6) Install pressure gauge, and with strut fully extended, inflate to 95 psi air pressure. There must be no pressure loss after 48 hours.

      (7) Ensure there is no sign of leakage at upper and lower ends of cylinder, or at joint of piston and fork.

THIS PAGE INTENTIONALLY LEFT BLANK

TROUBLESHOOTING

1. General

Refer to Table 801 for possible cause and correction of defects.

Table 801

Troubleshooting Information

TROUBLE	POSSIBLE CAUSE	CORRECTION
Hydraulic fluid leak at upper end of cylinder	Faulty O-rings at end cap assembly	Replace O-ring between end cap and cylinder and/or between end cap and support tube.
Hydraulic fluid leak at lower end of cylinder.	Faulty O-rings at floating piston on piston assembly.	Replace O-rings on floating piston.
Hydraulic fluid leak at locknut securing fork to piston tube	Faulty O-rings or packing at cartridge assembly plug.	Replace O-ring or packing on cartridge assembly plug.

NOTE: When correcting defects refer to the applicable DISASSEMBLY and REASSEMBLY procedures. After reassembly, test shock strut assembly as detailed in TESTING.

THIS PAGE INTENTIONALLY LEFT BLANK

STORAGE INSTRUCTIONS

1. Procedures

A. Preparation

(1) Release air pressure. Leave fluid in shock strut.

(2) Cap union connections on swivel fitting assembly.

(3) Secure steering actuator and steering collar assembly to shock strut assembly to prevent free movement of steering actuator. Wrap steering actuator, steering collar assembly, and actuator to outer cylinder mountings in water resistant vapor barrier material (refer to Table 901).

(4) Wrap exposed part of piston tube, and upper and lower torque arm mountings in water resistant vapor barrier material.

(5) Wrap axle, spacers, towing spools and axle mountings on fork lugs in water resistant vapor barrier material.

(6) Affix label giving following information:

(a) Part and serial number

(b) Date of Overhaul.

(c) Inspection.

SPECIAL TOOLS

1. General

Refer to Table 1001 for special tools required for the overhaul procedure detailed in this manual..

Table 1001

Special Tools and Equipment

HEROUX PART NO.	DESCRIPTION
T-187	Adapter for fork locknut.
T-188	Wrench for nut on end cap sub-assembly.
T-190	Adapter for shoulder nut on piston assembly.
T-191	Wrench for cylinder locknut
	Suitable cycling test rig.

ILLUSTRATED PARTS LIST

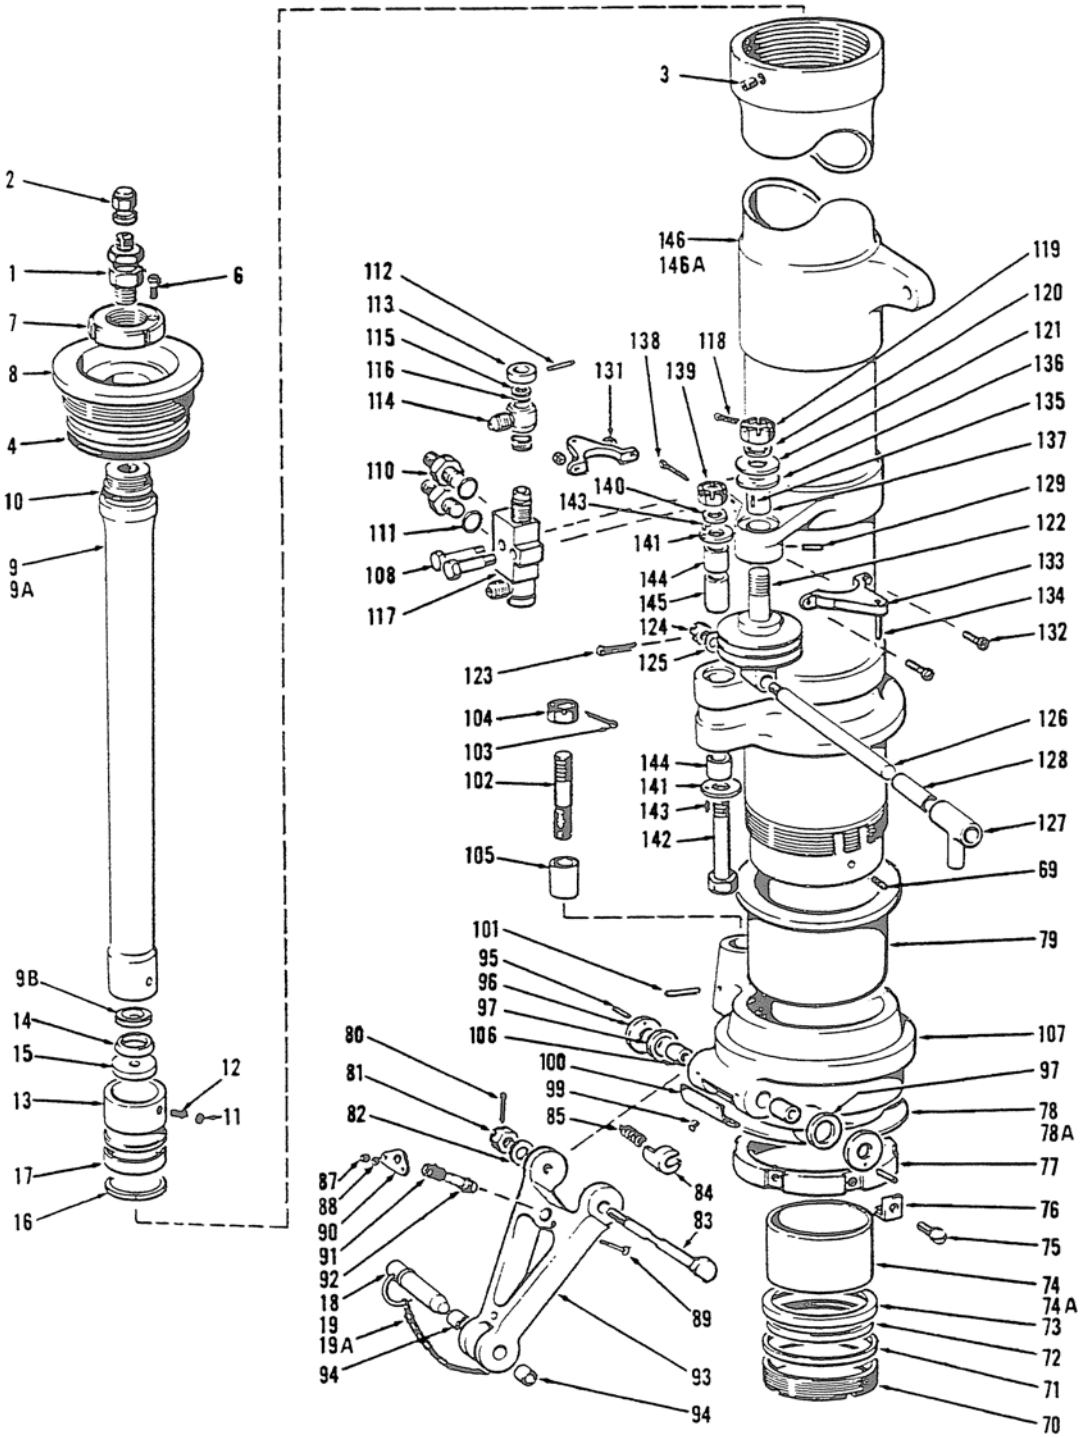
1. Vendor Codes

For explanation of vendor codes used in the Illustrated Parts List, refer to Table 1101.

Table 1101

Vendor Codes

CODE	NAME AND ADDRESS
02565	Hamler Corp. Mount Vernon, N.Y., U.S.A.
05694	Equi-Flex Products, Detroit, Michigan, U.S.A.
17194	Glacier Packing Co., Sanger, California, U.S.A.
36164	Heroux Machine Parts Ltd., Longueuil, P.Q., Canada
72902	Greene Tweed & Co., N. Wales, Pennsylvania, U.S.A.



2. Usage Code

To determine the applicability of the usage code letters used in the following Illustrated Parts List, refer to Table 1102.

Table 1102

OVERHAUL MANUAL
71-190

INTRODUCTION

This manual contains instructions for the overhaul of the Heroux Nosewheel Steering Actuator and Links Sub-assembly Part No. 71-190.

NOSEWHEEL STEERING ACTUATOR AND LINKS SUB-ASSEMBLY

HEROUX PART NO,. 71-190-1, -3, -7, -9, -11B, -13 AND -15

DESCRIPTION AND OPERATION

1. General (Figure 1)

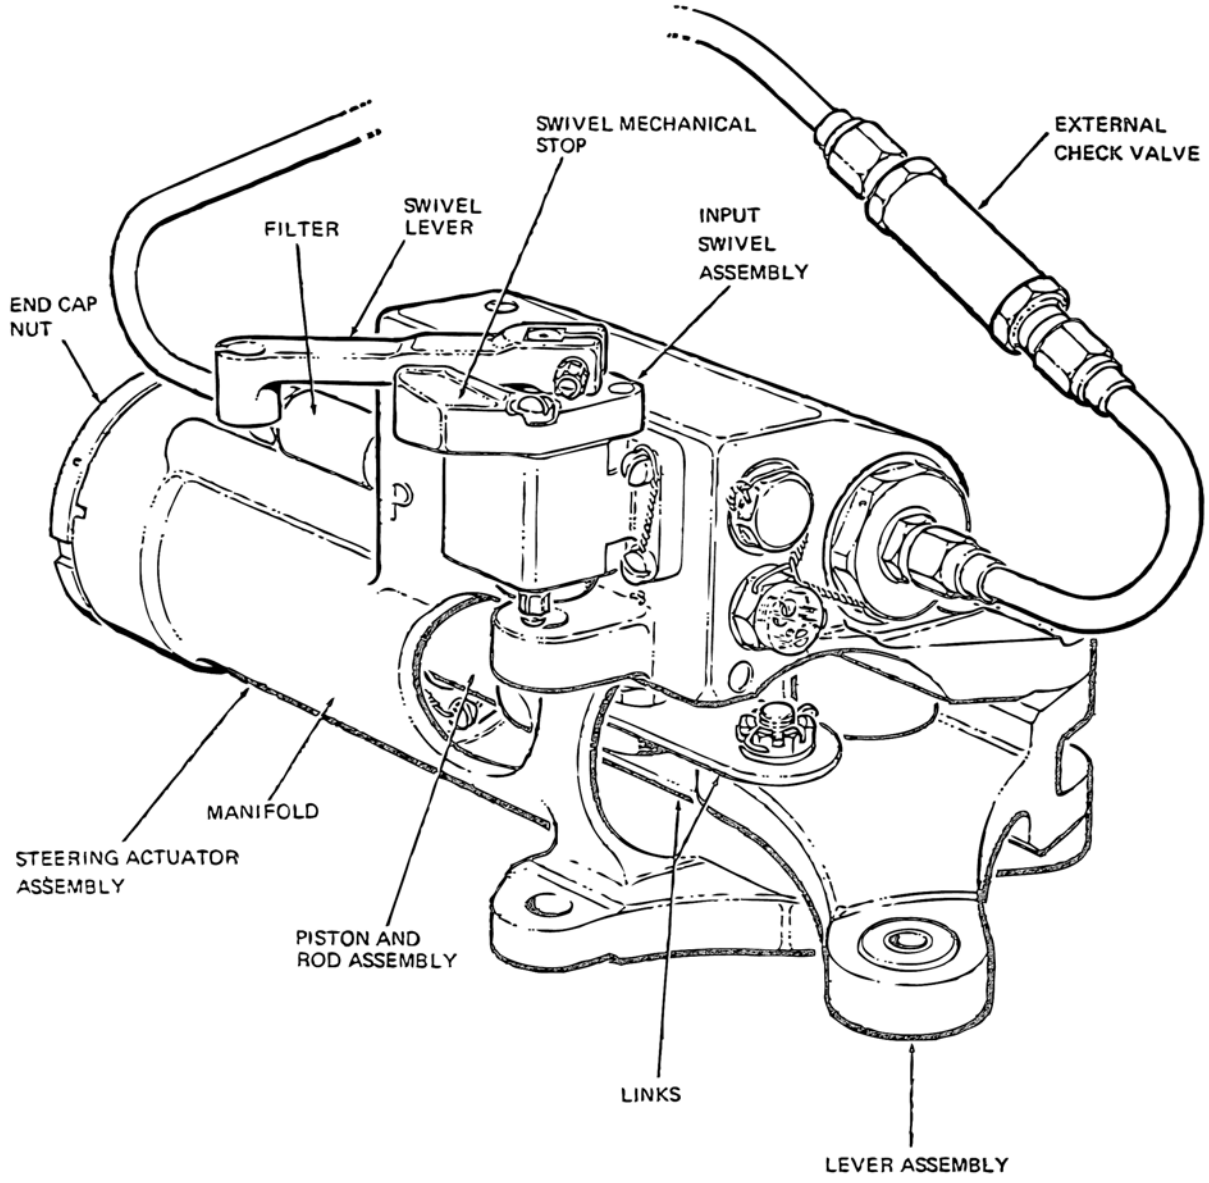
The nosewheel steering actuator and links sub-assembly is part of the nose gear leg assembly, and is mounted on the shock strut assembly. Refer to 32-20-11, NOSE GEAR LEG ASSEMBLY for configuration, and separation of the nose wheel steering actuator and links sub-assembly from the shock strut assembly.

The links sub-assembly consists of a lever assembly, two links, and the attaching part to connect the lever assembly and links to the steering actuator assembly. The lever assembly is attached at two lugs, and connected by the two links to a piston and rod assembly on the steering actuator assembly. When installed, the lever assembly is also connected to a steering collar on the shock strut assembly.

The steering actuator assembly is hydraulically-operated, and consists of a manifold, a piston and rod assembly, an input swivel assembly, a filter, and control valve, check valve, relief valve, and shimmy damper sub-assemblies which are housed within the manifold. On assemblies Part No. 71-190-7, 71-190-11B, 71-190-13 and 71-190-15, a check valve is fitted externally to replace a check valve within the manifold.

When installed and connected into the aircraft nosewheel steering system, movement of the system steering wheel is transmitted by cables and pulleys to move the input swivel shaft from its neutral position. An input swivel, driven by the input shaft positions a control valve in the actuator to direct hydraulic pressure to the appropriate side of the piston and rod assembly opening the other side to return. The pressure acts on the piston to extend or retract the piston and rod assembly and the links connected operating lever. The operating lever turns the steering collar to move the nosewheel to the left or right, as selected. Internal stops formed by the actuator end cap and an undercut at the opposite end of the manifold bore limits piston travel between fully extended and fully retracted. Actuator piston speed is limited by mechanical stops on the input swivel assembly.

2. Data



A. General

Hydraulic fluid	- MIL-H-5606
Operating Pressure	- 1500 psi
Proof Pressure	- 2250 psi
Flow Rate	- 1.0 to 1.3 Imp (1.2 to 1.6 US) gpm
Internal Relief	- 1.0 Imp (1.2 US) gpm at 1800 psi
Temperature Range	- 65°F to + 160°F

B. To Upgrade Steering Actuator and Links Sub-Assembly During Overhaul

By incorporating certain modifications during overhaul, the actuator and links sub-assembly may be upgraded to a later dash number standard. Refer to Tables 1 through 3A.

NOTE: If steering actuator and links sub-assembly are upgraded to the latest dash number during overhaul, they should be assembled to the appropriate assembly instructions for the later dash number using the required mod kits.

Steering Actuator and Links Sub-assembly

Figure 1

Table 1

Upgrade Part No. 71-190-9 to -11B Standard

MOD NO.	MOD KIT NO.	DESCRIPTION OF CHANGE
6/1380	C6MK1380	Improved shimmy damper with spring-loaded poppet valve, orifice plate with larger hole, modified restrictor and input swivel assembly installed in actuator.

Table 2

Upgrade Part No. 71-190-7 to -11B Standard

MOD NO.	MOD KIT NO.	DESCRIPTION OF CHANGE
*6/1240	C6MK1240	Improved check valve assembly installed in actuator.
6/1250	C6MK1250	Strengthened lever assembly and improved links.
6/1380	C6MK1380	Improved shimmy damper with spring-loaded poppet valve, orifice plate with larger hole, modified restrictor and input swivel assembly installed in actuator.
6/1386	C6MK1386	New end cap installed in actuator.

* Actuators Serial No. H344 and subsequent have this improvement embodied at manufacture.

Table 3

Upgrade Part No. 71-190-3 to -11B Standard

MOD NO.	MOD KIT NO.	DESCRIPTION OF CHANGE
6/1204	C6MK1204	External check valve introduced to replace check valve in actuator manifold.
6/1240	C6MK1240	Improved check valve assembly installed in actuator.
6/1250	C6MK1250	Strengthened lever assembly and improved links.
6/1380	C6MK1380	Improved shimmy damper with spring-loaded poppet valve, orifice plate with larger hole, modified restrictor and input swivel assembly installed in actuator.
6/1386	C6MK1386	New end cap installed in actuator.

NOTE: Upgrading an actuator and links assembly Part No. 71-190-1 to a higher dash number will not normally be done as this involves the changing of the manifold Part No. 71-201-1 to a manifold Part No. 71-201-3.

MOD NO.	MOD KIT NO.	DESCRIPTION OF CHANGE
6/1683	NO NUMBER (Refer to TAB or S/Bulletin)	Improved steering valve adjustment

C. Heroux Modification Kit

Table 4 lists the content of Heroux Modification Kit K71-506, for use with the Illustrated Parts List.

NOTE: The incorporation of De Havilland Modifications 6/1250 and 6/1386 satisfies the requirements of Mod Kit K71-506.

DISASSEMBLY

1. Procedures

A. Separate Links Sub-assembly and Steering Actuator Assembly (Figure 1101)

(1) Remove cotter pin (1), nut (2), washer (3), and withdraw bolt (4) attaching links (21) to lever (16). On steering actuator and links sub-assemblies Part No. 71-190-9, 71-190-11B and 71-190-13 only, remove two washers (22) positioned between links and lever.

(2) Remove cotter pin (5), nut (6), washer (7), and withdraw bolt (8) attaching lever (16) to lugs on steering actuator assembly (23).

(3) Remove two pins (9), two thrust washers (10), two dust rings (11), and two bushings (12) from lever (16).

NOTE: Do not remove spherical bearing (14) or spherical bearing (15) from lever (16) unless they are defective and have to be replaced (refer to FITS AND CLEARANCES).

(4) Remove cotter pin (17), nut (18), washer (19), turn piston and rod assembly to obtain clearance, and withdraw bolt (20) attaching links (21) to piston rod end of steering actuator assembly (23). On steering actuator and links sub-assemblies Part No. 71-190-9, 71-190-11B and 71-190-13 only, remove two washers (22) positioned between links and piston rod end.

B. Disassemble Steering Actuator Assembly, Heroux Part No. 71-200-1 and -3 (Figure 1102)

NOTE: If Mod 6/1204 is embodied, the steering actuator assembly should be disassembled in accordance with Paragraph 1.C. and Figure 1103.

(1) Disconnect pressure tube assembly (1) from filter (2). Cut lockwire, and remove filter (using special tool T-189) and packing (3) from manifold. Disconnect return tube assembly (4) from union (5), and remove union and packing (6) from manifold.

(2) Cut lockwire, remove four screws (7) and withdraw input swivel assembly and O-ring (8) from manifold.

(3) Loosen nut (11) on screw (12), and remove lever (13) with bearing (9) from input swivel assembly. Remove two nuts (14), two screws (15), two dowels (16) and end cap (17) with shims (18). Remove O-ring (19) from end cap. Withdraw shaft (21) of input shaft assembly and remove input swivel lever (22) and bearing (23) from shaft. Remove O-ring (24), race (25), bearing (26), race (27), and bearing (28) from swivel housing (29).

(4) On steering actuator assembly Part No. 71-200-1 only, remove set screw at end cap (31).

(5) Cut lockwire, unscrew end cap (31), and remove pellet (32). Remove O-ring (33) from end cap. Withdraw spacer (34) and control valve assembly from bore of manifold. Remove spring pin (36), unscrew extension (37) from spool and sleeve assembly, and remove two spring seats (38) with spring (39), spacer (40) and

shims (44). Note number of shims to assist reassembly. Remove spool (42) from sleeve (43) using special tool T-197. Remove four O-rings (45) from sleeve.

NOTE: Extension (37), spring seats (38), spacer (40), spool (42) and sleeve (43) are a matched marked set, and cannot be replaced individually. Keep parts in a separate container when disassembled.

(6) On steering actuator assembly Part No. 71-200-1 only, remove set screw at end cap (47).

(7) Cut lockwire, unscrew end cap (47) complete with adjustment screw (53) and insert (54), and remove pellet (48) from end cap (47). Remove O-ring (49), two screws (50), and cap (51) from end cap. Unscrew adjustment screw (53) from end cap, and remove insert (54) and O-ring (55) from adjustment screw.

(8) Withdraw spring seat (56), spring (57) and relief valve assembly from bore of manifold. Remove casing (59) and poppet (60) from sleeve (61) of relief valve assembly. Remove two O-rings (62) from sleeve.

NOTE: Casing (59), poppet (60) and sleeve (61) are a matched marked set and cannot be replaced individually. Keep parts in a separate container when disassembled.

(9) Remove orifice plate (63) and shimmy damper assembly from bore of manifold. Remove poppet (65) from sleeve (66) of shimmy damper assembly. Remove two O-rings (67) from sleeve.

NOTE: Poppet (65) and sleeve (66) are a matched marked pair, and cannot be replaced individually. Keep parts in a separate container when disassembled.

(10) Remove restrictor (68), spring (69) and check valve assembly from bore of manifold.

NOTE: Check valve assembly Mod 6/1240 is interchangeable, and may be fitted as a replacement for check valve assembly Pre Mod 6/1240. The poppet, seat, and O-ring comprising the assembly are restricted to their respective assembly.

(11) Disassemble check valve by removing poppet (71) from seat (72), and O-ring (73) from poppet; remove O-ring (74) from seat.

NOTE: Poppet (71) and seat (72) are a matched marked pair, and cannot be replaced individually. Keep parts in a separate container when disassembled.

(12) On steering actuator assembly Part No. 71-200-1 only, remove set screw at end cap (76).

(13) Cut lockwire, unscrew end cap (76) and remove pellet (77) from end cap (76A). Remove O-ring (78) from end cap. If installed, remove plug (76C) and packing (76B).

(14) Remove piston (79) from bore of manifold, and remove O-ring (80) from piston. Remove check valve assembly, spring (86), seat (87) and spring (88) from bore of manifold.

NOTE: Check valve assembly Mod 6/1240 is interchangeable and may be fitted as a replacement for check valve assembly Pre Mod 6/1240. The poppet, seat, and O-ring comprising the assembly are restricted to their respective assembly.

(15) Disassemble check valve assembly by removing poppet (82) from seat (83), and O-ring (84) from poppet; remove O-ring (85) from seat.

NOTE: Poppet (82) and seat (83) are a matched marked pair, and cannot be replaced individually. Keep parts in a separate container when disassembled.

(16) Cut lockwire, remove lock key (89), unscrew jam nut (90) using special tool T-194, and unscrew rod end (91) from piston. Cut lockwire, remove lock key (92), nut (93), and using special tool T-186, unscrew end cap (94) from manifold. Remove O-ring (95) from end cap. Cut lockwire, remove four screws (96), and remove plate (97), scraper (98) and O-ring (99) from end cap.

(17) Withdraw piston (100) from manifold, and remove piston ring (101) from piston.

(18) Cut lockwire, remove four screws (102), and remove plate (103), scraper (104) and O-ring (105) from manifold.

(19) Cut lockwire, and remove two plugs (106) and two packings (107) from test ports on manifold (110).

NOTE: Do not remove three pin plugs (108) or three pin plugs (109) from manifold unless they are defective and have to be replaced.

C. Dissasemble Steering Actuator Assembly, Heroux Part No. 71-200-7, 71-200-9, 71-200-11B, 71-200-13, and 71-200-15 (Figure 1103).

(1) Disconnect pressure tube assembly (1) from filter (2). Cut lockwire, and remove filter (using special tool T-189) and packing (3) from manifold. Disconnect return tube assembly (4) from union on end cap (76), and remove valve (5) and return tube assembly (6).

(2) Continue disassembly as detailed in Paragraph 1.B. steps (2), (3), (5), (7) and (8). On steering actuator Part No. 71-200-11B only, remove screw (10C) and spacer (10B).

(3) Remove orifice plate (63) and shimmy damper assembly from bore of manifold. Remove poppet (65) from sleeve (66) of shimmy damper assembly; on steering actuators Part No. 71-200-11B and 71-200-13 only, remove spring (68) from poppet. remove two O-rings (69) from sleeve.

NOTE: Poppet (65) and sleeve (66) are a matched marked pair, and cannot be replaced individually. Keep parts in a separate container when disassembled.

(4) Remove restrictor (70), spring (71) and check valve assembly for bore of manifold.

NOTE: Check valve assembly Mod 6/1240 is interchangeable, and may be fitted as a replacement for check valve assembly Pre Mod 6/1240. The poppet, seat, and O-ring comprising the assembly are restricted to their respective assembly.

(5) Disassemble check valve by removing poppet (73) from seat (74), and O-ring (75) from poppet; remove O-ring (76) from seat.

NOTE: Poppet (73) and seat (74) are a matched marked pair, and cannot be replaced individually. Keep parts in a separate container when disassembled.

(6) Cut lockwire, unscrew end cap (78) and remove pellet (79), union (80) and packing (81). Remove O-ring (82) from end cap.

(7) Remove piston (83) and spring (85) from bore of manifold, and remove O-ring (84) from piston. Remove air filter assembly and packing (89) from manifold.

NOTE: Do not remove filter from plug (87) of air filter assembly, unless it is defective and has to be replaced.

(8) Cut lockwire, remove lock key (90), unscrew jam nut (91) using special tool T-194, and unscrew rod end (92) from piston. Cut lockwire, remove lock key (93), nut (94), and using special tool T-186, unscrew end cap (95) from manifold. Remove O-ring (96) from end cap. Cut lockwire, remove four screws (97), and remove plate (98), scrapper (99) and O-ring (100) from end cap.

(9) Withdraw piston (101) and spacer (112) fom manifold, and remove piston ring (102) from piston.

(10) Cut lockwire, remove four screws (103), and remove plate (104), scraper (105) and O-ring (106) from manifold.

(11) Cut lockwire, and remove two plugs (107) and two packings (108) from test ports on manifold (111).

NOTE: Do not remove three pin plugs (109) or three pin plugs (110) from manifold unless they are defective and have to be replaced.

CLEANING

1. Procedures

A. General

(1) Clean components by washing or spraying with a dry cleaning solvent (refer to Table 201). Matched marked sets must be cleaned separately, and replaced in container after cleaning.

WARNING: USE SOLVENT IN A WELL-VENTILATED AREA, AND AVOID BREATHING FUMES. AVOID SKIN CONTACT AND KEEP AWAY FROM FLAME.

(2) Dry with moisture-free compressed air or a lint-free cloth.

B. Hydraulic Filter (item (2), Figure 1102 or 1103)

It is recommended that the filter element (Part No. 700419, Aircraft Appliances and Equipment Ltd., Toronto, Ontario, Canada.) complete with O-rings (MS28778-6 and MS28775-010) be replaced during overhaul. If replacement items are not available, filter can be cleaned by any conventional method.

After cleaning, pressure drop is not to exceed 10 psi at 0.8 Imp (1 US) gpm, using MIL-H-5606 fluid at 100° F (38° C).

Table 201

Cleaning Materials and Compounds

MATERIAL	SPECIFICATION OR MANUFACTURER
Solvent	P-D-680

INSPECTION/CHECK

1. Procedures

A. General

(1) Carry out a magnetic particle inspection of all magnetic metal components, where practicable.

(2) Inspect non-magnetic metal components using the fluorescent penetrant method, or an approved dye penetrant method.

(3) Inspect all parts visually for signs of fatigue and cracks, and for damage such as galls, scores, scratches, excessive wear and corrosion.

(4) Inspect all threaded parts for damaged, stripped, or crossed threads.

(5) Check all holes, internal and external diameters for wear, concentricity and taper. Refer to FITS AND CLEARANCES (Tables 601 and 602) for original tolerances and service limits. Repair or replace parts worn in excess of service limits.

(6) Check springs conform to operating values given in Table 301.

Table 301

Spring Values

FIG. 1102 ITEM NO.	FIG. 1103 ITEM NO.	CONDITION	LENGTH (INCHES)	LOAD (POUNDS)	SERVICE LIMITS (POUNDS)

REPAIR

1. Procedures

A. General

(1) Refer to FITS AND CLEARANCES. Replace all defective parts not listed in Tables 601 or 602.

(2) Replace all pellets of end cap assemblies at each overhaul.

(3) Replace standard parts such as cotter pins, spring pins, washers, nuts, bolts or screws, lock keys, dowels, and packing or O-rings at each overhaul.

(4) When anodized parts have had protective treatment damaged or removed, apply a protective coating of Alodine solution 1200S (refer to Table 401) to the affected area(s) or reanodize the part.

(5) Replate cadmium-plated parts which have had plating damaged or removed.

(6) Where indicated in Tables 601 or 602, parts may be repaired by hard chrome plating or hard anodizing the affected surface, then grinding or honing the surface to the original dimension shown in the table. Where parts were originally chrome plated, strip the original plating before repair. Parts not previously plated should be ground to the minimum necessary to produce a smooth surface before plating the part.

(7) When any item of a matched marked set is found to be defective, the complete set must be replaced.

ASSEMBLY

1. Procedures

A. Assemble Steering Actuator Assembly, Heroux Part No. 71-200-1 and -3 (Figure 1102)

(1) If removed for replacement of defective parts, install pin plugs (108) or pin plugs (109) to manifold (110).

(2) Temporarily install two packings (107) and two plugs (106) to test ports on manifold. Do not tighten or lockwire plugs until completion of testing (refer to TESTING).

(3) Coat O-ring (105) with grease G.E. Versilube G300. Install O-ring (105), scraper (104), and secure plate (103) to manifold using four screws (102). Torque screws to 12 pound-inches, and lockwire using MS20995-C20.

(4) Install piston ring (101) to piston (100). Insert piston into manifold using special tool T-193.

(5) Coat O-rings (99) and (95) with grease G.E. Versilube G300. Install O-ring (99), scraper (98), and secure plate (97) to end cap (94) using four screws (96). Torque screws to 12 pound-inches and lockwire using MS20995-C20. Install O-rings (95) to end cap (94).

Table 501

Assembly Materials and Compounds

MATERIAL	SPECIFICATION OR MANUFACTURER
Grease	G.E. Versilube G300
Lockwire, Corrosion Resistant	MS20995-C20
Lockwire, Corrosion Resistant	MS20995-C32
Hydraulic Fluid	MIL-H-5606B
Hydraulic Fluid, Preservative	MIL-H-6083
Petroleum	VV-P-236

(6) Install end cap (94) and set piston travel as follows:

(a) Screw end cap (94) into manifold using special tool T-186.

(b) Push piston into manifold until it butts firmly against internal stop. Measure and record the dimension along the piston from plate (103) to end of piston.

NOTE: To facilitate measurement, a 5/8-18 UNF bolt may be threaded into the piston. Insure bolt is not turned during setting of piston travel and check dimension from plate (103) to head of bolt.

(c) Push piston to other end of manifold until it butts firmly against end cap (94). Adjust end cap (using special tool T-186) so that dimension along piston from plate (103) to end of piston (or head of bolt) is equal to the recorded dimension minus 2.30 inches.

(d) Finger-tighten nut (93) onto end cap (94) and install lock key (92). Do not lockwire lock key until completion of testing (refer to TESTING).

(7) Temporarily thread rod end (91) with jam nut (90) into piston and position lock key (89). Do not tighten jam nut or lockwire lock key until assembly of steering actuator and links sub-assembly to shock strut assembly (refer to 32-20-11, NOSE GEAR LEG ASSEMBLY).

(8) Coat all O-rings with grease G.E. Versilube G300 and assemble spring (88), seat (87), spring (86), check valve assembly, piston (79) and end cap assembly into bore of manifold as follows:

(a) Check valve assembly: Install O-ring (84) to poppet (82) and position poppet in seat (83); install O-ring (85) to seat (83).

(b) Position check valve assembly in piston (79) and install O-ring (80) to piston. Position spring (86) in poppet of check valve assembly, and engage seat (87) with piston (79). Position spring (88) between seat and piston, and insert assembled parts into bore of manifold.

(c) Press fit pellet (77) into end cap (76A) and install O-ring (78), plug (76C) with packing (76B) to end cap. Thread end cap assembly (75) into manifold and tighten to 15 pound-feet. Do not lockwire end cap until completion of testing (refer to TESTING).

(9) On steering actuator assembly Part No. 71-200-1 only, install set screw at end cap (76A). Torque set screw to 12 pound-inches.

(10) Coat all O-rings with grease G.E. Versilube G300, and assemble check valve assembly, spring (69), restrictor (68), shimmy damper assembly, orifice plate (63), relief valve assembly, spring (57), spring seat (56), adjustment screw assembly and end cap assembly into bore of manifold as follows:

(a) Check valve assembly: Install O-ring (73) to poppet (71) and position poppet in seat (72); install O-ring (74) to seat (72).

(b) Install two O-rings (67) to sleeve (66) of shimmy damper assembly, and position poppet (65) in sleeve.

(c) Install two O-rings (62) to sleeve (61) of relief valve assembly, and position poppet (60) and casing (59) in sleeve.

(d) Position spring (69) in poppet of check valve assembly and position restrictor (68) at spring. Position orifice plate (63) between shimmy damper assembly and relief valve assembly, and insert assembled parts into bore of manifold.

(e) Position spring (57) and seat (56) in casing (59) of relief valve assembly.

(f) Press fit insert (54) into adjustment screw (53) and install O-ring (55) to adjustment screw. Thread adjustment screw into end cap (47). Press fit pellet (48) into end cap and install O-ring (49) to end cap. Thread end cap complete

with adjustment screw assembly into manifold and tighten to 8 pound-feet. Position cap (51) at end cap assembly and temporarily secure with two screws (50). Do not tighten screws or lockwire end cap assembly until completion of testing (refer to TESTING).

(11) On steering actuator assembly Part No. 71-200-1 only, install set screw at end cap (47). Torque set screw to 12 pound-inches.

(12) Coat all O-rings with grease G.E. Versilube G300 and assemble control valve assembly, spacer (34) and end cap assembly into bore of manifold as follows:

(a) Install four O-rings (45) to sleeve (43), and position spool (42) in sleeve.

(b) Position number of shims (44) noted at disassembly, and spacer (40) at spool and sleeve assembly, position two spring seats (38) with spring (39) in spacer and thread extension (37) onto spool of spool and sleeve assembly. Adjust extension so that length of two seats (38) with spring (39) is equal to length of spacer (40). Install spring pin (36) to secure extension at slot in spool.

(c) Position spacer (34) over extension of control valve assembly and insert assembled parts into bore of manifold. Insure spacer and extension are positioned to accept spherical end of input swivel lever (22).

(d) Press fit pellet (32) into end cap (31), and install O-ring (33) to end cap. Thread end cap assembly into manifold and tighten to 10 pound-feet. Do not lockwire end cap assembly until completion of testing (refer to TESTING).

(13) On steering actuator assembly Part No. 71-200-1 only, install set screw at end cap (31). Torque set screw to 12 pound-inches.

(14) Use small amounts of hydraulic fluid MIL-H-5606B, preservative hydraulic fluid MIL-H-6083, or petroleum VV-P-236 to assist installation of O-rings and bearings, and assemble input swivel assembly as follows:

NOTE When new Torrington bearings are installed, ensure that preservative and/or lubrication is removed before assembly.

(a) Position bearing (28), race (27), bearing (26) and race (25) in swivel housing (29). Install O-ring (24) in swivel housing. Position input swivel lever (22) and insert shaft (21) to engage input swivel lever in swivel housing.

(b) Install O-ring (19) to end cap (17) and position bearing (23) and end cap on swivel housing. Secure end cap using two screws (15) and two nuts (14). Tighten screws evenly and determine shims (18) required between end cap and swivel housing as follows:

(i) Measure gaps between end cap and swivel housing at four places.

(ii) Add 0.002 to 0.039 inch to maximum measured gap to make measurement a multiple of 0.002 inch.

(iii) Peel laminations from shim (18) till residue equals measurement calculated in (ii) above.

(c) Remove nuts (14), screws (15) and end cap (17), position shims (18) and reassemble end cap to swivel housing, Tighten two nuts (14) and two screws (15) evenly. Install two dowels (16) at end cap.

(d) Position lever (13) with bearing (9) on shaft (21) and secure using screw (12) and nut (11).

(15) Install O-ring (8) to manifold. Position input swivel assembly in manifold, and insure that spherical end of input swivel lever (22) engages extension (37) of control valve assembly. Secure input swivel assembly to manifold using four screws (7). Torque screws to 12 pound-inches and lockwire using MS20995-C20.

(16) Install packing (6) and union (5) to manifold and connect return tube assembly (4) to union. Install packing (3) and filter (2) (using special tool T-189) to manifold. Lockwire filter using MS20995-C20. Connect pressure tube assembly (1) to filter.

(17) Test steering actuator assembly (refer to TESTING) before installing links sub-assembly (refer to Paragraph 1.C.).

B. Assemble Steering Actuator Assembly, Heroux Part No. 71-200-7, 71-200-9, 71-200-11B, 71-200-13 and 71-200-15 (Figure 1103).

(1) If removed for replacement of defective parts, install pin plugs (109) or pin plugs (110) to manifold (111).

(2) Temporarily install two packings (108) and two plugs (107) to test ports on manifold. Do not tighten or lockire plugs until completion of testing (refer to TESTING).

(3) Coat O-ring (106) with grease G.E. Versilube G300. Install O-ring (100), scraper (105), and secure plate (104) to manifold using four screws (103). Torque screws to 12 pound-inches and lockwire using MS20995-C20. Install O-ring (96) to end cap (95).

(4) Install piston ring (102) to piston (101). Install spacer (112) into manifold. Insert piston into manifold using special tool T-193.

(5) Coat O-rings (100) and (94) with grease G.E. Versilube G300. Install O-ring (100), scraper (99), and secure plate (98) to end cap (95) using four screws (97). Torque screws to 12 pound-inches and lockwire using MS20995-C20. Install O-ring (96) to end cap (95).

(6) Install end cap (95) and set piston travel as follows:

(a) Screw end cap (95) into manifold using special tool T-186.

(b) Push piston into manifold until it butts firmly against internal stop. Measure and record the dimension along piston from plate (104) to end of piston.

NOTE: To facilitate measurement, a 5/8-18 UNF bolt may be threaded into the piston. Ensure bolt is not turned during setting of piston travel and check dimension from plate (104) to head of bolt.

(c) Push piston to other end of manifold until it butts firmly against end cap (95). Adjust end cap (using special tool T-186) so that dimension along piston from plate (104) to end of piston (or head of bolt) is equal to the recorded dimension minus 2.30 inches.

(d) Fingertighten nut (94) onto end cap (95) and install lock key (93). Do not lockwire lock key until completion of test (refer to TESTING).

(7) Temporarily thread rod end (92) with jam nut (91) into piston and position lock key (90). Do not tighten jam nut or lockwire lock key until assembly of steering actuator and links sub-assembly to shock strut assembly (refer to 32-20-11, NOSE GEAR LEG ASSEMBLY).

(8) If removed for replacement of defective parts, install filter to plug (87) of air filter assembly. Install packing (89) and air filter assembly to manifold.

(9) Coat O-rings (84) and (82) with grease G.E. Versilube G300. Install O-ring (84) to piston (83). Press fit insert (79) into end cap (78) and install O-ring (82), packing (81) and union (80) to end cap. Position spring (85) and piston (83) in bore of manifold and thread end cap assembly into manifold. Tighten end cap assembly to 15 pound-feet. Do not lockwire until completion of testing (refer to TESTING).

(10) Coat all O-rings with grease G.E. Versilube G300, and assemble check valve assembly, spring (71), restrictor (70), shimmy damper assembly, orifice plate (63), relief valve assembly, spring (57), spring seat (56), adjustment screw assembly and end cap assembly into bore of manifold as follows:

(a) Check valve assembly: Install O-ring (75) to poppet (73) and position poppet in seat (74); install O-ring (76) to seat (74).

(b) Install two O-rings (69) to sleeve (66) of shimmy damper assembly, and position poppet (65) in sleeve. On steering actuaters Part No. 71-200-11B and 71-200-13 only, install spring (68) to poppet before positioning in sleeve.

(c) Install two O-rings (62) to sleeve (61) of relief valve assembly, and position poppet (60) and casing (59) in sleeve.

(d) Position spring (71) in poppet of check valve assembly and position restrictor (70) at spring. Position orifice plate (63) between shimmy damper assembly and relief valve assembly, and insert assembled parts into bore of manifold.

(e) Position spring (57) and seat (56) in casing (59) of relief valve assembly.

(f) Press fit insert (54) into adjustment screw (53) and install O-ring (55) to adjustment screw. Thread adjustment screw into end cap (47). Press fit pellet (48) into end cap and install O-ring (49) to end cap. Thread end cap complete with adjustment screw assembly into manifold and tighten to 8 pound-feet. Position cap (51) at end cap assembly and temporarily secure with two screws (50). Do not tighten screws or lockwire end cap assembly until completion of testing (refer to TESTING).

(11) Continue assembly of steering actuator as detailed in Paragraph 1.A. steps (12), (14) and (15). On steering actuator Part No. 71-200-11B, install spacer (10B) and secure with screw (10C). Do not lockwire spacer until completion of testing (refer to TESTING). On steering actuator, Part No. 71-200-13, slacken lock nut (10E) and back-off adjusting screws (10D) in end cap to facilitate assembly of lever (13). Refer to paragraph 1.A. step 14 (d).

(12) Connect return tube assembly (6), valve (5) and return tube assembly (4) to union (80) of end cap assembly. Install packing (3) and filter (2) (using special tool T-189) to manifold. Lockwire filter using MS20995-C20. Connect pressure tube assembly (1) to filter.

(13) Test steering actuator assembly (refer to TESTING) before installing links sub-assembly (refer to Paragraph 1.C.).

C. Assemble Links Sub-assembly to Steering Actuator Assembly (Figure 1101)

(1) Position two links (21) at piston rod end of steering actuator assembly and install bolt (20), washer (19), nut (18) and cotter pin (17).

NOTE: On steering actuator and links sub-assemblies Part No. 71-190-9, 71-190-11B and 71-190-13 only, position two washers (22) (one between each link and piston rod end) before installing bolt (20).

(2) If removed for replacement of defective parts, install spherical bearing (15) and/or spherical bearing (14) to lever (16). Stake over bearings.

(3) Install two bushings (12), two dust rings (11), two thrust washers (10) and two pins (9) to lever (16).

(4) Position lever assembly at lugs on steering actuator assembly and install bolt (8), washer (7), nut (6) and cotter pin (5).

(5) Position links (21) at lever (16) and install bolt (4), washer (3), nut (2) and cotter pin (1).

NOTE: On steering actuator and links sub-assemblies Part No. 71-190-9, 71-190-11B and 71-190-13 only, position two washers (22) (one between each link and piston rod end) before installing bolt.

FITS AND CLEARANCES

1. Original Dimensions and Service Limits

A. Steering Actuator and Links Sub-assembly (Figure 1101)

Refer to Table 601 for original dimensions and service limits of the links sub-assembly and disposition of parts failing to meet inspection requirements.

B. Steering Actuator Assembly (Figures 1102 and 1103)

Refer to Table 602 for original dimensions, service limits and disposition of parts failing to meet inspection requirements.

Table 601

Links Sub-assembly - Original Tolerances and Service Limits

110	111	Manifold	I.D. Piston location	2.6240 - 2.6260	2.6270	Replace
			I.D. Piston shaft location	1.0000 - 1.0020	1.0030	Replace
			I.D. Piston (79) (Fig. 1102) or (83) (Fig. 1103) location	1.4910 - 1.4930	1.4940	Replace
			I.D. Spacer (40) location	0.8630 - 0.8650	0.8660	Replace
			I.D. Sleeve (43) location	0.7380 - 0.7400	0.7410	Replace
			I.D. Relief and shimmy damper valve location	0.8000 - 0.8020	0.8030	Replace
			I.D. Two holes in line at lugs	0.4996 - 0.5001	0.5005	Replace
			I.D. Two holes in line at lugs	0.3747 - 0.3756	0.3765	Replace

NOTES: (1) Spool lap fitted to sleeve. If diametrical clearance exceeds 0.00015 inch and assembly does not meet test requirements (refer to TESTING), replace spool and sleeve assembly.

(2) Poppet lap fitted to sleeve. If diametrical clearance exceeds 0.00015 inch and assembly does not meet test requirements (refer to TESTING), replace relief valve assembly (poppet, sleeve and casing).

(3) Poppet lap fitted to sleeve. If diametrical clearance exceeds 0.0004 inch and assembly does not meet test requirements (refer to TESTING), replace shimmy damper assembly.

(4) Poppet lap fitted to seat. If diametrical clearance exceeds 0.0007 inch and assembly does not meet test requirements (refer to TESTING), replace check valve assembly.

TESTING

1. Procedures (Figure 701)

A. Filling and Bleeding

(1) Remove test port plugs and connect test ports A and B together.

(2) Connect hydraulic test rig (fluid MIL-H-5606) supply line to pressure tube assembly and return line to the return tube assembly.

(3) Place actuator so that input swivel assembly is facing down.

(4) Apply pressure of 1500 psi, turn lever of input swivel assembly fully in one direction and hold for 10 seconds minimum. Turn lever fully in opposite direction and hold for 10 seconds minimum.

(5) Repeat step (4) a minimum of five times.

(6) Place actuator so that input swivel assembly is facing up, then repeat steps (4) and (5).

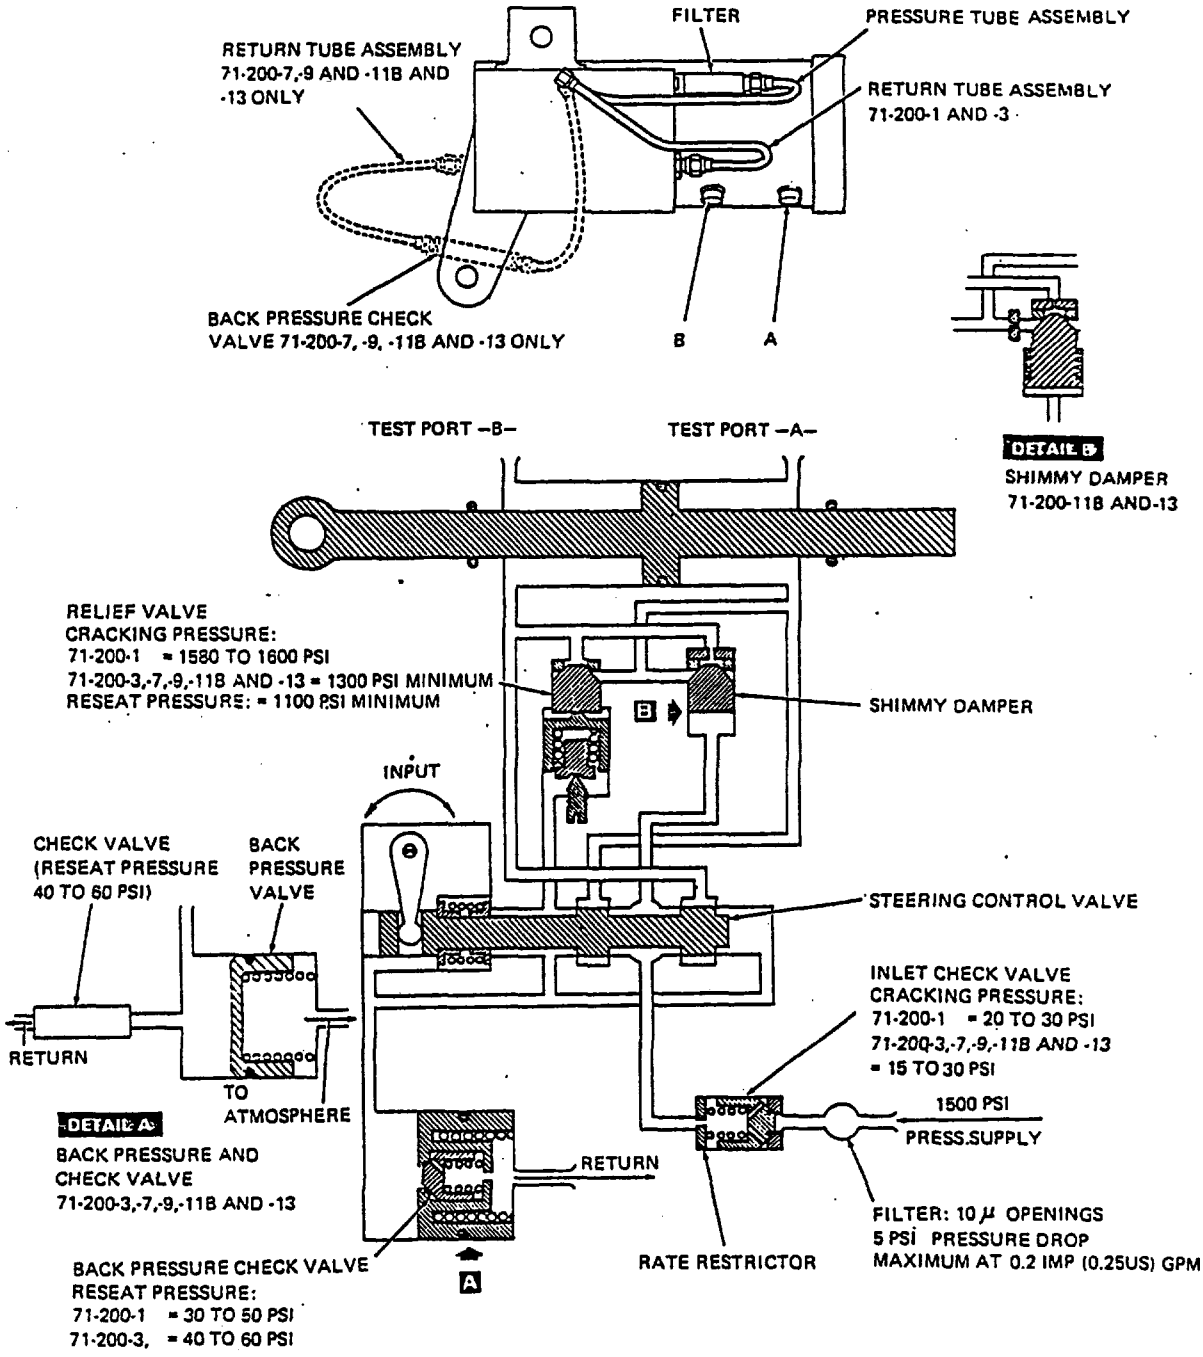
B. Cracking Pressure, Inlet Check Valve

(1) Connect hydraulic test rig supply line to pressure tube assembly. Remove test port plugs and leave test ports open.

(2) Turn lever of input swivel assembly fully in either direction and gradually increase supply pressure until a small steady flow is obtained at test port. Check that supply pressure is 20 to 30 psi for steering actuator assembly 71-200-1, or 15 to 30 psi for steering actuator assemblies 71-200-3, 71-200-7, 71-200-9, 71-200-11B and 71-200-13.

C. Reseat Pressure, Back Pressure Check Valve

(1) Open pressure tube assembly to atmosphere. Connect hydraulic test rig supply line to test port A.



(2) Place actuator so that input swivel assembly is facing up.

(3) Turn lever of input swivel assembly fully counterclockwise (looking from above). Raise supply pressure until a steady flow is obtained at return tube assembly. Decrease supply pressure gradually until flow stops. Check supply pressure is 30 to 50 psi at reseat for steering actuator assembly 71-200-1 or 40 to 60 psi for steering actuator assemblies 71-200-3, 71-200-7, 71-200-9, 71-200-11B and 71-200-13.

(4) Maintain reseat pressure. After 3 minutes, external leakage must not exceed five drops per minute at each port.

D. Relief Valve and Shimmy Damper

(1) Place lever of input swivel assembly in neutral position (control valve centered). Connect hydraulic test rig supply line to pressure tube assembly and apply pressure of 1500 psi.

Test Ports and Schematic Hydraulic Diagram

Figure 701

(2) Connect test port A to a regulated supply line. Raise regulated pressure until flow is increased over leakage flow at test port B. Cracking pressure must be between 1580 to 1600 psi for steering actuator assembly 71-200-1, or must not be less than 1300 psi for steering actuator assemblies 71-200-3, 71-200-7, 71-200-9, 71-200-11B and 71-200-13. Adjust relief valve setting as follows:

(a) Refer to Figure 1102 or 1103.

(b) Remove two screws (50) and cap (51) from end cap (47).

(c) Turn adjuster screw (53) clockwise to increase relief valve cracking pressure or counterclockwise to decrease cracking pressure.

(d) Replace cap (51) on end cap (47) and secure with two screws (50).

(3) Lower regulated pressure at test port A gradually until flow at test port B is reduced to leakage flow. Reseat pressure must not be less than 1100 psi.

(4) Connect a flowmeter at test port B. Increase regulated pressure at test port A until 1.0 Imp (1.2 US) gpm flow is obtained at test port B. Check that pressure does not exceed 1800 psi.

(5) Connect regulated supply line to test port B and flowmeter to test port A. Repeat tests similar to steps (1) through (4), noting that adjustment of relief valve cracking pressure should not be required.

(6) Release pressure supply at pressure tube assembly and disconnect supply line. Leave pressure tube assembly open to atmosphere to permit bypass through shimmy damper orifice.

(7) Apply regulated pressure of 1000 psi at test port B. Flow at test port A must be 1.1 to 1.3 Imp (1.4 to 1.6 US) gpm.

E. Control Valve

(1) Connect test ports A and B together. Connect hydraulic test rig supply line to pressure tube assembly. Place lever of input swivel assembly in neutral (control valve centered).

(2) Apply pressure of 1500 psi. Leakage flow at return tube assembly must be 12 to 20cc per minute. If required, shims (item (44). Figure 1102 or 1103) may be added or removed to center control valve with lever within 0.005 inch.

(3) Torque required at lever of input swivel assembly to crack control valve must not exceed 65 pound-inches, and the flow must stop on reduction to 40 pound-inches.

(4) Disconnect test ports A and B and install packing and plug at each port.

(5) With supply pressure at 1500 psi, apply torque of 75 pound-inches to lever of input swivel assembly in both directions from neutral. Extension and retraction rate must be 7 $\pm$ 1 seconds for a complete stroke in each direction. On actuators Part No. 71-200-11B, or actuators with Mod 6/1380 embodied, limit retractor extension and retraction rate by cutting sides of spacer (item 10B Figure 1103) vertically, as required. See Figure 702. On actuators Part No. 71-200-13 slacken locknuts and adjust screws (items (10D) and (10E), Figure 1103) to limit actuator extension and retraction speeds. See Figure 702.

(6) Position piston at center of stroke. With control valve centered, piston creep rate must be less than 0.030 inch per minute.

F. Proof Pressure

(1) With plugs installed at test ports A and B and return tube assembly capped, apply a pressure of 2250 psi at pressure tube assembly at a rate of not more than 25,000 psi per minute (400 psi per second).

(2) Turn lever of input swivel assembly slowly clockwise and hold for 2 minutes.

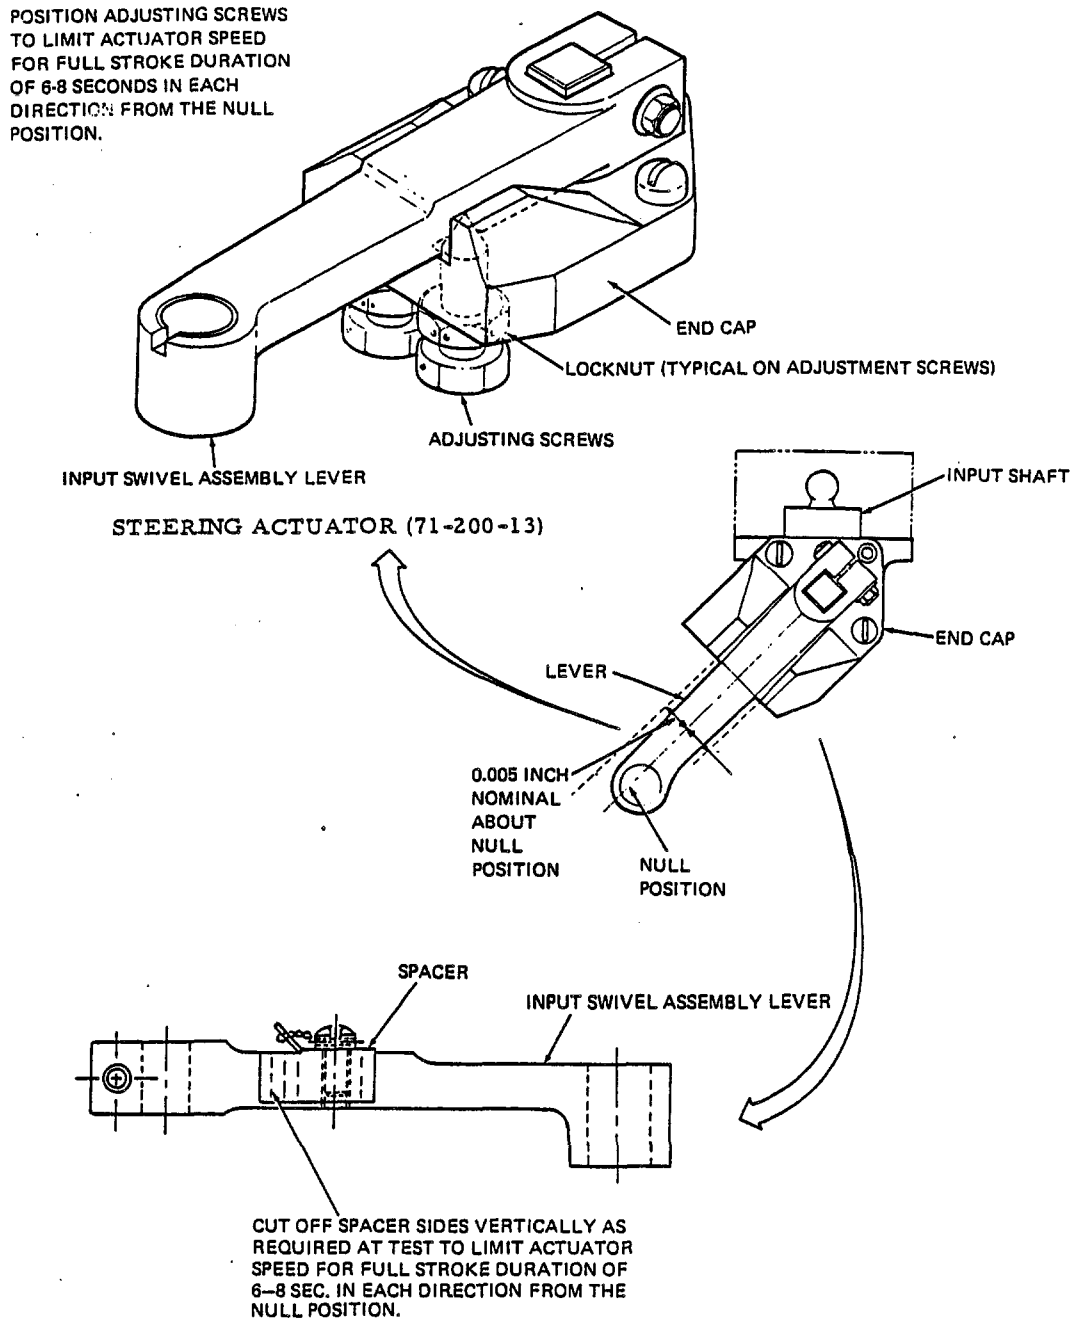
(3) Turn lever of input swivel assembly slowly counterclockwise and hold for 2 minutes.

(4) There must be no leakage or permanent set.

NOTE: A slight wetting insufficient to form a drop is acceptable.

(5) Release pressure completely and then apply 40 psi at pressure tube assembly. There must be no leakage.

G. Lockwiring After Test (Figure 1102 or 1103)



(1) Lockwire end cap (31), end cap (47) and end cap (item (76A), Figure 1102 or item (78), Figure 1103) using MS20995-C32.

(2) Lockwire lock key (item (92), Figure 1102 or item (93), Figure 1103) using MS20995-C20.

(3) Lockwire two plugs at test ports using MS20995-C20.

(4) On steering actuator 71-200-11B, lockwire spacer securing screw (item (10C), Figure 1103) to spacer, using MS20995-C20.

(5) On steering actuator 71-200-13, lockwire adjusting screw and locknut to end cap using MS20995-C32.

Input Swivel Assembly Lever Adjustment

Figure 702

TROUBLE SHOOTING

1. General

Refer to Table 801 for possible cause and correction of defects. For item numbers refer to Figure 1102 or Figure 1103.

Table 801

Trouble Shooting Information

TROUBLE	POSSIBLE CAUSE	CORRECTION
With lever (13) centered, piston creep exceeds 0.030 inch per minute	Control valve not centered with lever within 0.005 inch	Remove control valve assembly. Add or remove shims (44) to center control valve with lever to within 0.005 inch. Reassemble and test.
External leaks	Faulty O-ring or packing	Replace applicable O-ring or packing.
	NOTE: (1) Piston travel must be reset when end cap (item (94) Figure 1102, or item (95) Figure 1103) is removed for O-ring replacement. (2) Piston travel and rod end setting must be reset if piston is removed for replacement of O-ring (item (105) Figure 1102, or item (106) Figure 1103).	
Actuator extension or retraction does not meet requirements (6-8 seconds) for complete stroke.	Faulty O-rings on control valve sleeve (43)	Replace O-rings and test.
	Incorrect setting or poppet not seating at relief valve assembly	Remove and clean relief valve assembly. Reassemble, test and adjust relief valve setting.
	Input swivel assembly incorrectly adjusted.	Adjust spacer (item (10B), Figure 1103). Actuator Part No. 71-200-11B. Refer to TESTING. OR Adjust adjusting screws item (10D), Figure 1103 - Actuator Part No. 71-200-13. Refer to TESTING.

STORAGE INSTRUCTIONS

1. Procedures

A. General

(1) If steering actuator and links sub-assembly is mounted on the shock strut assembly, carry out storage instructions given in 32-20-11, NOSE GEAR LEG ASSEMBLY.

B. Preparation

(1) Fill steering actuator as far as possible with hydraulic fluid (refer to Table 901), and cap pressure and return tube assemblies.

(2) Secure links sub-assembly to steering actuator to prevent movement of piston assembly.

(3) Wrap steering actuator and links sub-assembly in water resistant vapor barrier material (refer to Table 901), or enclose in a plastic bag.

(4) Affix label giving following information:

(a) Part and serial number.

(b) Date of overhaul

(c) Inspection

Table 901

Storage Materials and Compounds

MATERIAL	SPECIFICATION OR MANUFACTURER
Barrier Material	MIL-B-121
Hydraulic Fluid	MIL-H-5606

SPECIAL TOOLS

1. General

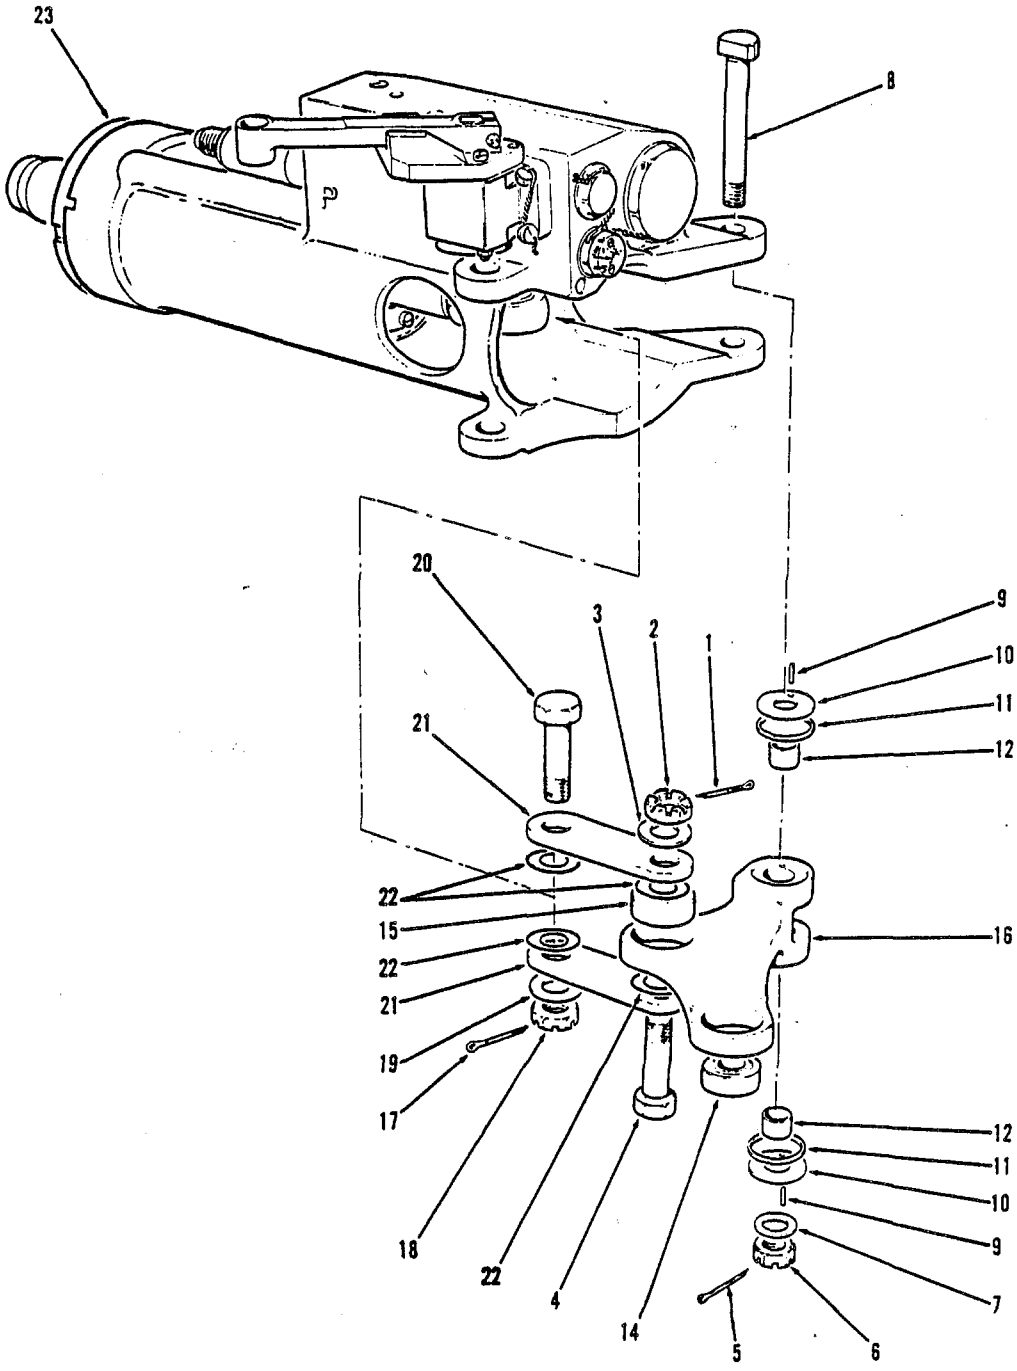
Refer to Table 1001 for special tools required for the overhaul procedure detailed in this manual.

Table 1001

Special Tools and Equipment

HEROUX PART NO.	DESCRIPTION
T-186	Wrench for end cap
T-189	Adapter for filter
T-193	Guide for piston installation
T-194	Wrench assembly, piston rod end jam nut
T-197	Extractor, spool and sleeve assembly
-	Torque wrench to 100 pound-inches
-	Flowmeter to check flow rate 1.0 to 1.3 Imp (1.2 to 1.6 US) gpm
-	Hydraulic test rig, two pressure supplies 2250 psi, and flow rate 1.3 Imp (1.6 US) gpm

ILLUSTRATED PARTS LIST



1. Vendor Codes

For explanation of vendor codes used in the Illustrated Parts List, refer to Table 1101.

Table 1101

Vendor Codes

CODE	NAME AND ADDRESS
05694	Equi-Flex Products, Detroit, Michigan, U.S.A.
15860	Astro Division of New Hampshire Ball Bearing Inc., El Segundo, California, U.S.A.
17194	Glacier Packing Co., Sanger, California, U.S.A.
35076	Aircraft Appliances and Equipment Ltd., 152 East Drive, Bramalea, Ontario, Canada.
36164	Heroux Machine Parts Ltd., Longueuil, P.Q., Canada.
36972	Tor Manufacturing Co. Ltd., 3289 Lenworth Drive, Cooksville, Ontario, Canada
80648	The Torrington Co., South Bend, Indiana, U.S.A.
86768	Republic Manufacturing Co., Cleveland, Ohio, U.S.A.
92555	The Lee Co., Westbrook, Connecticut, U.S.A.
96881	Thomson Industries Inc., 1029 Plandome Rd., Manhasset, N.Y., 11030, U.S.A.
97613	Kahr Bearing, Burbank, California, U.S.A.
97820	W.S. Shamban & Co., Culver City, California, U.S.A.

REVISION HIGHLIGHTS!!

MANUAL 266

INSTALLATION, MAINTENANCE, AND OVERHAUL
3-1197
Nose Landing Gear Wheel
(De Havilland DHC-6)

REVISED: 1 February 1974

This manual has been completely revised to include the latest overhaul and rework procedures.

1. DESCRIPTION

1.1 The 3-1197 wheel is designed for use with 8.90 - 12.50, Type III, six-ply rated, low-pressure, tubeless tire, and has a maximum static rating of 1900 lb. The wheel consists of the following parts.

1.2 Inner (27) and outer (20) cast magnesium wheel halves are bolted together with bolts (11) and nuts (9). Washers (10, 12) are used beneath the nuts and bolt heads to prevent galling and stress concentration. A packing (13) mounted in the groove in the inner wheel half seals against air leaking from tubeless tires.

1.3 Bearing cups (19, 26) and cones (8) are installed in the hub area of both wheel halves. Balance weights (14, 22), to balance the wheel, are fastened with nuts (15, 23) and screws (16, 24) to the inner surfaces; and an instruction plate (17) is fastened to the outer wheel half (20). A tubeless valve (1 thru 6), installed in the outer wheel half, is used to inflate or deflate the tire.

2. ASSEMBLY

2.1 The wheel is shipped from the factory completely assembled. The bearings are packed with the proper grease and may be installed as received. To install the tire, proceed as follows.

2.2 Remove nuts (9), washers (10, 12), bolts (11), and separate the wheel halves (20, 27).

2.3 Remove packing (13) from its package and install on the inner wheel half (27). Mount tire on the inner wheel half.

2.4 Assemble the outer wheel half (20) onto the inner wheel half (27).

2.5 Install bolts (11), washers (10, 12), and nuts (9). Tighten the nuts to 240 to 260 lb inch torque, using the following procedure.

2.5.1 Apply a generous coat of thread compound, specification MIL-T-5544, to threads of bolts (11), faces of washers (10, 12), and bearing face of nuts (9). Tighten to 192 lb inch torque, four nuts, approximately diametrically opposite and at 90°.

2.5.2 Stagger-tighten the remaining nuts to 192 lb inch torque, then, using the same procedure, retighten all nuts to 240 to 260 lb inch torque.

NOTE: Do not use impact wrench when applying final torque. Use hand torque wrench only.

3. INSTALLATION

3.1 Check axle for burrs and thread damage. Hand file to remove damaged threads. Smear bearing grease on axle nut threads on axle.

3.2 Install wheel onto axle being careful not to damage the grease seals (7) located on each side of the wheel.

3.3 Install axle nut. While rotating wheel, torque axle nut to 30 ft-lbs to properly seat bearings. Loosen axle nut to zero torque, and while rotating wheel, retighten to 15 ft-lbs. Check for alignment of locking hole. If locking holes are not aligned, continue tightening to first locking hole and safety-lock axle nut.

3.4 Inflate tire.

4. MAINTENANCE (While equipment is on aircraft)

4.1 Inspect wheel half flanges for cracks and corrosion.

4.2 Check for loose bolts and nuts and retighten or replace.

NOTE: No repair or replacement is recommended while equipment is on the aircraft except the tightening or replacing of bolts and nuts.

4.3 At each tire change visually inspect wheel halves for evidence of corrosion (white powder on surface) noting especially the bead seat area (tire contact surface) and the tie-bolt hole areas. Corrosion areas which can be removed by sanding with emery cloth (240 grit) may be touched up with Dow No. 19 solution, followed by zinc chromate (MIL-P-8585) primer. Paint all bare magnesium.

NOTE: Bare magnesium is silver in color, the protective finishes put on the wheel at the factory is gold (Dow #7). If corrosion cannot be removed by sanding down to bare metal within the limits given in Figure 5-2, the wheel should not be continued in service.

4.4 To replace a valve core (2, Figure 6-1), use a standard extraction tool to unscrew the valve core. If the valve stem (5) is replaced, a new grommet (5) should be installed on the stem.

5. OVERHAUL

5.1 Dismounting.

5.1.1 Deflate tire. Remove valve core (2) from valve stem (6) to assure complete deflation. Remove outer seal (7) and bearing cone (8). Dismount wheel and tire assembly from axle as a unit. Remove inner seal (7) and bearing cone (8).

5.2 Disassembly.

WARNING: TIRE MUST BE DEFLATED BEFORE LOOSENING TIE BOLTS.

5.2.1 Break tire beads away from wheel flanges with a bead breaker or pneumatic tire dismounter.

CAUTION: DO NOT USE TIRE IRONS. THEY MAY DAMAGE THE WHEEL FLANGES OR TIRE BEADS AND PREVENT PROPER AIR RETENTION.

5.2.2 Remove nuts (9), washers (10, 12) and bolts (11) from the wheel.

5.2.3 Separate the wheel halves (20, 27) and remove tire and packing (13).

5.2.4 If packing (13) is to be reinstalled, place it on a clean sheet of paper for cleaning.

5.2.5 Balance weights (22) should only be removed if loose, or for zyglo inspection of the wheel half.

5.2.6 Bearing cups (19, 26) are shrunk fit into the wheel halves (20, 27) and should not be removed unless replacement is necessary. If a bearing cup is to be replaced, heat the wheel half to 149°C (300°F) maximum for 20 minutes before trying to remove the cup. Support the wheel hub while removing the cup, as in Figure 5-1.

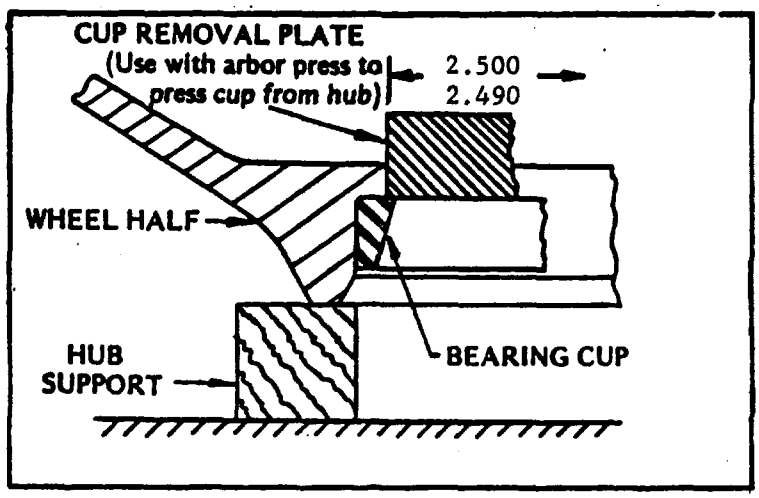

Figure 5-1. Supporting Wheel Hub

5.3 Cleaning.

5.3.1 Clean all metal parts in Stoddard solvent, or equivalent, and dry with compressed air.

5.3.2 Wipe bearing seals clean with dry cloth. Do not use cleaning solvents on rubber parts.

5.3.3 Wash bearing cones in uncontaminated cleaning solution, rotate the bearing cage by hand while submerged in the solution. Repack bearing with grease immediately after inspection to prevent corrosion and place in a clean, closed container.

CAUTION: DO NOT SPIN DRY BEARINGS OR HANDLE BEARINGS WITH BARE HANDS.

5.3.4 Remove paint from wheel halves using any of the methods that follow, taking care to avoid removing the surface treatment underneath the paint.

5.3.5 Remove paint from wheel halves by abrasive blasting using ground walnut hulls per MIL-G-5634, Types II or III. This method is recommended as it will not remove the surface treatment and does not require masking or removal of the bearing cup.

NOTE: Sand blasting may be used if adequately controlled to prevent damage to the surface.

5.3.6 Paint can be stripped from wheel halves using acetone, methylene chloride, or Formula No. 1006 (Allied Ketite Chemical Co., 2400 East Devon Avenue, Des Plaines, Illinois 60018). Commercial paint strippers not harmful to magnesium may be used.

WARNING: USE PAINT STRIPPERS IN A WELL VENTILATED AREA AND AVOID PROLONGED INHALATION OF FUMES.

CAUTION: REMOVE OR MASK BEARING CUP PRIOR TO PAINT STRIPPING THE WHEEL HALF.

5.4 Inspection.

NOTE: Inspect bolts (11) and wheel halves (20, 27), per 5.4.1 and 5.4.2, at each fifth tire change, and each third subsequent tire change, for a total of twenty tire changes; and on each tire change thereafter.

5.4.1 Magnaflux bolts (11) for cracks and breaks.

5.4.2 With dy-check or fluorescent penetrant, inspect wheel halves (20, 27) for cracks and breaks, noting in particular the bead seat, tubewell, and web junction areas.

5.4.3 Visually inspect all metal parts for pitting, corrosion, cracks, breaks, uneven wear, and other surface defects.

5.4.4 Inspect packing sealing surfaces for surface smoothness.

5.4.5 Inspect packings (13), grommets (5), and bearing grease seals (7) for pits, cuts, and other defects. Replace as necessary.

5.5 Repair and Replacement.

5.5.1 Wheel Half (20, 27) Repair and Surface Treatment.

5.5.2 Rework limits and the areas in which they are permitted are shown in Figure 5-2.

5.5.3 All allowable blending of damaged areas should be done over an area of from 1/2" to 1" around the damage. The blended surface should be smooth and free from any abrupt changes in contour. Blended area should be as smooth as is possible to obtain with a fine (240 grit) emery cloth.

5.5.4 Repair can be made to both sides of a section as long as the total removal limit of both sides is not exceeded.

5.5.5 Repairs can be made adjacent to each other as long as the blended areas do not touch or any one blended area does not exceed 3" in length.

5.5.6 Repair damaged O-ring, wheel half mating surfaces and torque key slots with Metalset A4 (Obtain from Smooth-On Incorporated, 1000 Valley Road, Gillette, New Jersey 07933) as follows:

5.5.7 Blend damaged area with a hand file to provide minimum patching surface 1/16 inch square. Maximum patching surface should not exceed width of the gasket groove 2" long, (O-ring seal) or 1/4 x 2" long (wheel half mating surface).

5.5.8 Remove all surface treatment, dirt, and other contaminants from the damaged area and thoroughly clean with thinner or alcohol.

5.5.9 Thoroughly blend equal amounts of Metalset "A" and "B", apply to damaged area, and let harden.

NOTE: Metalset hardens in a few hours at room temperature ($77^{o}F$). Heat to speed hardening. At $150^{o}F$, Metalset will harden in a few minutes. Use disposable equipment in mixing and applying Metalset to prevent permanent adherence to tools if not cleaned immediately after use.

5.5.10 After hardening, blend and smooth surfaces to original configuration with emery cloth.

5.5.11 If any Dow No. 7 surface treatment has been removed from the magnesium wheel halves, prepare the surface of the wheels for painting as follows.

5.5.12 Apply chromic acid etch solution (Dow #1) by brushing, dipping, spraying, or with a pad. The solution will complete its action in two minutes. Wash off with cold water.

Dow No. 1 Chromic Acid Etch Solution Formula

Chromic Acid: 1 lb.
Nitric Acid (1.4 sp. Gr.): 0.9 pint (426 CC): 1.3 lb.
Water: To make one gallon of solution.

5.5.13 Follow the chromic acid etch treatment with Dow No. 19 surface treatment using the same application procedure as above.

Dow No. 19 Solution Formula

Chromic Acid: 1-1/3 oz.
Calcium Sulfate: 1 oz.
Water: To make one gallon of solution

NOTE: Solutions described in 5.5.12 and 5.5.13 can be safely stored in containers made of glass, stainless steel, aluminum, vinyl or polyethurane rubber-lined tanks.

5.5.14 Paint prepared surfaces with two coats zinc chromate primer, specification MIL-P-8585 and one coat aluminum lacquer, specification MIL-L-7178.

NOTE: Use only one coat zinc chromate primer and no finish coat on packing groove and mating surfaces of the wheel halves.

5.5.15 Replace all parts damaged beyond repair.

5.5.16 Replace packings (13) at each overhaul.

5.5.17 To replace bearing cups (19, 26), proceed as follows:

5.5.18 Heat wheel halves (20, 27) to 149°C (300°F) maximum and cool cups to -18°C (0°F).

5.5.19 Support wheel hub and paint the ID of the hub with zinc chromate primer. Then press cup into wheel half.

NOTE: The wet zinc chromate primer lubricates the parts to be pressed together and acts as a protective against galvanic corrosion between the parts.

5.5.20 If corrosion is beyond limits or if cups have loosened, rework seal and bearing bore areas in accordance with Figures 5-3 and 5-4 or 5-5, plus the following.

5.5.20.1 Machine seal or bearing bore as shown in Figure 5-3, 5-4, or 5-5.

5.5.20.2 Spray with one coat zinc chromate primer in accordance with MIL-P-8585.

5.5.20.3 Heat the wheel to 135 to 149°C (275 to 300°F), cool the bushing to -18°C (0°F), and rapidly install the bushing in the wheel, using a hand arbor press. If bushing starts to bind during installation, remove it immediately.

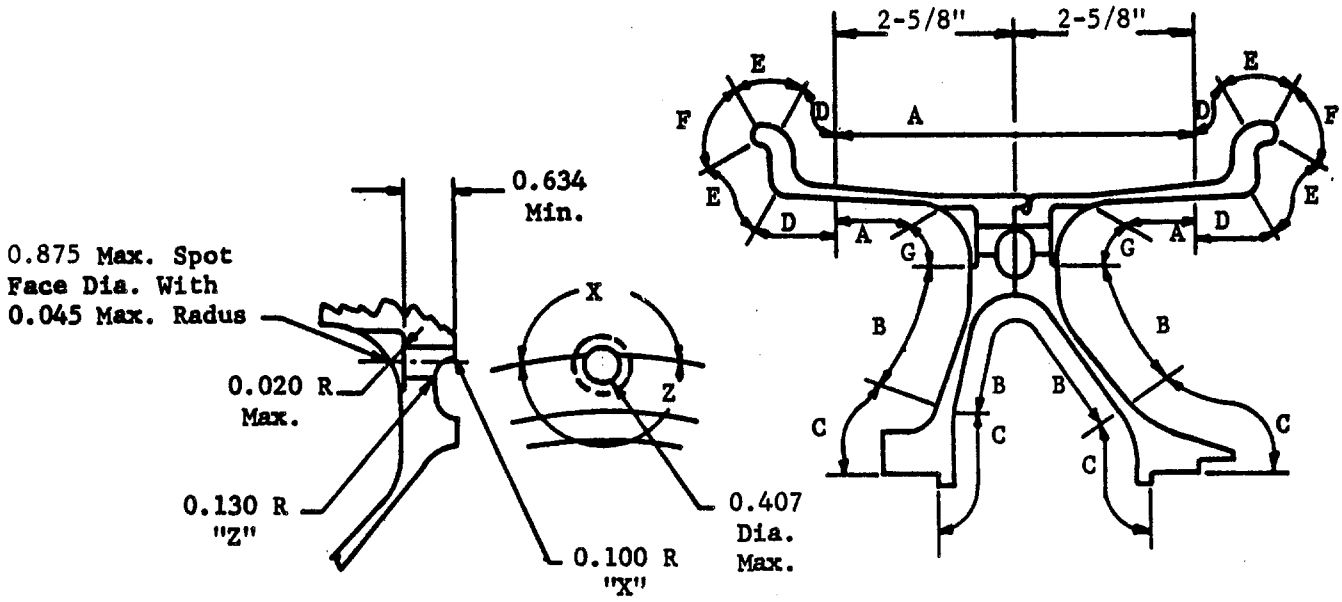
NOTE: This procedure must be done rapidly as the bushing absorbs heat quickly and may expand in the bore of the wheel before being properly seated.

5.5.20.4 Rough- and finish-bore the bushing in the wheel as shown in Figure 5-3 or 5-4 and 5-5.

NOTE: After final machining the seal bushing, hardcoat the ID with Alumilite 226 in accordance with AMS 2468 or MIL-A-8625, Type III.

5.5.20.5 Spray seal and bearing bushings with one coat of zinc chromate primer MIL-P-8585, before installing bearing cup.

5.5.20.6 See that 0.002 inch feeler gage will not go between the end of the bushing and the bottom face of the bearing bore.

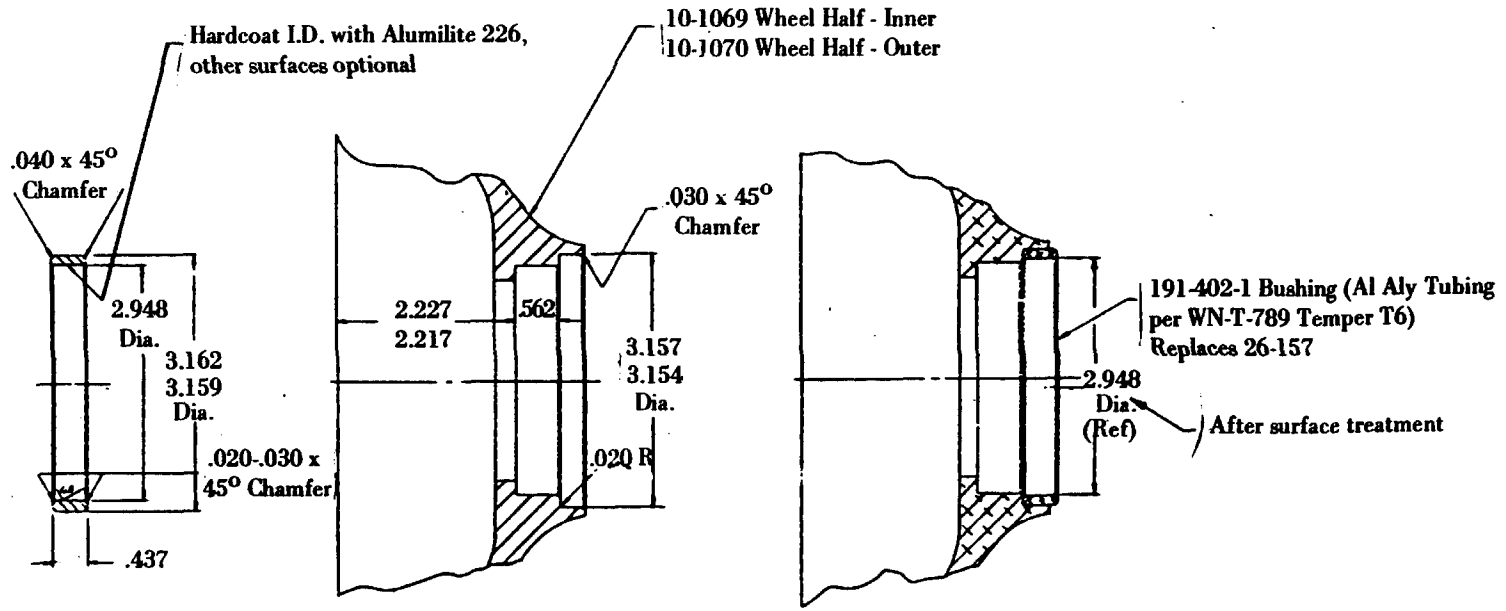


5.5.21 Replace packing at each overhaul.

5.6 Lubrication.

5.6.1 Bearings. Pack with Aeroshell #7 grease, specification MIL-G-23827A, into bearing cones and smear grease on ends of rollers. Do not overlubricate. Spread a thin coat of grease on the surface of the bearing cups.

CAUTION: IF GREASE IS CHANGED, TAKE CAREFUL NOTE OF MANUFACTURER'S REQUIREMENTS CONCERNING COMPATIBILITY WITH RECOMMENDED GREASE AND CLEANING REQUIRED BEFORE APPLICATION.



5.6.2 Bolts, Nuts, and Washers. Lubricate threads of bolts and nuts and face of the washers with thread compound, specification MIL-T-5544.

xx = ± 0.030

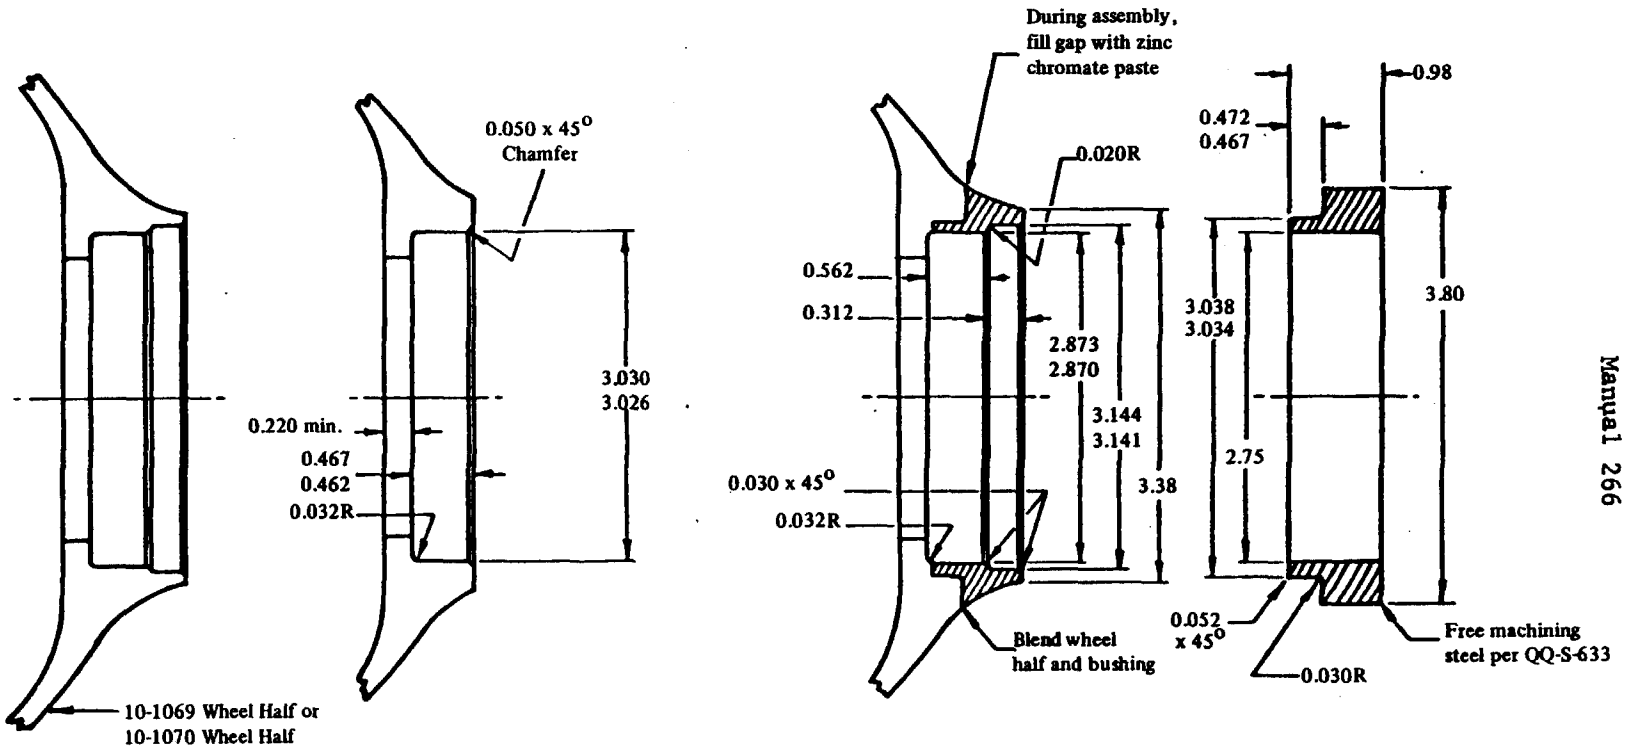

Figure 5-5. Alternate Bearing Bore Rework

5.7 Reassembly.

5.7.1 Reassemble in reverse sequence of the index numbers of Figure 6-1, noting the following.

5.7.2 Clean and lubricate bearings as instructed in Paragraphs 5.3.3 and 5.6.1.

5.7.3 If bearing cups (19, 26) have been removed, install cups as instructed in Paragraphs 5.5.18 and 5.5.19.

5.7.4 If balance weights (14, 22) have been removed, reinstall in their original location.

5.7.5 Apply a generous coat of thread compound, specification MIL-T-5544, to threads of bolts (11), faces of washers (10, 12), and bearing face of nuts (9). Tighten to 192 lb inch torque, four nuts, diametrically opposite and at 90°. Stagger-tighten remaining nuts to 192 lb inch torque. Then, using the same procedure, retighten all nuts to 240 to 260 lb inch torque.

NOTE: Do not use impact wrench when applying final torque. Use hand torque wrench only.

5.8 Testing.

5.8.1 After tire growth has stabilized, the wheel shall be required to hold the normal inflation pressure for 24 hours with not more than four per cent loss in pressure.

CAUTION: DO NOT INFLATE TIRE IN EXCESS OF 60 PSI.

1. Description and Operation

A. The hydraulic fuse is a device designed for installation in a hydraulic line to prevent excessive loss of hydraulic fluid in the event of a failure in the system downstream of the fuse. The hydraulic fuse is completely non-functional in normal operation, yet reacts automatically to shut off all flow when flow has reached the predetermined amount. The hydraulic fuse covered in this manual is of the self-resetting type. Leading particulars of the hydraulic fuse are presented in Table 1.

Waterman Part Number	G831-8-10A
Operating Pressure	3,000 psi
Proof Pressure	4,500 psi
Operating Fluid	Skydrol 500A
Operating Temperature	
Minimum	−65°F
Maximum	+160°F
Nominal Volumetric Capacity	10 cu. in.
Test Volumetric Capacity	
at Flow Rate of 2.4 gallons per minute	10.5 to 12.5 cu. in.
at Flow Rate of 1.2 gallons per minute	10.5 to 12.5 cu. in.
at Flow Rate of 0.25 gallons per minute	10.5 to 20.0 cu. in.
at Flow Rate of 0.5 gallons per minute	10.5 to 20.0 cu. in.
Connections	accommodating 1/2 in. tube
Dimensions	
Length	5-11/32 in.
Diameter	1-3/8 in.
Width Across Flats	1-1/8 in.
Weight (not to exceed)	9-1/2 oz.

Leading Particulars
Table 1

Principles of Hydraulic Fuse Operation
Figure 1

B. Fluid entering the hydraulic fuse is divided into two flow paths by the control head (1, figure 1). The main flow follows the path noted by the heavy arrows. The main flow entering chamber (2) forces piston (3) to the right, compressing piston spring (5). With piston (3) displaced, hydraulic fluid flows through ports in sleeve (4) to the downstream connection. Note that when piston (3) moves to the right, it is no longer in contact with main piston (6). Since the inlet holes into the inside of sleeve (4) are smaller than the outlet holes, a pressure drop occurs in chamber (2).

This pressure drop is proportional to the flow rate. The metered flow through orifice (7) forces main piston (6) to the right. The rate at which main piston (6) moves toward the right is proportional to the pressure in chamber (2), which (as stated above) is proportional to the flow rate through the fuse. During a normal flow cycle, main piston (6) does not travel its entire stroke, since the rated capacity of the fuse in cubic inches of fluid is larger than the capacity of the system or subsystem connected to the downstream side. In the event of a failure in the downstream system or subsystem, main piston (6) travels its entire stroke, contacting shoulder (8). This prevents further downstream flow. Once in this condition, the line will remain fused until upstream pressure is reduced to approximately 5 psi. Reduction of the upstream pressure allows piston spring (5) to return piston (3) and main piston (6) to their original positions. The fuse is thus prepared for another cycle.

C. In normal operation, the check (9) will permit a small quantity of fluid to flow downstream to preclude the possibility of the fuse closing at extremely low flow rates. During any reverse flow, the check will upset to permit free reverse flow. Under these conditions, the orifice (7) also acts as a check valve since it is displaced from its seat to permit free exit of fluid which has moved main piston (6) to the right.

2. Disassembly

A. With flats of body (60, Figure 3) held securely in a protected vise, remove lockwire (290), unscrew cap (10) and remove packing (20) from groove in cap (10).

B. Invert body (60) and tap outlet end with a wooden or fiber mallet until sleeve (280) can be grasped with the fingers. Gently withdraw sleeve with its associated internal parts and remove spring washer (70), spacer (80), and spring (90) from body (60) and sleeve (280).

NOTE: Do not remove nameplate (50) from body (60).

C. Remove piston (100) from sleeve (280); then remove retaining rings (110 and 150), plate (120), spring (130), check (140), and check stop (160) from piston (100).

D. Gently remove control sub-subassembly (110, 200 through 250) from end of sleeve (280); then, remove retaining ring (110), orifice seat (200), preformed packing (210), orifice (220), orifice retainer (230), and washer (240) from head (250). Remove preformed packing (260) from groove in head (250).

E. Carefully remove piston (270) from bore in sleeve (280) and remove preformed packing (170) from groove in sleeve (280).

3. Cleaning

A. Clean all metallic parts by immersing in solvent (Federal Specification P-S-661, or other similar approved solvent). Soaking of parts for several hours is recommended to remove accumulation of dirt and gum from ports and orifices. Use a soft brush or lint-free cloth to wash parts. Clean drilled ports with a fine bottle brush.

B. Dry parts with compressed air under moderate pressure. Direct compressed air into holes, ports, and orifices.

CAUTION: DO NOT INSERT METAL RODS OR WIRES INTO PORTS OR OTHER OPENINGS. THIS PROCEDURE COULD RESULT IN ENLARGEMENT OF THE PORTS OR OPENINGS, CAUSING UNSATISFACTORY OPERATION OR A CHANGE IN CALIBRATION.

4. Inspection/Check

A. Inspect all metallic parts for burrs, scratches, scores, nicks, dents, distortion, blemishes, or other surface defects affecting serviceability.

B. Check that check (140) slides freely in corresponding bore of piston (100) and that piston (100) slides freely in corresponding bore of sleeve (280).

C. Check that piston (270) slides freely in corresponding bore of sleeve (280).

NOTE: Since normal wear is insignificant, there are no wear limits established for parts. Surface defects caused by dirt or other foreign matter will be the most common type of defect. The ultimate determination of serviceability must be made on the basis of test results (paragraph 7).

5. Repair

A. No remachining, resurfacing, or other repair of parts is recommended. Parts found to be defective during disassembly and inspection must be replaced with serviceable parts.

B. Replace all preformed packings with new parts at each assembly regardless of the apparent serviceability of parts removed.

NOTE: Many parts are matched and are not therefore individually replaceable. These parts are designated by an asterisk (*) following the description in the parts list. Replacement must be made by replacing the entire assembly or subassembly in which the defective part is used.

6. Assembly

A. Install preformed packing (170, Figure 3) in groove on sleeve (280). Carefully insert piston (270) into corresponding bore of sleeve (28).

B. Place washer (240), orifice retainer (230), orifice (220) with counter-sunk side toward orifice seat (200), preformed packing (210), and orifice seat (200) into recess in head (250), and secure with retaining ring (110).

C. Place preformed packing (260) in groove on head (250) and install head in end of sleeve (280).

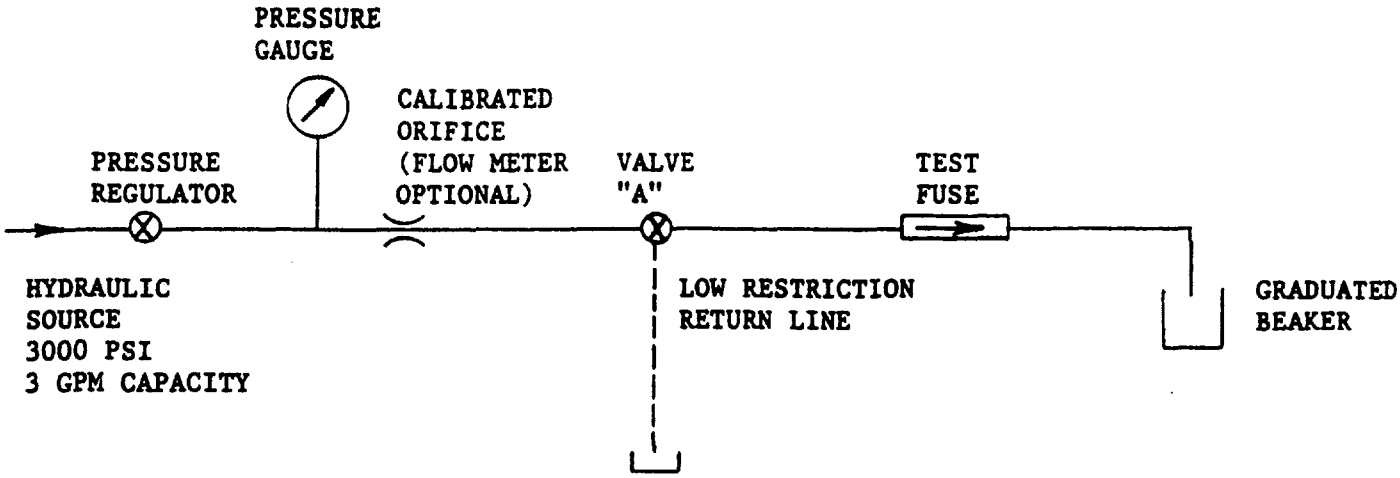
D. Place check stop (160) in piston (100) and secure with retaining ring (150).

E. Place check (140) in piston (100), followed by spring (130) and plate (120). Depress plate (120) to compress spring (130) and install retaining ring (110) in internal groove in piston (100).

F. Place body (60) open end up in a protected vise. Place spring washer (70), spacer (80), and spring (90) in body (60). Then insert piston (100) into sleeve (280) and insert sleeve (280) into body (60) so that spring (90) contacts retaining ring (150).

G. Install preformed packing (20) in groove of cap (10) and screw cap (10) into end of body (60). Tighten cap (10) securely.

H. Lockwire (290), cap (10) to body (60).



7. Testing

A. Install the assembled hydraulic fuse in a test setup as shown in figure 2, using fluid specified in Table 1. Assure that the system is filled with clean fluid. Purge all air from lines and valves by permitting rated flow to pass through the fuse, then reversing the flow. Repeat this cycle at least five times to insure complete elimination of air from the system.

B. Apply a fluid pressure of 4500 psig to the hydraulic fuse and maintain this pressure for five minutes. There must be no evidence of external leakage, and no failure, distortion, permanent set, or other damage due to the applied pressure. Reduce system pressure to zero.

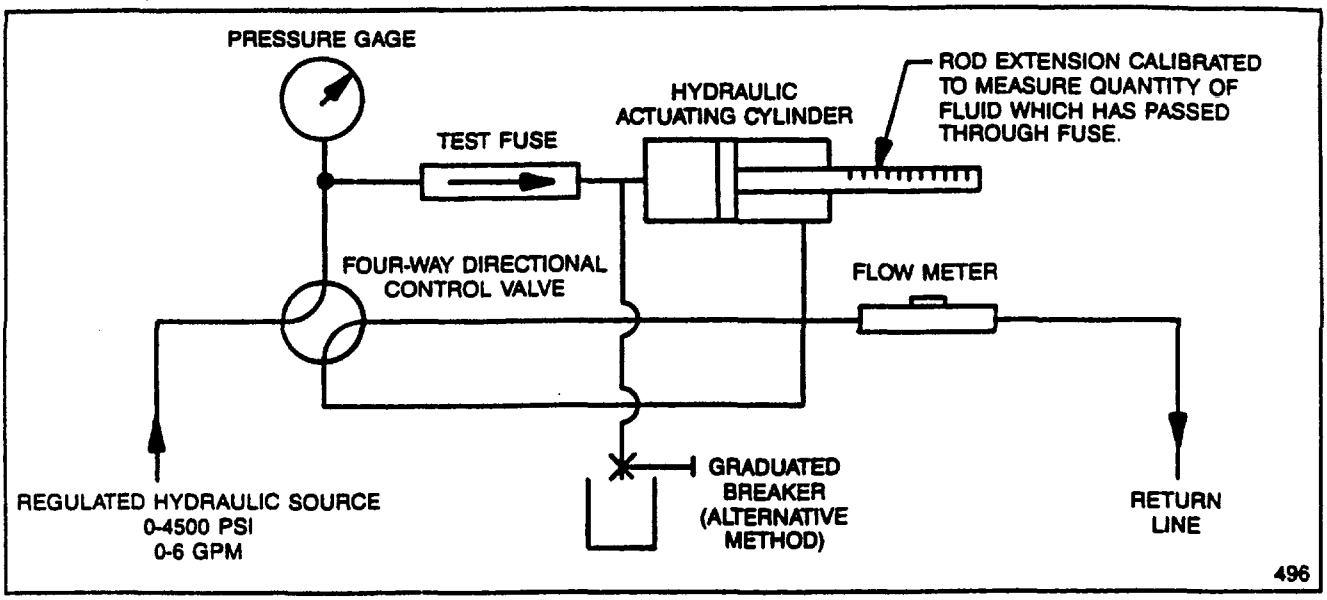
TEMPORARY REVISION NO. 32-1

INSERT FACING PAGE 6, 32-42-00

Setup for Testing Hydraulic Fuse
Figure 2

To set flow:

1. Install orifice in test setup as shown.
2. Install return line in place of test fuse and graduated beaker.
3. Open valve "A" completely and apply required inlet pressure (see following paragraphs).



NOTE: If a 3 or 4 way valve is available, setup valve "A" to divert flow between test fuse and return line, otherwise, a ball valve is recommended.

To test fuse:

1. With proper flow established and test setup operating, close valve "A".
2. Replace return line with test fuse and graduated beaker.
3. Open valve "A" and measure volume of fluid required to close fuse.

C. Test volumetric capacity at flow rates of 1.2 and 2.4 gallons per minute using a calibrated orifice size of .0477 inches (suggested Lee part number JEHB1875425L) with inlet pressures of 750 and 2900 pounds per square inch respectively. At both flow rates, capacity must be within the range of 10.5 to 12.5 cubic inches (172 to 205 ml).

D. Test volumetric capacity at flow rates of .5 and .25 gallon per minute using a calibrated orifice size of .0218 inches (suggested Lee part number JETB1875190D) with inlet pressures of 2400 and 600 pound per square inch respectively. At both flow rates, capacity must be within the range of 10.5 to 20.0 cubic inches (172 to 328 ml).

Setup for Testing Hydraulic Fuse
Figure 2

C. Test volumetric capacity at a flow rate of 1.2 gallons per minute ±10 percent and at 2.4 gallons per minute ±10 percent. At both flow rates, capacity must be within the range of 10.5 to 12.5 cubic inches.

D. Test volumetric capacity at flow rates of 0.5 gallon per minute ±10 percent and 0.25 gallon per minute ±10 percent. At both flow rates, capacity must be within the range of 10.5 to 20.0 cubic inches.

E. With fuse closed, adjust upstream pressure to 40 psig ±10 percent. Disconnect line from downstream side of fuse and maintain upstream pressure for five minutes. During last three minutes of this interval, the leakage from the downstream port must not exceed 5 drops per minute.

F. Increase upstream pressure to 3000 psig ±10 percent. Maintain this pressure for five minutes. During last three minutes of this interval, leakage from downstream port must not exceed one drop per minute. Reduce pressure to zero.

NOTE: In steps E and F leakage will usually be much less than allowable maximum or much greater. High leakage is usually an indication of dirt or other foreign matter in the fuse. Disassemble, clean thoroughly, reassemble, and retest fuse.

G. Reconnect line to fuse downstream port. Apply upstream pressure and allow flow through fuse to continue until rated capacity is reached. Decrease upstream pressure to zero. Reapply upstream pressure after a slight delay and check that flow through fuse continues as evidence of resetting.

NOTE: Please see the ***TEMPORARY REVISION*** *that revises this page.*

TROUBLE	PROBABLE CAUSE	REMEDY
External leakage during pressure test.	Defective packing (20, figure 3) or improper installation of packing.	Remove cap (10) and packing (20).
	Crack or rupture in cap (10) or in body (60).	Replace cracked or ruptured part.
Volumetric capacity higher than specified maximum.	Obstruction of fluid flow through orifice (220).	Disassemble parts from head (250), clean parts and reassemble.
	Piston (270) does not slide freely in bore of sleeve (280).	Disassemble and determine cause of binding. Replace defective parts and reassemble.
	Piston (100) does not complete full stroke.	Remove piston (100) and check for binding between piston and bore of sleeve (280). Clean or replace binding parts and reassemble.
Volumetric capacity lower than specified minimum.	Improperly sized orifice (220).	Replace orifice (220).
	Leakage past packing (260) due to defective packing or improper installation.	Replace packing (260), being careful to install properly.
	Leakage past packing (210) due to defective packing or improper installation.	Replace packing (210), being careful to install properly.
Fuse fails to reset when upstream pressure is reduced.	Binding between check (140) and bore of piston (100).	Disassemble check (140) from piston (100), clean or replace defective parts and reassemble.

Trouble Shooting
Table 2

H. Disconnect hydraulic fuse from test setup.

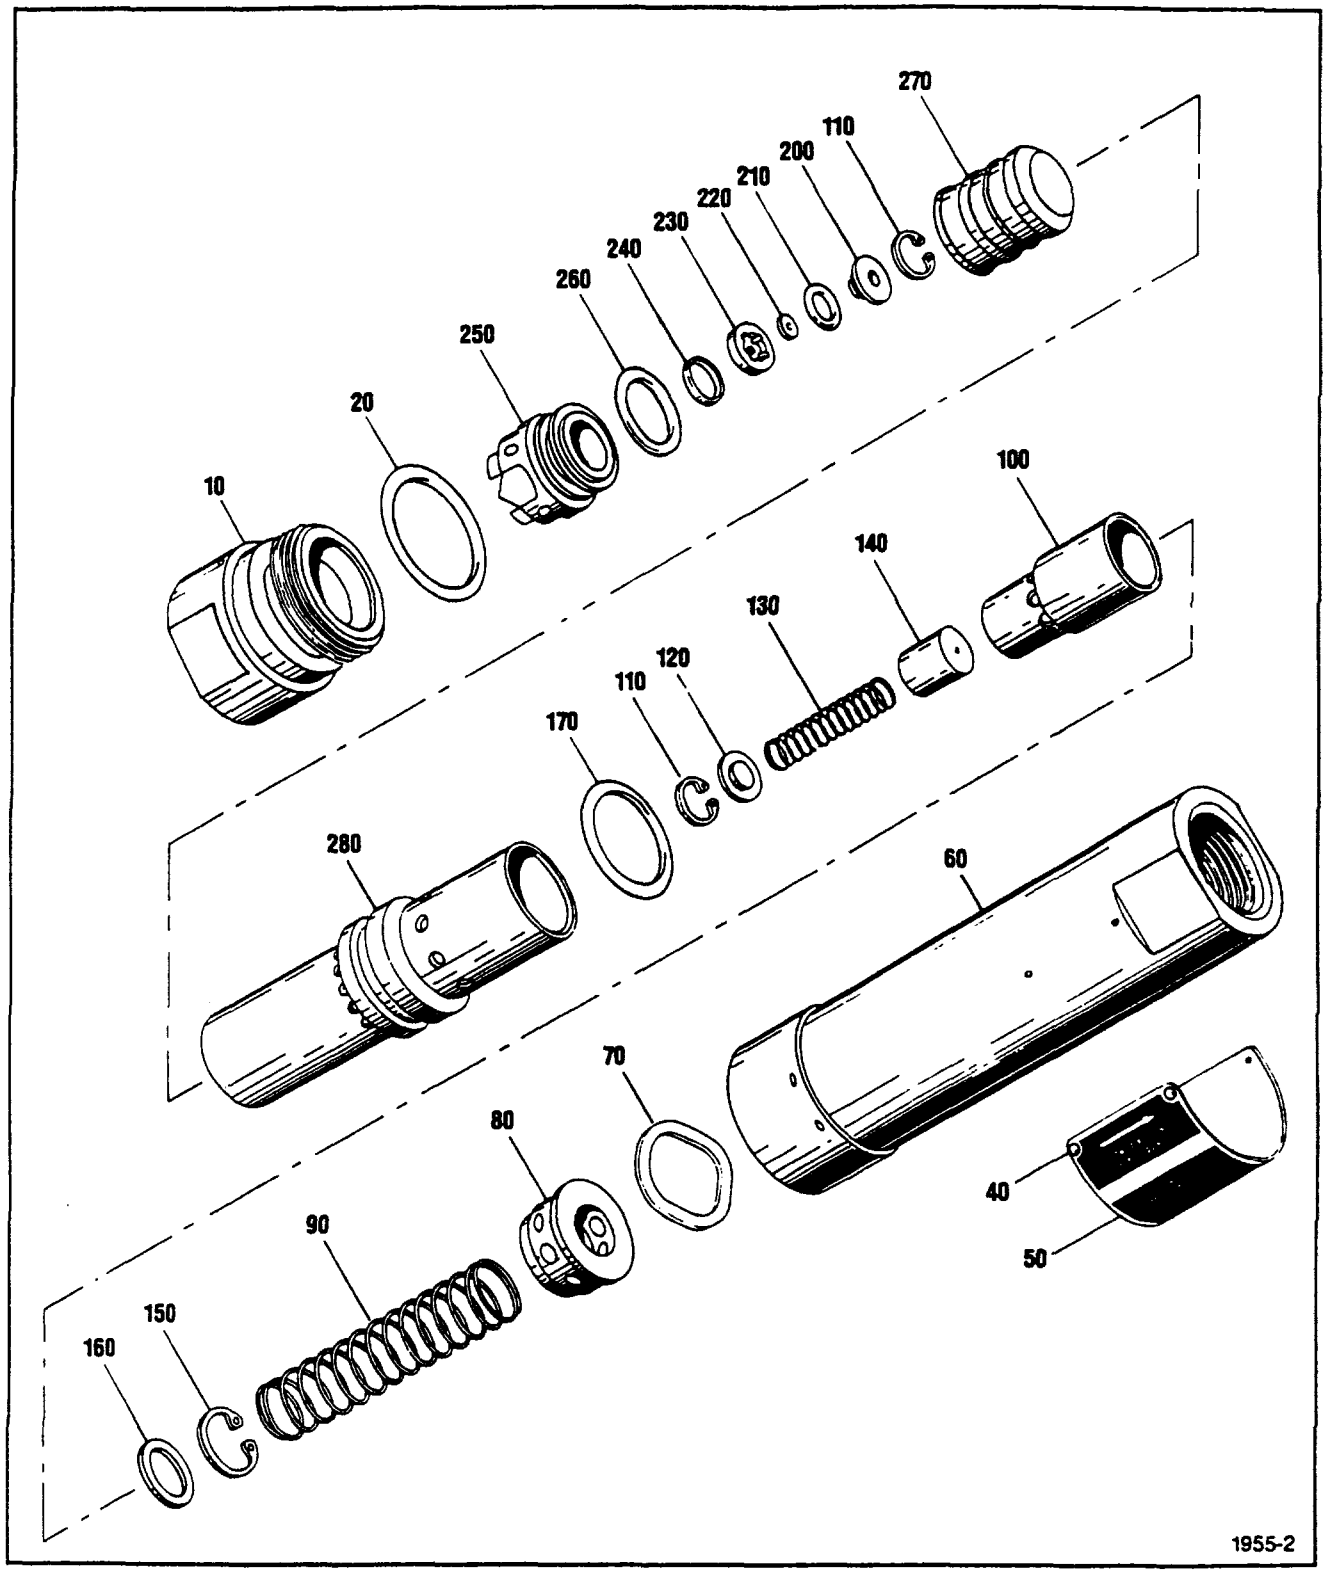
8. Troubleshooting (See Table 2)

9. Storage Instructions

A. Partially fill hydraulic fuse with Skydrol 500A fluid after testing has been completed.

B. Install preformed packing (310, figure 3) and shipping plug (300) in each end of fuse.

10. Special Tools, Fixtures and Equipment



No special tools, fixtures, or test equipment are required to overhaul the hydraulic fuse as described in this manual.

11. Illustrated Parts List

A. Following is an illustrated parts list for the hydraulic fuse covered in this publication. Parts are listed in one possible order of disassembly.

B. The following code numbers are included in the parts list to identify manufacturers or vendors:

V82271 - Waterman Hydraulics, 6565 W. Howard, Niles, Illinois.

SERVICE BULLETIN

HYDRAULIC FUSE CONVERSION

1 --- PLANNING INFORMATION

A --- EFFECTIVITY

This service bulletin is applicable to the following hydraulic fuse.

Waterman Part Number	BCDD Part Number	Aircraft Application
G831-8-10	7SC0110	Dash 7, Dash 8

Serial numbers affected. All.

B --- REASON

(1) To eliminate corrosion problems with piston assembly.
(2) Background. Fuses were reported to have been corroding and not shutting off after downstream failure. Piston was corroded and sticking.
(3) Action. To eliminate corrosion, piston and plug material were changed from magnesium to aluminum.

C --- DESCRIPTION

This service bulletin provides information required to convert hydraulic fuses from part number G831-8-10 to part number G831-8-10 A.

D --- APPROVAL

BCDD approval has been granted to G831-8-10 A.

E --- MANPOWER

No additional manpower is required to accomplish this conversion over that required for overhaul or repair.

F --- MATERIAL COST AND AVAILABILITY

New parts may be procured from Parker Hannifin Waterman Operation within 12 weeks after issue of service bulletin. Valves supplied on aircraft sold to operators by BCDD within the past two (2) years will be repaired under warranty at no cost to the operator. Valves supplied on aircraft sold prior to this period, conversion kits to complete the modification may be procured at a cost of $57.08, or the unit may be returned to the factory for conversion at a cost of $106.26. These costs are valid for an 18 month period after issuance of service bulletin.

G --- TOOLING

No special tooling required.

Parker Hannifin Corporation
Hydraulic Valve Division
6565 West Howard Street
Chicago, Illinois 60648-3387 USA
Phone (708) 647-0450
FAX (708) 647-1854

SERVICE BULLETIN

H --- WEIGHT AND BALANCE

Not applicable.

I --- OTHER PUBLICATIONS AFFECTED

None.

2 --- CONVERSION INSTRUCTIONS

A --- Remove safety wire and end cap.

B --- Discard o-ring on cap.

C --- Remove valve sub-assembly. Use care not to drop or damage the spring piston, see Fig. 1.

D --- Place spring piston into new valve S/A in relation shown in Fig. 1.

E --- Ensure wave washer is seated in counterbore in bottom of the body, below the spacer.

F --- Place spring in body, make sure spring is seated in the spacer, see Fig. 1.

G --- Replace sleeve seal and lubricate with BM3-11G. Place the valve S/A with the spring piston into the body with the spring going inside the spring piston. Press firmly on the valve S/A to insure valve S/A is seated properly.

H --- Replace o-ring on cap, lubricate with BM3-11G and screw cap in body, torque to 250 in-lbs.

I --- Function test.

J --- Safety wire cap to body.

K --- Metal stamp an "A" after the 10 in G831-8-10 on the nameplate to signify updated model.

GRIMES MANUFACTURING COMPANY
OVERHAUL MANUAL WITH
ILLUSTRATED PARTS LIST
PART NO. G8400A

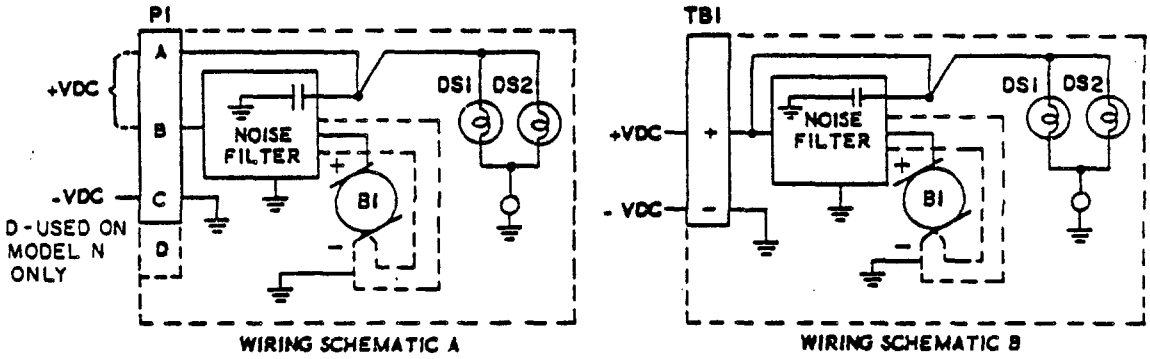
DESCRIPTION AND OPERATION

1. Description

A. The G8400A series Aircraft Navigational Rotating Warning Lights (Ref. Figure 1), are designed for installation in either the top or bottom of an aircraft fuselage, to provide adequate warning to approaching aircraft. The high intensity flashes of light are very effective, even under adverse weather conditions, for ascertaining aircraft location.

B. To simplify identification of the light assembly models described in this manual, an alphabetical designation has been assigned to each. The designators used as as follows:



MODEL	CODE	MODEL	CODE	MODEL	CODE
G8400A12	A	G8400A12-12	K	G8400A36-24	U
G8400A24	B	G8400A13-24	L	G8400A37-24	V
G8400A3-12	C	G8400A14-24	M	G8400A39-24	W
G8400A3-24	D	G8400A15-24	N	G8400A41-24	X
G8400A8-12	E	G8400A21-24	P	G8400A43-24	Y
G8400A8-24	F	G8400A22-24	Q	G8400A45-12	Z
G8400A9-24	G	G8400A23-24	R	G8400A47-24	AA
G8400A10-24	H	G8400A24-24	S	G8400A49-24	AB
G8400A11-24	J	G8400A31-24	T		

Aircraft Navigational Rotating Warning Light
Figure 1

2. Operation

Two high intensity lamps are installed diametrically opposed on a turntable which revolves at a controlled speed, producing intermittent visible light. A red glass lens protects the mechanism and produces the approxed warning color. Electrical power is supplied from the aircraft electrical system (Ref. Figure 2). Wiring Schematic B applies to models C, D and R. Wiring Schematic A applies to all other models.

Electrical Schematic Diagram
Figure 2

3. Leading Particulars

Refer to Figure 3 for leading particulars.

Operating Voltages	
Models A,C,E,K,Z	13 VDC
Models B,D,F-J,L-Y,AA,AB,G,H,M,N,P,Q,R,S,T,U,V,W,X	28 VDC
Flashes per minute	85 ±5
Radio noise filter	In accordance with ATA specifications
Dimensions	
Mounting flange diameter:	
Models C,D,E,F,G,H,J,K,N,T,U,Y,Z,AB	5.00 ±0.015
Models Q,R,S,W,X,AA	5.25 ±0.015
Model V	4.75 ±0.015
Height:	
With bottom connector	4-15/16 in.
Without connector	4-3/8 in.
Weight	2 pounds (max).

Leading Particulars
Figure 3

DISASSEMBLY

1. Disassemble Light Assembly

   A. Remove lens retaining band assembly (Ref. 22, IPL Fig. 1).

   B. Pull lens and plug assembly (consisting of items 24 through 30) off the light assembly. Do not disassemble the lens and plug assembly unless drain plug replacement is required. If required, disassemble the lens and plug assemblies as follows:

      NOTE: The lens installed on model Q is not equipped with a drain plug.

      (1) Remove screw (25) and drain hole plug (24).

      (2) Separate lock washer (26), washers (27 and 28) and drain hole plug gasket (29) from lens (30).

   C. Remove incandescent lamps (32).

   D. Remove screws (36) and motor cover (34). Do not disassemble the motor cover unless repair is required. If necessary disassemble the motor cover as follows:

      (1) Remove screws (42), lock washers (43) and cover plate (41). Remove screws (50B), lock washers (50A) and cover plate (50). Remove grommet (39).

         NOTE: Light assemblies designated with the suffix "X" utilize an alternate design incorporating rivets (38) instead of screws to attach cover plate (37).

   E. Remove screws (46), lock washers (48) and connector assembly (44).

   F. Do not remove terminals (51) unless replacement is required.

   G. Remove screws (58) and pry mounting flange (52) from mechanism assembly (69) except for models A, B, L, M and P.

   H. Remove screws (66), lock washers (67), nuts (68) and baffle on models G, H, J, L and M only.

2. Disassemble Mechanism Assembly

   A. Remove lock nut (Ref. 9, IPL Fig. 2) and washer (10). Pull lamp gear assembly (8) off the base assembly post.

   B. Disassemble Lamp Gear Assembly (8) as follows:

      (1) Remove screws (12), lock washers (13), nuts (15), lock washers (14), insulators (16 and 17) and contact assembly (11).

(2) Remove screws (20), nuts (21), lock washers (22), flat washers (23), bushings (24), insulators (25) and lampholder and ferrule assemblies (18 and 19).

(3) Unsolder the brush lead and remove electrical brush (27) and brush spring (28).

(4) Do not remove rivets (31), plate (30) and bracket (29) from mounting bracket (26) unless part replacement is required.

(5) Remove roll pin (33), groove pin (34), bearings (37), spacers (35 and 36), hub (32) and gear (38).

C. Remove screw (40) and self-locking nut (41). Remove one screw and lock washer that secures the base of motor (45) to support bracket (39). Remove the support bracket.

D. Remove the remaining screw and lock washer and end plate from the base of motor (45). Remove screw (43), lock washer (44) and lug terminal (42) from inside of motor (45).

E. Remove screws (47), lock washers (48) and motor (45).

F. Remove setscrews (50) and worm (49) from motor shaft.

G. Remove screws (52), lock washers (53), nuts (54), radio noise filter (51) and noise filter spacer (55).

H. Remove screw (57), lock washers (58), nut (59) and terminal block (56) from models C, D and R.

I. Remove screws (60), lock washers (61) and nuts (62) from base (95).

J. Do not remove instruction plate (63) or identification plate (64) from base (95) unless replacement is required.

K. Disassemble Base Assembly as follows:

(1) Remove terminal (71), on models C, D and R only, contact (69) and insulator (70) from flange and shaft assembly (86).

(2) Remove setscrews (73) and worm wheel and hub assembly (72).

(3) Remove pinion shaft (83), bearings (84) and washer (85). Drill out rivets (82) and remove screw (76), lock washer (78), nut (80) and bearing retainer assembly (74).

(4) Drill out rivets (90) and remove support (89). Do not remove inserts (88) from support (89) unless replacement is required.

(5) Drill out rivets (87) and remove flange and shaft assembly (86).

(6) Remove drain tubes (91) and plate (92) from base (95).

(7) Do not remove clinch nuts (93) from base (95) unless replacement is required.

CLEANING

1. Clean electrical parts with a clean, lint-free cloth moistened with isopropyl alcohol, Federal Specification TT-I-735, or equivalent. Allow to air dry.

   WARNING: SOLVENT AND ACETONE FUMES ARE TOXIC. PROLONGED INHALATION OF THE FUMES MAY CAUSE ILLNESS.

2. Clean metal parts with dry cleaning solvent, Federal Specification P-D-680, or equivalent.

3. Clean lamps (Ref. 32, IPL Fig. 1) with acetone, Federal Specification O-A-51, or equivalent.

INSPECTION/CHECK

1. Inspect all gears for cracks, chips, broken teeth and excessive or uneven wear.

2. Observe condition of all electrical contact points, see that they are free of excess pitting or burning.

3. Check condition of all threaded parts for crossed or stripped threads.

4. Inspect the length and contact surface of electrical brush (Ref. 27, IPL Fig. 2). Replace if less than 0.437 inch or worn unevenly.

5. Inspect the radio noise filter (51) for damage to the case, shorts between circuits and shorts between circuits and case. If the case is damaged, replace the noise filter.

6. Check legibility of instruction plate (63) and identification plate (64).

7. Inspect lens (Ref. 30, IPL Fig. 1) for cracks, chips or discoloration.

8. Inspect insulator (Ref. 70, IPL Fig. 2) for evidence of deterioration.

9. The following preventive maintenance procedures shall be made every 1000 hours:

   A. Replace contact assembly (11).

   B. Replace bearings (37) on turntable.

   C. Replace bearings (84) on pinion shaft (83).

   D. Replace worm wheel and hub assembly (72).

   E. Replace contact (69) at top of flange and shaft assembly (86).

   F. Replace electrical brushes (27) and brush springs (28) if total brush length is less than 0.437 inch.

   G. Clean dust and dirt from the light assembly.

   H. Return motor (45) to factory for bearing and brush replacement.

   I. Polish the brush ring portion of flange and shaft assembly (86), or replace if badly pitted or burned.

   J. Inspect the light assembly for miscellaneous damage, such as broken gear teeth, defective wire leads, broken or distorted metal parts and deteriorated non-metallic parts. Replace defective parts.

K. Apply Dow Corning M77 molybdenum disulfide grease to turntable gear (38).

REPAIR

1. Replace all bearings removed in disassembly.

2. Replace defective contact assembly (Ref. 11, IPL Fig. 2) and contact (69). Adjust center contact pressure to 6-9 ounces using a Pelouze Scale, Model 2-T, or equivalent.

3. Replace all parts determined defective during INSPECTION/CHECK, TESTING and TROUBLE SHOOTING.

ASSEMBLY

1. Assemble Base Assembly

   A. If clinch nuts (Ref. 93, IPL Fig. 2) were removed, press replacement clinch nuts on base (95).

   B. Position plate (92) on base (95) and install drain tube (91).

   C. Install flange and shaft assembly (86) on base (95) and secure with rivets (87).

   D. If inserts (88) were removed, press replacement inserts on support (89). Install support (89) on base (95) and secure with rivets (90).

   E. Press bearing (84) into bearing retainer assembly (74). Position the bearing retainer assembly on base (95) and secure with rivets (82), screw (76), lock washer (78) and nut (80). Insert the drive end of pinion shaft (83) through the top bearing (84). Place washer (85) and worm wheel and hub assembly (72) on the other end of the pinion shaft and secure with setscrews (73). Ensure that the pinion shaft rotates freely with 0.004 to 0.005 inch end play.

   F. Install insulator (70) in flange and shaft assembly (86). Solder the electrical lead to contact (69) and press contact into insulator (70). Attach terminal (71), on models C, D and R, to the other end of the electrical lead.

2. Assemble Lamp Gear Assembly

   A. Press spacer (Ref. 35, IPL Fig. 2) into hub (32) until centered. When properly centered the spacer will be located 0.164 $\pm$0.005 inch from the lower end of the hub. (Ref. Figure 501).

   B. Drill a 0.0625 inch diameter hole 0.377 inch from the largest diameter end of the hub. Insert new groove pin (Ref. 34, IPL Fig. 2) flush with the outside surface of the hub.

   C. Position hub (32) into gear (38). Drill two holes 0.062 inch diameter through the gear and hub as shown in Figure 501.

   D. Install new roll pins (Ref. 33, IPL Fig. 2) into both holes.

   E. Install spacer (36) and press new bearings (37) into both ends of hub (32). The inside diameter of the spacer must be aligned with the inside diameter of both bearings.

Hub Installation
Figure 501

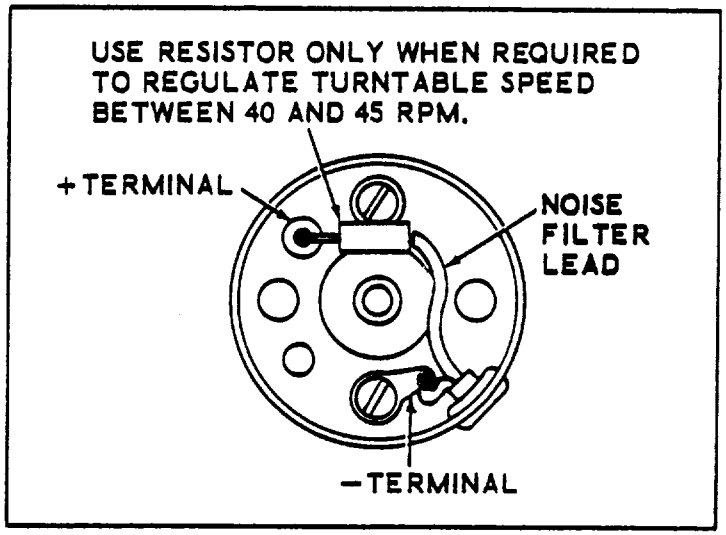
F. Position lampholder and ferrule assemblies (18 and 19) with the inclines toward the center of gear (38). Place two insulators (25) between the lampholders and gear. Loosely install one screw (20), flat washer (23), bushing (24), lock washer (22) and nut (21) into the end of each lampholder toward the contact arm side of the gear.

G. If bracket (29) and plate (30) were removed, secure replacement bracket and plate to mounting bracket (26) with rivets (31).

H. Install brush spring (28) and electrical brush (27) into brush holder assembly (consisting of items 26, 29, 30 and 31). Solder electrical brush lead to the brush holder assembly.

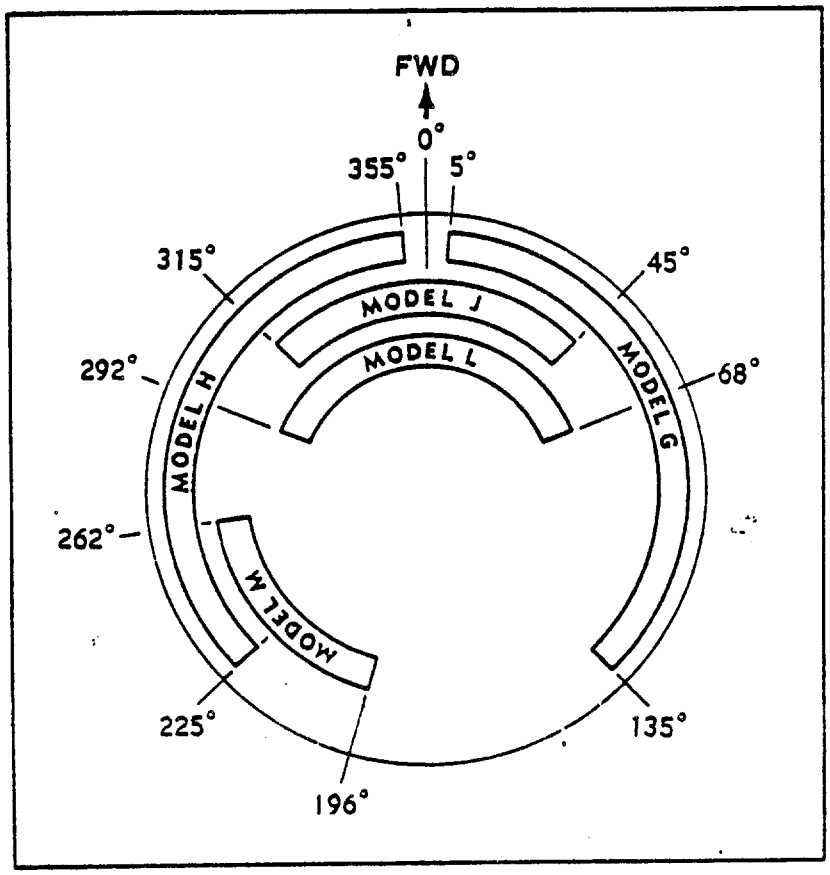
I. Position the holes in mounting bracket (26) over the lampholder mounting holes, with electrical brush (27), towards the outside diameter of gear (38). Install the remaining insulators (25), screws (20), flat washers (23), bushings (24), lock washers (22) and nuts (21). Tighten four screws (20).

J. Insert contact assembly (11) through the gear opening. Position insulator (16) on the top side of the gear, position insulator (17) between the gear and contact assembly. Secure the contact assembly to the gear with screws (12), lock washers (13 and 14) and nuts (15). Adjust the center contact pressure to 6-9 ounces using Pelouze Scale, Model 2-T, or equivalent.



3. Assemble Mechanism Assembly

A. Attach terminal block (Ref. 56, IPL Fig. 2) to base (95) with screw (57), lock washers (58) and nut (59), models C, D and R only. Refer to Figure 2 for wiring instructions.



B. Position noise filter spacer (Ref. 55, IPL Fig. 2) against the bottom of base (95) with the square opening in the spacer toward the center of the base. Ensure that the spacer fits flush against the base. Attach radio noise filter (51) and the spacer to the base with screws (52), lock washers (53) and nuts (54). Place the terminal on electrical lead from connector pin c between one lock washer and the radio noise filter.

NOTE: Light models C, D and R do not have connector assemblies.

C. Remove the end plate from the base of motor (45). Refer to Figure 502 and connect lug terminal (Ref. 42, IPL Fig. 2) to the motor negative terminal with screw (43) and lock washer (44). Solder radio noise filter lead to the motor positive terminal.

Motor Wiring Diagram
Figure 502

Light Baffle Installation
Figure 503

D. Install the motor end plate and insulator with one screw and lock washer opposite the grommet. Attach support bracket (39) to motor (45) with the remaining screw and lock washer.

E. Insert the motor shaft through the support (89) and attach motor (45) with screws (47) and lock washers (48).

F. Attach support bracket (39) to base (95) with screw (40) and self-locking nut (41).

G. Place two washers (10) onto flange and shaft assembly (86). Slide gear assembly (consisting of items 11 through 38) onto the shaft. Place one washer (10) onto the gear assembly and secure the gear assembly with lock nut (9).

H. Slide worm (49) onto the motor shaft. Ensure that the worm is properly engaged with worm wheel and hub assembly (72). Tighten two setscrews (50).

I. Connect the wiring as shown in Figure 2 as applicable.

J. Install screws (Ref. 60, IPL Fig. 2), lock washers (61) and nuts (62) on base (95).

K. If instruction plate (63) and identification plate (64) were removed, affix new instruction plate and identification plate on base (95).

4. Assemble Light Assembly

A. Install baffle (Ref. 61, IPL Fig. 1) in the position as applicable and as shown in Figure 503. Attach with screws (Ref. 66, IPL Fig. 1), lock washers (67) and nuts (68), applies to models G, H, J, L and M only.

B. Slide mounting flange (52) onto mechanism assembly (69) and attach with screws (58).

C. Apply sealant EC801, manufactured by Minnesota Mining and Manufacturing Company, St. Paul, Minnesota, onto the outer surface of the base near the flange (models S, W, Y only).

NOTE: The flange is installed with the mounting ring in the downward position on models G, H, X. Models A, B, L, M and P are supplied without a flange.

D. Attach cover plate (37) to motor cover (40) with rivets (38), models C, D and R only. Install grommet (39).

E. Attach connector assembly (44) to motor cover (34) with screws (46) and lock washers (48). Refer to Figure 504 for connector position.

NOTE: Where connector location is indicated as either bottom or side, the light is normally supplied with connector in the bottom position. A suffix "S" is added to the light part number if these light assemblies are supplied with the connector in a side position.

MODEL	CONNECTOR POSITION
A	Bottom or Side
B	Bottom or Side

AB	Bottom

Connector Position
Figure 504

F. Install cover plate (Ref. 41 or 50, IPL Fig. 1) to the remaining connector hole, with screws (42 or 50B) and lock washers (43 or 50A) as applicable.

G. If terminals (51) were removed during disassembly, crimp replacement terminals on Model R.

H. Install motor cover (34) with screws (36).

I. Cement lens gasket (31) on the mechanism assembly flange using EC-847 adhesive manufactured by Minnesota Mining and Manufacturing Company, St. Paul, Minn.

J. Install incandescent lamps (32).

K. If the drain hole plug (24) has been removed from lens (30), install as follows:

(1) Place drain hole plug gasket (29) onto drain hole plug (24). Insert the drain hole plug through the outer side of lens (30).

(2) Place washer (28) onto the drain hole plug shank. Place washer (27), bossed side away from lens (30) onto washer (28).

(3) Secure the parts with screw (25) and lock washer (26).

L. Position lens and plug assembly (consisting of items 24 through 30) on mechanism assembly (69) and secure with lens retaining band assembly (22).

TESTING

1. Test the rotating mechanism prior to installation into the base assembly.

2. With the lamps removed, connect the rotating mechanism as shown in Fig. 501 and observe the following:

   A. The gears shall engage and operate with no excessive noise.

   B. The lamp gear shall rotate at a rate of 45 ±5 RPM. A wire wound resistor, 18 ohm, 1-1/2 watt, can be added to the motor lead to control motor speed (Ref. Figure 502).

3. Install the lamps and operate the mechanism. The lamps shall illuminate with no evidence of dimming or flickering.

4. Install the mechanism into the base assembly. Test the light unit as described in paragraph 2.

TROUBLE SHOOTING

Refer to Figure 801 for trouble shooting procedures.

TROUBLE	CAUSE	ISOLATION PROCEDURE	REMEDY
Lamps (Ref. 32, IPL Fig. 1) fail to illuminate	No power	Check line fuses or circuit breaker. If tripped, check wiring in light and between light and fuse. Also check for defective center contact insulator (Ref. 70, IPL Fig. 2) causing shorted center contact.	Replace defective wiring or defective center contact insulator. Replace blown fuse or reset tripped circuit breaker.
	Defective lamps	Install lamps known to be operational.	Replace defective lamps.
	Worn electrical brushes (Ref. 27, IPL Fig. 2)	Remove the lens and plug assembly. Electrical brush must be visible through the inspection hole located in the side of the brushholder.	Replace worn brush.
	Defective radio noise filter (51)	Install a by-pass circuit around the noise filter.	Replace noise filter.
	Defective electrical leads	Install a by-pass circuit to check each lead.	Replace defective lead.
	Burned center contact (69)	By-pass both contacts with the motor (45) disconnected.	Replace contact.
Turntable does not rotate	Gear train inoperative	Check all gears for worn or broken teeth.	Replace defective gear.
		Gears loose on shaft.	Tighten setscrews.
	Motor worm misadjusted	Check for motor worm being too tight with worm wheel.	Loosen motor attaching screws and adjust for proper mesh of worm, then retighten screws.

Trouble Shooting
Figure 801 (Sheet 1 of 2)

TROUBLE	CAUSE	ISOLATION PROCEDURE	REMEDY
Turntable does not rotate (cont)	Motor (Ref. 45, IPL Fig. 2 does not operate	Bench check motor with external power source.	Replace defective motor.
	Defective radio noise filter (51)	Install a by-pass circuit around the radio noise filter to the motor.	Replace defective radio noise filter.

Trouble Shooting
Figure 801 (Sheet 2 of 2)

STORAGE INSTRUCTIONS

1. Wrap the Aircraft Navigational Rotating Warning Light with cushioning material, Military Specification MIL-C-81013.

2. Enclose the assembly and desiccant, Military Specification MIL-D-3464, in heat sealable film, Military Specification MIL-F-22191, and seal the film using a sealing iron, Military Specification MIL-S-43336.

3. Store the assembly in an area with a temperature range of 65°F to 120°F.

MAINTENANCE DOCUMENT WITH
ILLUSTRATED PARTS LIST
PART NO. 70-0075

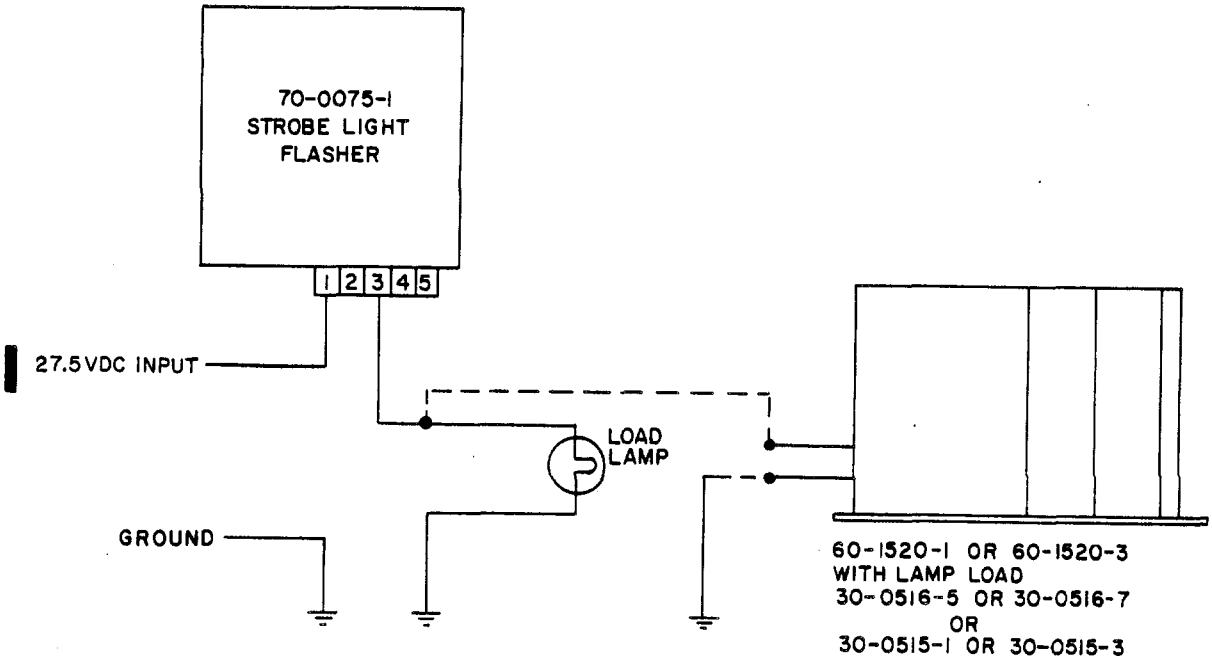
DESCRIPTION AND OPERATION

1. Description

A. Strobe Light Flasher Assembly, part number 70-0075-1, provides control voltage to strobe flashtube power supplies (Ref. Fig. 1).



B. The Strobe Light Flasher Assembly provides three each outputs of 27.5 VDC for a period of 900 milliseconds with a resting period of 100 milliseconds at zero voltage, resulting in a flashrate of 60 ±10% flashes per minute.

Strobe Light Flasher Assembly
Figure 1

2. Operation

A. With a 1.0 to 2.0 AMP, 28 VDC incandescent lamp connected to any of the three outputs of the Strobe Light Flasher Assembly and 28 VDC applied to the test set-up shown in Figure 2, the incandescent lamp shall come on for a period of 900 milliseconds and then turn off for a period of 100 milliseconds. An oscilloscope can be used to measure the "on" "off". If either a 60-1520-1 or 60-1520-3 power supply with a 30-0516-5 or -7 light assembly connected, or a 30-0515-1 flashtube position light assembly is used in place of the incandescent lamp the strobe lights will flash each time the input power to the assemblies is interrupted by the Strobe Light Flasher Assembly.

Test Set-Up
Figure 2

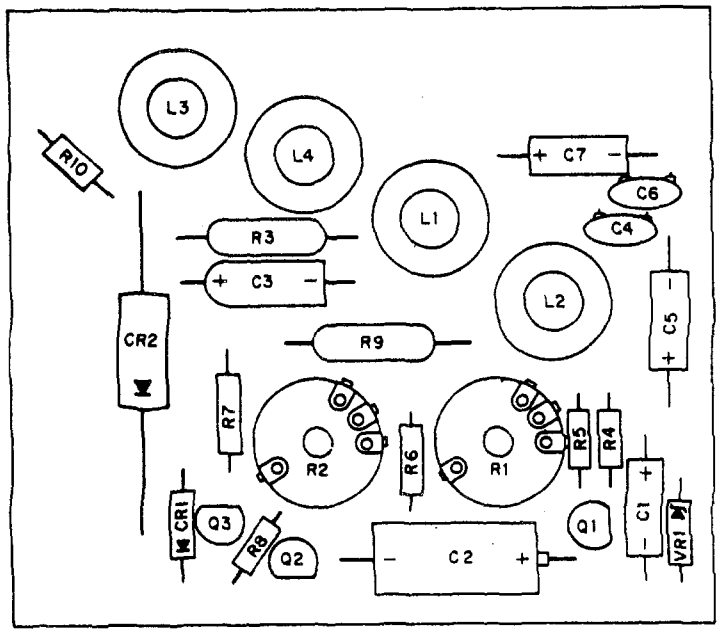
B. The zener diode VR1 (Ref. Fig. 4) regulates the 27.5 VDC input power to 15 volts for use by the pulse generator and pulse shaper circuits. Resistor R3 is used as a dropping resistor between the input voltage and the 15 volts zener diode VR1. Capacitor C1 is used to filter the output.

C. The pulse generator develops a pulse with the proper timing to feed the remaining circuits. Resistor R4, transistor Q1, resistors R1 and R5 and capacitor C2 make up a free running unijunction multi-vibrator. The over all period is determined by adjusting resistor R1. Resistors R2 and R6 determine the time that the output of the pulse generator is below the threshold of the input to the pulse shaper. The "off time" is determined by the adjustment of resistor R2. The adjustment of the over all output is dependant on both resistor R1 "on time" and resistor R2 "off time" being set correctly. There is some interreaction between the two controls. After setting both controls it may be necessary to re-adjust one or the other, or both controls to obtain 900 milliseconds "on time" to 100 milliseconds "off time" ratio.

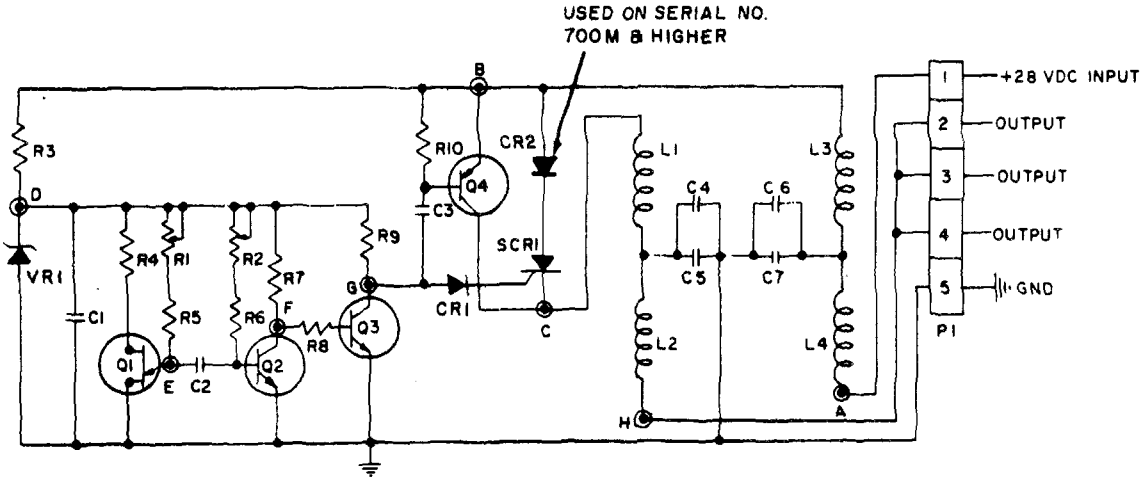
D. The pulse shaper detects the pulse from the generator and creates a well defined pulse that can be used by the pulse amplifier. Transistor Q2 acts as a threshold detector. Transistor Q2 turns off when the input is less than 0.6 volts. This off period represents the output of the flasher. Resistors R7, R8 and R9 and transistor Q3 act as an amplifier to produce a wave shape which is identical to the required output but having a maximum swing of only 14 volts.

E. The pulse amplifier amplifies this pulse from the pulse shaper to produce the 27.5 volt output of 900 milliseconds "on time" and 100 milliseconds "off time". Diode CR1 supplies gate drive to silicon controlled rectifier SCR1 turning SCR1 on when the output of the pulse shaper is high. Rectifier SCR1 will remain on as long as the current through the device remains above the holding current. When the output of the pulse shaper goes to zero volts, capacitor C3 turns transistor Q7 on momentarily diverting the load current of SCR1 through transistor Q4. The current through SCR1 drops to zero and since transistor Q3 is on and there is no gate drive available for SCR1, SCR1 turns off. Transistor Q4 is only on momentarily while current is supplied by the base of Q4 to charge capacitor C3. Resistor R10 is used to discharge C3 when the off period is completed. SCR1 remains off as long as the output of the pulse shaper is zero. This represents the "off time" on the output. The cycle repeats from point on.

F. The radio frequency interference filter (RF1 filter) is designed to reduce the RF1 generated by the pulse amplifier turning on and off. Chokes L3, L7, capacitors C6 and C7 make up the input filter and chokes L1 and L2 and capacitors C5 and C4 make up the output filter.



3. Leading Particulars



For leading particulars, refer to Figure 3.

Electrical requirements:	
Input voltage	27.5 ±0.25 VDC
Output voltage	27.5 VDC
Cycle Time (Milliseconds):	
On	900
Off	100
Dimensions (inches):	
Length	4.062
Width	3.453
Height	0.781

ILLUSTRATED PARTS LIST

The following is a compilation of the vendor codes with the names and addresses of suppliers for purchased parts used in this illustrated parts list.

CODE	NAME AND ADDRESS
00779	AMP, Inc. P. O. Box 3608 Harrisburg, Pa. 17105
01121	Allen-Bradley Company 1201 South 2nd Street Milwaukee, Wis. 53204
01295	Texas Instruments, Inc. Semiconductor Components Div. 13500 North Central Expressway Dallas, Texas 75231
03508	General Electric Company Semiconductor Products Dept. Electronics Park, N. Y. 13201
04713	Motorola Semiconductor Products, Inc. 5005 East McDowell Road Phoenix, Ariz. 85008
05397	Union Carbide Corp. Material Systems Division 11901 Madison Avenue Cleveland, Ohio 44101
56289	Sprague Electric Company North Adams, Mass. 01247
81483	Internal Rectifier Corp. 9220 Sunset Blvd. Los Angeles, Calif. 90069
83761	Molded Rubber and Plastic Corp. 13161 West Glendale Ave. Butler, Wis. 53007
91637	Dale Electronics, Inc. P. O. Box 609 Columbus, Nebr. 68601
99942	Globe Union, Inc. Centralab Semiconductor Div. 4501 North Arden Drive El Monte, Calif. 91734

GRIMES

STROBE REPAIR MANUAL
PART NO. 60-1755

GENERAL NOTES:

1. CAUTIONS:
   A HIGH VOLTAGE SHOCK HAZARD IS PRESENT ACROSS TERMINALS OF C11 & C12 & PINS A & C OF OUTPUT CONNECTOR (TEST POINTS R & G)
   EXTREME CAUTION SHOULD BE USED WHILE WORKING ON UNIT WITH VOLTAGE APPLIED TO INPUT LEADS. WAIT AT LEAST 15 MINUTES AFTER UNIT IS TURNED OFF BEFORE PERFORMING WORK WITHIN THIS UNIT AND DISCHARGE CAPACITORS C_{11} & C_{12} -
   BEFORE MAKING ANY RESISTANCE OR CONTINUITY CHECKS - DISCHARGE C_{11} & C_{12} - WHEN MEASURING UNKNOWN CIRCUIT VOLTAGES, SET METER & SCOPE FUNCTIONS ON HIGH RANGE---(1KV). INSURE THAT UNIT IS PROPERLY GROUNDED WHILE TROUBLE-SHOOTING UNIT.

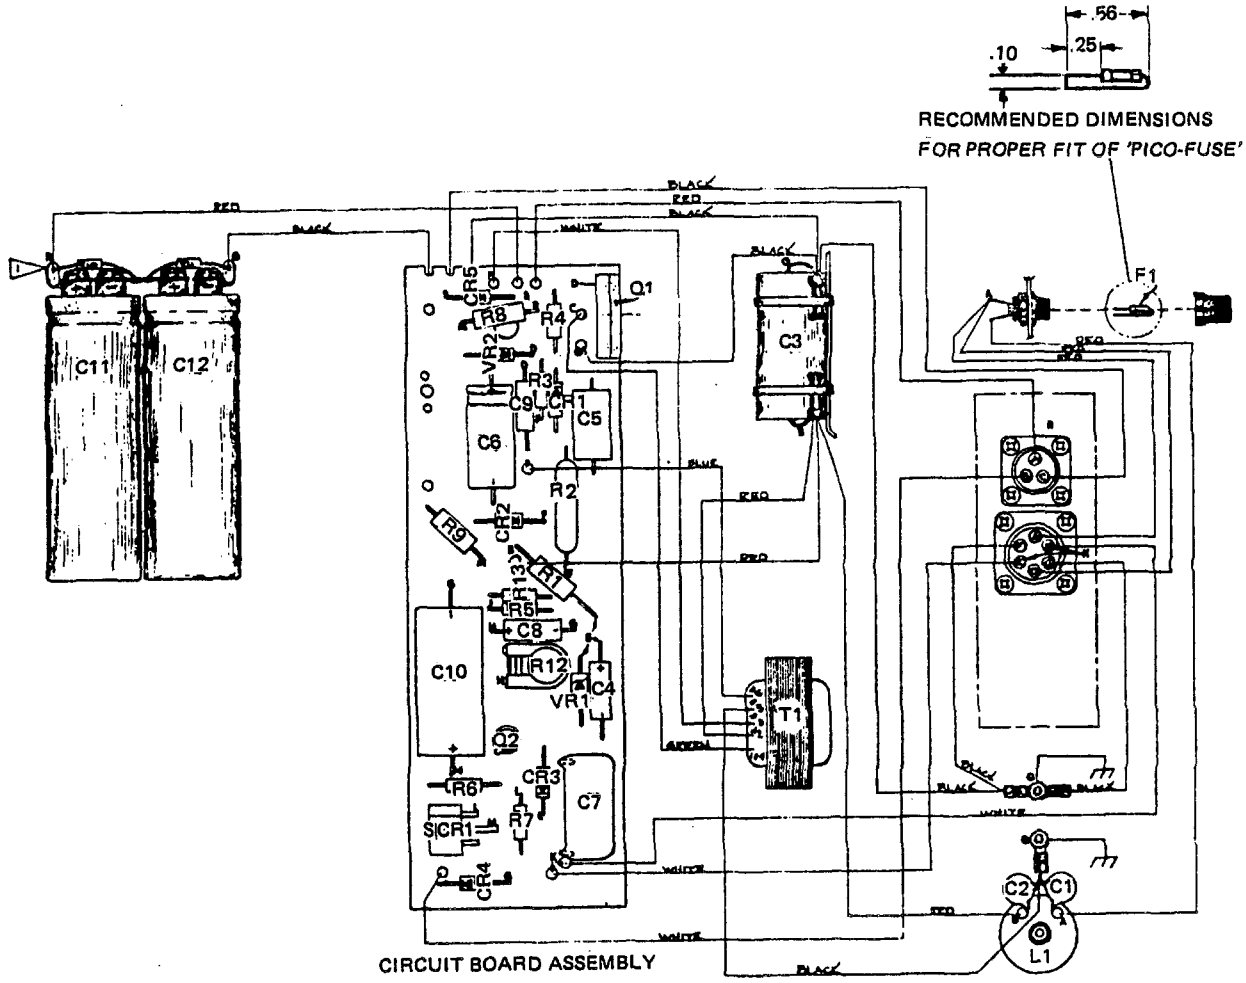
2. LAMPCHECK WITHOUT THE REMOVAL OF POWER SUPPLIES FROM AIRCRAFT CAN BE MADE BY INTERCHANGING CABLE PLUGS AT POWER SUPPLY RECEPTACLES. (POWER SUPPLY MUST BE TURNED 'OFF' BEFORE INTERCHANGING PLUGS) -
   IF INTERCHANGE FAILS TO INDICATE LAMP FAILURE, CHECK FOR CONTINUITY & CORRECT WIRING OF CABLES, RECEPTACLE & PLUG PINS & PROPER VOLTAGES ON RECEPTACLE PINS.
   (TEST POINTS: R & G)

3. OSCILLOSCOPE ONLY CAN BE USED TO CHECK NORMAL VOLTAGE READING AS SHOWN - (METER RESPONSES INADEQUATE).

4. DIODE CR4 SHOULD BE CHECKED WITH LAMP DISCONNECTED FOR ACCURATE INDICATION.

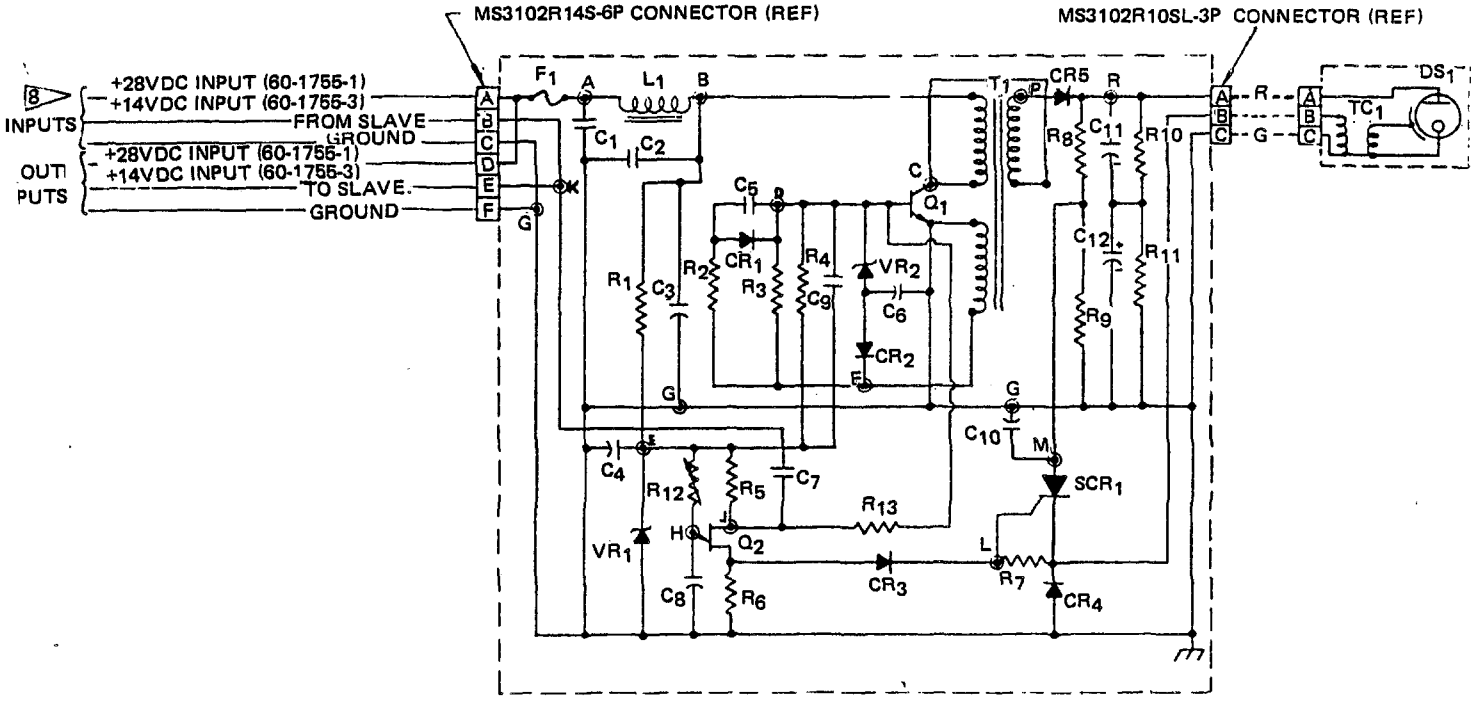
5. R12 IS FLASHRATE ADJUST RESISTOR AND IS PRESET TO FAA FLASHRATE REQUIREMENTS. DO NOT ATTEMPT TO CHANGE R12 SETTING UNLESS NATURE OF FAILURE WARRANTS ALIGNMENT.

6. ALL WIRING IN THIS UNIT NO. 20 GUAGE TEFLON INSULATED, MIL-W-16878/E -



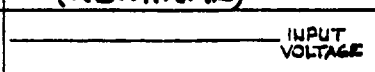
7. THESE COMPONENTS WILL VARY WITH 14 VOLT DC INPUT UNIT 60-1755-3 AND 28 VOLT DC INPUT UNIT 60-1755-1:
   R_1 {-3 100Ω ½ W - ALLEN BRADLEY
   {-1 470Ω ½ W - ALLEN BRADLEY
   R_2 {-3 10Ω 3 W - DALE RS-2B
   {-1 75Ω 3 W - DALE RS-2B
   C_3 {-3 2200 mf@15V SPRAGUE NO. 39D408G015JL4
   {-1 4000 mf@25V SPRAGUE NO. 39D228G025JL4

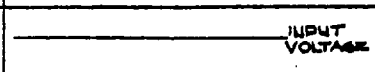
8. "POLARITY MUST BE OBSERVED"
   POWER SUPPLY WILL BE DAMAGED IF VOLTAGE POLARITY IS NOT OBSERVED----BLACK WIRE IS NEGATIVE AND MUST BE SUITABLY GROUNDED. DO NOT APPLY POSITIVE VOLTAGE TO BLACK WIRE.

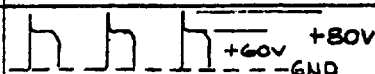


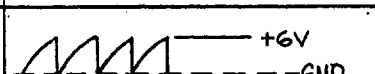
9. TO OBSERVE PULSE MORE CLEARLY INCREASE SCOPE 'INTENSITY' TO FULL.

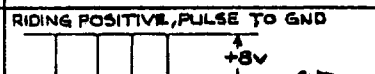
10. A TIMES-TEN (X10) MULTIPLIER PROBE MUST BE USED TO EXTEND VOLTAGE RANGE OF SCOPE WHEN MEASURING VOLTAGES IN EXCESS OF 100 VOLTS.

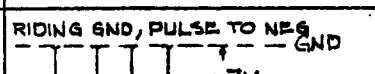


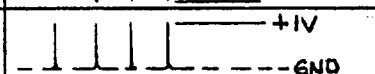


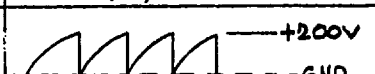


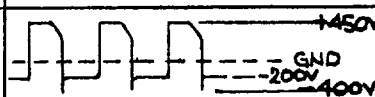


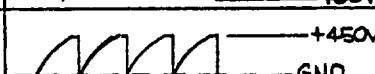












11. ZENER DIODE 'VR2' MAY BE EITHER OF THE FOLLOWING:
    NO. IN5241B - 11 VOLT @ 500 MW
    NO. IN5243B - 12 VOLT @ 500 MW
    NO. IN5243B - 13 VOLT @ 500 MW
    REPLACEMENT ZENER SHOULD BE THE SAME VALUE OF ZENER REMOVED.

GRIMES MANUFACTURING COMPANY
COMPONENT MAINTENANCE MANUAL
WITH ILLUSTRATED PARTS LIST
PART NO. 30-0863

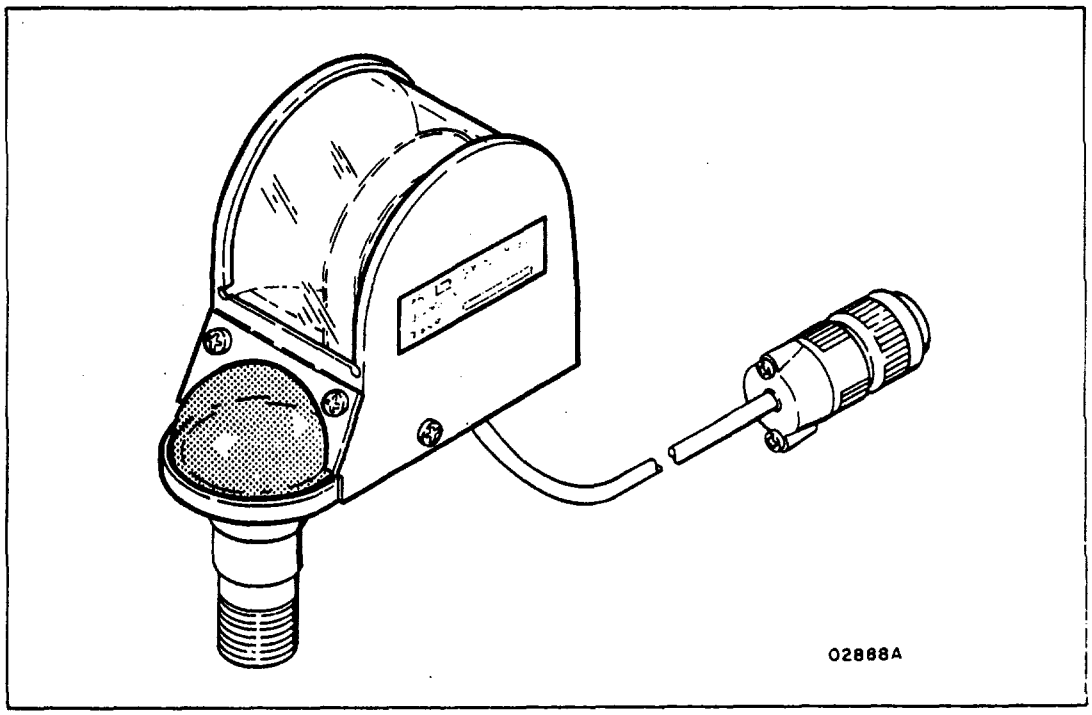
INTRODUCTION

This manual contains shop instructions for testing, trouble shooting, and repairing the components listed on the title page. The instructions are divided into sections as shown in the preceding table of contents.

The instructions in this manual only apply to the assembly part numbers listed on the title page. Insure that the part number on the unit is listed on the title page before performing any of these instructions.

The procedures within this manual are only to be performed by qualified shop mechanics who are familiar with this type of equipment.

The contents of this manual have been verified by the manufacturer prior to the distribution of printed copies.

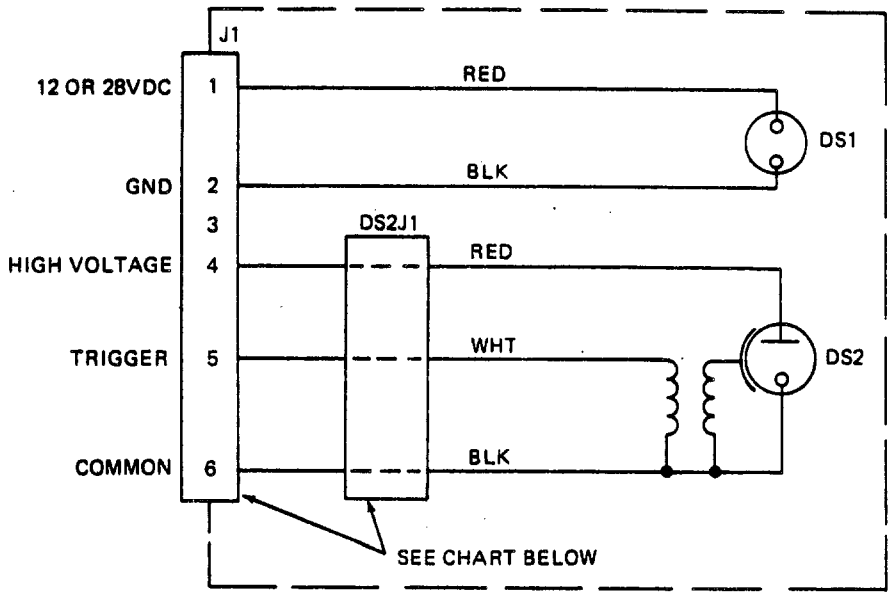


GRIMES MANUFACTURING COMPANY
COMPONENT MAINTENANCE MANUAL
WITH ILLUSTRATED PARTS LIST
PART NO. 30-0863

DESCRIPTION AND OPERATION

1. Description

Wing Position Aircraft Navigational Light, part numbers 30-0863-1 thru -12, are installed on aircraft to provide a flashing source of high intensity illumination to indicate the position of the aircraft (Ref. Fig. 1).



Model differences are in external wiring connections (Ref. Fig. 2) and in lens color (Ref. Fig. 3).

Wing Position Aircraft Navigational Light
Figure 1

2. Operation

The light has two light sources. An incandescent lamp, energized by 12 or 28 VDC as applicable, provides illumination for continuous operation. A flashtube, with an input voltage of 400 VDC and triggered by a 200 volt pulse, operates at a flashrate of 60±10 per minute, determined by the trigger pulses. Refer to figure 2 for electrical connections.

Electrical Wiring Diagram
Figure 2

3. Leading Particulars

For leading particulars, refer to Figure 3.

Electrical requirements:

Incandescent lamp:
30-0863-1 thru -8 ..... 28 VDC
30-0863-9 thru -12 ..... 12 VDC
Flashtube:
Input voltage ..... 400 VDC
Trigger pulse ..... 200 VDC

Lens color:
Incandescent lamp:
30-0863-1, -3, -5, -7, -9, -11 ..... AVN red
30-0863-2, -4, -6, -8, -10, -12 .... AVN green
Flashtube:
30-0863-1 thru -6, -9 thru -12 ..... AVN red
30-0863-7, -8 ..... AVN white

Dimensions:
Length ..... 3.95 inches (10.0 cm)max.
Width ..... 1.84 inches (4.7 cm)max.
Height ..... 5.12 inches (13.0 cm)max.
Weight ..... 0.75 pounds (0.34 Kg)max.

Leading Particulars
Figure 3

TESTING AND TROUBLE SHOOTING

1. Connect 12 or 28 VDC to the incandescant lamp wires or connector pins as applicable. If the lamp fails to light, replace lamp (Ref. 250, Fig. 7).

2. Using a 60-2290-1 Strobe Light Power Supply, apply 400 VDC between pins 4 and 6 of connector per Figure 2. Apply a 200 volt trigger pulse for a duration of 2.0 microseconds to pin 5. Flashtube shall illuminate at the repetition rate of the trigger pulses. If the lamp fails to flash, replace flashtube assembly (Ref. 280, Fig. 7).

DISASSEMBLY

NOTE: See Testing and Trouble Shooting to establish the condition of the component or most probable cause of its malfunction. This is to determine the extent of disassembly required, without completely tearing down and rebuilding the component.

1. If only lamp (Ref. 250, Fig. 7) requires replacement, remove screws (210) and lift off retainer (240), lens (220) and gasket (340). Lamp (250) can then be removed.

2. Remove screws (150) and lift off housing assembly (180) from flashtube assembly (280).

3. Cut sealant from lens (160) and remove lens (160) from housing assembly (180), only if required.

4. Peel identification plate (420) from housing assembly (180), only if illegible.

5. If required, remove conduit nut (350) and remove items (360 thru 390) from base assembly (430).

6. Do not attempt to disassemble flashtube assembly (280) beyond replacing ty-raps (330) or connector (320).

CLEANING

1. Refer to figure 4 for a list of cleaning materials.

   NOTE: Equivalent substitutes may be used for listed items.

PART NUMBER	NOMENCLATURE	SPECIFICATION	MANUFACTURER
	Isopropyl alcohol	Federal Specification TT-I-735	
	Dry Cleaning Solvent	Federal Specification P-D-680	
	Acetone	Federal Specification O-A-51	

Cleaning Materials List
Figure 4

1. Clean electrical parts with a clean, lint-free cloth moistened with isopropyl alcohol, Federal Specification TT-I-735, or equivalent. Allow to air dry.

   WARNING: SOLVENT AND ACETONE FUMES ARE TOXIC. PROLONGED INHALATION OF THE FUMES MAY CAUSE ILLNESS.

2. Clean metal parts with dry cleaning solvent, Federal Specification P-D-680, or equivalent.

3. Clean the lamps with acetone, Federal Specification O-A-51, or equivalent.

CHECK

1. Visually inspect lenses (Ref. 160 and 220, Fig. 7) for cracks and discoloration.
2. Visually inspect terminal assembly (390) for a good electrical contact.
3. Visually inspect connector (320) for evidence of arcing between pins.
4. Visually inspect metal parts for distortion and damage.

REPAIR

Repair consists of replacing parts found defective during Testing and Trouble Shooting, and Check procedures.

ASSEMBLY

1. Refer to Figure 7 for an exploded view, and to its parts list for usable on code information. Refer to Figure 5 for materials used during assembly.

2. If flashtube assembly (Ref. 280, Fig. 7) was replaced, make wiring connections per Figure 2.

3. Insert terminal assembly (Ref. 390, Fig. 7), spring (380), insulator (370), and terminal (360) into base assembly (430). Install conduit nut (350).

4. Install new lamp (250).

5. If previously removed, install new pressure sensitive identification plate (420).

6. Install lens (160) into housing assembly (180) and seal inside and outside mating surfaces with sealant.

7. Assemble housing assembly (180), flashtube assembly (280), and base assembly (430). Install screws (150).

8. Install new gasket (340), lens (220), and retainer (240). Secure with screws (210).

9. Perform testing procedures in testing and trouble shooting section.

10. Prepare for storage by wrapping the unit with cushioning material. Enclose the assembly and desiccant in heat sealable film and seal the film using a sealing iron, Military Specification MIL-S-43336. Store the assembly in an area with a temperature range of 65 to 120°F (18 to 49°C).

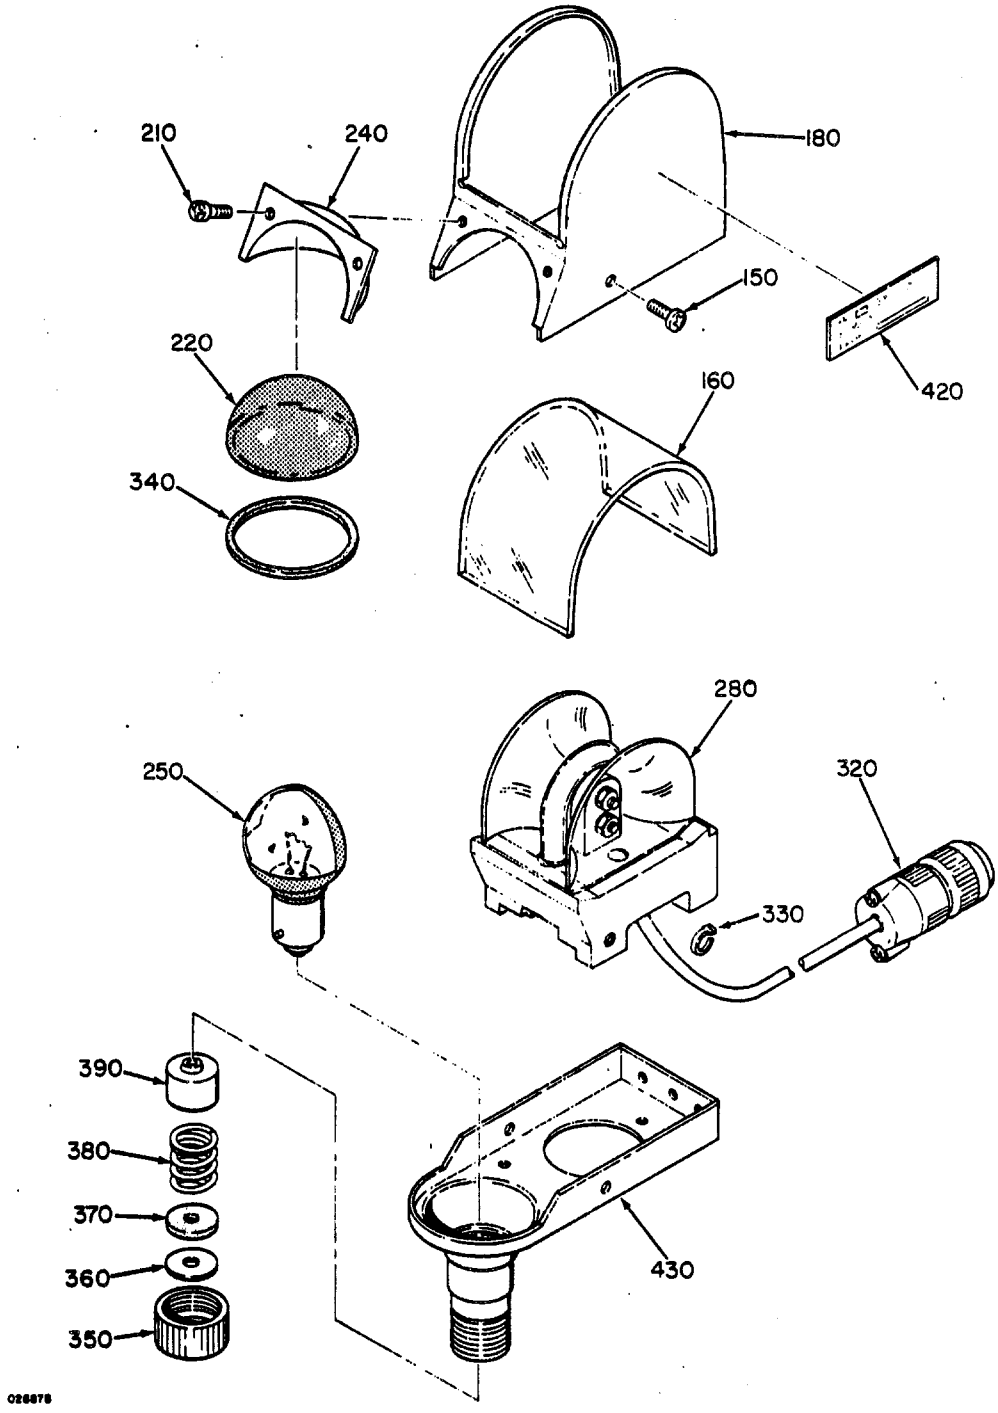
ILLUSTRATED PARTS LIST

General information and instructions for use of the Illustrated Parts List are as follows:

1. The Illustrated Parts List is a breakdown of assemblies, subassemblies, and detail parts of the items listed on the title page. Index numbers on the exploded view illustration accompanying the parts list indicate the general order of disassembly. Component parts are indented in the list to show subordinate relationship to the complete assembly.

2. The Units Per Assembly column of the parts list indicates the quantity of each part required for the next higher assembly.



3. Part numbers and description in the parts list identify each part. The index numbers in the parts list refer to the accompanying exploded view illustration.

4. The following is a compilation of the vendor codes with the names and addresses of suppliers for purchased parts used in this illustrated parts list.

VENDOR CODE	NAME AND ADDRESS

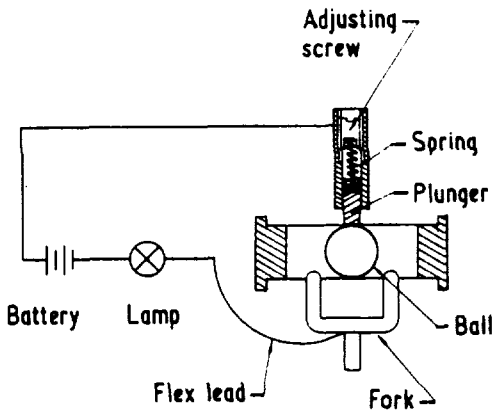
SERVICE BULLETIN LIST

Service Bulletin No.	Manual Incorporation Date

OSM 614/JR/RFC

Printed in Great Britain

DESCRIPTION, OPERATION AND DATA



1. Description (Fig. 2)

The Emergency Lighting Units Mk.2 are a compact, self-contained lighting unit, operated by an internal inertia switch which provides automatic illumination inside the aircraft under abnormal landing conditions which may put out of action the normal lighting system.

They are constructed for roof or wall mounting, and are retained in position by a ball click mechanism and bayonet catch in a circular retaining ring. Provision is made for a sealing wire to be fitted by two small cross-drilled bosses, one on the mounting ring and the other on the unit. The wire should be fine tinned copper fuse wire which will break easily and not interfere with the removal of the lamp for use as a hand torch if required in an emergency.

The illumination from the Emergency Lighting Unit Mk.2 is evenly distributed over an angle of 180°.

Cover is provided by two internal dry cells, type 105 to BS.397. The bulb is 2.5 volt, 0.3 amp., with an M.E.S. cap. The initial light intensity exceeds 7.5 lumens and at the end of half-hour of continuous use is not less than 3 lumens. An aluminium reflector is fitted at the base of the bulb. The reflector and bulb are capped by a clear Diakon moulded cover. The mounting ring requires fixing to the aircraft roof or wall, the unit being inserted and retained by the mounting ring. The units are interchangeable and are available in two colours, black or ivory.

2. Operation (Fig.1)

The inertia switch element consists of a plated steel ball in an insulating tube and is normally retained in a central position by an adjustable spring-loaded plunger. When the unit is subjected to acceleration, the ball will be displaced against one of the fork prongs and held there by the pressure of the plunger.

Thus an electrical circuit is completed, from the plunger via the ball to the fork. The lamp and battery are connected in series across the form and plunger which forms an electrical circuit whenever the ball is displaced. This causes the lamp to light and it will remain lit until the mechanism is reset by hand. The reset mechanism also operates as the manual 'on/off' switch and comprises of a fork so dimensioned that the inside fits tightly around the ball. When the fork is depressed the ball is centralised and contact is made between the fork and base. As the ball is always in contact with the plunger the circuit between the plunger and form is complete, and the lamp will light. When the fork is withdrawn the ball is retained in a central position by the plunger, but the circuit between the base and the fork will be broken. The switch is now reset and ready for use. The inertia switch is designed to operate in a fore and aft direction only at a positive or negative acceleration between 2 and 4g. This is adjustable and in production is set at 3g, with a test allowance of ±10 per cent.

3. Data

Power supply	2 internal dry cells each 1.5 volt (type 105 to BS.397)
Light output	Not less than 7.5 lumens at commencement of discharge falling to not less than 3 lumens after 0.5 hour use.
Weight	Approximately 8 ozs.
Mounting position	The longitudinal plane of the inertia switch must be kept horizontal and parallel to the fore and aft line of the aircraft. Provided these conditions are complied with the unit may be mounted to any angle in the roof or side wall.
Radio interference	Free to BS.800 and B.C.A.R. Section J, Chapter 6, clause 4.2.
Grading to G100	Altitude and climatic Grade 1 Vibration Grade 3 Compass safe distance 12 in.
Performance	Operates on deceleration with the range between 2-4g with a tolerance of ±10%.
Conditions	Section 1, Clause 5.3, provided that it is installed in accordance with Fig. , of this manual, using 4BA steel screws.

Plessey Dynamics

DISMANTLING

1. General

The items mentioned throughout the text are illustrated in the 'Exploded view of the unit', Fig.1. The number in brackets refer to the code allocated to parts in Fig.1.

2. Dismantling the unit

A. Break the sealing wire and remove the unit from the mounting ring (54,55).

B. Unscrew the clear Diakon moulded cover (2) and remove the bulb (3).

C. Remove the bakelite guard plate and lift out the two dry cells.

NOTE: Further dismantling and subsequent reassembly of the inertia switch must be carried out under scrupulously clean conditions and will impair the adjustment of the unit. The re-adjustment requires the use of a calibrated acceleration table - if this is not available the unit must be returned to the manufacturers for setting.

3. Dismantling of inertia switch

A. Remove the adjusting screw and take out spring and plunger (39).

B. Unscrew reset plunger (36) with the fork (38) pushed fully in and remove. The spacer (37) may now be lifted out and the fork (38) then withdraw.

C. Remove the two plug screws (40), lift out the end plugs (42) and remove the ball (43).

CLEANING

1. General

The inertia switch must be kept scrupulously clean and free of all lubricants.

A. Wipe the switch tube clean from dust, grease or moisture.

B. Wipe the ball clean from dust, grease or moisture.

C. Clean the battery top contact spring.

D. Clean the clear Diakon cover with a lint-free cloth.

WARNING: DO NOT LUBRICATE

OSM 614/JR/RFC

Printed in Great Britain

INSPECTION/CHECK

1. In-Situ Checks

   A. The batteries and bulb can be tested while the unit is retained in its mounted position. When the plunger is depressed the lamp should light.

   B. Ensure the unit is firmly retained by the mounting ring.

   C. Ensure the sealing wire is unbroken.

   D. Check visually for damage, corrosion and cracks.

2. Checks necessitating removal of unit

   When the unit has been removed and the inertia switch has been dismantled, carry out the following checks.

   A. Check the switch tube is clean and free from dust, grease and moisture.

   B. Check the condition of the reset fork and adjust if necessary, to make contact with the ball.

   C. Check the tube diameter of the inertia switch exceeds the ball diamter by 0.002 in. to 0.007 in. If the correct clearance cannot be obtained the body must be replaced.

   D. Check the switch tube bore is free from scores or ridges. Replace the body if damaged.

   E. Check the battery terminals for corrosion.

   F. Check visually for damage, corrosion or cracks.

REPAIR

1. General

Repair is by replacement only. Any item found to be damaged should be replaced or the unit returned to the manufacturer or base.

OSM 614/JR/RFC

Printed in Great Britain

ASSEMBLY

1. General

When dismantling the inertia switch all work should be carried out in a dust free atmosphere and tools and equipment kept scrupulously clean.

2. Assemble the inertia switch

A. Replace one end plug (42) and screw into position on the body (52,53).

B. Replace the ball (43).

C. Replace the second end plug and screw in position.

D. Fit the fork (38) into the body (52,53).

E. Pass the reset plunger (36) through the aperture in the top of the body.

F. Place the spacer (37) on the stem of the reset plunger (36) with the small end towards the fork (38), fit the end of the flexible lead (34) between the spacer (37) and the fork (38).

G. Screw up the reset plunger tightly.

H. Check the reset plunger operates freely.

J. Assemble the plunger (39) in barrel with shallow hole towards the ball, replace the spring and adjusting screw.

WARNING: DO NOT LUBRICATE

3. Assemble the unit

A. Replace the batteries ensuring the centre connection of the holes are correctly located in the hole in the top contact spring.

B. Replace bakelite guard plate.

C. Carry out an acceleration check on the inertia switch.

Plessey Dynamics

FITS AND CLEARANCES

1. General

All dimensions are in inches.

2. Tube diameter

The tube diameter of the inertia switch must exceed the ball diameter by 0.002 in. to 0.007 in. If this tolerance cannot be obtained the body must be replaced.

OSM 614/JR/RFC

Printed in Great Britain

TESTING

1. General

Frequent checks should be carried out on the batteries and bulb to ensure deterioration is kept to a minimum.

2. Test equipment

The operation of the emergency lighting unit must be carried out on an acceleration table.

3. Acceleration test

The operation of the unit must be checked on an acceleration table with the longitudinal axis of the inertia switch mounted radially. The inertia switch should be tested using the foll owing formula.

Formula: $G = r N^2 0.00034$

When r = radius of rotation in feet and N = speed of table in R.P.M.

When r = 7 in. N = 116 for g = 2.7 (Lower limit of operation)

N = 129 for g = 3.3 (Upper limit of operation)

The unit be be tested for operation in both fore and aft directions. After tripping the unit must be capable of being tilted in any direction without the lamp going out.

FAULT FINDING

1. General

The following table is intended as a guide to locate and rectify a fault in the shortest possible time.

2. Table of faults

Fault	Possible cause	Remedy
Lamp remains lit	Ball trapped against fork	Adjust ball and test
Ball will not centralise	Damaged switch tube bore	Replace body
Lamp will not light (manual)	Batteries discharged	Replace
	Bulb ruptured	Replace
	Flexible lead ruptured	Replace or repair
Lamp will not light (acceleration)	Damaged switch tube bore	Test, replace body
	No supply	Check batteries and circuit
	Bulb ruptured	Replace

Plessey Dynamics

STORAGE INSTRUCTIONS

1. General

   The batteries must be stored separately from the units.

2. Storage

   Store the units in a dry, temperate atmosphere, away from injurious fumes.

3. Shelf life

   The shelf life of the emergency lighting unit is 12 months if stored under the correct conditions.

Plessey Dynamics

SPECIAL TOOLS AND EQUIPMENT

1. General

There are no special tools associated with the repair and maintenance of the emergency lighting unit.

2. Special equipment

1. Introduction

A. Purpose

(1) This list describes the parts required for the Emergency Lighting Unit Mk.2, 614-1-03460 and 614-1-03460-001 and is issued in conjunction with the Overhaul Manual to serve as an aid to disassembly. The list is arranged in order of disassembly and is indented to show the assembly and detail relationship. Attaching parts are listed immediately following the assembly or item they attach and precede detailed parts of that assembly.

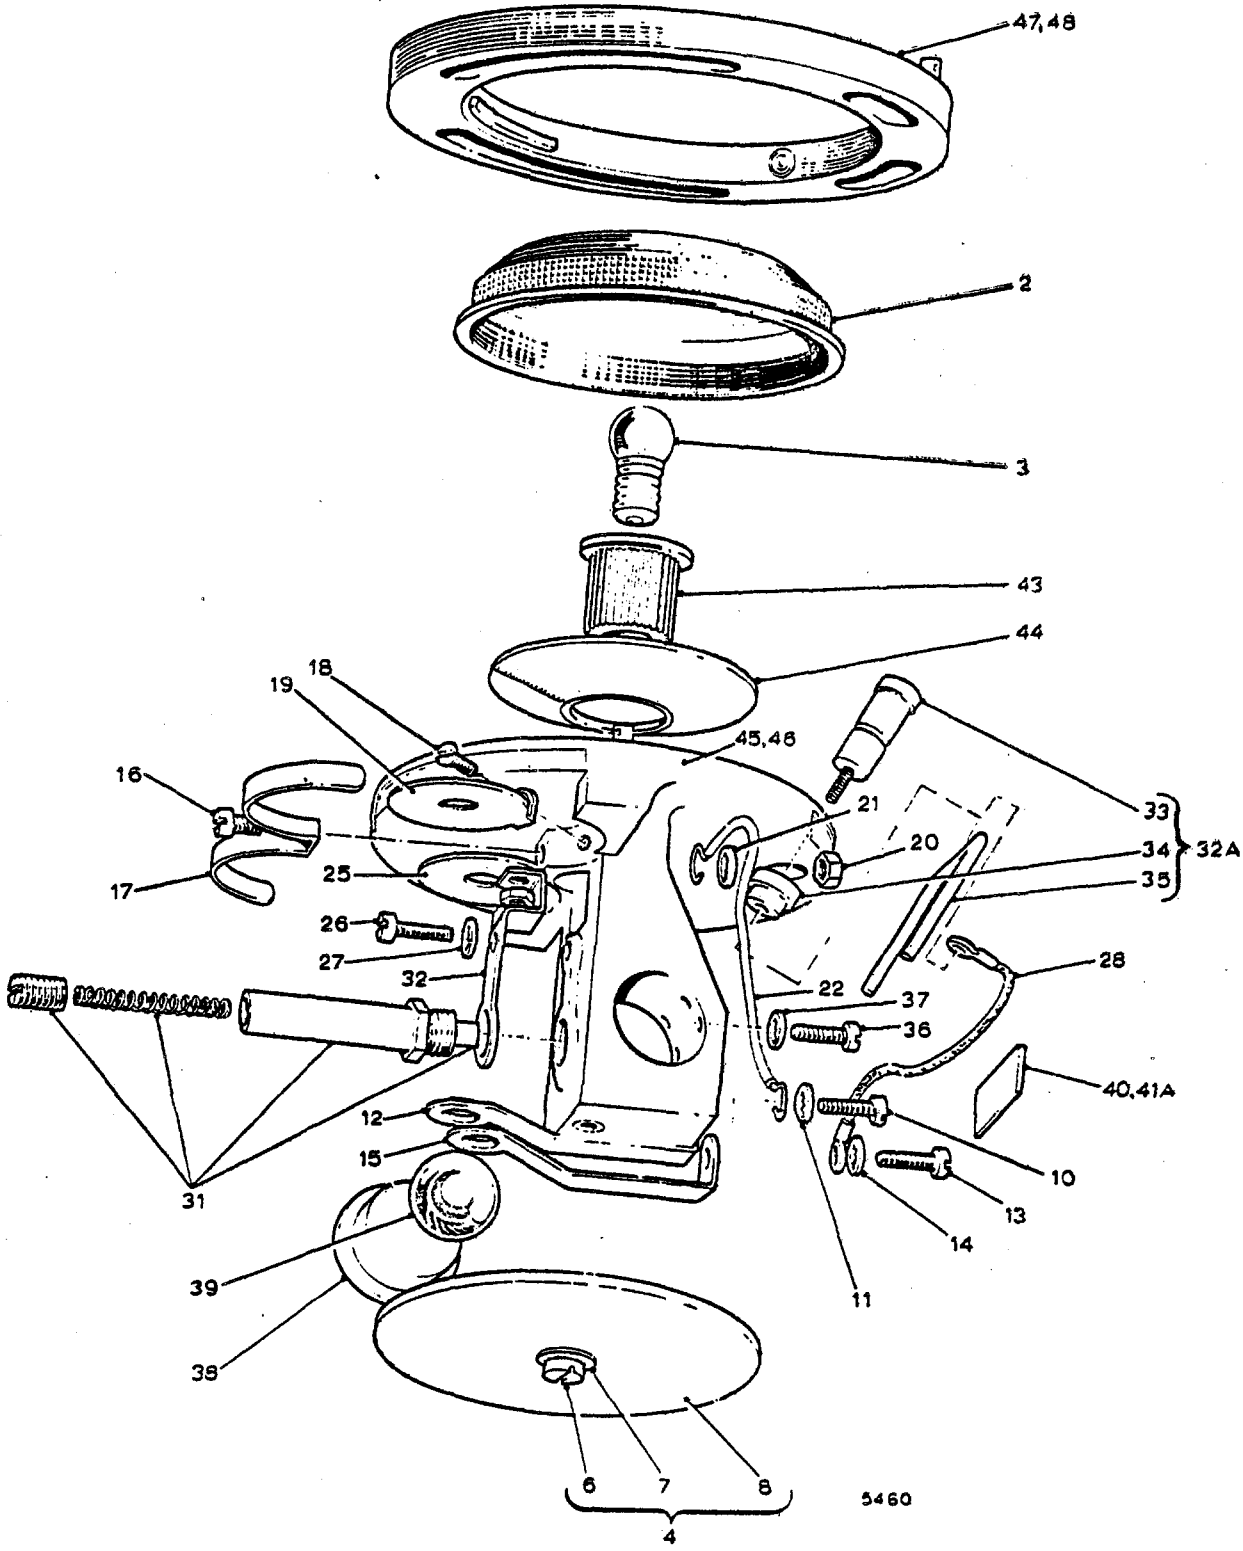
B. Usage

(1) Detailed parts list

(a) The first column lists the figure number of the relevant exploded view and index numbers of all parts. Parts and index numbers prefixed by a dash (-) are not illustrated.

(b) The second and third columns list the part numbers and description of all assemblies, sub-assemblies and detail parts. Due to computer complexities, vendors part numbers or specific ordering numbers in excess of fifteen digits are shown in column three. The vendors are listed in para. 'D'.

(c) The fourth column provides for model variations as applicable.



(d) The fifth column shows quantity per assembly.

C. Part numbering system

The current Plessey part numbering system is completely numerical in form, eleven to fifteen digits maximum in length for computerisation purposes the eleven digit numbers are made up of three elements of fixed lengths separated by dashes (-). Suffix numbers of three digits may be added to the third element of an elevem digit number to provide for variations to dimensions, materials, finishes, etc. of the same basic part number.

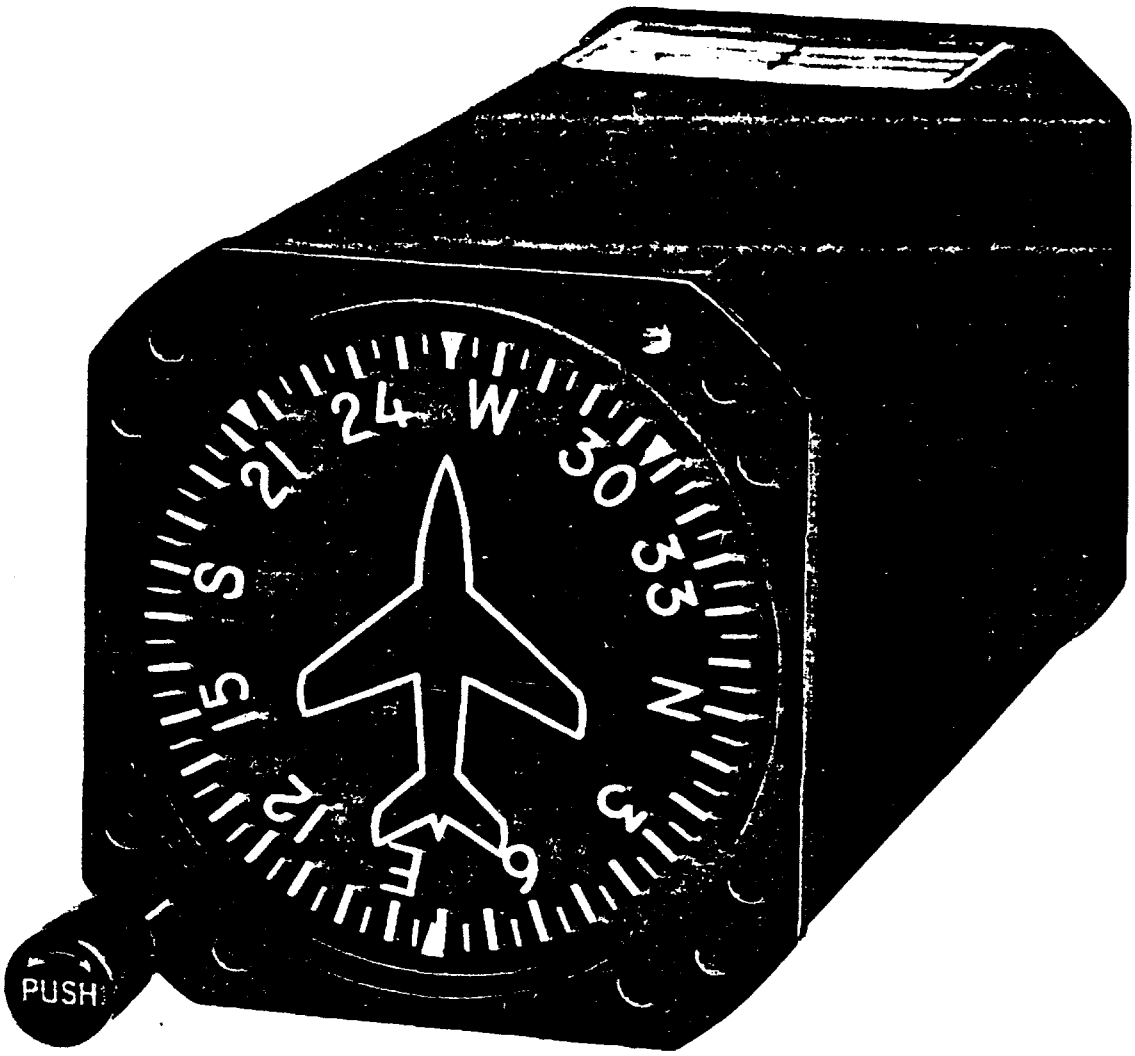

FIGURE 1-1. TYPICAL AIM 200 SERIES DIRECTIONAL GYRO

SECTION 1
GENERAL INFORMATION

1.1 SCOPE

This manual contains maintenance and overhaul procedures for Aviation Instrument Manufacturing Corporation's AIM 200 Series Directional Gyros. Specific models covered are:

AIM 200	AIM 200EDC
AIM 200 (18-380021)	AIM 200EDC (Bezel Mt.)
AIM 200 (CM2675-1)	AIM 200DC (14)
AIM 200E	AIM 200DC (28)
AIM 200E (AeroCom)	AIM 200DC (14) P
AIM 200ED	AIM 200DC (28) P

Additional models will be subsequently covered by the inclusion of Supplemental Data Sheets in the manual.

1.2 GENERAL DESCRIPTION

Although the Directional Gyros described in this manual contain many variations from model to model, the basic theory of operation is common to all units covered.

The AIM 200 Series Directional Gyros are precise, gyroscopic flight instruments designed to furnish the aircraft pilot with a constant directional reference which is not subject to the temporary errors inherent in magnetic compasses.

The function of each instrument is to maintain a stabilized datum reference from which the azimuth movements of an aircraft can be measured. This is accomplished by a universally mounted, high-speed rotor which develops sufficient angular momentum to overcome normal bearing friction and thus becomes stable relative to space. This stability, known as "rigidity in space", resists small forces which attempt to displace the axis of rotation and, consequently, its position in space.

1.2 GENERAL DESCRIPTION (Cont'd)

The instruments described in this manual are identical in function, and differ primarily in the means by which the high-speed rotor movement is achieved. Some models are vacuum-operated, some are ac-operated, and some are dc-operated. Detailed functional descriptions of each model are provided in paragraph 1.3.

In addition to variations in input requirements either of two distinct mechanical design configurations may also be encountered. The two configurations are shown in Figures 1-2 and 1-3.

In the "top-gear" configuration of Figure 1-2, the indicator card is positioned through a large spur-gear/clutch assembly at the top of the gimbal. A smaller spur gear at the top of an intermediate shaft, and two bevel gears at the bottom of the shaft, convert changes in azimuth into angular rotation of the card.

The "bottom-gear" configuration of Figure 1-3 positions the indicator card through a large spur gear at the bottom of the gimbal. A cup-gear/clutch assembly, mounted directly on the card shaft, converts azimuth changes into angular rotation of the card.

The clutch mechanism in both configurations permits resetting the card with minimum repositioning of the gimbal. A caging knob marked "PUSH" is provided on the front panel to simultaneously cage the gyro and to readjust the indicator card to the desired heading.

The diameter of the caging shaft provides a convenient key to determining the internal configuration of the gyro, even with the instrument mounted in a panel. The top-gear configuration has a 1/8 inch shaft, and the bottom-gear configuration uses a 3/16 inch shaft.

All AIM 200 Series instruments fit a standard 3-1/8 inch instrument panel cut-out. The small size of the instruments, combined with their substantially reduced weight, permits panel layouts in accordance with SAE and airline standards.

The instruments are spill-proof and will not tumble regardless of the aircraft's attitude. A self-erecting feature incorporated in each instrument eliminates the need for periodic caging of the rotor, except for the usual heading resets.

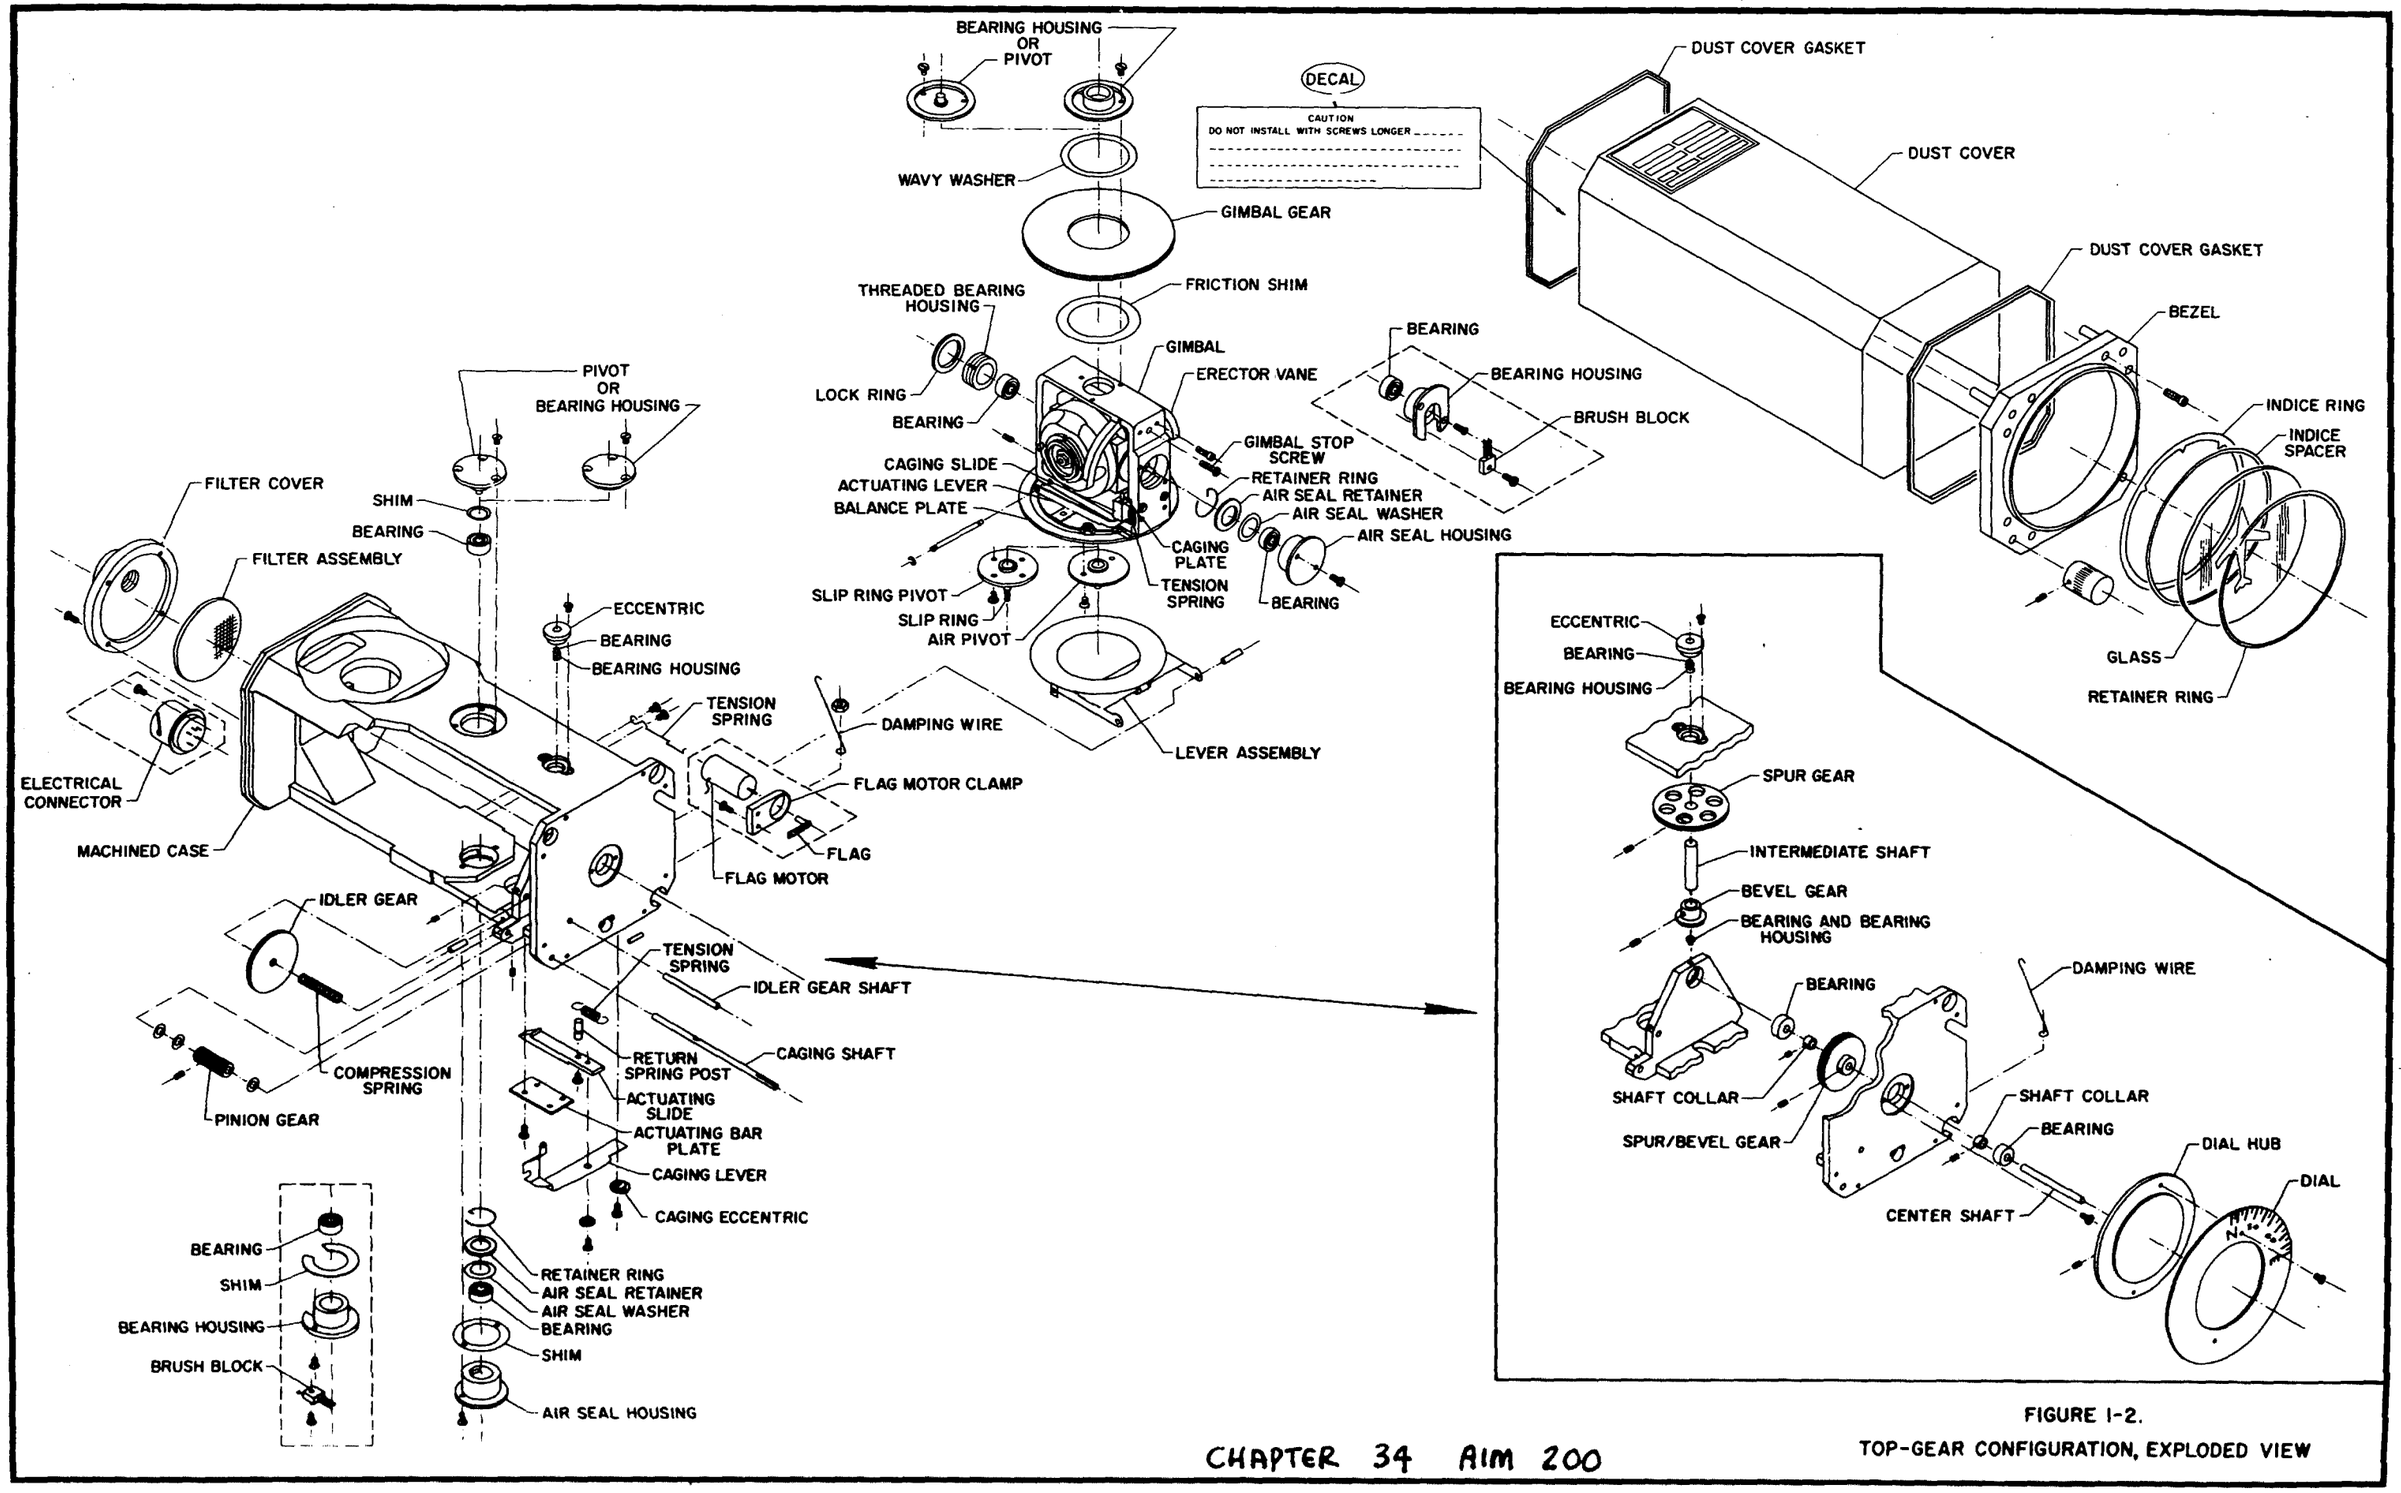

FIGURE 1-2.
TOP-GEAR CONFIGURATION, EXPLODED VIEW

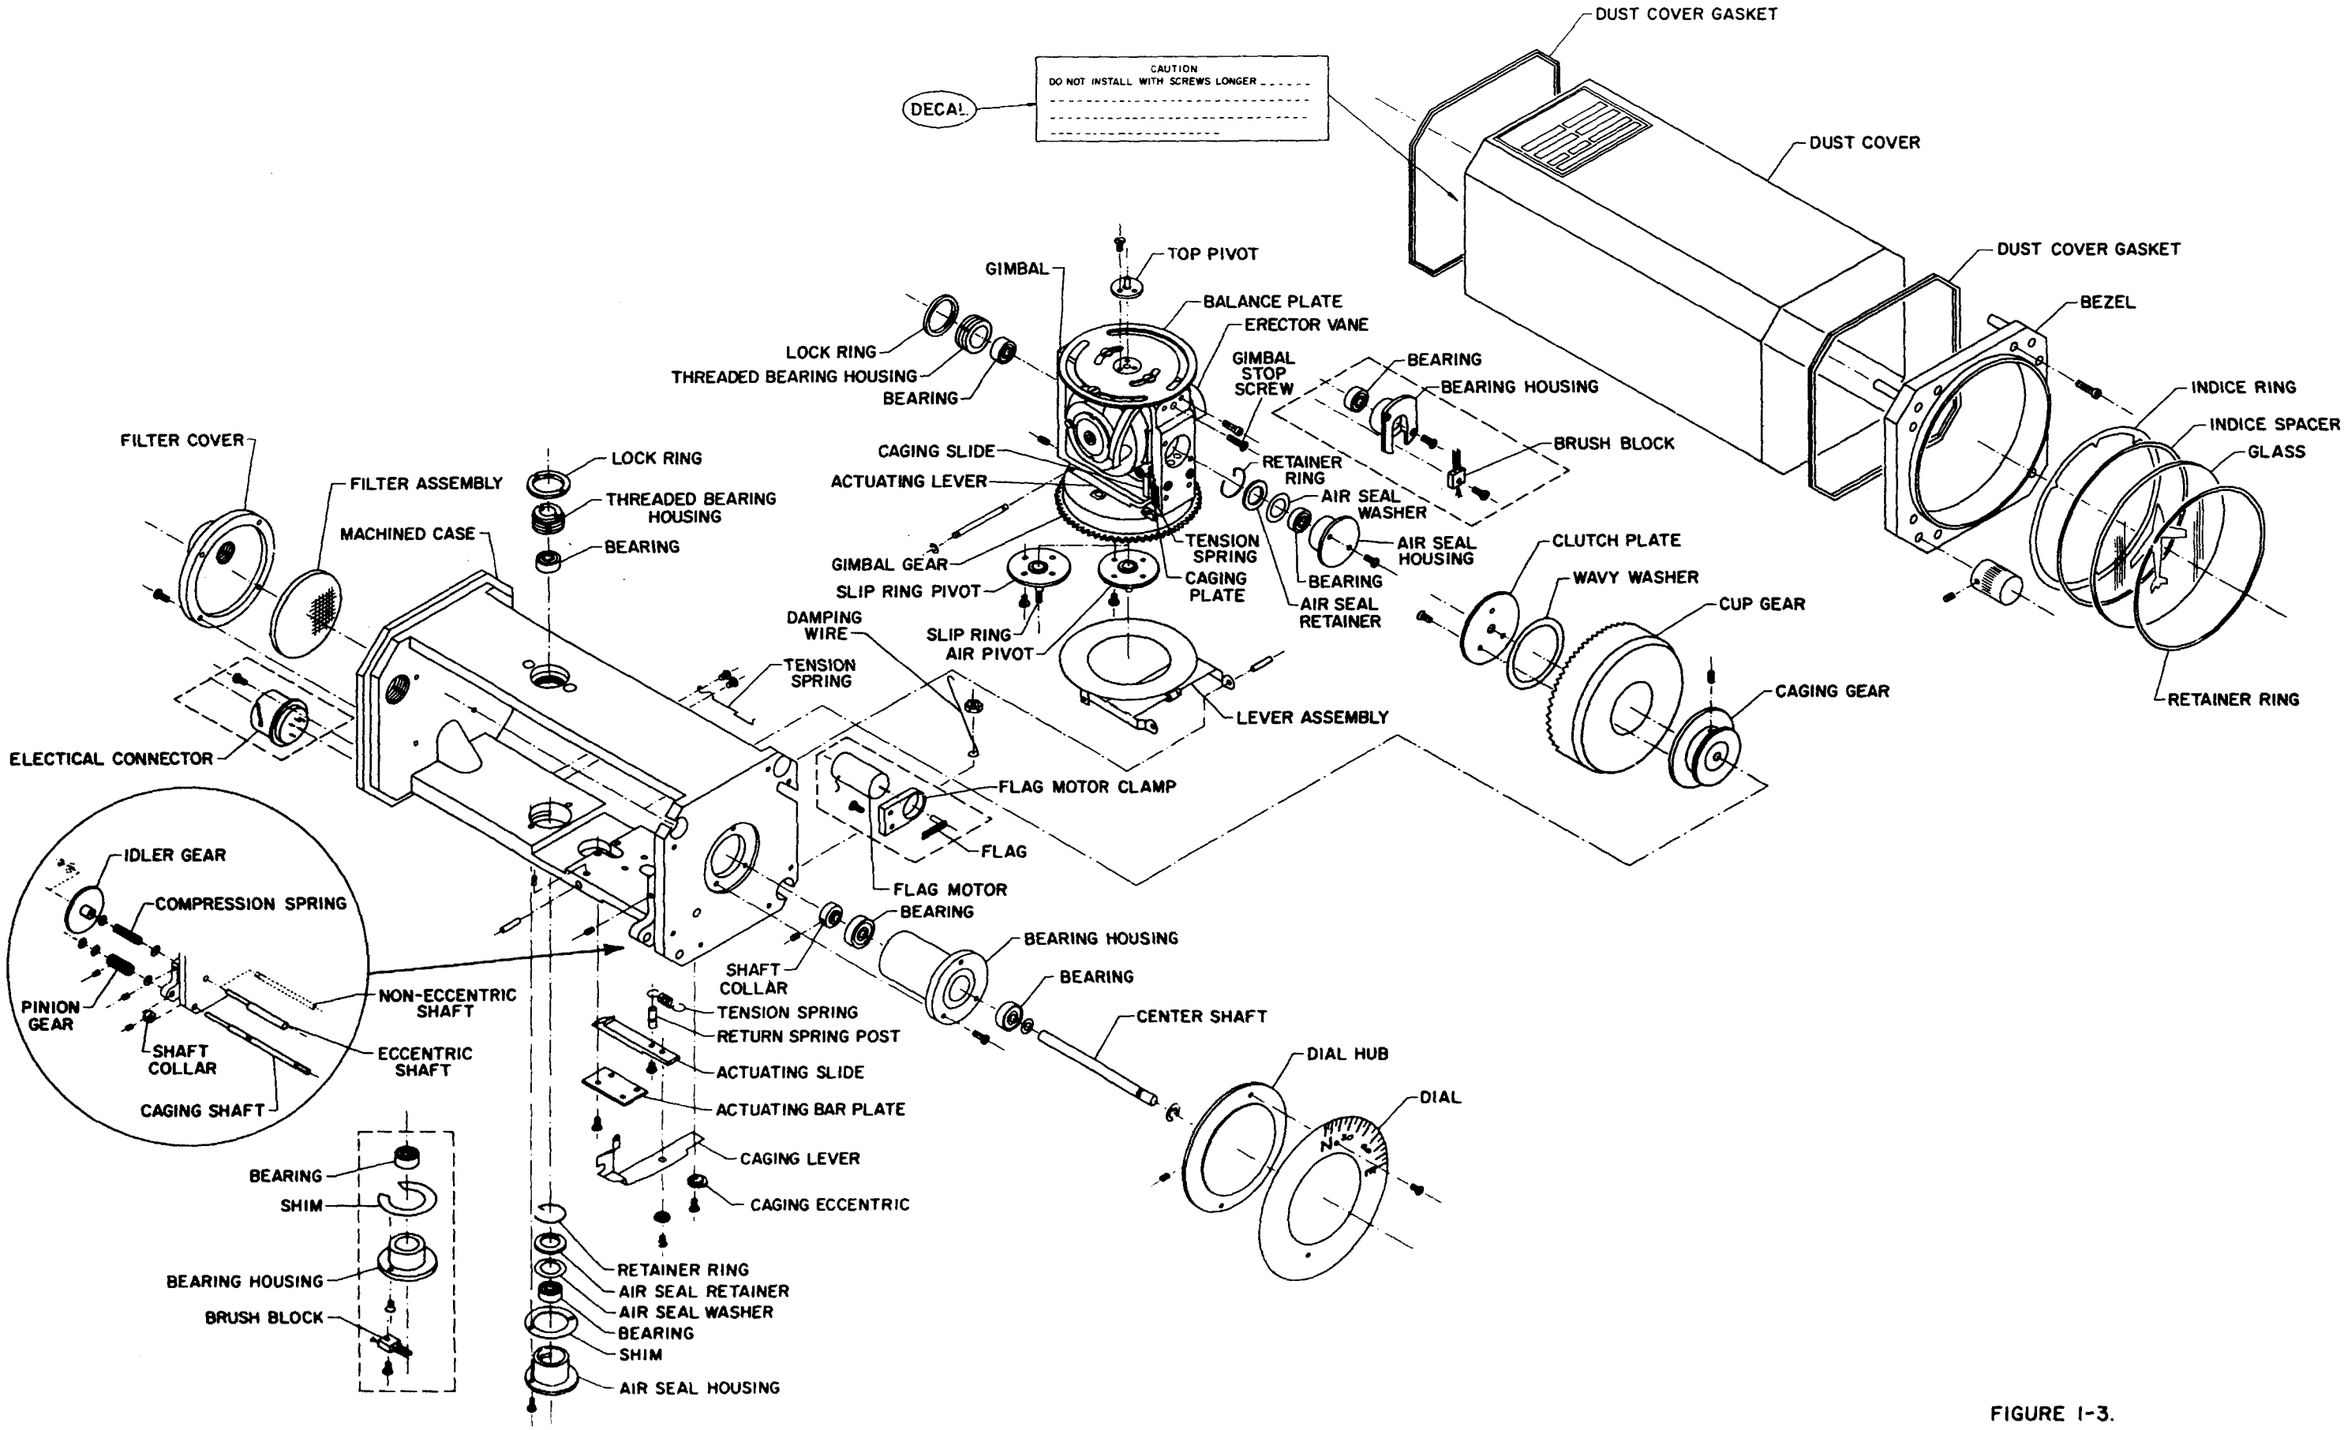

FIGURE 1-3.
BOTTOM-GEAR CONFIGURATION, EXPLODED VIEW

1.3 CONSTRUCTION DETAILS

1.3.1 General

The two basic instrument configurations, top-gear and bottom-gear, are shown in Figures 1-2 and 1-3, respectively. Each illustration is a composite exploded-view drawing of a vacuum instrument, with corresponding electric-instrument components such as the electrical connector, brush blocks, etc., enclosed in dashed areas near their actual location in the instrument. Electronic components, such as resistors, capacitors, diodes, etc., are omitted from both figures, and instead, are shown schematically in Figures 1-4 thru 1-7. In instruments where inverter or flag circuit components are mounted on a component board, refer to the appropriate schematic for parts identification.

The functional center of both vacuum and electric instruments is an accurately balanced, high-speed rotor which is mounted on precision bearings inside an enclosed rotor housing. The rotor housing is suspended from bearings mounted in the gimbal assembly and is free to pivot in the vertical plane up to $\pm 80^{\circ}$ from horizontal. In turn, the gimbal assembly is suspended from bearings mounted in the instrument case so that the over-all assembly has complete freedom of movement about its vertical axis.

1.3.2 Vacuum Instruments

A vacuum system capable of maintaining a suction of 4.5 to 4.7 inches of mercury is connected to the vacuum (outlet) port on the rear of the instrument. This port opens directly into the air sealed instrument case. Air, at normal atmospheric pressure, is then drawn through the AIR INLET filter and along a duct in the bottom of the instrument case to an air seal housing which contains the lower gimbal bearing. The air is then drawn through a duct in the gimbal to a second air seal housing which contains one of the bearings which supports the rotor housing. Air passes through the rotor housing pivot and is directed at the buckets in the rotor periphery, causing the rotor to revolve at very high speed.

Air is exhausted from the rotor housing through two horizontally opposed erector jets, and pushes against a semi-circular erector vane attached to the gimbal. The entire assembly acts as an air valve so that when the spin axis of the rotor is inclined from the horizontal position, one erector

1.3.2 Vacuum Instruments (Cont'd)

jet will be closed while the air being expelled from the opposite erector jet will exert torque about the vertical axis of the gimbal. This action precesses the spin axis of the rotor to the horizontal position so that the opposing jets are opened an equal amount and the gimbal is again stable.

1.3.3 Electric Instruments

Both ac and dc-operated units utilize a 115 vac, 400 Hz. electric rotor. DC-operated units employ a self-contained solid state inverter to produce the required ac drive voltage from the applied dc input.

The input voltage on ac units, and the internally produced drive voltage on dc units, is 115 vac, 400 Hz., single phase power. A capacitor, electrically connected between the two rotor windings, produces the two-phase effect necessary for operation of the rotor.

The rotor drive voltage is applied to leads inside the gimbal through a brush block and slip ring assembly on the bottom of the instrument case. From there, the drive voltage is transferred through a gimbal brush block and slip ring assembly to wiring which leads to the stator inside the rotor housing.

The rotor and hysteresis armature ring are mounted around the fixed stator on precision bearings so that when power is applied to the stator, the desired rotor movement is achieved.

Small impellers are affixed to the top and bottom of the spinning rotor to generate the air flow required in order to utilize the same self-erection system used in the vacuum-driven units.

1.3.4 AIM 200E Rotor and Flag Circuitry

A schematic diagram of the AIM 200E is shown in Figure 1-4A, along with an alternate flag circuit (B) which may also be encountered.

In circuit "A", diode CR1 is used for operation of the dc flag motor, and capacitor C1 produces the two-phase effect necessary for rotor operation. Both components are located in the rear of the instrument case.

With diode CR1 connected at point "1" (Figure 1-4A), the flag is retracted by a feedback voltage generated by the spinning rotor. Therefore, even if adequate power is supplied to the instrument, the warning

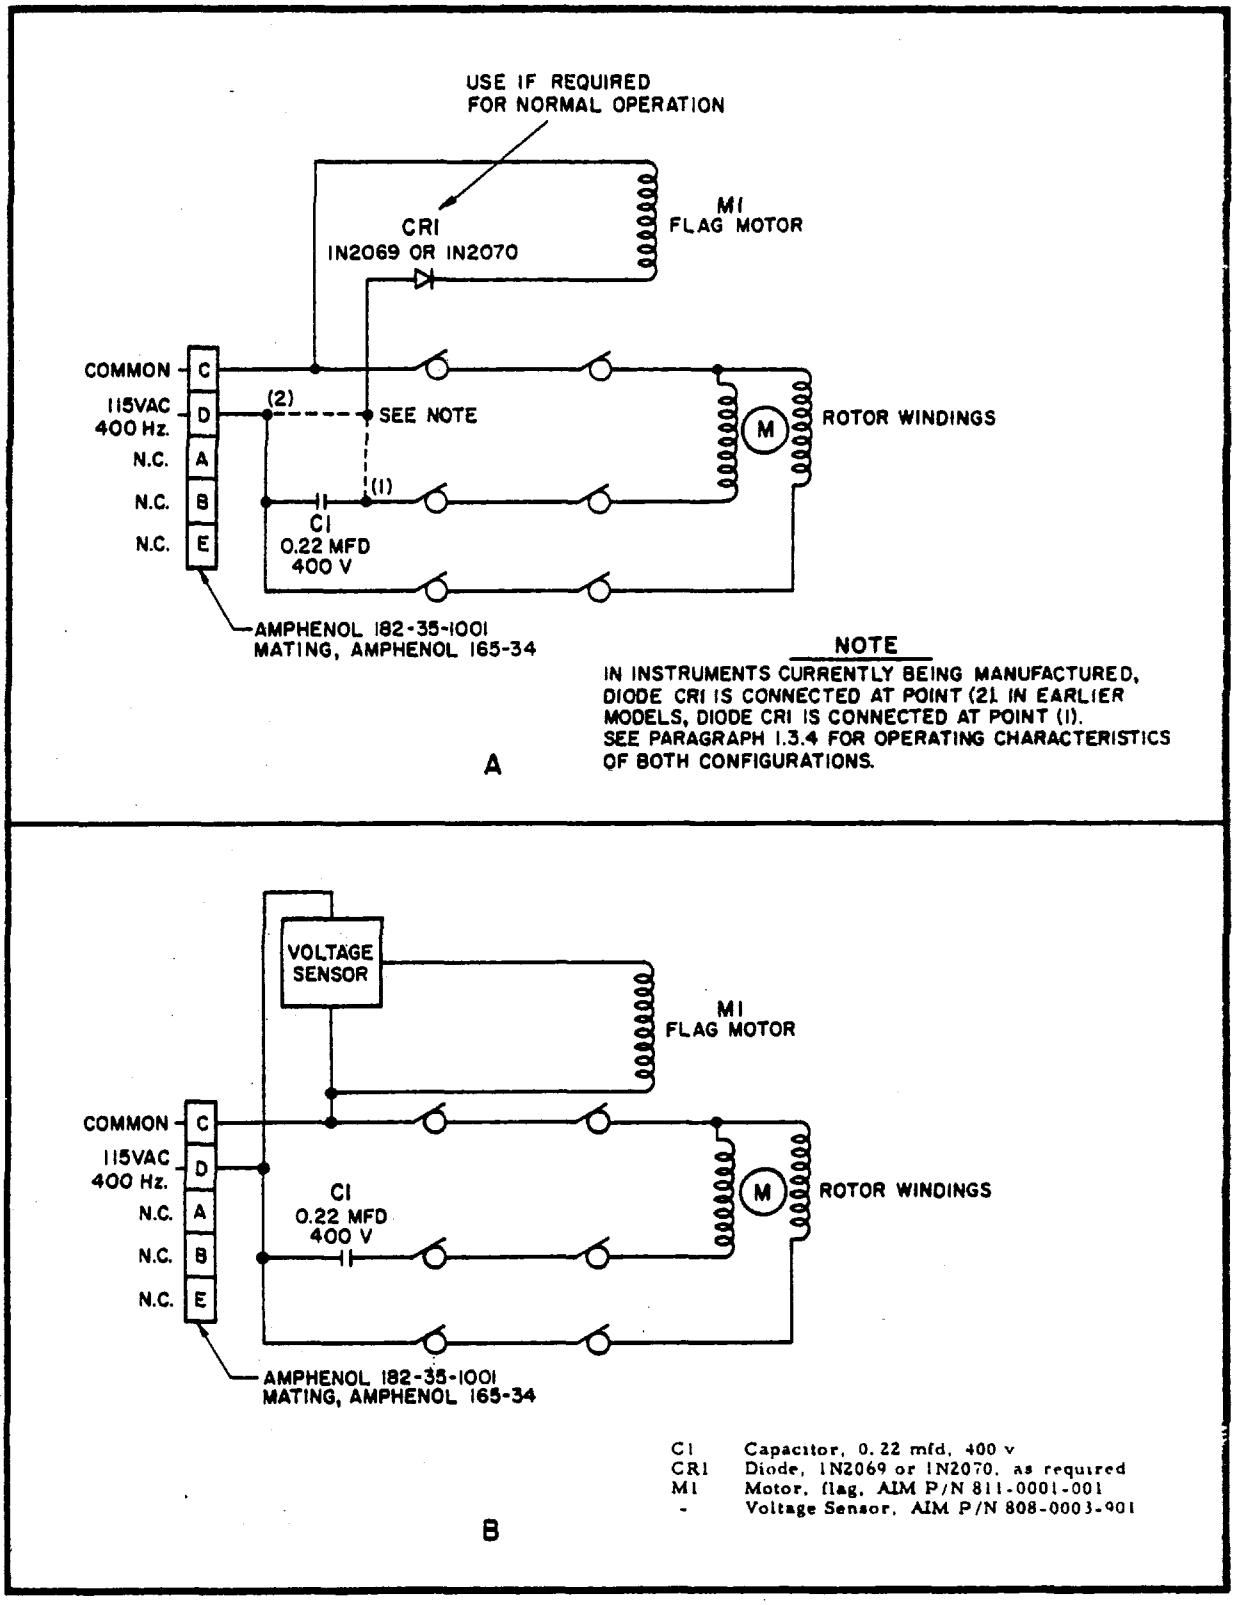

FIGURE 1-4. SCHEMATIC DIAGRAM, AIM 200E

1.3.4 AIM 200E Rotor and Flag Circuitry (Cont'd)

flag will not retract unless the rotor is functioning. With CR1 connected at point "2", the flag is retracted when the applied voltage reaches a pre-determined level, regardless of the rotor speed. Either circuit may be encountered during overhaul.

Alternate circuit "B" (Figure 1-4) includes a voltage sensor network which retracts the flag when the applied voltage reaches a pre-determined level, regardless of the rotor speed.

Operating specifications for circuits "A" and "B" are provided in the Test and Calibration procedures of Section 3.

1.3.5 AIM 200EDC Rotor, Flag, and Inverter Circuitry

A schematic diagram of the AIM 200EDC is shown in Figure 1-5. Choke L1 in the inverter input serves as a transient suppressor and also blocks squarewave noise from feeding back into the dc power source. Diode CR2 provides reverse polarity protection for the inverter circuitry.

CR3 is a 36 v Zener diode which protects against large positive over-voltages. Capacitor C2 stabilizes the dc input voltage to improve the output waveshape.

Circuit operation is sustained by the alternating polarity of feedback windings FB1 and FB2. The resultant output is a 115 vac, 400 Hz., single phase squarewave applied directly to the rotor windings. Capacitor C1 produces the two-phase effect necessary for rotor operation.

Diode CR1 produces the dc voltage required for operation of the flag motor. The output from the inverter alone is insufficient to actuate the flag. As the rotor speed increases, a feedback voltage developed across the rotor winding augments the inverter voltage and actuates the flag.

1.3.6 AIM 200DC (14) Rotor, Flag, and Inverter Circuitry

The AIM 200DC (14), schematic is shown in Figure 1-6A, along with an alternate flag circuit (B) which may also be encountered.

In circuit "A" choke L1 and capacitor C2 in the inverter input serve as a transient suppressor and also block squarewave noise from feeding back into the dc power source. Diode CR2 provides reverse polarity protection for the inverter circuitry.

C1	Capacitor, 0.22 mfd, 400 v
C2	Capacitor, 40 mfd, 35 v, electrolytic
CR1	Diode, 1N2070 or 1N4004, Motorola
CR2	Diode, 1N1115, Texas Instrument
CR3	Diode, Zener, 1N2991A, Texas Instrument

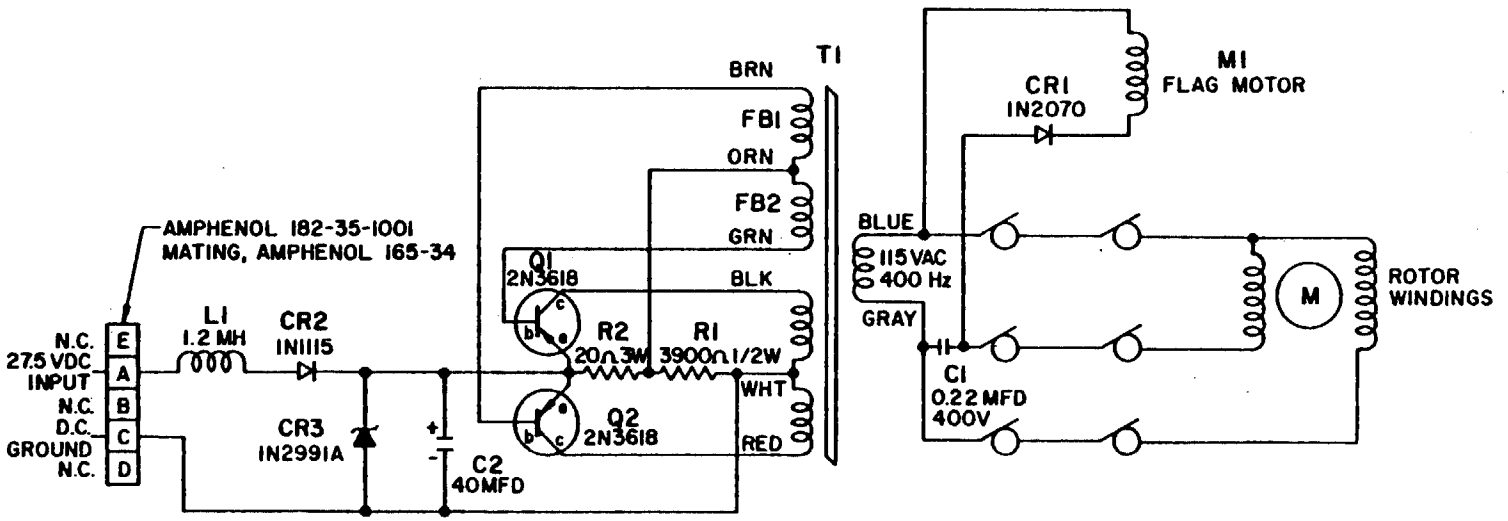

FIGURE 1-5. SCHEMATIC DIAGRAM, AIM 200EDC

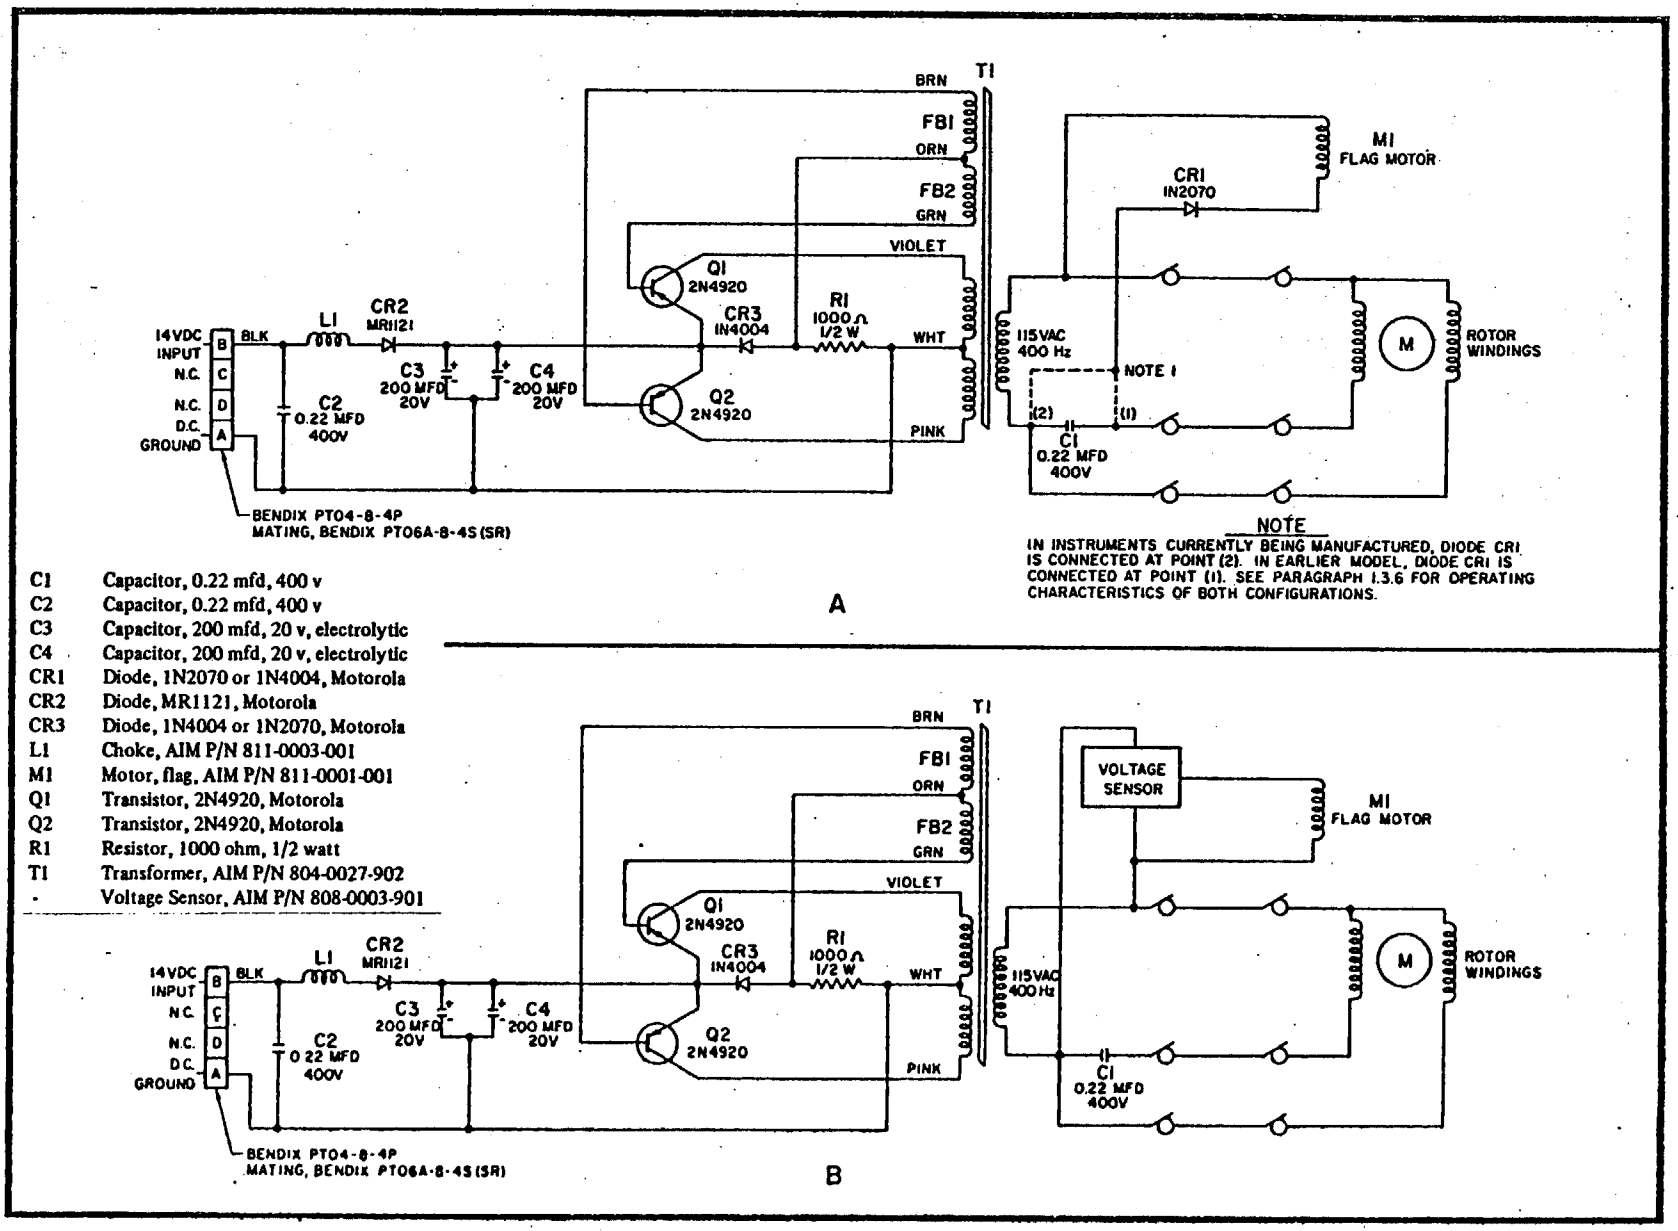
1.3.6 AIM 200DC (14) Rotor, Flag, and Inverter Circuitry (Cont'd)

Capacitors C3 and C4 stabilize the dc input voltage to improve the output waveshape, and also assist in suppression of transients. Diode CR3 prevents the voltage across either half of the primary winding from exceeding the supply voltage when the inverter switches from one conducting transistor to the other.

Circuit operation is sustained by the alternating polarity of feedback windings FB1 and FB2. The resultant output is a 115 vac, 400 Hz., single phase squarewave applied directly to the rotor windings. Capacitor C1 produces the two -phase effect necessary for rotor operation. Diode CR1 produces the dc voltage required for operation of the flag motor.

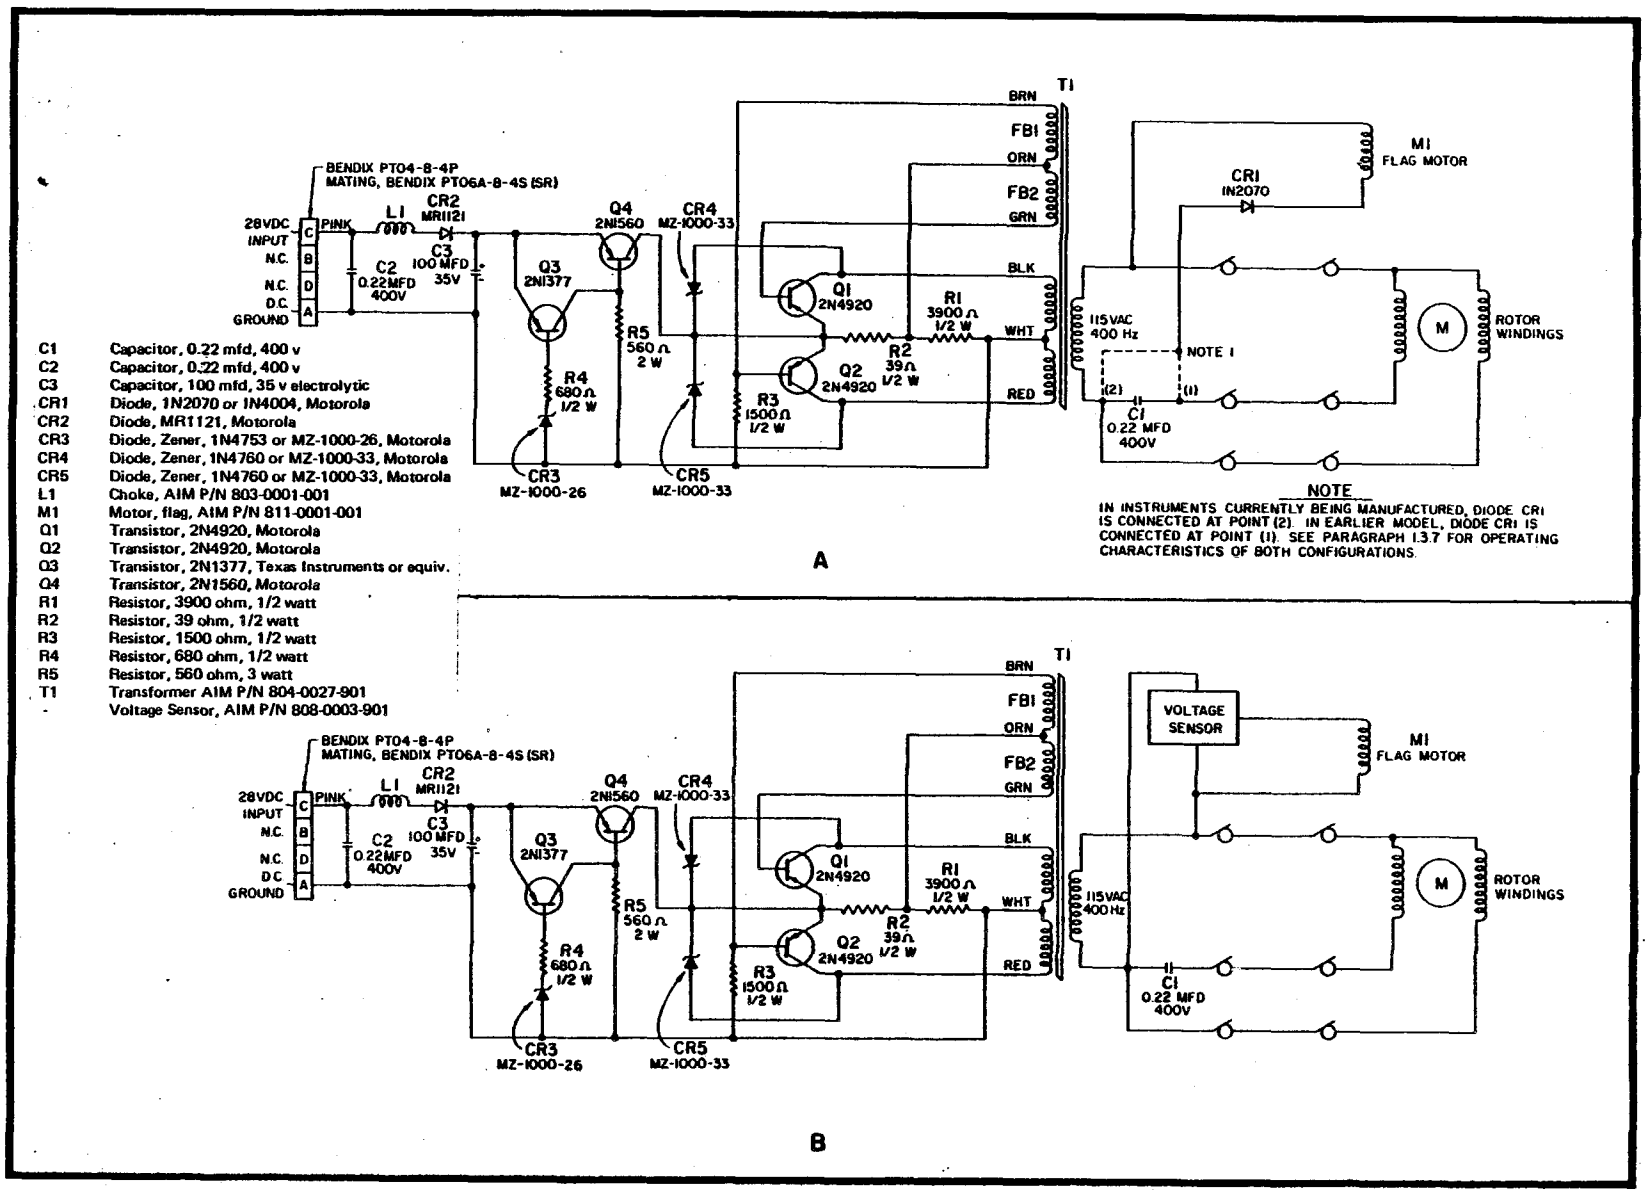
With diode CR1 connected at point "1" (Figure 1-6A), the flag is retracted by a feedback voltage generated by the spinning rotor. Therefore, even if adequate power is supplied to the instrument, the warning flag will not retract unless the rotor is functioning. With CR1 connected at point "2", the flag is retracted when the applied voltage reaches a pre-determined level, regardless of the rotor speed. Either circuit may be encountered during overhaul.



Alternate circuit "B" (Figure 1-6) includes a voltage sensor network which retracts the flag when the applied voltage reaches a pre-determined level, regardless of the rotor speed.

Operating specifications for circuits "A" and "B" are provided in the Test and Calibration procedures of Section 3.

1.3.7 AIM 200DC (28) Rotor, Flag, and Inverter Circuitry



The AIM 200DC (28) schematic is shown in Figure 1-7A, along with an alternate flag circuit (B) which may also be encountered. Choke L1 and capacitor C2 in the inverter input serve as a transient suppressor and also block squarewave noise from feeding back into the dc power source. Diode CR2 provides reverse polarity protection for the inverter circuitry.

Transistors Q3 and Q4 provide transient suppression and also protect against sustained over-voltage conditions at the input. Applied voltage levels in excess of 28 vdc cause Q3 to bias Q4 toward cutoff; thus, the voltage level at the emitters of Q1 and Q2 is maintained constant.

FIGURE I-7. SCHEMATIC DIAGRAM, AIM 200DC (28)

1.3.7 AIM 200DC (28) Rotor, Flag, and Inverter Circuitry (Cont'd)

Inverter circuit operation is sustained by the alternating polarity of feedback windings FB1 and FB2. Zener diodes CR4 and CR5 improve the output waveshape by eliminating the leading edge spike caused by the inductive collapse of the transformer primary during switching. The resultant output is a 115 vac, 400 Hz., single phase squarewave applied directly to the rotor windings. Capacitor C1 produces the two-phase effect necessary for rotor operation. Diode CR1 produces the dc voltage required for operation of the flag motor.

With diode CR1 connected at point "1" (Figure 1-7A), the flag is retracted by a feedback voltage generated by the spinning rotor. Therefore, even if adequate power is supplied to the instrument, the warning flag will not retract unless the rotor is functioning. With CR1 connected at point "2", the flag is retracted when the applied voltage reaches a pre-determined level, regardless of the rotor speed. Either circuit may be encountered during overhaul.

Alternate circuit "B" (Figure 1-7) includes a voltage sensor network which retracts the flag when the applied voltage reaches a pre-determined level, regardless of the rotor speed.

Operating specifications for circuits "A" and "B" are provided in the Test and Calibration procedures of Section 3.

1.4 SPECIFICATIONS

Operating Limits	Azimuth; 360° Pitch and Roll; 360° freedom through controlled precession
Drift	Maximum of 3° in 10 minutes for any heading when subjected to roll, pitch, and yaw oscillations with an amplitude of ± 3 degrees about each axis, at a frequency of 5 to 7 oscillations per minute.
Operating Temperature Range	-30°C (-22°F) to +50°C (+122°F)
Rotor Speed	Vacuum; 24,000 rpm, nominal Electric; 23,500 rpm, nominal

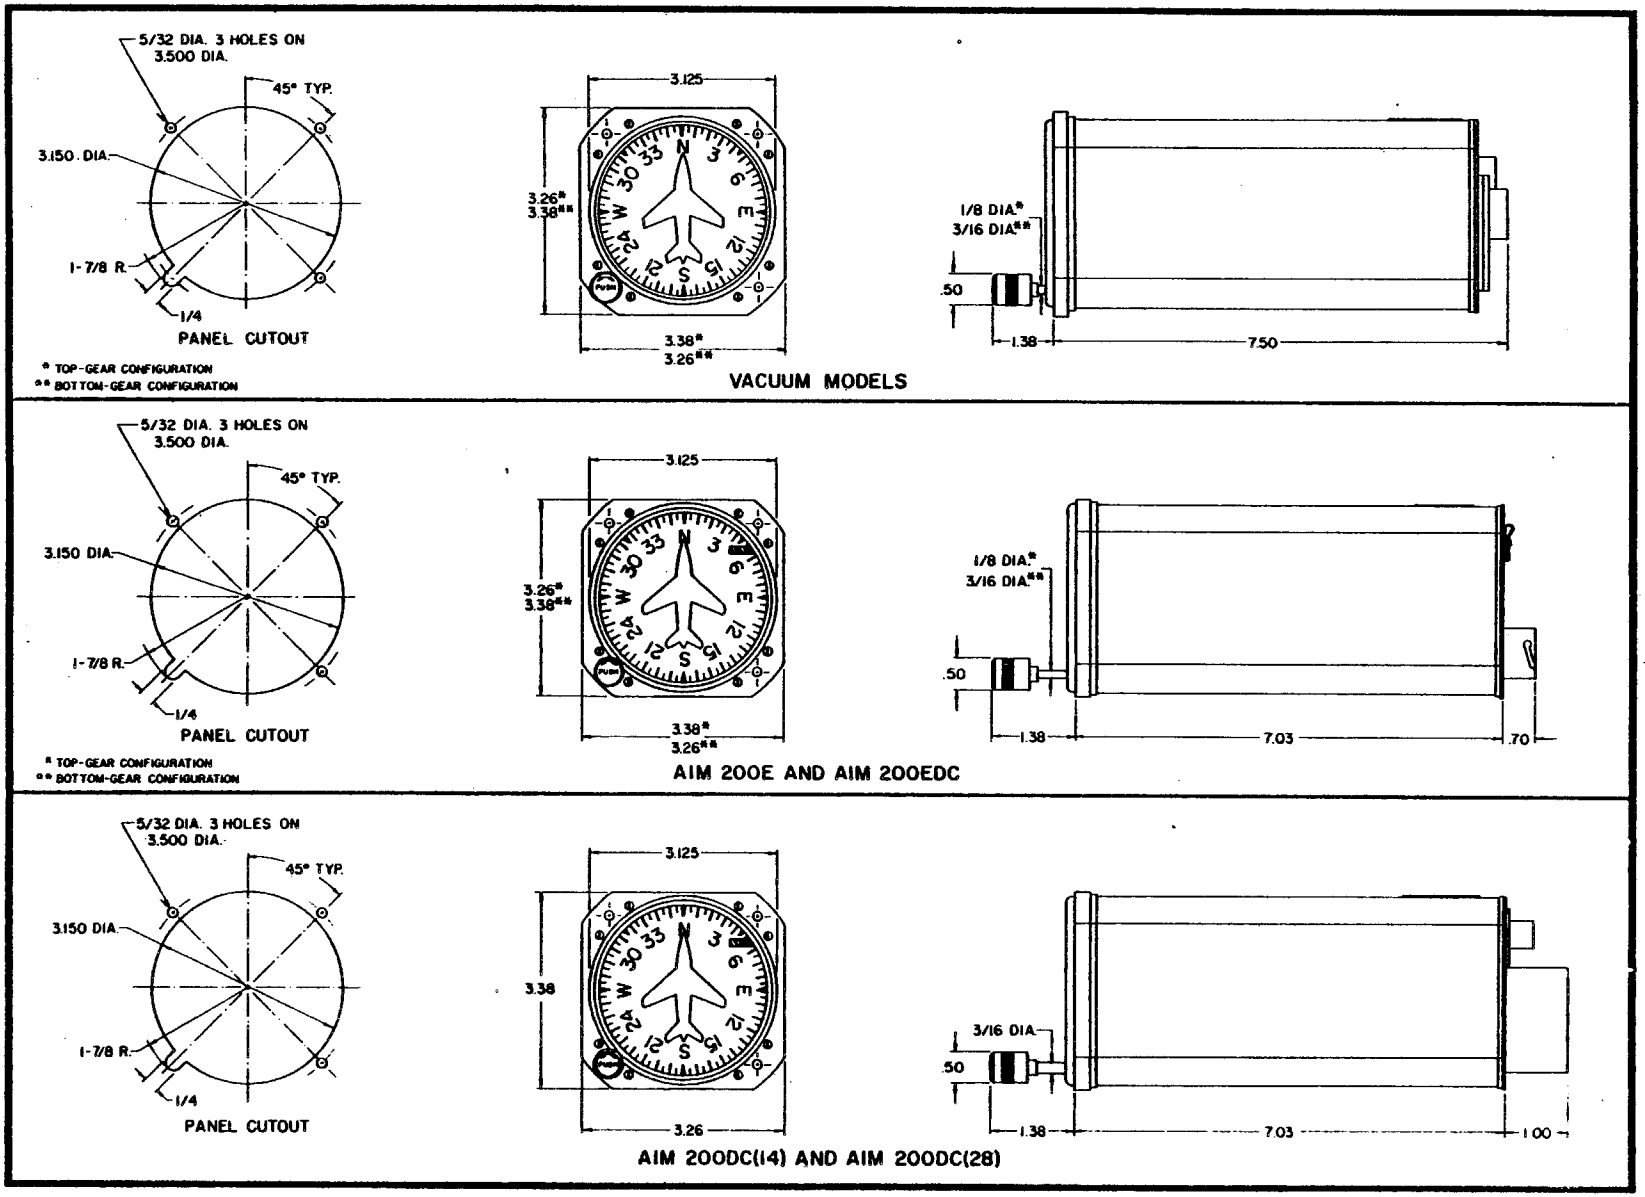

FIGURE I-8. TYPICAL OUTLINE DIMENSIONS

1.4 SPECIFICATIONS (Cont'd)

Heading Indicator	Vertical card presentation with matte white 30° primary markings, 10° secondary markings, and 5° tertiary markings.
Mounting	Standard 3-1/8 in. cutout in shock-mounted panel.
Case Size	See outline drawing, Figure 1-8.
Weight	2.7 lbs. nominal
FAA Specification	TSO-C5c
Vacuum Units Only	
Vacuum Required	4.5 to 5.2 inches of mercury
Air Consumption	1.7 cu. ft./min., nominal
Electric Units Only	
Power Requirements	
AIM 200E	115 vac, 400 Hz., single phase 115 ma nominal running current 140 ma nominal starting current
14 vdc Instruments	14 vdc, 1.0 to 1.4 amps
28 vdc Instruments	28 vdc, 0.5 to 0.7 amps

1.5 GYRO HANDLING*

High gyro removal rate can often be directly related to rough or improper handling. Gyros are delicate instruments and cannot withstand the shock of being dropped, jarred, or struck by other pieces of equipment.

To preclude damage to the gyro, it should be transported to and from the aircraft in its original shipping container. When this procedure is impractical, the gyros should be hand-carried with special care.

Gyros should never be removed while they are running or spinning down. A gyro normally operates between 20,000 to 24,000 rpm and takes 10 or more minutes to run down. If a gyro is removed while it is running and if it is tilted more than 90 degrees, it will develop a gimbal lock. The gimbal will tumble and start to spin. If gimbal lock occurs while the gyro is turning, the gimbal may spin fast enough to damage the gimbal bearings.

*Reprinted from the July-August, 1966 issue of Aviation Mechanics Bulletin published by Flight Safety Foundation, Inc.

1.5 GYRO HANDLING (Cont'd)

Even though a gyro has malfunctioned and is being removed from the aircraft, the gyro must be handled with the same respect due a new one. It is easy to think of a gyro that has malfunctioned as one destined for the scrap pile. This is not so. It can probably be fixed. It is therefore very important that proper handling procedures also be employed during removal.

Gyro handling techniques are summarized as follows: (1) Keep the gyro in the original shipping container as long as possible or provide a well padded, shock-absorbent container for transporting the gyro. (2) Wait at least 10 minutes after removing electrical or vacuum power from the aircraft and/or gyro before removing gyro. Do not remove a gyro while it is running. (3) Lift gyro from the base and carry in an upright position. (4) Handle the gyro with care at all times and avoid subjecting it to shock or vibration.

SECTION 2
OVERHAUL

2.1 GENERAL

Overhaul may be required due to a specific malfunction or merely as a routine step in a periodic maintenance program. Regardless of the reason, the disassembly and overhaul procedures in this section should be closely followed.

Each instrument consists of several distinct subassemblies which may be separately disassembled, cleaned, reassembled and tested. As each assembly is disassembled, the location of each component should be noted so that it can be replaced in the same position. This is particularly true of bearings, pivots, or jewels. Although the same bearing type may be used in several positions, the bearings are designed to provide different amounts of radial play according to their use and location within the instrument.

When handling the circular indicator card, care should be taken to avoid soiling the dial markings. All bearings, pivots, and jewels should be handled with assembly tweezers to avoid contamination. Iridited, oxided, or passivated parts must be secured in final adjusted position by "Glyptal" (G. E. trademark). Solvents used for cleaning must be high grade, such as Chlorothene-Nu (Dow Chemical Co.).

2.2 TOOLS REQUIRED

2.2.1 General

Although the instruments can be completely disassembled and reassembled using only the standard instrument-shop handtools listed in paragraph 2.2.2, special attention should be given to the additional equipment required in paragraph 3.2. This equipment, although not directly used in assembling or disassembling the instruments, must be available to properly calibrate and check-out the instruments' operating characteristics after overhaul.

Construction of the spanner wrenches listed under paragraph 2.2.2 (g) is shown in Figure 2-1. Spanner wrench "B" is used in removing the threaded bearing housing from the gimbal assembly. Spanner "A" is used

2.2.1 General (Cont'd)

in conjunction with spanner "B" to simultaneously hold the lock ring (some models only) in place around it. On bottom-gear instruments, spanners "A" and "B" are also used to remove and install the gimbal bearing housing on top of the instrument.

Spanner "C" is used in removing the threaded housings from each end of the 34B and R3H rotor housings, and in removing the lock rings securing the threaded housings in place.

2.2.2 Handtools

a. Assembly tweezers
b. Eye loupe
c. Selection of small screwdrivers
d. No. 4 and No. 8 Allen wrenches
e. No. 2 and No. 4 Bristol spline wrenches
f. 1/4 inch and 3/16 inch open-end wrenches
g. Spanner wrenches of Figure 2-1

2.2.3 Expendable Supplies

The following expendable supplies should be available before attempting to overhaul the instruments:

a. 1/2 gallon of Chlorothene-Nu (Dow Chemical Co.)
b. Watch paper
c. Blue Glyptal (General Electric Co.)
d. Red Locktite

2.3 DISASSEMBLY PROCEDURES

2.3.1 General

Before proceeding with disassembly of any component, the degree of wear, end play, backlash, and general physical appearance must be checked and noted as an aid in reassembly.

During disassembly, extreme care must be used in the removal of any component. Use of proper tools is important to prevent damage by scratching or marring. Many of the parts are secured with Glyptal and it will be necessary to dissolve the Glyptal before removing these

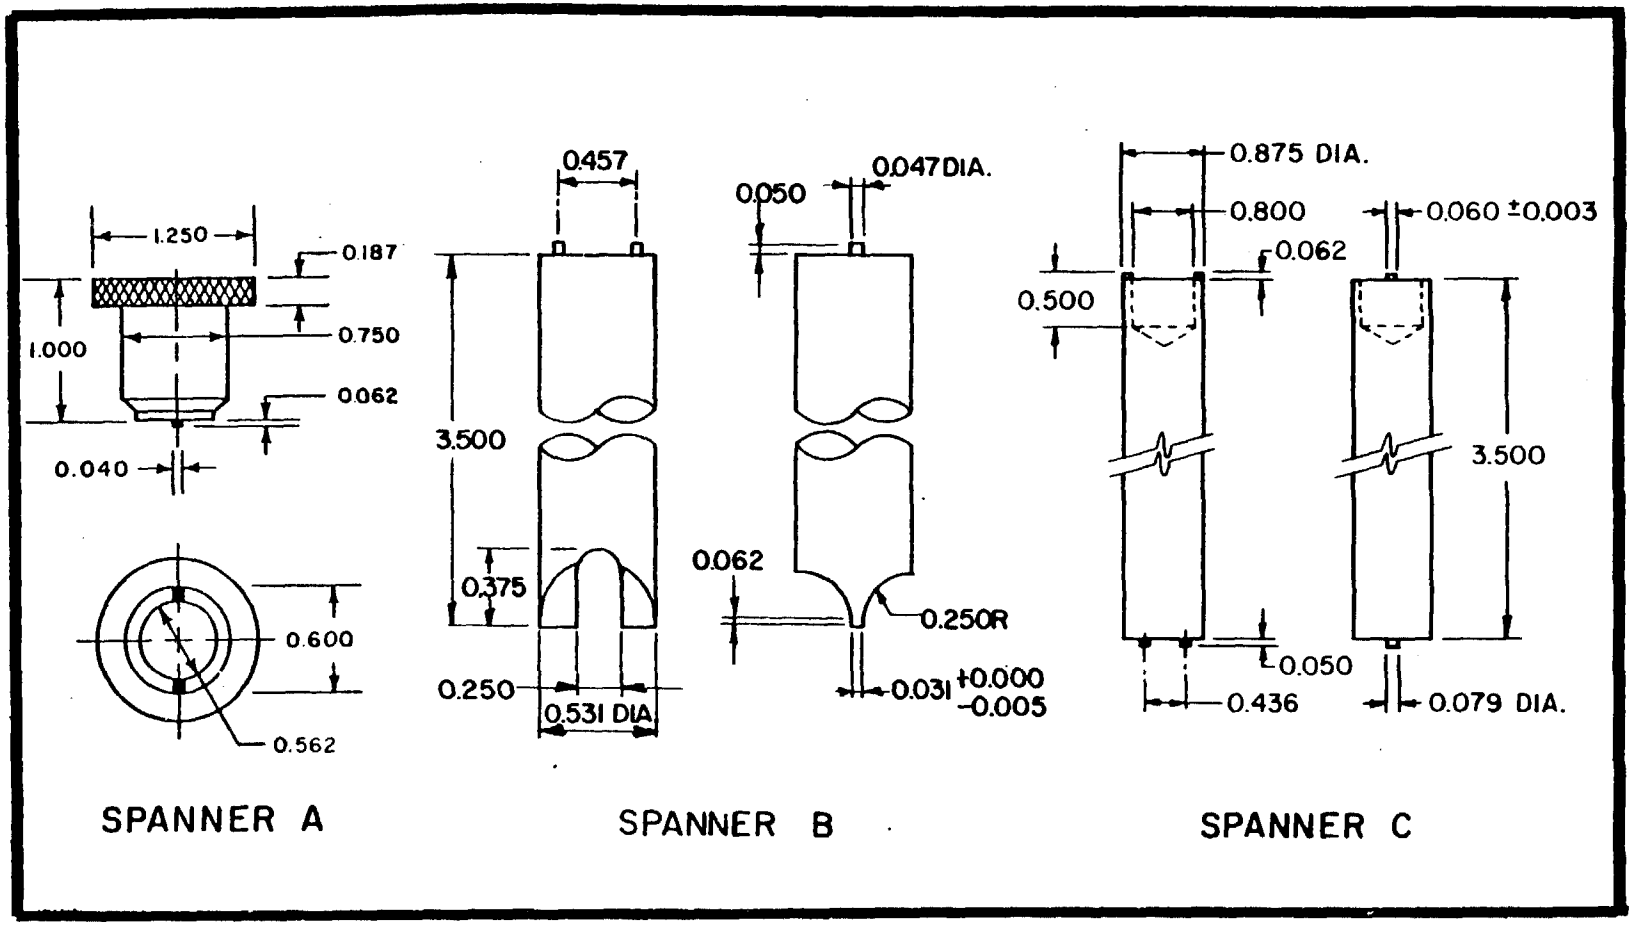

FIGURE 2-1. CONSTRUCTION OF SPECIAL TOOLS

2.3.1 General (Cont'd)

parts. Screws or other attaching parts must be carefully identified during disassembly for correct replacement during reassembly.

Due to delicate rebalancing required, and the precision parts involved, disassembly and overhaul of the rotor and rotor housing assembly is not recommended. Should the rotor become defective and fail to meet the performance requirements set forth in Section 3, return the used rotor housing and pivot assembly to AIM for an exchange discount on a new replacement assembly.

If overhaul of the rotor should become necessary in the field, specific instructions are provided in paragraph 2.6.

2.3.2 Case Access

1. Remove the PUSH knob by loosening the #4-40 spline setscrew which secures the knob to the shaft. A #4 Bristol spline wrench is provided on the rear of the case for this purpose.

NOTE

The #4 Bristol spline wrench is intended to facilitate the rapid installation and removal of the unit from an instrument panel. It should not be used to remove screws inside the instrument due to the possibility of paint flakes contaminating the unit. Instead, an unpainted wrench should be used.

2. Remove the 7 screws securing the bezel assembly to the instrument case. One of the mounting-screw recesses is filled with sealing wax which must be removed. Care should be taken to insure that the front gasket remains in position on the bezel when the bezel is removed. This is done to minimize the possibility of contaminating the unit with paint flakes from the rubber gasket.
3. Carefully remove the dust cover, making sure that the rear gasket remains in position on the rear panel of the instrument housing.
4. When the dust cover has been removed, slip the rear gasket over the rear panel and away from the unit. The front and rear gaskets and the dust cover should be taken to a remote area and thoroughly cleaned of all paint and foreign matter. The gaskets can be cleaned

2.3.2 Case Access (Cont'd)

by stretching until the paint cracks and then scraping the flakes away. The same gaskets can be reused when the dust cover is again installed.

2.3.3 Removal of Gimbal Assembly

1. Type 1, Figure 2-2
    1. Place the instrument in its normal position with the PUSH knob in the lower left corner of the instrument front.
    2. Remove three flat head screws and remove the upper gimbal-bearing housing from the top of the instrument.
    3. Shims are sometimes used inside the bearing housing to reduce gimbal end-play. If shims have been used, retain for use during reassembly.
    4. Turn the instrument over, being careful to avoid damage to the gimbal.
    5. On electric instruments, carefully remove the brush block assembly from the bottom of the case.
    6. Remove the two screws securing the lower bearing housing in place. On vacuum instruments, the housing may contain alignment shims which are used to align the air passage in the housing with the air passage in the instrument case. If shims are included, they should be retained for use during reassembly.
    7. Removal of the lower bearing housing permits access to the two screws securing the pivot to the bottom of the gimbal. When the pivot is lifted into the bearing housing recess, the entire gimbal assembly may be removed.
    8. Disassembly of the upper gimbal-pivot and clutch assembly is not recommended unless specific replacement of component parts is required. If disassembly becomes necessary, proceed as follows:

       Remove the three screws from the gimbal pivot assembly at the top of the gimbal. During disassembly, notice the order in which the gimbal pivot, the washer, the gimbal gear, and the friction shim are removed. First comes the gimbal pivot, then the spring washer, the gimbal gear, and then the friction

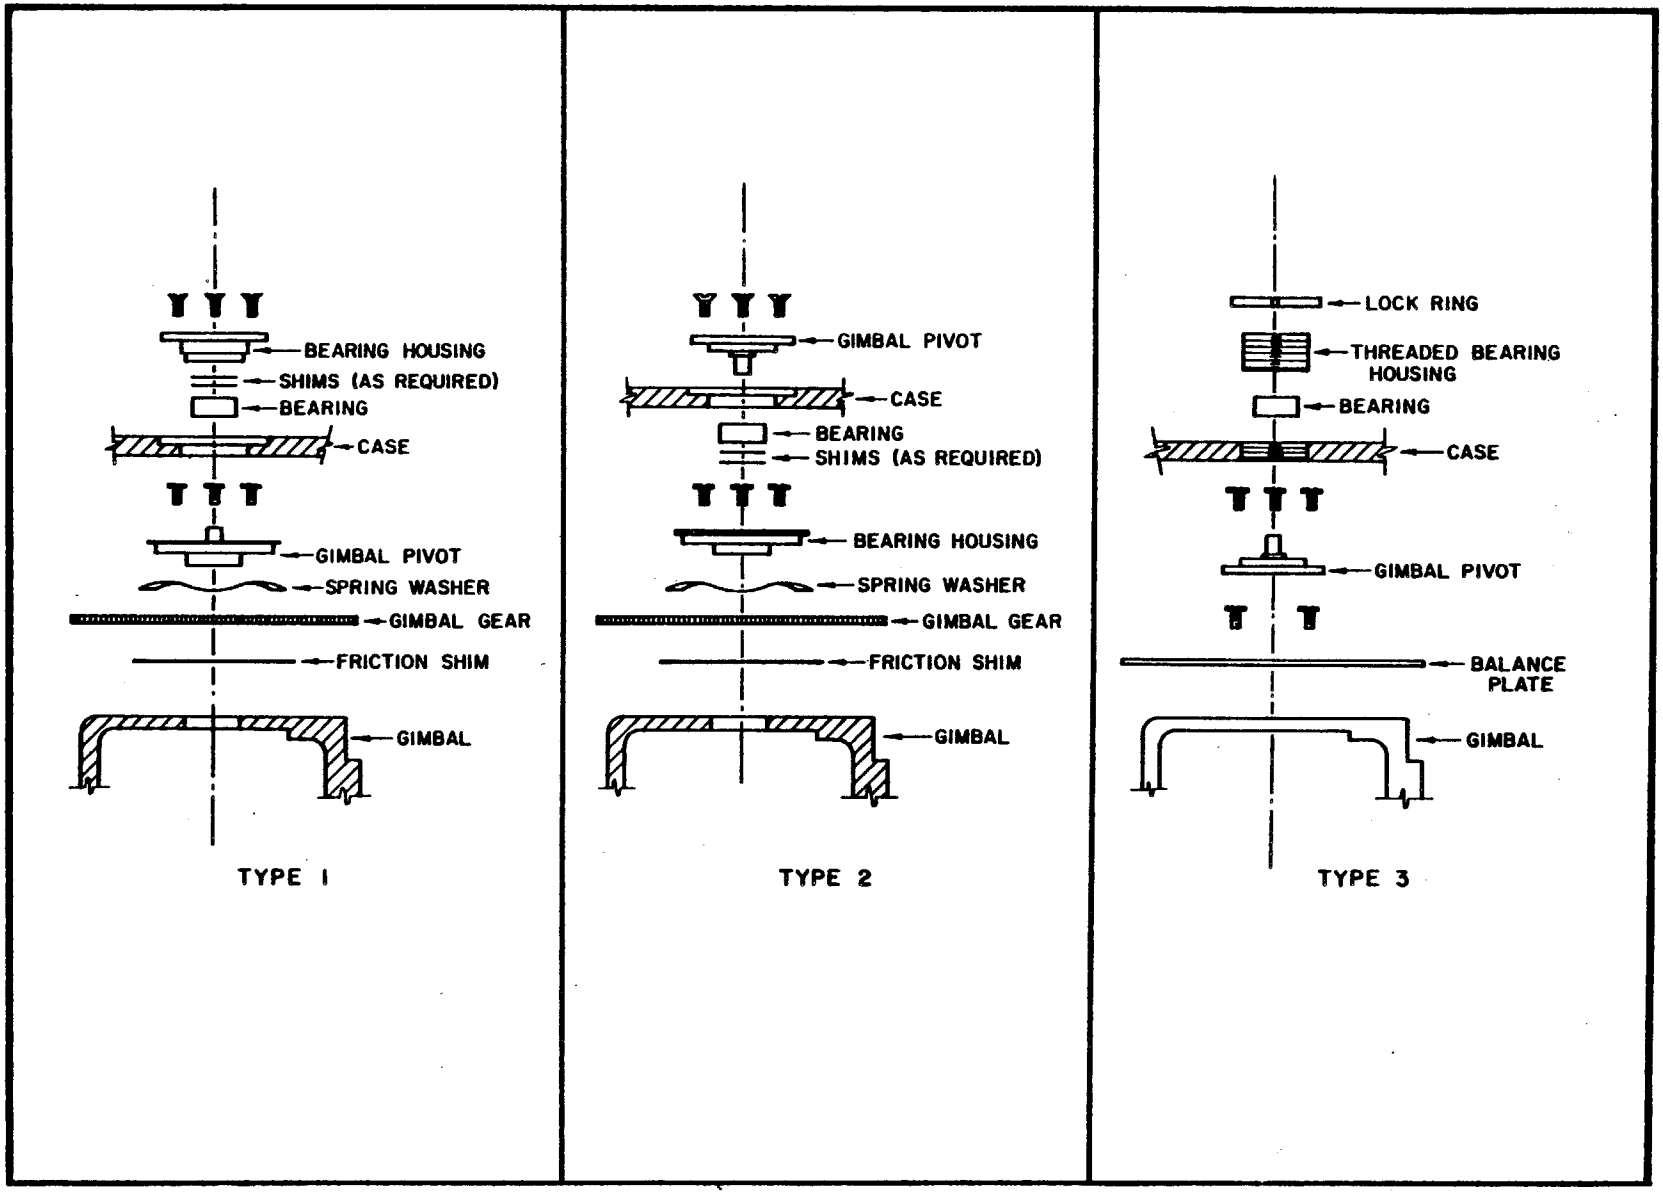

FIGURE 2-2. PIVOT DESIGN VARIATIONS, TOP OF GIMBAL

2.3.3 Removal of Gimbal Assembly (Cont'd)

1. Type 1, Figure 2-2 (Cont'd)

   shim which is mounted between the gimbal gear and the gimbal.

2. Type 2, Figure 2-2

   1. Place the instrument in its normal position with the PUSH knob in the lower left corner of the instrument front.
   2. Remove three flat head screws and remove the upper gimbal-pivot from the top of the instrument.
   3. Remove the bearing from the housing on top of the gimbal. Shims are sometimes used inside the bearing housing to reduce end-play. If shims have been used, retain for use during reassembly.
   4. Turn the instrument over, being careful to avoid damage to the gimbal.
   5. On electric instruments, carefully remove the brush block assembly from the bottom of the case.
   6. Remove the two screws securing the lower bearing housing in place. On vacuum instruments, the housing may contain alignment shims which are used to align the air passage in the housing with the air passage in the instrument case. If shims are included, they should be retained for use during reassembly.
   7. Removal of the lower bearing housing permits access to the two screws securing the pivot to the bottom of the gimbal. When the pivot is lifted into the bearing housing recess, the entire gimbal assembly may be removed.
   8. Disassembly of the bearing housing and clutch assembly at the top of the gimbal is not recommended unless specific replacement of component parts is required. If disassembly becomes necessary, proceed as follows:

      Remove three screws securing the bearing housing to the top of the gimbal. During disassembly, notice the order in which the bearing housing, the spring washer, the gimbal gear, and the friction shim are removed. First comes the bearing housing, then the spring washer, the gimbal gear, and then the friction

2.3.3 Removal of Gimbal Assembly (Cont'd)

2. Type 2, Figure 2-2 (Cont'd)

shim which is mounted between the gimbal gear and the gimbal.

3. Type 3, Figure 2-2

1. Place the instrument in its normal position with the PUSH knob in the lower left corner of the instrument front. Remove the threaded upper gimbal-bearing housing from the top of the instrument case.
2. Removal of the upper bearing permits access to the three screws securing the pivot to the top of the gimbal. Remove these screws and lift the pivot through the opening.
3. Turn the instrument over, being careful to avoid damage to the gimbal.
4. On electric instruments, carefully remove the brush block assembly from the bottom of the case.
5. Remove the two screws securing the lower bearing housing in place. On vacuum instruments, the housing may contain alignment shims which are used to align the air passage in the housing with the air passage in the instrument case. If shims are included, they should be retained for use during reassembly.
6. Removal of the lower bearing housing permits access to the two screws securing the pivot to the bottom of the gimbal. When the pivot is lifted into the bearing housing recess, the entire gimbal assembly may be removed.

2.3.4 Removal of Rotor Housing

1. Loosen the two #2-56 Bristol setscrews holding the erector vane to the gimbal and remove the erector vane. Also loosen the binder head stop screw enough to permit 360° rotation of the rotor housing.
2. On electric instruments, carefully remove the brush block from the side of the gimbal.
3. Remove two screws and remove the bearing housing on the air seal or brush block side of the gimbal.
4. Remove two screws securing the pivot to the side of the rotor.

2.3.4 Removal of Rotor Housing (Cont'd)

5. Remove the threaded bearing housing from the opposite side of the gimbal. On some models, the housing is secured in place with a lock ring. On other models, the housing port is slotted and a clamping screw through the gimbal frame secures the housing in position.
6. Remove three screws and lift the rotor pivot off the rotor housing and out through the threaded opening.

2.3.5 Disassembly of Gear Train, Top-Gear Configuration (Figure 1-2)

1. Remove two #2-56 setscrews holding the indicator card to the main (horizontal) drive shaft.

NOTE

Care should be taken to avoid soiling the dial markings.

2. Loosen the setscrew in the intermediate spur gear. Slide the gear down the shaft so that it no longer engages with the gimbal gear.
3. Spin the gear train slowly and check for freedom and smoothness of rotation.
4. The intermediate shaft is suspended in two precision bearings. A threaded bearing housing at the top of the shaft permits adjustment of the preload on the shaft bearings. On some models, the threaded housing is held in place with a lock nut; on other models the housing is secured with Glyptal. The lock nut must be loosened or the Glyptal dissolved before adjustment can be made.

   The threaded housing is mounted in an eccentric which permits adjustment of the gear mesh between the intermediate gear and the gimbal gear. If desired, the eccentric may be removed without disturbing the preload adjustment.

   With the eccentric removed, the intermediate shaft and its associated gears may easily be lifted from the instrument. Care should be taken that the position of the two gears on the intermediate shaft be noted to insure correct replacement. Unless replacement or adjustment of the bevel gear is required, do not loosen the setscrew holding the gear to the shaft. This simplifies reassembly and eliminates the possibility of reinserting the shaft backwards.

2.3.5 Disassembly of Gear Train, Top - Gear Configuration (Cont'd)

5. The card shaft may be removed by first removing the two screws securing the front bearing in the face of the instrument case.
6. By pressing the combination spur/bevel gear toward the front, the main bearing at the front of the shaft will be pushed out of the case.
7. If the spur/bevel gear and the associated shaft collars are to be removed, note their approximate position along the shaft. Also notice that the flanged face of each collar is toward its respective bearing.
8. When the spur/bevel gear and the shaft collars are loosened on the shaft, the main bearing which supports the rear of the shaft may easily be removed.
9. Removal of the rear bearing permits access to the bearing housing at the base of the intermediate shaft. The housing is secured with Glyptal and a solvent must be used before removal is attempted. By inserting an L-shaped bar into the opening created by removal of the rear bearing, the housing at the base of the intermediate shaft may be easily removed with a slight upward pressure. In turn, the bearing can be removed from the housing in the same way, by pushing through the opening in the bottom and forcing the bearing out of the housing.
10. The small piece of piano wire attached to the case is designed to ride against the card shaft and to damp out any oscillations in the dial due to excessive play in the gear mechanism. If the wire is to be removed, notice its position so that it may be properly re-installed.

2.3.6 Disassembly of Gear Train, Bottom-Gear Configuration (Figure 1-3)

1. Loosen the two #2-56 setscrews securing the dial to the card shaft.

NOTE

Care should be taken to avoid soiling the dial markings.

2. Loosen the three setscrews on the caging gear. Slide the combination cup-gear and caging gear assembly off the card shaft.
3. Loosen one setscrew and remove the shaft collar from the rear of the card shaft.

2.3.6 Disassembly of Gear Train, Bottom-Gear Configuration (Cont'd)

4. Slip the card shaft out through the front of the instrument case.
5. The card-shaft bearing housing contains two bearings, set in a recess in each end. The rear bearing can be removed by inserting a small rod through the front opening. The front bearing may be removed by reversing the procedure and inserting the rod from the rear. The housing may be removed by removing the three retaining screws on the front, then pressing the housing out through the front of the case.

2.3.7 Disassembly of Caging Mechanism

Repair of the caging mechanism should seldom be necessary, and only occasional adjustment should be required. Before proceeding with any repairs or adjustments, the following points should be considered.

In removing the caging shaft, notice the order in which the single metal washer and the two nylon washers are installed. From the rear of the shaft, first comes the metal washer, then a nylon washer, then the pinion gear, then another nylon washer nearer the front. Special care should be taken to avoid loss of these parts during disassembly.

Before loosening the caging eccentric on the bottom of the case, notice its approximate position. The purpose of this eccentric is to permit adjustment of the caging mechanism so that the rotor will be 80 to 90% caged when the idler gear engages the spur gear on the card shaft. Observing the position of the eccentric prior to disassembly will permit reassembly with a minimum of trial and error adjustment.

An additional adjustment of the caging mechanism is possible on some bottom-gear instruments. On these instruments, the idler gear is mounted on an eccentric shaft which may be rotated as required to adjust the gear mesh with the caging gear.

2.3.8 Inspection of Air Seal Housing Assemblies, Vacuum Units Only

A typical air seal housing is shown in Figure 2-3. It consists of the basic housing, the bearing assembly, the air seal washer, the air seal retainer, and a spring type retaining ring.

Two housings of this type are used. One housing is mounted in the

2.3.8 Inspection of Air Seal Housings (Cont'd)

instrument case and serves as a transfer point for the passage of air from the case to the gimbal assembly. The second housing is mounted in the gimbal, and transfers air from the gimbal to the rotor housing. Although the two housings are similar in appearance, they are not identical. For reference purposes, diminsion "A", Figure 2-3 is 0.375 inches on the housing that mounts in the case, and 0.437 inches on the housing that mounts in the gimbal. Extreme care should be taken that each housing is properly identified as to its proper location in the instrument.

Disassemble each air seal housing and check that the air seal washer fits freely over the diameter of its respective pivot assembly without binding. Check that a clean, used bearing will fit the diameter of the pivot assembly with no more than finger pressure applied. If difficulty is encountered, refer to the inspection and repair procedures of paragraph 2.5.

Remove the used bearing and replace the air seal washer in the air seal housing, along with the new bearing to be used. Reassemble the housing and set aside, properly covered, for future use.

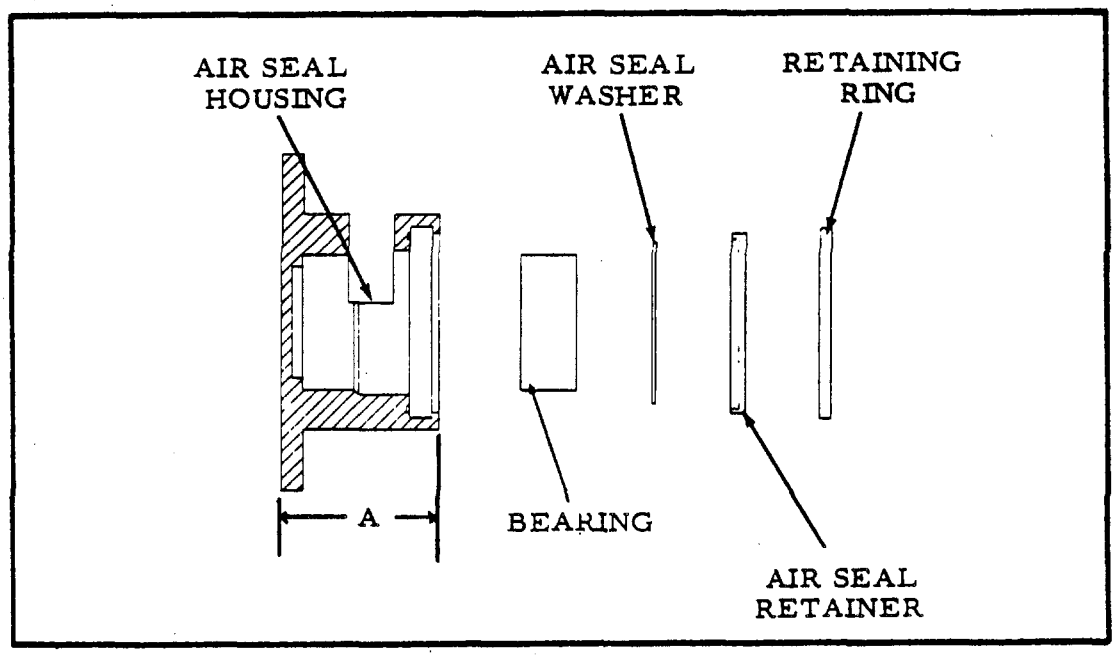

FIGURE 2-3. TYPICAL AIR SEAL HOUSING

2.4 CLEANING

2.4.1 General

Due to the precision components and close tolerances employed in the manufacture of these units, foreign matter can greatly impair their overall operating efficiency and service life. It is therefore recommended that every possible step be taken to insure maximum possible protection of each sub-assembly during disassembly, repair, and reassembly. As each component is removed during disassembly, it should be placed in a dust-free environment and protected with a dustproof cover.

2.4.2 Air Filters, Vacuum Units Only

The instrument air filter on the rear of the unit cannot be cleaned by washing and must be replaced when dirty. This should be done routinely at each overhaul of the instrument and the filter should be inspected after each 100 hours of operation. Access to the filter may be gained by removing the four screws in the AIR INLET cover plate at the rear of the instrument. After the filter has been replaced, reinstall the cover and tighten the screws securely.

The amount of dust, lint, tobacco tars, and other foreign matter reaching the instrument filter may be greatly reduced by the use of an efficient central filter system installed in the aircraft. The Type F-4 Air Filter, available from AIM, is especially designed to filter these undesirable elements from the vacuum system and to effectively extend the service life of any air-driven instrument.

2.4.3 Pivots, Housings, Etc.

During overhaul, all parts should be cleaned carefully to remove oil, dirt, and moisture. If possible, the use of ultrasonic cleaning is highly recommended to insure that all parts with small bores or tapped holes can be effectively cleaned. If this is not possible, component parts such as pivots, bearing housings, shims, etc. should be thoroughly cleaned in a high-grade solvent such as Chlorothene-Nu (Dow Chemical Company), and then thoroughly air dried with clean, low pressure air. If cleaning solvent is used, it must not be allowed to become dirty and must be changed frequently.

2.4.3 Pivots, Housings, Etc. (Cont'd)

Interiors of small holes should be cleaned with pegwood dipped in solvent. The teeth of gears and pinions should be cleaned with a glass fiber brush.

Extreme care should be taken to avoid damage to small or delicate parts during cleaning. In addition, some arrangement must be made to permit identification of each part with respect to its previous location in the instrument. This is particularly true of bearings, pivots, and screws. After cleaning, some provision must be made to adequately protect the parts from damage and dust while awaiting inspection and reassembly.

2.5 INSPECTION AND REPAIR

2.5.1 General

All parts should be thoroughly examined with an eye loupe for any evidence of excessive wear or damage prior to reassembly. Repair of defective parts is recommended only when it can be done without adversely effecting the proper operation of the instrument. If doubt exists as to the operating condition of any part or assembly, refer to the parts list section of this manual and order replacement parts directly from AIM.

During overhaul, examine each part for evidence of corrosion or breakdown in the plating material. Aluminum parts of the gyro are protected by anodize or iridite treatment and stainless steel parts are passivated. If a crocus cloth is used to remove corrosion, or if the plating material appears to be worn through, replate or protect the defective area with a light coat of clear lacquer.

Particular attention should be given to parts which contain internal or external threads. If any evidence of damage to the threads is found, repairs should be made using the correct tap or thread restorer. The part should then be thoroughly recleaned and re-examined prior to assembly.

2.5.2 Bearings

The precision bearings used throughout the instrument are designed to

2.5.2 Bearings (Cont'd)

provide extremely efficient service over long periods of time. Each bearing should be individually examined for evidence of damage. If defects are noted, the entire bearing should be replaced. No attempt should be made to polish the balls, or otherwise repair the separate bearing parts.

Bearings used in this instrument are precision, instrument grade and must not be replaced with inferior substitutes. Each bearing is lubricated with specific quantities and types of lubricants best suited for its individual function. This lubricant improves the performance of the bearings and substantially increases their service life. It is therefore recommended that replacement bearings be ordered directly from AIM in order to insure maximum operating efficiency.

2.5.3 Pivots

The four pivots used to support the gimbal and rotor housing assemblies are specially designed for specific functional locations in the instrument. Each pivot is distinctly constructed so that it must not be interchanged with other pivots during reassembly.

Each pivot or support shaft should be examined carefully for evidence of pits and scoring. Due to the precision fit of their respective bearings, the pivots should seldom incur any type of excessive damage. If small scratches are noted, a light polishing should be all that is necessary to remove them. However, if scoring or other excessive wear is noted, replacement pivots should be secured from AIM.

For information pertaining to the rotor pivots, refer to paragraph 2.6 in this manual.

2.6 ROTOR OVERHAUL

2.6.1 General

As previously stated, disassembly and overhaul of the rotor and rotor housing assembly is not recommended. Due to the precision parts involved, and the high speed of the rotor, reassembly and proper adjustment is extremely critical and should not normally be attempted in

2.6.1 General (Cont'd)

the field. Should the rotor become defective and fail to meet the performance requirements set forth in this manual, the used rotor housing and pivot assembly should be returned to AIM for an exchange discount on a replacement assembly. However, if this is not possible, and disassembly and overhaul does become necessary in the field, the procedures shown in the remainder of Section 2.6 should be followed. Do not attempt to overhaul the rotor unless it fails to meet the operating requirements set forth in Section 3.

2.6.2 Equipment Required

Before disassembling the rotor housing, it should be noted that the following equipment must be available in order to properly readjust the assembly after overhaul. This equipment is in addition to the instrument-shop handtools described in paragraph 2.2.2.

1. Vacuum Rotor Overhaul
    1. Mercury manometer capable of reading up to 6 in. Hg.
    2. Pressure source capable of producing a pressure of 4.7 in. Hg. (approximately 2.5 psi). A vacuum source is also recommended but is not required.
    3. Stop watch
    4. Optical tachometer
    5. Clean, dust-free work area.
2. Electric Rotor Overhaul
    1. 115 vac, 400 Hz., single phase power source
    2. 0-150 ac milliameter
    3. Voltmeter capable of reading 85 vac to 115 vac
    4. Stop watch
    5. Variac power transformer or similar means of varying the supply voltage from 85 to 115 vac
    6. Optical tachometer
    7. Clean, dust-free work area

Additional equipment required for final calibration of the over-all instrument is listed in Section 3 of this manual.

2.6.3 Type R3H Vacuum Rotor (Figure 2-4)

1. Disassembly
   1. Remove the rotor support nut and the four screws holding the two halves of the rotor housing together.
   2. Carefully remove one half of the rotor housing and thread the rotor out of the second half.
   3. To obtain access to the rotor bearings, remove one preload nut from the end of the rotor shaft, and six 1-72 x 3/16 binder head screws securing the bearing plate and the bearing retainer to the end of the rotor.

2. Inspection, Cleaning, and Repair

   Once the rotor is disassembled, check that the buckets in the rotor are free of accumulated dust, tobacco tars, and other foreign matter. Clean the various parts in accordance with procedures set forth in paragraph 2.4. After cleaning, each part must be adequately protected from dust while awaiting re-assembly.

   No attempt should be made to clean, re-oil, or otherwise repair the rotor bearings. If the bearings are defective, they should be replaced.

3. Reassembly and Adjustment
   1. Slip the rotor shaft through the rotor and install one bearing, one spacer, one bearing retainer, one bearing plate, and one preload nut over each end. The bearings must be installed so that the engraved type numbers are not visible. This is imperative with this type bearing.
   2. Installation of the rotor in the housing will be performed during the preload and adjustment procedures. During installation, refer to Figure 2-4 and note the curvature of the rotor buckets with respect to the rotor housing and the position of the air pivot. The rotor must be positioned so that the air entering the housing will be properly directed to achieve maximum rotation.

      On some models, such as that shown in Figure 2-4, a small orifice is cast as a part of the housing to direct air at the rotor buckets. On other models, the orifice is a part of the air

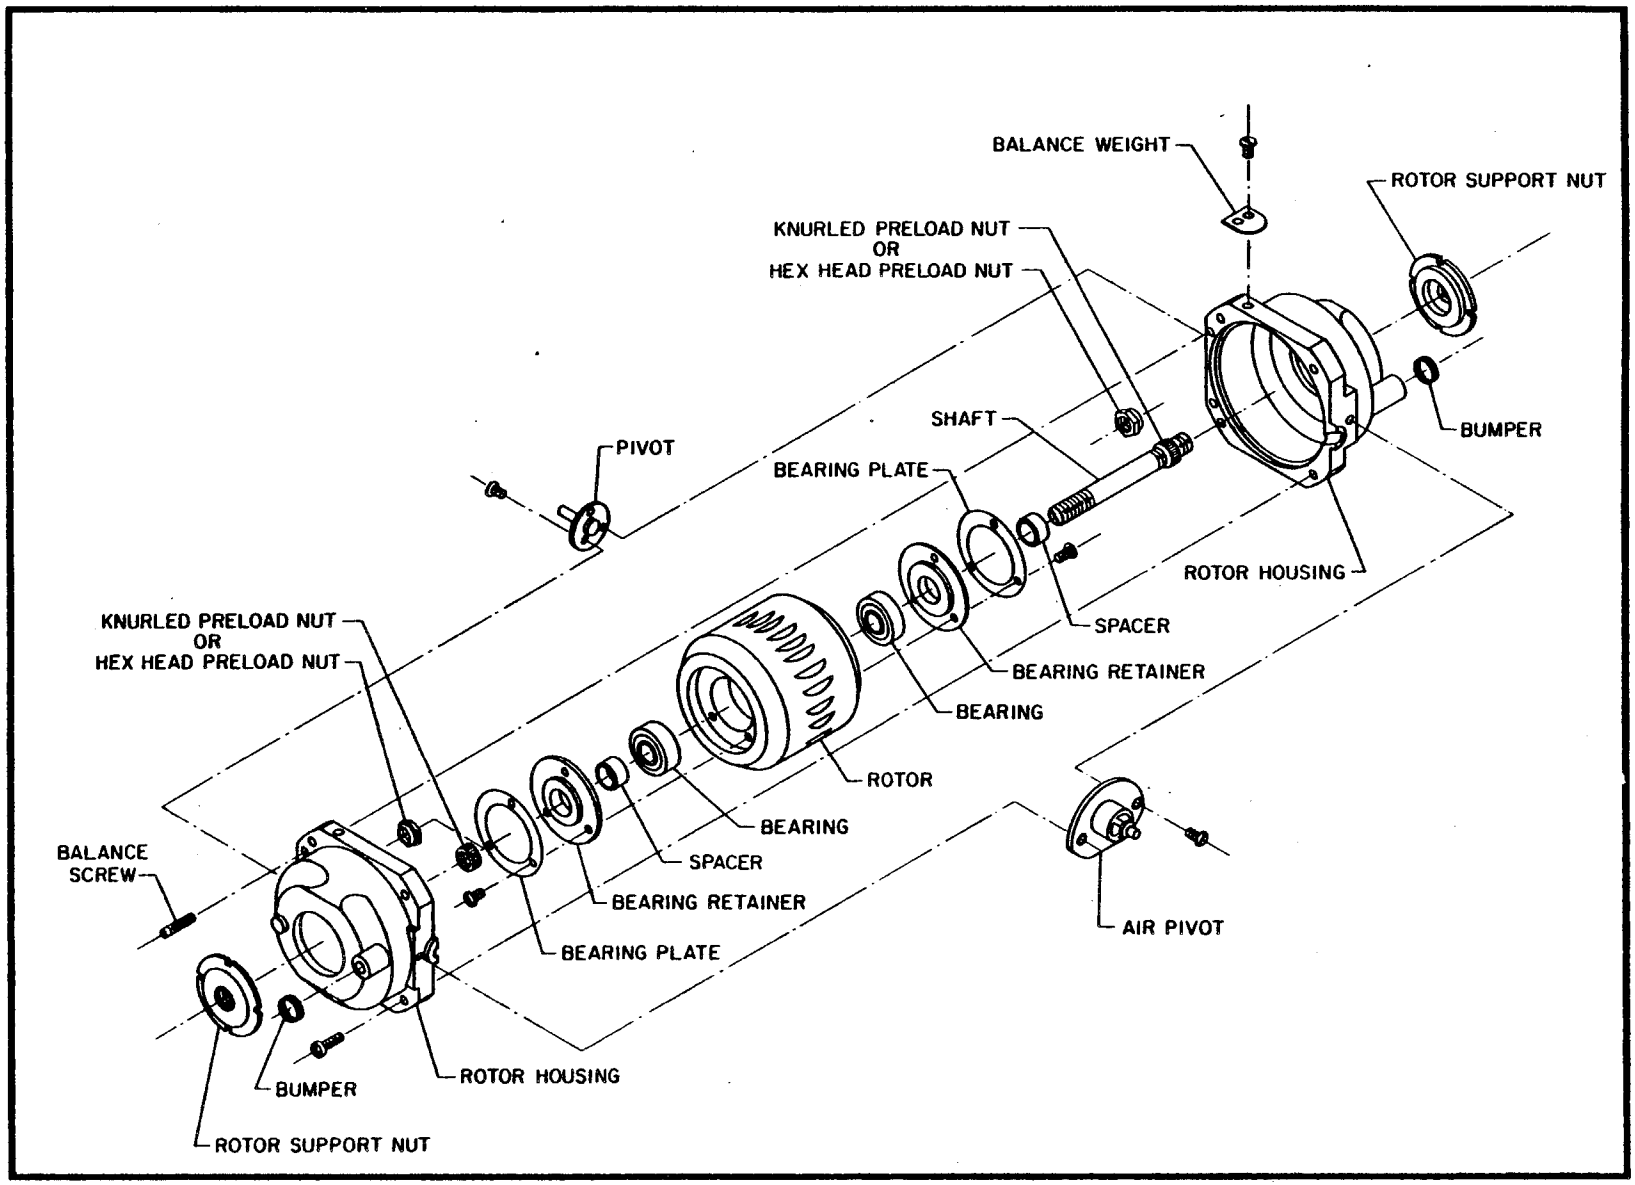

FIGURE 2-4. TYPE R3H VACUUM ROTOR, EXPLODED VIEW

2.6.3. Type R3H Vacuum Rotor (Cont'd)

3. Reassembly and Adjustment (Cont'd)

pivot. In either case, check that the flat side of the air pivot flange is toward the bottom of the instrument and that air flow from the orifice is toward the bottom.

4. Rotor Bearing Preload Adjustment and Run-in Procedures

1. Set the front preload nut tight against the bearing spacer.
2. Carefully tighten the nut on the opposite end until the detectable axial end play between rotor and shaft just disappears. This rotor bearing preload adjustment is very critical and must not be exceeded if normal bearing life is to be realized. At the correct setting, the rotor shaft will spin freely in the rotor assembly and have no detectable end play. To check for proper adjustment, hold the rotor stationary and spin the rotor shaft. If a noticeable roughness is apparent, the preload is set too tight or the bearings are damaged. Do not apply Glyptal to either preload nut at this time.
3. When preload has been completed, install the rotor in the rotor housing as described in paragraph 2.6.3 (3).
4. Install the rotor housing and the air pivot in the gimbal or in a suitable run-in fixture.
5. Run the rotor for 48 hours with 4.5 - 4.7 in. Hg. air pressure applied. Recheck the preload setting after run-in and readjust as required in step 2.
6. Run the rotor for an additional 24 hours and check that the rotor will start and continue running with 0.4 to 0.8 in. Hg. pressure applied to the air pivot. The run-down time should be between 5 and 9 minutes. If the rotor fails to start within these prescribed limits, and run-down time is not as required, the preload nut should be readjusted. If successive rotor starts vary widely, and run-down time will not exceed 5 minutes, the bearings are contaminated or worn and must be replaced.
7. Check that the rotor attains a speed of approximately 28,000 rpm with 4.5 to 4.7 in. Hg. pressure applied to the rotor housing.

2.6.3 Type R3H Vacuum Rotor (Cont'd)

4. Rotor Bearing Preload Adjustment and Run-in Procedures (Cont'd)

8. After it has been established that the rotor meets the requirements of the above paragraphs, apply a small amount of Glyptal to both preload nuts. Avoid excessive Glyptal on the free threads at each end of the rotor shaft.

9. Install the rotor housing in a balancing fixture or in the gimbal to properly locate the rotor in the housing. Balance the assembly by turning the rotor shaft as required to center the rotor in the housing. When proper adjustment has been obtained, secure the rotor shaft and support nuts with Glyptal. Proceed with 2.6.6.

2.6.4 Type 34B Vacuum Rotor (Figure 2-5)

1. Disassembly

1. Remove one strut nut and one lock nut from either end of the rotor strut. Do not disturb the strut nut and lock nut on the opposite end of the rotor.
2. Remove the rotor strut from the rotor housing.
3. Remove four #3-48 screws securing the front and rear halves of the rotor housing.
4. The housing may now be opened to expose the rotor. The rotor bearing outer race assemblies are fitted into the housings in each end of the assembly and may be easily removed. The two bearing housings may also be removed by simply loosening the respective lock rings and threading the bearing housings out of the rotor housing.

2. Inspection, Cleaning, and Repair

Once the rotor housing is disassembled, check that the buckets in the rotor are free of accumulated dust, tobacco tars, and other foreign matter. Clean the various rotor parts in accordance with the procedures set forth in paragraph 2.4. After cleaning, each part must be adequately protected from dust while awaiting reassembly.

No attempt should be made to clean, re-oil, or otherwise repair the rotor bearings. If the bearings are defective, they should be replaced. In addition, no attempt should be made to polish or lap the

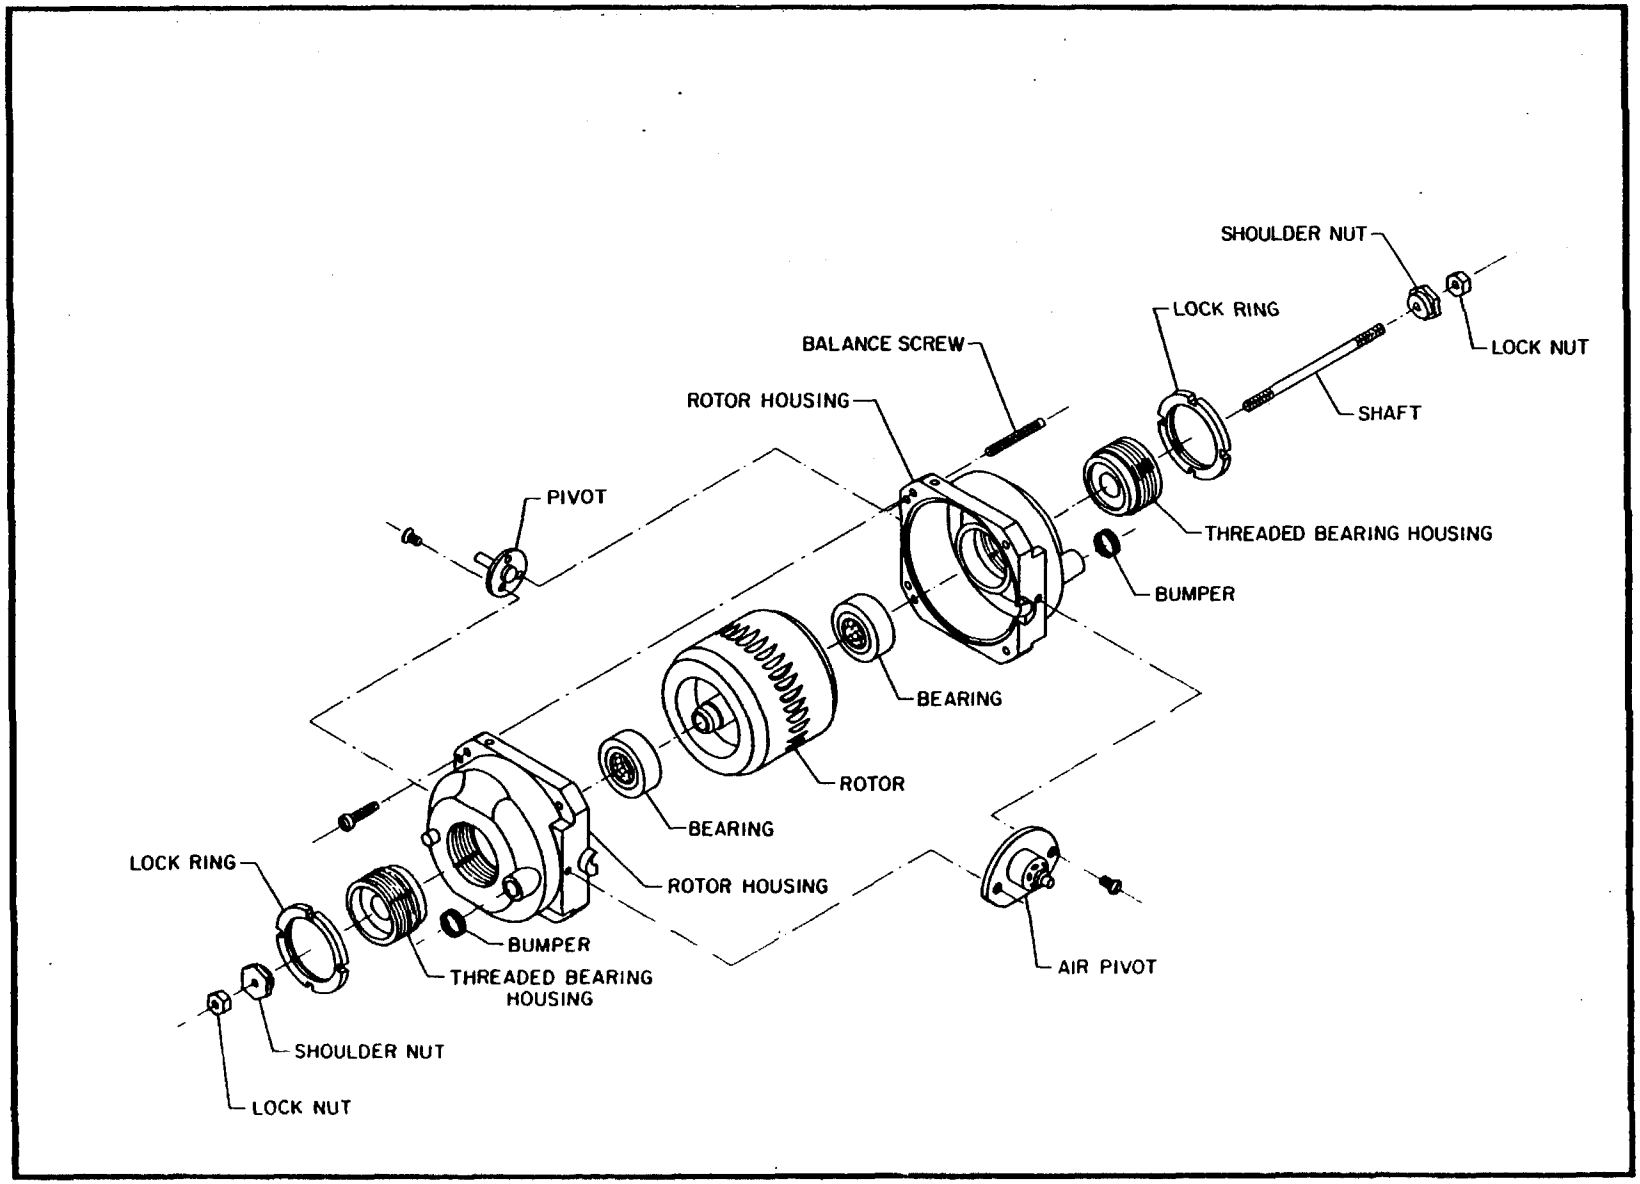

FIGURE 2-5 TYPE 34B VACUUM ROTOR, EXPLODED VIEW

2.6.4 Type 34B Vacuum Rotor (Cont'd)

2. Inspection, Cleaning, and Repair

rotor pivots on the ends of the rotor shaft. These pivots are actually the inner race of the rotor bearings and are manufactured to a precision geometry to match the bearing outer race assemblies. Any attempt at polishing or lapping could change the curvature of the pivot taper, with subsequent damage to the pivot and the bearing. Each pivot should be carefully examined for pits or scoring. If damage is found, a new rotor housing and pivot assembly must be obtained from AIM. The replacement rotor housing and pivot assembly will be completely run-in and ready for installation when received.

3. Reassembly and Adjustment

1. Check the bearing bore in each half of the rotor housing by pressing a clean, used bearing into each bore, using finger pressure only. Each bearing must be a gauge fit.
2. Remove the used bearings from the bore in each half of the rotor housing. Apply a small quantity of Threadlube to the threads of each threaded bearing housing.
3. Thread the bearing housings into their respective halves of the rotor housing approximately three turns.
4. Apply a small quantity of Threadlube to each lock ring, then thread each lock ring onto its respective bearing housing until finger tight.
5. Using instrument tweezers or a similar tool, install the new rotor bearings in their respective housings. Check that each bearing is fully seated in the bottom of its respective housing. Do not handle bearings with bare fingers.
6. Grasp the rotor with watch paper or other high grade lintless tissue and place in position in one half of the rotor housing. Check that the rotor is positioned so that air entering the housing will strike the rotor buckets in the correct direction to obtain maximum rotation.
7. Place the opposite half of the rotor housing in position and check that the air inlet ports on each half correspond.

2.6.4 Type 34B Vacuum Rotor (Cont'd)

3. Reassembly and Adjustment (Cont'd)

8. Attach the back half of the rotor housing to the front half with four screws. Tighten screws and secure with Glyptal.

NOTE

The front and back halves of the rotor housing may be distinguished by the four screw-holes used to hold the two halves together. The holes are threaded in the back half and are not threaded in the front half. Consequently, the four screws should be inserted from the front half toward the back.

9. Position the threaded bearing housings at each end of the rotor shaft so that rotor end play is barely perceptible. Readjust lock rings until finger tight.

10. Mount the side pivot on the rotor housing and insert three attaching screws. Tighten the screws but do not secure with Glyptal since the side pivot must be removed during installation of the rotor housing into the gimbal assembly.

11. Hold the rotor housing so that the spin axis of the rotor is horizontal, the back half of the rotor housing is to the left, the front half is to the right, and the air pivot side is directly visible. Apply Locktite to two attaching screws and mount the air pivot on the rotor housing so that the flat side of the air pivot is toward the bottom.

4. Rotor Bearing Preload Adjustment and Run-in Procedures

1. Place the rotor housing in a suitable run-in fixture. If none is available, install the rotor in the instrument as described in paragraphs 2.7.2 and 2.7.3.

2. Adjust the threaded bearing housings at each end of the rotor until the rotor is centered in the over-all assembly.

3. Apply enough low pressure air at the air pivot or at the AIR INLET port to permit the rotor to start and continue to rotate at approximately 500 rpm. Disconnect air supply hose, then gently shake the assembly to check for excessive rotor bearing end play. If excessive end play is evident, readjust the threaded bearing housings evenly.

2.6.4 Type 34B Vacuun Rotor (Cont'd)

4. Rotor Bearing Preload Adjustment and Run-in Procedures (Cont'd)
    4. Re-attach the air supply hose and recheck end play in the same manner as above. End play is properly adjusted when minutely evident with the rotor spinning at approximately 500 rpm.
    5. When end play is properly adjusted, tighten lock rings and secure with Glyptal.
    6. Insert the rotor strut through the rotor shaft. Install strut nuts and lock nuts on the threaded ends so that equal amounts of threads are showing.
    7. Again attach an air supply hose to the air pivot or AIR INLET port. Tighten strut nuts and lock nuts evenly and sufficiently to permit rotor to start and continue to rotate at an air pressure of 0.5 to 1.0 in. Hg. if the rotor housing is in a run-in rack, or not in excess of 2.25 in. Hg. if it is installed in the instrument. Secure strut nuts and lock nuts in their final adjusted position with Glyptal.
    8. Connect air supply hose and allow the rotor to run for 48 hours at its rated pressure of 4.6 in. Hg.
    9. After the 48-hour run-in period, check that the rotor meets the rotor start, rotor speed, and rotor coast performance tests in Section 3 of this manual. Proceed with paragraph 2.6.6.

2.6.5 Electric Rotor (Figure 2-6)

1. Disassembly
    1. Remove the four screws securing the two halves of the rotor housing.
    2. Carefully separate the two halves and thread the rotor assembly out of the rotor housing using the screwdriver slot in the end of the rotor shaft.
    3. To obtain access to the rotor bearings, remove the impellers from each end, and remove the preload nut and spacer from each end of the rotor shaft. The bearings are protected by a small bearing retainer over each end of the rotor shaft.
    4. Care should be taken to avoid loss of the spacers and bearing

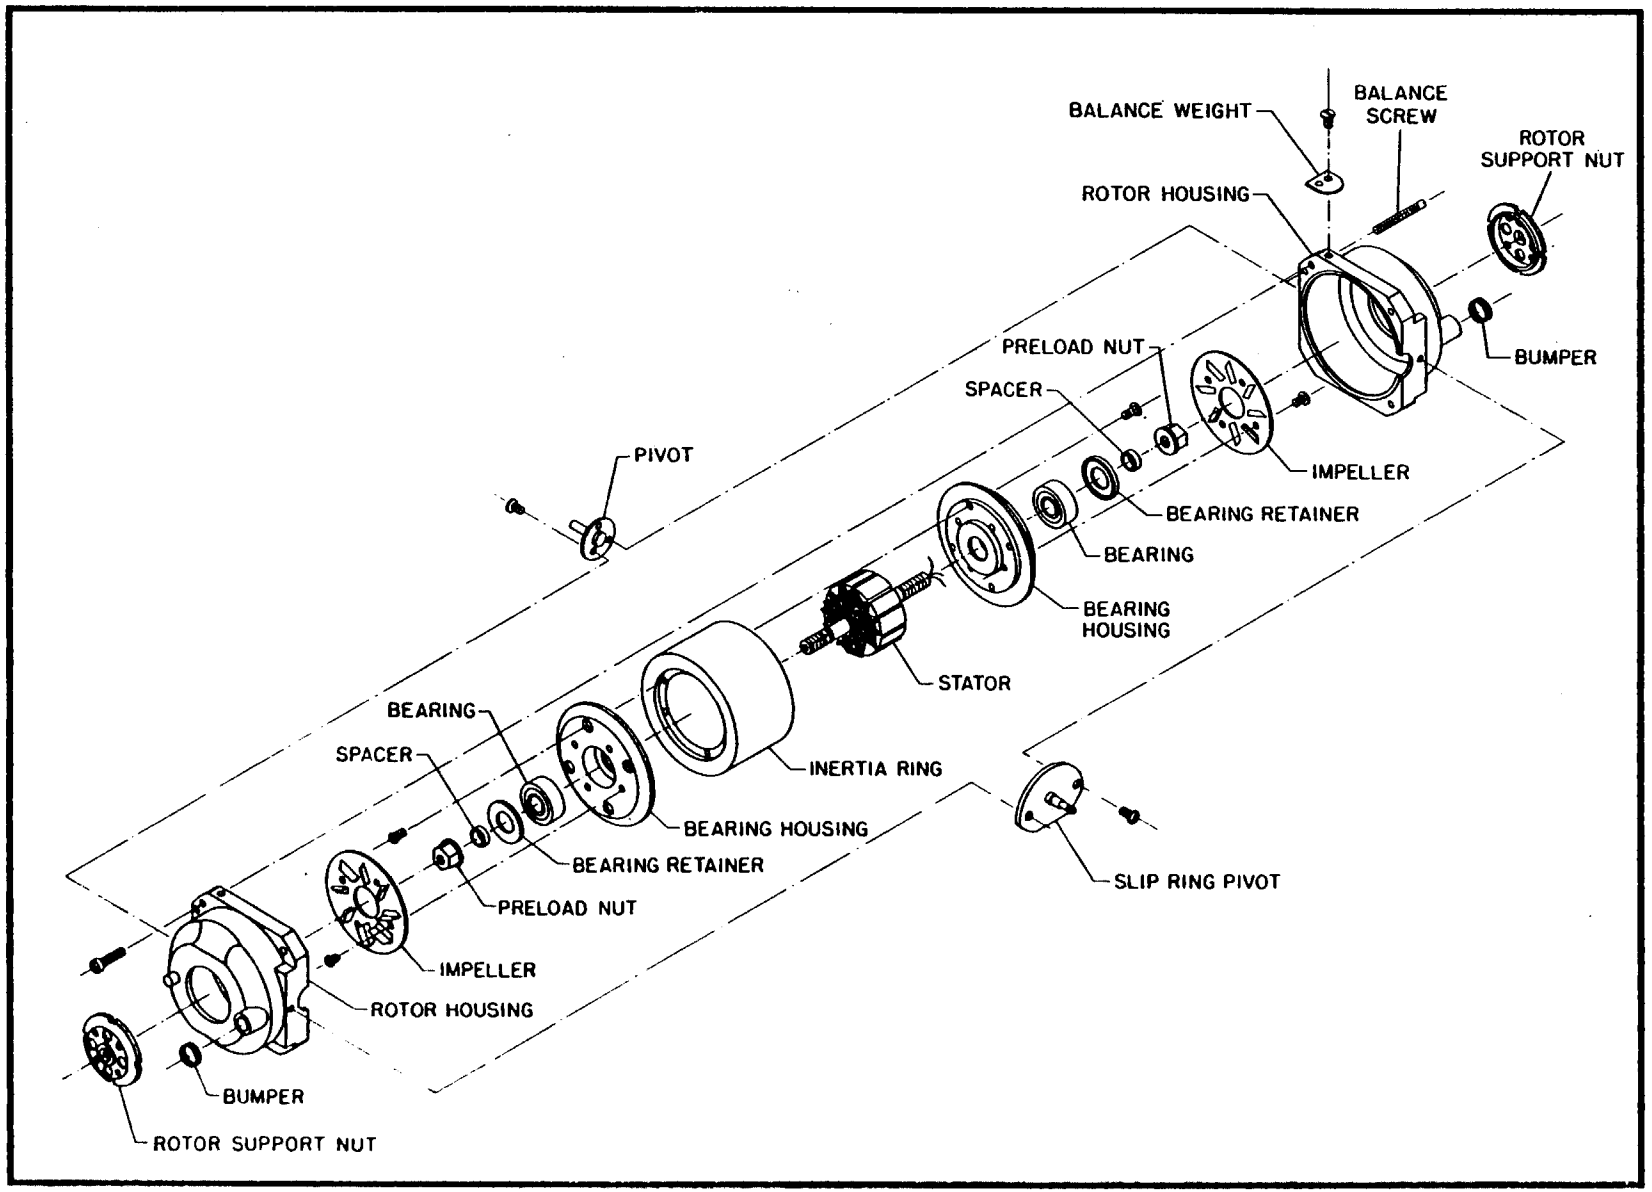

FIGURE 2-6 ELECTRIC ROTOR, EXPLODED VIEW

2.6.5 Electric Rotor (Cont'd)

1. Disassembly (Cont'd)

retainers located between the preload nut and the bearing on each end of the rotor shaft.

NOTE

Removal of the bearing housings on each end of the inertia ring is not normally required, and is not recommended. If either housing is removed, delicate rebalancing of the inertia ring assembly will be required. If the housing must be removed to obtain access to the stator, it is suggested that a mark be made at the interface between the inertia ring and each housing to simplify reassembly and minimize rebalancing required.

2. Inspection, Cleaning, and Repair

Clean the various rotor parts in accordance with the procedures set forth in paragraph 2.4. After cleaning, each part must be adequately protected from dust while awaiting reassembly.

No attempt should be made to clean, re-oil, or otherwise repair the rotor bearings. If the bearings are defective, they should be replaced.

3. Reassembly and Adjustment

1. Install the rotor bearings over each end of the rotor shaft with the word "thrust" toward the center of the rotor.
2. Install the bearing retainers with the recessed side toward the center of the rotor.
3. Reinstall the impellers on each end of the rotor. Tighten all attaching screws securely.
4. Install the spacer and preload nut on each end of the rotor shaft.

4. Rotor Bearing Preload Adjustment and Run-in Procedures

1. Set the preload nut opposite the wire outlet end tight against the bearing spacer.
2. Carefully tighten the nut on the wire outlet end until the detectable axial end play between rotor and shaft disappears. This rotor bearing preload adjustment is very critical and must not be exceeded if normal bearing life is to be realized.

2.6.5 Electric Rotor (Cont'd)

4. Rotor Bearing Preload Adjustment and Run-in Procedures (Cont'd)

At the correct setting the rotor shaft will spin freely in the rotor assembly and have no detectable end play. To check for proper adjustment hold the rotor stationary and spin the rotor shaft. If a noticeable roughness is apparent, the preload is set too tight or the bearings are damaged. Do not apply Glyptal to either preload nut at this time.

3. When preload has been completed, thread the rotor and rotor shaft into the rotor housing and install the rotor support nut.
4. Install the rotor housing and both pivots in the gimbal or in a suitable run-in fixture.
5. Run rotor for 48 hours with 115 vac, 400 Hz., single phase power applied and using a .18-.22mf, 600 v, phase shift capacitor to shift the phase of one winding by 90°. Recheck the preload setting after run-in and readjust as required in paragraph (2) above.
6. Run the rotor for an additional 24 hours and check the rotor start and run-down performance. The rotor must start and continue running with 90 vac, 400 Hz. applied, and run-down time should be between 6 and 10 minutes. If the rotor fails to start at 70 to 90 vac, and run-down time is not within limits, the top preload nut should be readjusted. If successive rotor starts vary more than 15 vac, the bearings are contaminated or worn and must be replaced.
7. Check that the rotor attains a speed of approximately 23,500 rpm with 115 vac, 400 Hz. applied. The rotor should draw approximately 140 milliamperes starting current and approximately 115 milliampers running current.
8. After it has been established that the rotor meets the requirements of the above paragraphs, apply a small amount of Glyptal to both preload nuts. Avoid excessive Glyptal on the free threads at each end of the rotor shaft.
9. Install the rotor housing in a balancing fixture or in the gimbal to properly locate the rotor in the housing. Balance the assembly by turning the rotor shaft as required to center the rotor in the

2.6.5 Electric Rotor (Cont'd)

4. Rotor Bearing Preload Adjustment and Run-in Procedures (Cont'd)

housing. When proper adjustment has been obtained, secure the rotor shaft and the rotor support nuts with Glyptal.

2.6.6 Rotor Housing Static Balancing

1. The rotor housing should be statically balanced inside the instrument. Install two balancing screws from the back of the rotor housing toward the front so that the screws are centered horizontally.
2. Turn the instrument on its side and position the rotor housing so that the rotor strut is vertical.
3. Place a small weight and a piece of tape on a gram scale and cut the tape until the total weight of the two is 3/10 gram.
4. Attach the weight to the top of the rotor housing where the two halves come together.
5. Return the rotor strut to the vertical position and let go. The rotor should not move from this position. As a further check, a screwdriver handle or similar device should be rattled along the instrument case to induce vibrations which will assist in determining any imbalance. If the rotor tends to fall, either to the top or to the bottom, appropriate weight should be added at the four #2-56 tapped holes where the two halves come together.
6. Set the instrument in the upright position with the air passage or slip ring side of the gimbal toward the back of the instrument. The rotor housing should assume about a 10° tilt to the left when viewed from the front of the instrument. Again, a screwdriver handle or similar device rattled on the instrument case, will cause the rotor housing to seek its stable position.
7. A rough adjustment may be accomplished by centering the two balancing screws and shifting the rotor inside the housing until the assembly is approximately balanced. Final adjustment may be accomplished by positioning the two balancing screws as required. Secure the balancing screws with a minimum amount of Glyptal, since additional adjustment may be necessary during the drift and calibration tests in Section 3.

2.7 REASSEMBLY PROCEDURES

2.7.1 General

Throughout the reassembly procedures, extreme care must be taken to prevent damage or contamination of the various component parts and sub-assemblies. When joining two parts, they must not be forced together. As each subassembly is completed, it must be covered while awaiting further installation to a mating assembly or component.

All adjusting screws must be secured in their final adjusted position by use of Glyptal or a similar sealer.

2.7.2 Installation of Rotor in Gimbal Assembly

1. Remove the side pivot from the rotor housing. Carefully position the rotor housing inside the gimbal by placing the air pivot or slip ring into the opening in the gimbal. Install the air seal or slip ring bearing in the gimbal so that the bearing engages the pivot.

   On vacuum instruments, check that the air seal housing is turned properly to permit air flow through the gimbal ductwork. Also check that any shims required to align the opening in the housing with the ductwork in the gimbal are properly installed.

   Install two mounting screws, then tighten and secure with Glyptal. On electric instruments, install the brush block over the slip ring pivot.
2. Place the side pivot through the threaded port in the gimbal and attach to the rotor housing with three screws. Tighten pivot screws and secure with Glyptal.
3. Screw the threaded bearing housing into the gimbal until end play is barely perceptible when moderate hand pressure is exerted toward either pivot.
4. Secure the threaded housing in the gimbal. On some models, a lock ring is provided for this purpose. On other models, the threaded port is slotted toward the top of the gimbal, and a binder head screw, through the gimbal, clamps the housing in place.
5. Position the rotor housing so that the flat side of the flange on the air pivot or slip ring pivot is toward the caging mechanism at the bottom of the gimbal.

2.7.2 Installation of Rotor in Gimbal Assembly (Cont'd)

6. Install the erector vane so that it is an equal distance from each erector jet on the rotor housing. The ends of the erector vane must bisect the erector ports when the spin axis of the rotor is horizontal. The erector vane must not touch the erector jets at any point.

2.7.3 Installation of Gimbal Assembly

The gear train and caging mechanism should be installed and balanced before installation of the gimbal assembly (see paragraphs 2.7.4 thru 2.7.6 for procedures).

1. Insert the air pivot or slip ring pivot into the bearing housing port in the bottom of the instrument case.
2. Carefully place the completed gimbal and rotor assembly into the instrument with the air pivot or slip ring end centered above the lower pivot.
3. Turn the entire instrument over, being careful not to drop the gimbal or the pivot.
4. Mount the pivot to the bottom of the gimbal with two screws inserted through the bearing housing port.
5. Install the bearing housing with two screws and secure with Glyptal.

   On vacuum instruments, check that the air seal housing is turned properly to permit air flow through the instrument ductwork. Also check that any shims required to align the opening in the housing with the ductwork in the instrument are properly installed.

   On bottom-gear instruments, shims are sometimes installed to achieve proper alignment between the gimbal gear and the cup gear. If shims were used prior to disassembly, they should be re-installed.

6. On electric instruments, install the brush block over the slip ring pivot.
7. Return the instrument to its normal upright position and slip the upper pivot or bearing housing (See Figure 2-2) through the port in the top of the instrument. Center the pivot or housing in position on the gimbal and secure with three retaining screws. Secure the screws with Glyptal.

2.7.3 Installation of Gimbal Assembly (Cont'd)

8. On bottom-gear instruments, screw the threaded bearing housing into the instrument case for enough that the assembly will be securely held, and yet loose enough so that it will move slightly up and down when lifted and released.

   On top-gear instruments, install the upper bearing housing or pivot (See Figure 2-2) with three screws and secure with Glyptal.

9. Balance the gimbal by positioning balance screws around the slots in the gimbal balance plate. Provisions have also been made for the installation of additional screws and weights in the #2-56 tapped holes on the side of the gimbal. Repeated trials will be necessary in order to achieve perfect balancing of the assembly. All balancing can be effected by adding or subtracting weight from opposing sides of the assembly.

   Balancing techniques vary according to shop practices. However, it is necessary to point out that trial-and-error methods are always required to obtain near perfect balancing of a precision assembly. During all stages of balancing, assemblies must be vibrated moderately to induce movement and to insure that an absolute minimum of friction between adjacent moving parts is evident.

2.7.4 Reassembly and Adjustment of Caging Mechanism

Reassembly and adjustments of the caging mechanism requires no specific sequence of operations. However, special attention should be given to the following details.

If the caging plate and the caging slide (Figure 1-2 and 1-3) are removed during disassembly, care should be taken to insure that the springs are properly positioned during reassembly. The springs should be stressed so that the caging slide will be pulled clear of the rotor pivot when the caging shaft is released.

When reassembling the caging shaft, check that the associated gears and washers are installed in the order in which they were disassembled. Improper installation of the washers could cause undue wear on the pinion and the related hardware.

2.7.4 Reassembly and Adjustment of Caging Mechanism (Cont'd)

After the caging mechanism is properly assembled, adjust the caging eccentric on the bottom of the instrument until the rotor housing is 80% to 90% caged before the caging gear begins to engage the combination spur/bevel gear on the card shaft. Trial-and-error will be necessary until the proper adjustment is obtained.

2.7.5 Reassembly of Gear Train, Top-Gear Configuration

1. Insert the proper bearing in the brass housing which supports the intermediate shaft. Apply a small amount of Glyptal to the base of the housing and insert the housing in position in the case.
2. Place the intermediate shaft in position along with the associated spur and bevel gears.
3. Insert the bearing, the threaded housing and the eccentric in place at the top of the vertical shaft and secure the eccentric with two binder head screws. A slight amount of end play should be left in the intermediate shaft in order to compensate for case variations when the bezel assembly and dust cover are installed.
4. Position the spur gear near the top of the shaft so that it engages the gimbal drive gear. Tighten the setscrew and secure the gear in place. Check that the spur gear does not bind with the gimbal gear at any place throughout one complete revolution of the gimbal. If binding is evident, loosen two binder -head securing screws and rotate the eccentric on top of the instrument case until the binding is relieved. When proper adjustment has been achieved, secure the eccentric and the two binder-head screws in place with Glyptal.
5. Press the bearing used to support the rear of the card shaft into the proper recess in the instrument case. The bearing must be inserted from the front toward the rear.
6. Insert the card shaft, along with the associated spur/bevel gear and shaft collars into the rear bearing. The rear of the shaft should extend through the rear bearing approximately 1/32 inch.
7. Move one flanged shaft collar along the shaft toward the rear until the collar flange is against the rear bearing. Secure the collar in this position.

2.7.5 Reassembly of Gear Train, Top-Gear Configuration (Cont'd)

8. Slip the card-shaft bearing over the front of the shaft and into position inside the front case. Check that a shaft collar, with its flanged side toward the front, is installed between the spur/bevel gear and the front bearing.
9. Move the shaft collar along the card-shaft toward the front until it is against the rear of the front bearing. Tighten the setscrew and secure the collar in position. Insert two screws in the front face of the instrument casting to secure the bearing in place.
10. Position the spur/bevel gear along the card-shaft toward the rear and the spur gear down the intermediate shaft until they are properly engaged. Secure both gears in their engaged positions.

2.7.6 Reassembly of Gear Train, Bottom-Gear Configuration

1. Insert bearings into ends of card-shaft bearing housing. Insert housing into the instrument case and secure with three retaining screws. Secure screws with Glyptal.
2. Clip the lock ring on the card shaft and install brass washer. Insert the card shaft through the front opening in housing. Care should be taken so as not to dislodge the rear bearing from the housing.
3. Slip the shaft collar, with its flanged side toward the front, on the rear of the center shaft. The collar should be flush against the rear bearing with no noticeable play apparent in the shaft. Tighten the setscrew and secure with Glyptal.
4. Slip the indicator card assembly on the front end of the shaft. To check the balance of the indicator card, rotate the card by hand in both directions. The card should come to a slow even stop without any reverse spin. To correct any imbalance, stick small amounts "mud" (3M Company Sealer EC 612) to the backside of the card. Repeated trials may be necessary to obtain perfect balancing.
5. Slip the combination cup gear and caging gear onto the rear end of the card shaft. Position on the shaft so that the caging gear fully engages with the idler gear when the caging shaft is actuated. Tighten the three setscrews.

   To check the balance of the cup gear, rotate by hand in both directions.

2.7.6 Reassembly of Gear Train, Bottom-Gear Configuration (Cont'd)

The cup gear should come to a slow even stop without any reverse spin. To correct any imbalance, stick small amounts of "mud" to the backside of the cup gear. Repeated trials may be necessary to obtain perfect balancing.

SECTION 3
TEST AND CALIBRATION

3.1 GENERAL

The following test and calibration procedures may be used to either isolate malfunctions in the instrument prior to overhaul, or to checkout and recalibrate the instrument after overhaul has been accomplished. Included with each test are suggested corrective measures which should be employed if the instrument fails to meet the required performance specifications.

3.2 TEST EQUIPMENT REQUIRED

3.2.1 General

1. Scorsby test stand capable of producing roll, pitch, and yaw oscillations with an amplitude of ± 3 degrees about each axis at a frequency of 5 to 7 cycles per minute.
2. Stop watch
3. Clean, dust-free work area

3.2.2 Vacuum Instruments

1. Mercury manometer capable of reading up to 6 in. Hg.
2. Pressure source capable of producing a pressure of 4.7 in. Hg. (A vacuum source is also recommended but is not required.)
3. Either a volumetric flow meter or a similar device capable of measuring approximately 2.0 cfm air consumption.

3.2.3 AC Instruments

1. 115 vac, 400 Hz., single phase power source
2. Variac power transformer or similar means of varying supply voltage from 85 vac to 115 vac.
3. Vacuum-tube Voltmeter
4. 0-200 ac milliameter

3.2.4 DC Instruments

1. 14 or 28 vdc power source, as required
2. Vacuum-tube Voltmeter
3. 0-5 amp dc meter

3.3 ROTOR SPEED TEST, VACUUM INSTRUMENTS

This test is an "open" calibration test and should be performed with the instrument dust cover removed. Apply a pressure line of 4.5 to 4.7 in. Hg. to the AIR INLET port on the rear of the instrument. Allow approximately five minutes for the rotor to gain speed and stabilize.

The rotor should attain a speed of 23,000 rpm or greater if the rotor is installed in the instrument and the instrument ductwork is used. If the rotor is outside of the instrument, and air pressure is applied directly to the air pivot, rotor speed must be in excess of 29,000 rpm.

If the rotor fails to reach the required speed, a new rotor assembly should be installed. If replacement is not possible, overhaul the rotor as described in paragraph 2.6 of this manual.

3.4 ROTOR SPEED TEST, ELECTRIC INSTRUMENTS

This test is an "open" calibration test and should be performed with the instrument dust cover removed.

Insert a milliameter in series with the power source. On ac instruments, use a 0-200 ac milliameter. On dc instruments, use a 0-5 amp dc meter. Apply power to the instrument and allow approximately five minutes for the rotor to gain speed and stabilize. The rotor should attain a speed of 23,000 rpm or greater.

On ac instruments, check for approximately 115 milliamperes running current. On dc instruments, running current should be approximately 1.0 to 1.4 amperes for 14 vdc units, and 0.5 to 0.7 amperes for 28 vdc units.

Rotate the instrument horizontally through 360° and check for any variation in current. Also tilt the rotor to its limits of travel and check for current variation. If current does vary, readjust tension on the appropriate brushes so that the brushes do not drop away from their respective slip ring. The tension on each brush should be between 1/2 and 1-1/2 grams.

3.5 ROTOR COAST TEST

After the conditions described in the Rotor Speed Test have been attained, disconnect electrical power or pressure line from the instrument. Rotor run-down time must be six minutes or more for electric instruments

3.5 ROTOR COAST TEST (Cont'd)

and 4-1/2 minutes or more for vacuum instruments. If the rotor fails to coast the required length of time, replacement or overhaul of the complete rotor should be accomplished.

3.6 STILL RUN DRIFT AND CALIBRATION

1. Mount the instrument in a panel or secure it on a bench so that the bezel is vertical and the instrument will not change its position.
2. Apply appropriate air pressure or electrical power for the remainder of this test. Allow five minutes for the rotor to attain full speed.
3. Set the indicator card on 0° or North heading and allow the gyro to run for 15 minutes. At the end of 15 minutes, the card reading must be between 357° and 3°. If the reading is greater than 3° turn one of the balancing screws shown in Figure 2-4 thru 2-6, counterclockwise. If the reading is less than 357°, turn one of the balance screws clockwise.

   To correct for a 10° change in drift rate, turn each balancing screw, 1-1/2 to 2-1/2 turns. To simplify calibration, the original drift and the correction made should be recorded. This procedure should be repeated and evaluated for the next correction.
4. Repeat the above procedure for headings of 90°, 180°, and 270°. Maximum permissible drift for any cardinal heading is $\pm 3^{\circ}$ in 15 minutes.

   If the instrument fails to maintain the required performance levels, the following items should be checked for proper assembly.

   a. The gear train which drives the card must be free throughout its entire range of rotation. Refer to paragraph 2.7.5 or 2.7.6 for adjustment procedures.
   b. Check the bearings which support the rotor housing for rough spots or excessive preload. Either replace the bearings or adjust the preload as described in paragraph 2.7.2.
   c. Check the bearings which support the gimbal for proper clearance between the gimbal and the case. The gimbal assembly must move up and down when the gimbal is lifted and released. See paragraph 2.7.3 for proper installation.

3.7 ERECTION TEST IN STILL RUN

Mount the instrument securely with the frame placed in a level position. Apply electrical power or air pressure, as required, and allow five minutes for the rotor speed to increase and stabilize. Displace the rotor spin axis 55° from horizontal and check that the rotor automatically erects. If the rotor fails to erect, the rotor is improperly installed or the erector vane is improperly adjusted. For proper installation and adjustment, refer to paragraph 2.7.2.

3.8 CAGING

The rotor must be 80% to 90% caged before the idler gear becomes sufficiently engaged to permit readjustment of the indicator card. When the caging shaft is fully in, the rotor must be fully caged. If adjustment is required, refer to paragraph 2.7.4.

3.9 ROTOR START TEST, VACUUM INSTRUMENTS

To perform this test and those following, the instrument must be completely assembled and sealed. Apply vacuum to the vacuum port on the rear of the instrument. By listening carefully against the case, any rotation of the rotor can be heard. The amount of vacuum required for the rotor to start and continue running should not exceed 2.5 in. Hg.

If the rotor fails to start at the prescribed vacuum, a new rotor assembly should be installed. If replacement is not possible, overhaul the rotor assembly as described in paragraph 2.6.

3.10 ROTOR START TEST, ELECTRIC INSTRUMENTS

3.10.1 AC Instruments

The rotor must start with 90 vac, 400 Hz. applied to the rear connector. This check should be repeated several times. If successive starts vary more than 15 vac, the rotor bearings are worn or contaminated, and should be replaced.

With the flag motor disconnected, check that the starting current is approximately 140 milliamperes and running current is approximately 115 milliamperes. If the rotor fails to conform to the above requirements, a new rotor assembly should be installed. If replacement is not

3.10.1 AC Instruments (Cont'd)

possible, overhaul the rotor assembly as described in paragraph 2.6.

3.10.2 DC Instruments

Check that the running current is approximately 1.0 to 1.4 amperes for 14 vdc instruments and 0.5 to 0.7 amperes for 28 vdc instruments.

If the instrument fails to meet the above requirements, the rotor bearings are worn, or the inverter circuitry is malfunctioning. Use a voltmeter to check that the inverter is producing 115 vac, 400 Hz. output with appropriate 14 vdc or 28 vdc input applied.

If the rotor is at fault, a new rotor assembly should be installed. If replacement is not possible, overhaul the rotor assembly as described in paragraph 2.6.

3.11 SCORSBY TEST

Mount the instrument on a Scorsby Test stand which should be set for 5-7 oscillations per minute at an amplitude of $\pm$ 3 degrees about each axis.

For each cardinal heading, the instrument drift must not exceed 3° in 10 minutes. If drift is excessive, check for possible defects and recalibrate as explained in paragraph 3.6. Also check freedom of the gear train as described in paragraph 2.7.5 or 2.7.6.

3.12 AIR CONSUMPTION TESTS, VACUUM INSTRUMENTS

3.12.1 General

These tests should be performed after the instrument is calibrated because the instrument must be completely assembled and fully sealed. An air volumetric flow meter or similar device must be used to perform the following tests.

3.12.2 Leak Test

Block the AIR INLET port and apply a vacuum of 4.5 in. Hg. to the vacuum port. Air consumption must not exceed 0.2 cfm. If excessive leakage occurs, check the dust cover gaskets, air filter housing, and glass for excessive leakage.

3.12.3 Air Consumption When Running

Apply a vacuum of 4.5 in. Hg. to the vacuum port. Air consumption must not exceed 2.1 cfm. If air consumption is greater than 2.1 cfm, check for internal leaks such as omitted air seals, loose bearing housings, loose pivots, etc.

3.13 FLAG CIRCUIT TESTS, ELECTRIC INSTRUMENTS

Refer to paragraphs 1.3.4 through 1.3.7 for operating characteristics of the various flag circuits.

Flag circuits which include the voltage sensor network (Figures 1-4B, 1-6B, and 1-7B) should be checked for conformance to the following requirements: (1) The flag should retract (raise) when the applied voltage is increased to approximately 102 vac; (2) The flag should remain up until the applied voltage drops below approximately 80 vac.

3.14 APPEARANCE

There should be no bright surfaces on the face of the indicator card. The indicator card, glass, indice, and bezel should be free of scratches or flaking paint. The nameplate and serial number should be clearly legible.

On vacuum instruments, plastic pipe plugs should be installed in both the AIR INLET port and the vacuum port until the instrument is installed in the aircraft.

SECTION 4
PARTS LIST

This section contains exploded-view drawings of both "top-gear" and "bottom-gear" instruments, showing the location of each replaceable part. Tables associated with the drawings identify each component or assembly and list the appropriate AIM part number by which replacement parts should be ordered.

Figures 4-1 and 4-2 are composite drawings of basic vacuum instruments, with corresponding electrical parts shown near their actual location in the instrument.

Many parts are identified by a single callout number, and yet several part numbers are shown in the parts list. Carefully check that the instrument model number, case configuration and type (vacuum or electric) coincide with the instrument being overhauled.

NOTES

1. For complete rotor housing assembly, consisting of all parts shown below, order P/N 652-0016-901 (brass rotor) or P/N 652-0016-902 (heavy metal rotor). Assembly will be correctly preloaded and will require only minor balancing when installed.
2. For preloaded rotor assembly consisting of items 4, 11, 13, 14, 16, 19 and 23, order P/N 636-0018-901 (brass rotor) or P/N 636-0018-902 (heavy metal rotor).

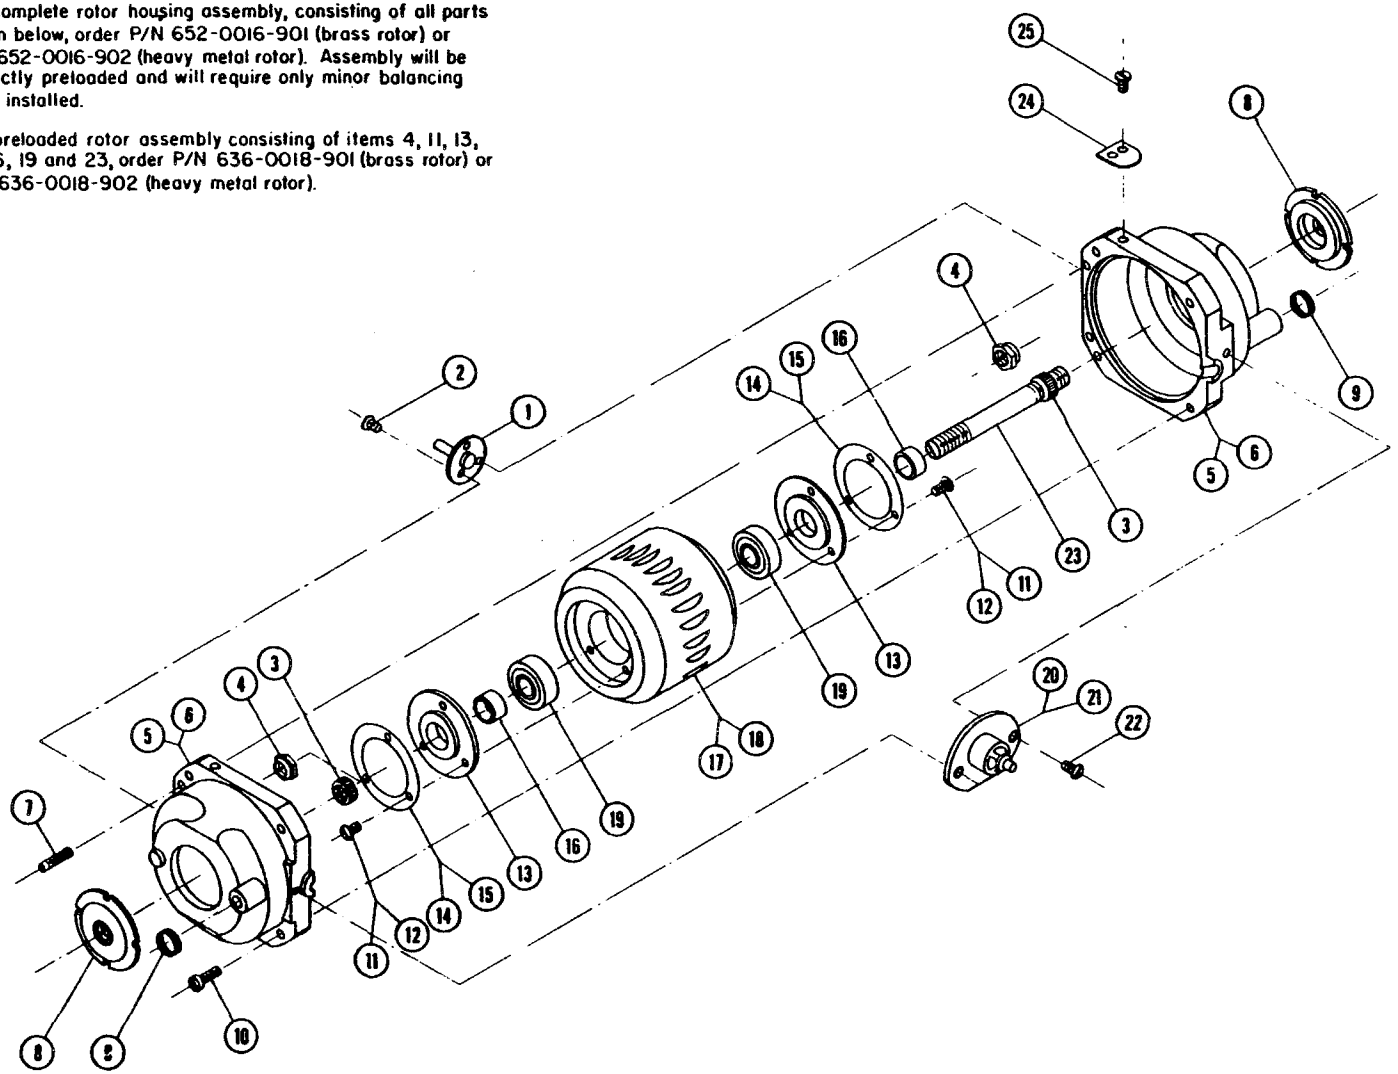

FIGURE 4-3. TYPE R3H VACUUM ROTOR, EXPLODED VIEW

TABLE 4-2. TYPE R3H VACUUM ROTOR (Figure 4-3)

NO.	DESCRIPTION	AIM PART NO.
	NOTE This parts list and the drawing of Figure 4-3 cover several versions of the basic R3H rotor. Where parts are identified by two callout numbers in the illustration, check the part description closely to insure the interchangeability of replacement parts.	
1	Pivot	639-0003-902
2	Screw, 1-72 x 1/8, flat hd., st. st.	—
3	Nut, preload, knurled	605-0012-001
4	Nut, preload, Esna, hex (used only with Item 18)	605-0015-001
5	Rotor Housing (with cast orifice)	652-0005-901
6	Rotor Housing (without cast orifice)	652-0006-901
7	Screw, balance	603-0009-002
8	Nut, rotor support	605-0011-001
9	Bumper, 1/8 x 1/4 I. D. vinyl tubing	—
10	Screw, 3-48 x 3/8, fillister hd., st. st.	—
11	Screw, 1-72 x 3/16, binder hd., st. st. (used only with Item 18)	—
12	Screw, 1-72 x 3/16, flat hd., st. st. (used only with Item 17)	—
13	Retainer, bearing	608-0011-001
14	Plate, bearing (used only with Item 18)	628-0070-001
15	Plate, bearing, with counter-sunk holes for flat-head screws (used only with Item 17)	628-0082-001
16	Spacer, bearing	616-0019-001
17	Rotor, brass, counterbored 3/32 inch to accommodate Items 3, 13 and 15	636-0006-001
	NOTE If defective, replace with Item 4, 18, and 23 as a set.

SECTION 1
GENERAL INFORMATION

1.1 SCOPE

This manual contains maintenance and overhaul procedures for Aviation Instrument Manufacturing Corporation's AIM 400 Slaved Gyro Direction Indicator Systems and AIM 800 Gyro Direction Indicator/RMI Systems. Specifications and complete parts lists for the systems and their accessory components are also included.

Although this manual was prepared with considerable attention to detail, no attempt has been made to instruct non-qualified personnel in the specific procedures required to successfully overhaul the instrument. Instead, the manual is intended only as a guide for experienced gyro mechanics.

1.2 GENERAL DESCRIPTION

1.2.1 Over-All Systems

The basic AIM 400 Slaved Gyro Direction Indicator System is designed to furnish the aircraft pilot with a constant directional reference which is not subject to the temporary errors inherent in magnetic compasses nor to the drift errors normally associated with non-slaved gyro instruments.

In addition to providing a constant directional reference, AIM 800 Systems employ either single or dual synchro-driven pointers which utilize ADF/VOR inputs to provide continuous indications of magnetic bearings to specific ground stations.

Both systems contain a gyro direction indicator and an electronic compass. The electronic compass continually compares the gyro indication with the aircraft magnetic heading obtained from a remote flux detector and applies continuous correction as required. This correction is limited to approximately two degrees per minute so that erroneous information generated by the compass in turns and in rough air will not noticeably effect the gyro indication.

1.2.1 Over-All Systems (Cont'd)

The system is provided with a card set knob which permits initial adjustment of the gyro card to coincide with the heading information obtained from the electronic compass. A slaving indicator provides a visual indication at its centered position, that synchronization has been obtained. It also provides a continuous indication of system operation by showing that slaving corrections are being applied to the gyro.

Several variations of the basic AIM 400 and AIM 800 Systems are available to accommodate a wide variety of operational requirements. Directional gyros may be provided with either vacuum-driven or electric rotors. Systems which contain directional gyros with electric rotors are denoted by the suffix "EL" following the system model number.

The various models of both the AIM 400 and AIM 800 Systems are shown in the following table. With one exception, each AIM 400 System has an AIM 800 counterpart which is designed to provide all the functions of the AIM 400 plus the additional feature of either single or dual ADF/VOR pointers. The single exception is the AIM 400 BC which, due to space limitations, does not have an AIM 800 counterpart.

An additional "bootstrap" power heading synchro is available on selected AIM 800 systems. This is required to drive various RMI converters which, in turn, provide VOR pointer inputs to the AIM 800.

1.2.2 Gyro Direction Indicator

The Gyro Direction Indicator used in each system is a precise gyroscopic flight instrument. The purpose of the instrument is to maintain a stabilized datum reference from which the angular movements of an aircraft in azimuth can be measured. This is accomplished by a universally mounted high speed rotor which develops sufficient angular momentum to overcome normal bearing friction and thus becomes stable relative to space. This stability, known as "rigidity in space" resists small forces which attempt to displace the axis of rotation and consequently its position in space.

TABLE 1-1. SYSTEM DESIGNATIONS AND FUNCTIONS

SYSTEM DESIGNATION	GYRO MODEL NO.	GYRO DESCRIPTION					AIM 292 RMI Coupler	REMARKS
		Rotor	ADF/VOR Pointers	Autopilot Output	4-Power Synchro Output	1-Power Synchro Output		
AIM 400	254-92	vac.	0	-	-	-	-	Basic Slaved Gyro and Gyro/RMI Systems.
AIM 800	254-1S	vac.	1	-	-	-	-

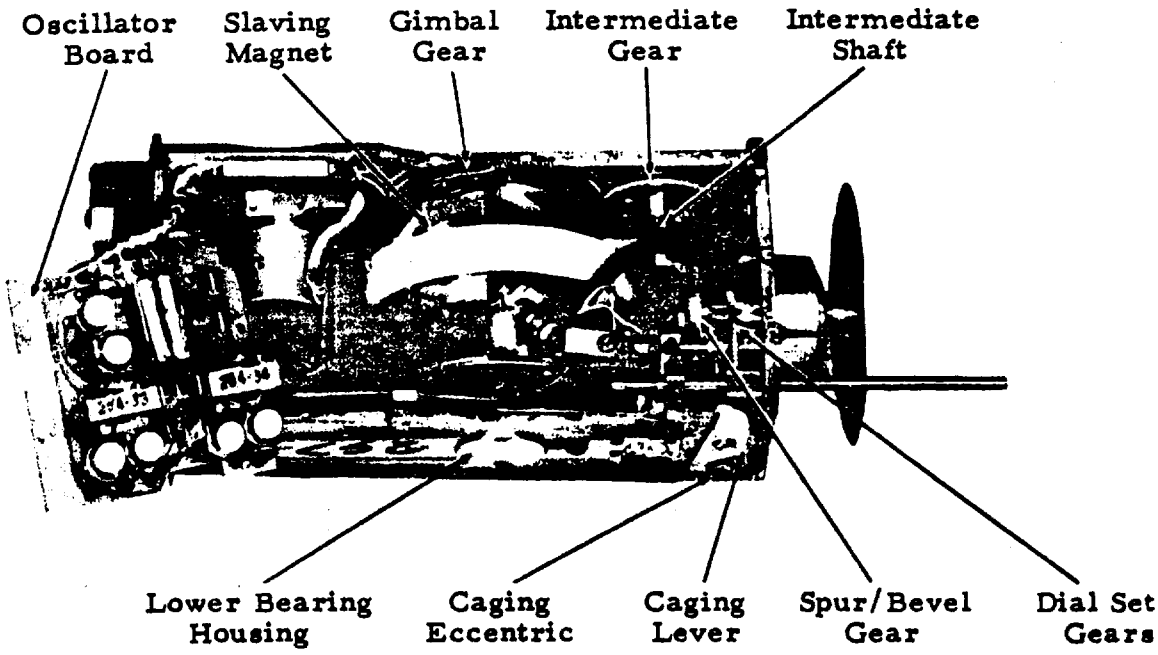
1.2.2 Gyro Direction Indicator (Cont'd)

Angular movements of the aircraft in azimuth are indicated on a circular vertical dial which is graduated in five degree increments.



The instrument is compact and fits a standard 3-1/8" instrument panel cutout. The small size of the instrument combined with its substantially reduced weight permits panel layouts in accordance with SAE and airline standards.

The gyro is spillproof and will not tumble regardless of the aircraft's attitude. The instrument incorporates a self erecting feature so that no periodic caging of the gyro inner gimbal is necessary.

The basic internal construction of an AIM slaved gyro is shown in Figure 1-2 along with the indentification of major sub-assemblies and components. Since each of the specialized gyros used in the various systems is actually an adaptation of the same basic design, the model shown is suitable for the purposes of this discussion regardless of the specific gyro to be overhauled.

The functional center of the gyro direction indicator is an accurately balanced high speed rotor which is mounted on precision bearings inside an enclosed rotor housing. The rotor housing is suspended from bearings mounted in the gimbal assembly and is free to pivot in the vertical plane up to $\pm 80^{\circ}$ from horizontal. In turn, the gimbal assembly is suspended from bearings mounted in the instrument case so that the over-all assembly has complete freedom of movement about its vertical axis. Over-all operation of the instrument is as follows:

On vacuum-driven models, a vacuum system capable of maintaining a suction of 4.5 to 4.7 in. Hg. is connected to the vacuum port on the rear of the instrument. This port opens directly into the air-sealed instrument case. Air, at normal atmospheric pressure, is drawn through the AIR INLET filter and along the ducts in the instrument to an air seal housing which contains the lower gimbal bearing. From this point a duct in the gimbal leads to a second air seal housing which contains the bearings for the rotor housing. At this point, air passes through the rotor housing pivot and is directed at the buckets in the rotor periphery, causing the rotor to revolve at very high speed.

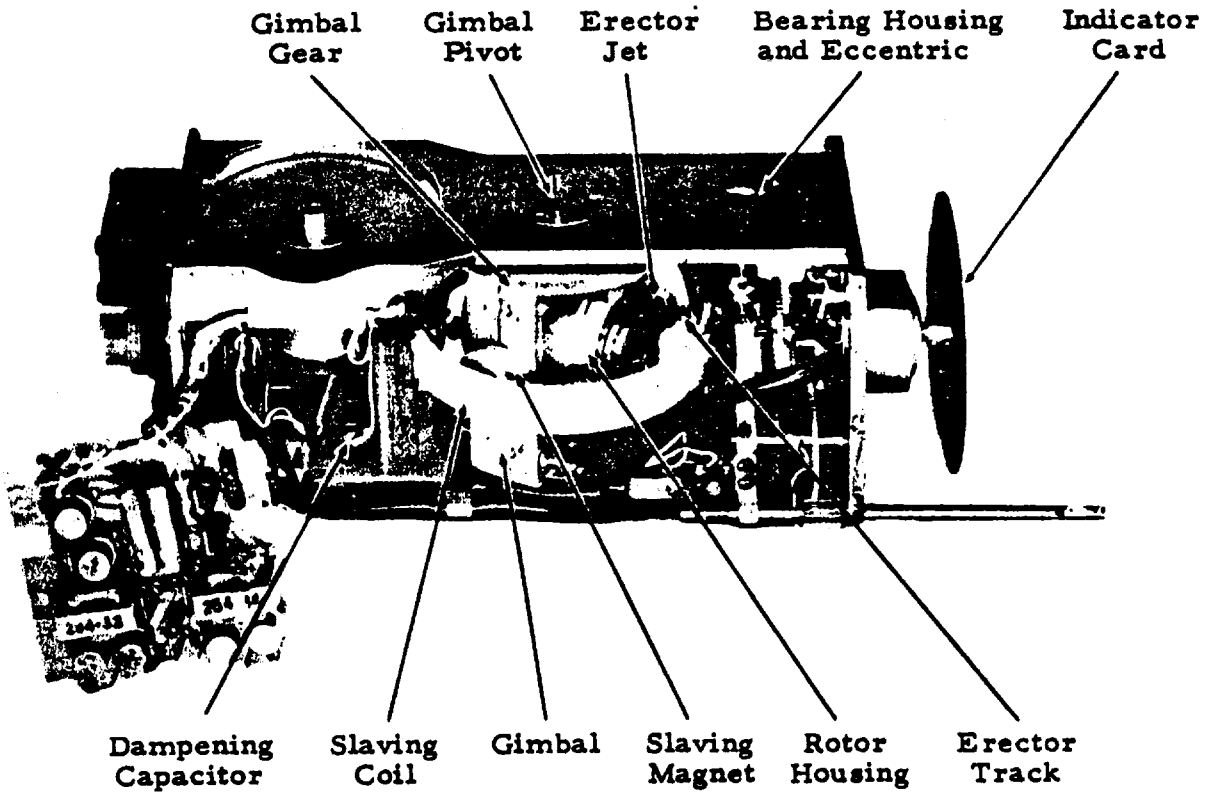


FIGURE 1-2. INTERNAL CONSTRUCTION FEATURES

1.2.2 Gyro Direction Indicator (Cont'd)

Electric models are provided with 115 vac, 400 cps, single phase drive voltage which is applied to the instrument through a 5 pin electrical connector on the rear of the case. A capacitor is then used to obtain the two-phase supply voltage necessary to drive the rotor. The drive voltage is then transferred through brush and slipring assemblies in the bottom of the instrument casting and in the gimbal, to a stator inside the rotor housing. The rotor is mounted around the fixed stator on precision bearings so that when voltage is applied to the stator the desired rotor movement is obtained. Small impellers are attached to the top and bottom of the spinning rotor to generate the air flow required to operate an internal self-erect system.

The self-erect features of the air-driven and electric rotors are identical. Air from the rotor housing is exhausted through two horizontally opposed erector jets and pushes against the semi-circular baffled track attached to the gimbal. The entire assembly acts as an air valve
at when the spin axis of the rotor is inclined from the horizontal
ion, one erector jet will be closed while the air being expelled
the opposite erector jet will exert torque about the vertical axis
e gimbal. This action precesses the spin axis of the rotor to the
zontal position so that the opposing jets are opened an equal amount
the gimbal is again stable.

Azimuth movements of the gimbal assembly are transmitted to the vertical indicator card and to the electronic compass circuitry by means of a precision gear system. A standard gear-driven, synchro resolver continuously monitors the gyro heading, represented by the position of the outer gimbal assembly, and relays this information electrically to the electronic compass circuitry. There the heading obtained from the gyro direction indicator is compared with the heading obtained from the flux detector. Any deviation of the gyro direction indicator heading from that of the flux detector will result in the generation of a corrective signal by the electronic compass. This correction voltage is applied to a slaving coil affixed to the instrument case. The magnetic field generated by this coil acts against a small permanent magnet affixed to one end of the rotor housing shaft. This force, attempting

1.2.2 Gyro Direction Indicator (Cont'd)

to change the pitch position of the rotor housing causes precession of the outer gimbal assembly around its vertical axis. When the position of the gimbal assembly and the resultant heading of the gyro direction indicator corresponds with the magnetic heading information obtained from the flux detector, the corrective voltage generated by the electronic compass circuitry ceases. The gyro heading correction is a continuous process which automatically maintains the gyro heading within 1° of the electronic compass heading.

1.2.3 Electronic Compass

The electronic compass circuitry is housed in the rear section of the gyro direction indicator case. Components are mounted on convenient circuit boards which are easily accessible for maintenance purposes. A block diagram of the compass circuitry is shown in Figure 1-3.

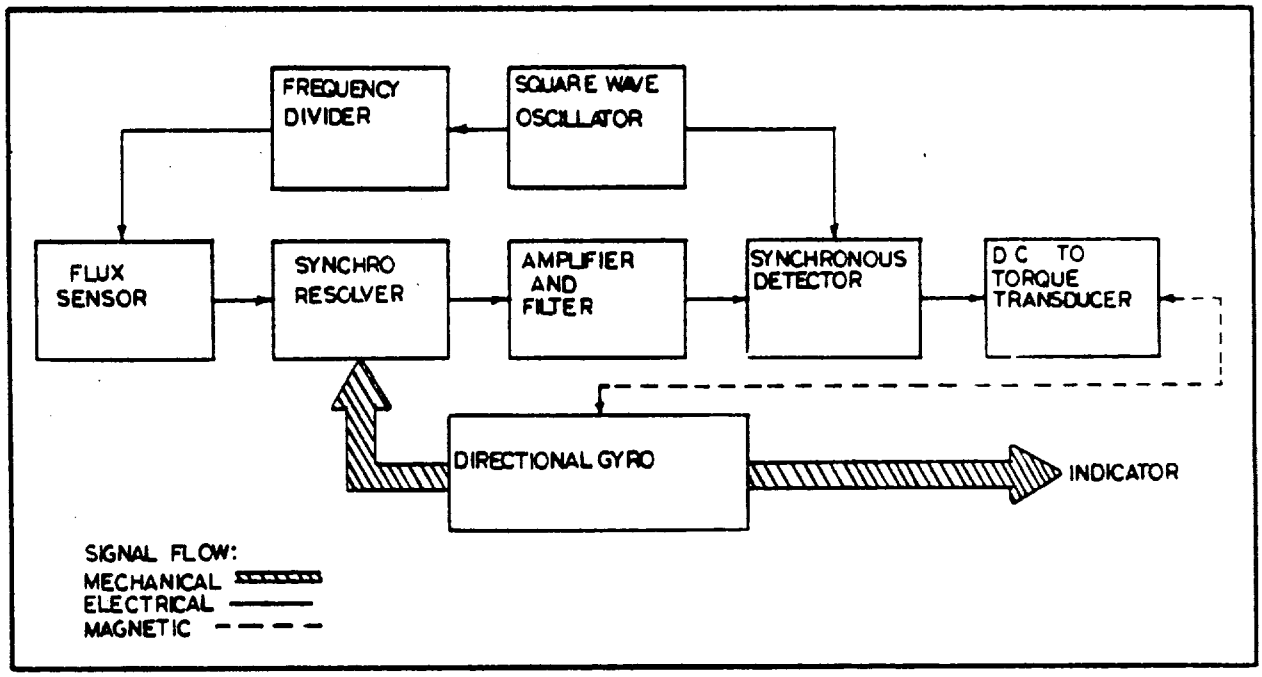

FIGURE 1-3. BLOCK DIAGRAM, ELECTRONIC COMPASS CIRCUITRY

1.2.3 Electronic Compass (Cont'd)

The purpose of the electronic compass is to generate a dc voltage proportional to the angular difference between the actual magnetic heading of an aircraft and that which is indicated by the gyro direction indicator. Operation of the circuit may be most easily understood by beginning with the 1680 cps square wave generator, the output of which is applied to a frequency divider. The 840 cps output of the divider is then applied to a second harmonic magnetic flux sensor which in turn produces a usable signal at a frequency of 1680 cps. The flux detector output may be considered to be equivalent to the stator signal of a synchro resolver in which the rotor is excited. This signal is then applied to the stator of a synchro resolver which serves as a control transformer and a heading error is present at the rotor terminals. This output signal is proportional to the difference between the angular position of the resolver rotor and the angle at which the horizontal component of the earth's magnetic field passes through the flux sensor. The ac error signal, after being amplified and filtered, is applied to a synchronous detector, the output of which is a dc voltage having amplitude and polarity corresponding with the heading error signal. The presence of an error signal, and the subsequent slaving of the directional gyro, is indicated by means of a small voltmeter normally located adjacent to the gyro instrument. Any difference in the gyro heading and that of the electronic compass will result in a deflection of the meter needle either positive or negative depending on the correction required. The meter centers at its null position when synchronization has been obtained.

1.3 CIRCUIT DESCRIPTION

1.3.1 Square Wave Oscillator

A circuit diagram of the 1680 cps square wave oscillator is shown in figure 1-4. The frequency of the oscillator is determined by a high Q series resonant circuit inserted in the feedback network. During the half cycle in which Q3 is conducting, the feedback current path is through diode CR2 and the emitter base junction of transistor Q3. The

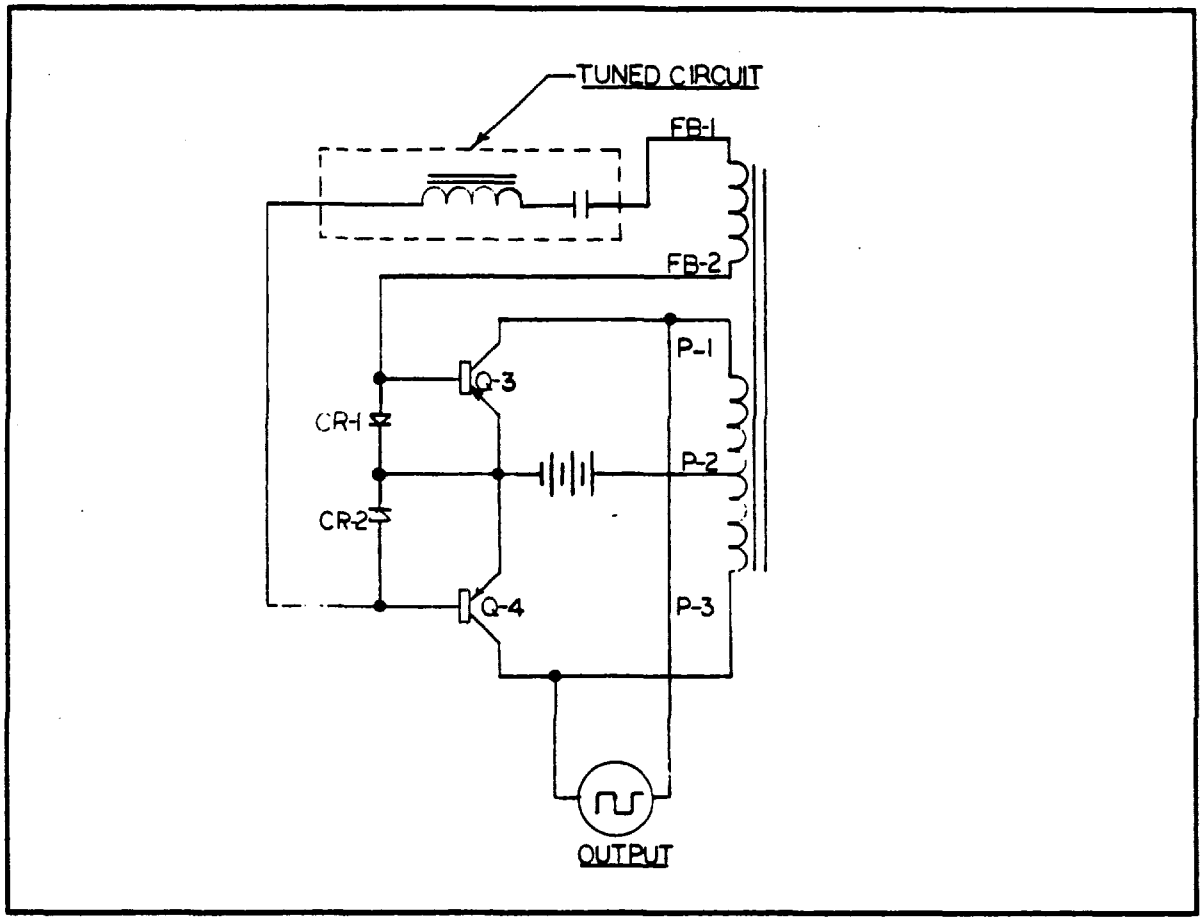

FIGURE 1-4. CIRCUIT DIAGRAM, SQUARE WAVE OSCILLATOR

1.3.1 Square Wave Oscillator (Cont'd)

amplitude of this feedback current is sufficient to drive the transistor into saturation very early in each half cycle. The resultant output is an extremely symmetrical square wave at a frequency of 1680 cps.

1.3.2 Frequency Divider Circuit

The Frequency Divider Circuit is shown in Figure 1-5. The circuit is identical to that of the commonly used saturable core square wave oscillator except that free funning oscillation is prevented by the synchronization pulses derived from the 1680 cps square wave oscillator.

A square wave applied to capacitor C4 is differentiated by the network consisting of C4 and the parallel combination of R7 and R4 to

1.3.2 Frequency Divider Circuit (Cont'd)

provide sync pulses at the center tap of the feedback winding. Assume that transistor Q1 is conducting and that the induced voltage across the feedback winding FB1 is holding Q2 at cutoff. A positive pulse applied to the center tap of the feedback winding will cut off transistor Q1. The same positive pulse applied to the base of Q2 is partially cancelled by

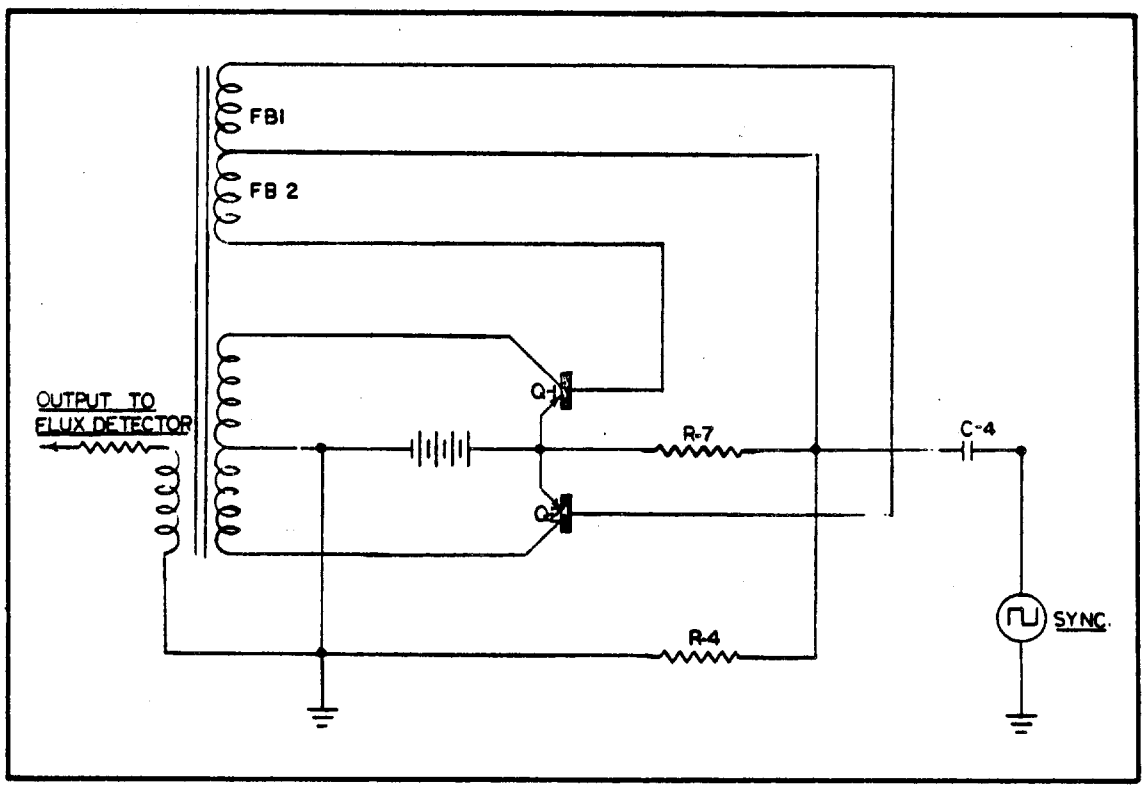

FIGURE 1-5. CIRCUIT DIAGRAM, FREQUENCY DIVIDER CIRCUIT

the collapsing field of feedback coil FB1. The result is that transistor Q2 begins to conduct and transistor Q1 is held at cutoff. A negative pulse applied to the center tap of the feedback winding will merely assist each transistor in maintaining its present state and will consequently have no effect on the output. Thus, the output from the frequency divider is an 840 cps square wave or exactly half the frequency generated by the square wave oscillator.

1.3.3 Magnetic Flux Detector

Operation of the Magnetic Flux Detector may be considered to be

1.3.3 Magnetic Flux Detector (Cont'd)

similar to that of a synchro resolver. The device is capable of shifting the phase of an applied input signal in a direction and magnitude proportional to its relative position with respect to magnetic north. Apart from the wave form being non-sinusoidal, the flux detector output may be considered as equivalent to the stator signal of a synchro resolver in which the rotor is excited. The magnetic flux detector produces a 1680 cps output signal which is the second harmonic of the applied 840 cps input signal.

1.3.4 Synchro Resolver

The output signal from the magnetic flux detector is applied to the windings of a standard synchro resolver mounted in the gyro case. This resolver is mechanically engaged with the large gimbal drive gear so that the heading of the directional gyro is continuously monitored. The synchro resolver electrically compares the heading information obtained from the magnetic flux detector with the mechanical heading information obtained from the gyro. Any difference in the angular position of the two will result in an output voltage across the rotor terminals of the synchro resolver. The phase and amplitude of the resolver output is determined by the direction and amount of correction required.

1.3.5 Amplifier/Filter Circuit

A detailed schematic diagram of the amplifier/filter circuit is shown in Figure 1-6. Since the output of the flux detector is extremely high in harmonic content and the desired 1680 cps signal is severely attenuated, the unwanted signals must be filtered out and the remaining signal must be amplified. Filtering is accomplished by transistors Q7, Q8, capacitors C9 and C10, and resistor R10. The transistors are operated as switches with the switching excitation obtained through resistors R12 and R13 from the collector of the oscillator transistors. During the half cycle in which transistor Q7 is turned on, the energy of the usable signal is being supplied to capacitor C9 and the instantaneous output from the filter is the voltage across C9. During

1.3.5 Amplifier/Filter Circuit (Cont'd)

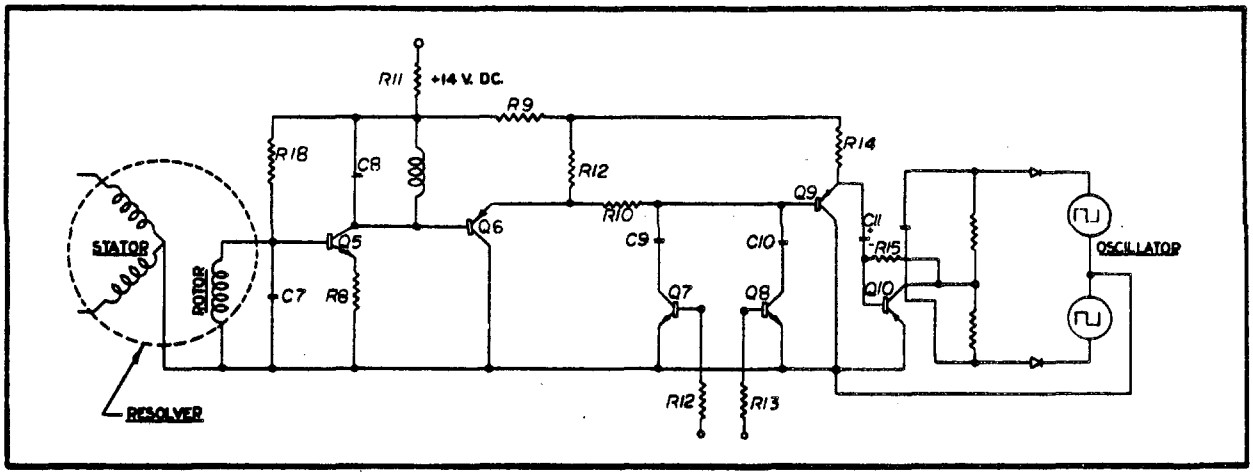

FIGURE 1-6. CIRCUIT DIAGRAM, AMPLIFIER/FILTER CIRCUIT

the other half cycle, switch Q8 is closed and the output voltage is that appearing across capacitor C10. Since the time constants of networks R10-C9, and R10-C10 are much greater than one half cycle of the signal frequency, the output of the synchronous filter is a good square wave.

The square wave output of the synchronous filter is applied to the grounded collector stage transistor Q9 to lower the impedance level. The signal is then applied to the phase detector transistor Q10.

It can be seen that if the voltage applied to the base of Q10 is in phase with the output from the square wave oscillator, the variation in the conductivity of Q10 will result in a greater average current through one-half of the slaving coils than the other. Thus, the direction of torque applied to the inner gimbal assembly is dependent upon the phase relationship between the output of the square wave oscillator and the signal appearing at the base of Q10. The magnitude of this torque is entirely dependent on the magnitude of the signal appearing at the base of Q10.

1.3.6 Electronic Compensator

Compensation of any magnetic compass requires the cancellation of magnetic disturbances which are introduced by magnetic materials

1.3.6 Electronic Compensator (Cont'd)

and electrical equipment fixed to the airframe. By setting up fixed signals and injecting them in addition to the heading signal, the disturbance of the airframe can virtually be eliminated.

The conventional method of compensation is to introduce adjustable magnetic signals (east-west and north-south) in the proximity of the compass element. The method employed in the AIM 400 and AIM 800 systems is to add adjustable electrical signals in series with each flux detector signal. It should be noted that this is a two axis system in which the axes correspond to north-south and east-west.

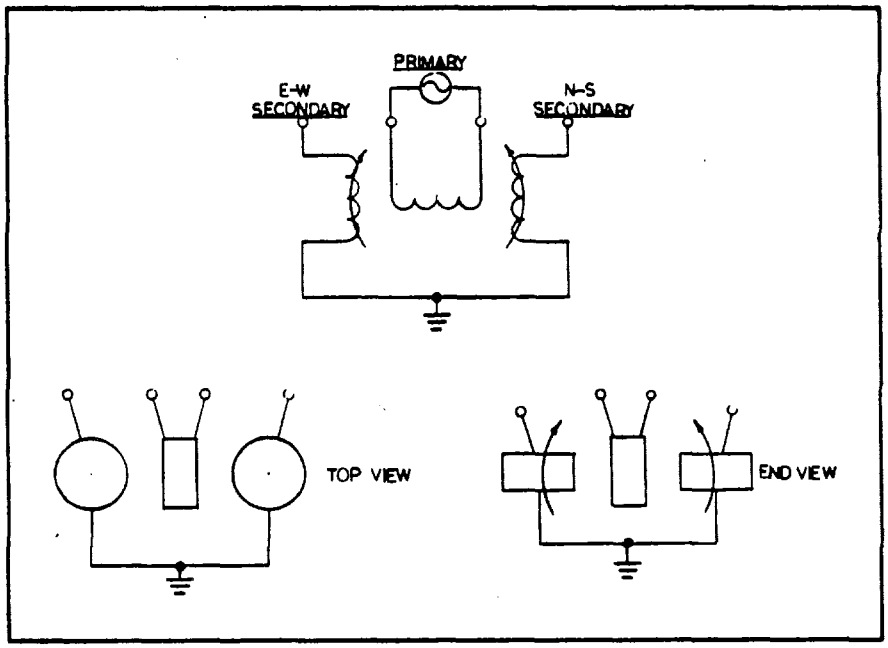

FIGURE 1-7. ELECTRONIC COMPENSATOR

The schematic diagram and physical configuration of the electronic compensator is shown in Figure 1-7. The compensator consists of an air wound transformer with one primary winding and two secondary windings. Each secondary can be rotated to adjust the phase and magnitude of the induced voltage in either the north-south or east-west axes.

The compensator itself is located on the rear of the instrument case. The device is easily accessible and may be adjusted without disassembly of the compensator or the instrument case.

1.3.7 Bootstrap Synchro

Gyros used in AIM 800D and 800E systems are available with an additional "bootstrap" heading synchro designed to supply heading signals to an external differential synchro in an RMI converter. The output of the differential synchro is used to position an ADF/VOR needle on the front of the gyro case. Instruments equipped with the bootstrap synchro are identified by a "-2" designation following the basic model number. These instruments, along with their non-bootstrap counterparts are as follows: 297-2S/297-1S, 297-2D/297-1D, 297-2ES/297-1ES, 297-2ED/297-1ED, 424-2S/424-1S, 424-2D/424-1D, 424-2ES/424-1ES, and 424-2ED/424-1ED.

Due to the size of the bootstrap synchro (size 11 as compared to size 10 of other synchros), it must necessarily be positioned vertically in the rear of the instrument case. Consequently, on all "-2" instruments the slaving synchro is displaced from the rear of the case to a vertical position in the front. See Table 2-1 and Figure 2-0.

1.3.8 RMI Coupler

A schematic diagram of the optional RMI Coupler is shown in Figure 1-9 along with the schematic diagram of a complete AIM 400 system. The schematic for AIM 800 systems is identical to the one shown, with the addition of the synchro-driven ADF/VOR pointers.

The RMI Coupler is actually a servo amplifier which may be used to to drive the heading card of any standard servo-driven RMI. A power source of 26 vac, 400 cps, 8 volt-amperes, is required to operate the coupler circuitry. The 26 vac is internally rectified and filtered so that no additional dc power is required.

The RMI Coupler consists of a three stage servo amplifier with internal rate feedback dampening. Heading information from the gyro slaving resolver is amplified to a sufficient level to operate any of the ARINC standard, servo-driven cards. An auxiliary DC output is provided to actuate a warning flag, if required.

1.4 OPERATING SPECIFICATIONS

NOTE

The following specifications apply to basic system operations only, and do not include the various autopilot outputs and ADF/VOR pointer combinations which are available with many systems.

1.4.1 Electric Gyros

Normal Operating Power	13 VA
Maximum Starting Power	16 VA
Input Voltage	115 vac ± 15%, 400 cps ± 10% single phase, sine or square waveform.
Stability (free gyro)	Can be used as a temporary heading reference if slaving circuitry becomes inoperative.
Rotor Speed	23,500 RPM
Full Scale Slaving Rate	1°/minute, nominal
ADF/VOR Pointer Synchro (s) (AIM 800 Systems only)	Standard ARINC Synchro receiver(s).

1.4.2 Vacuum Gyros

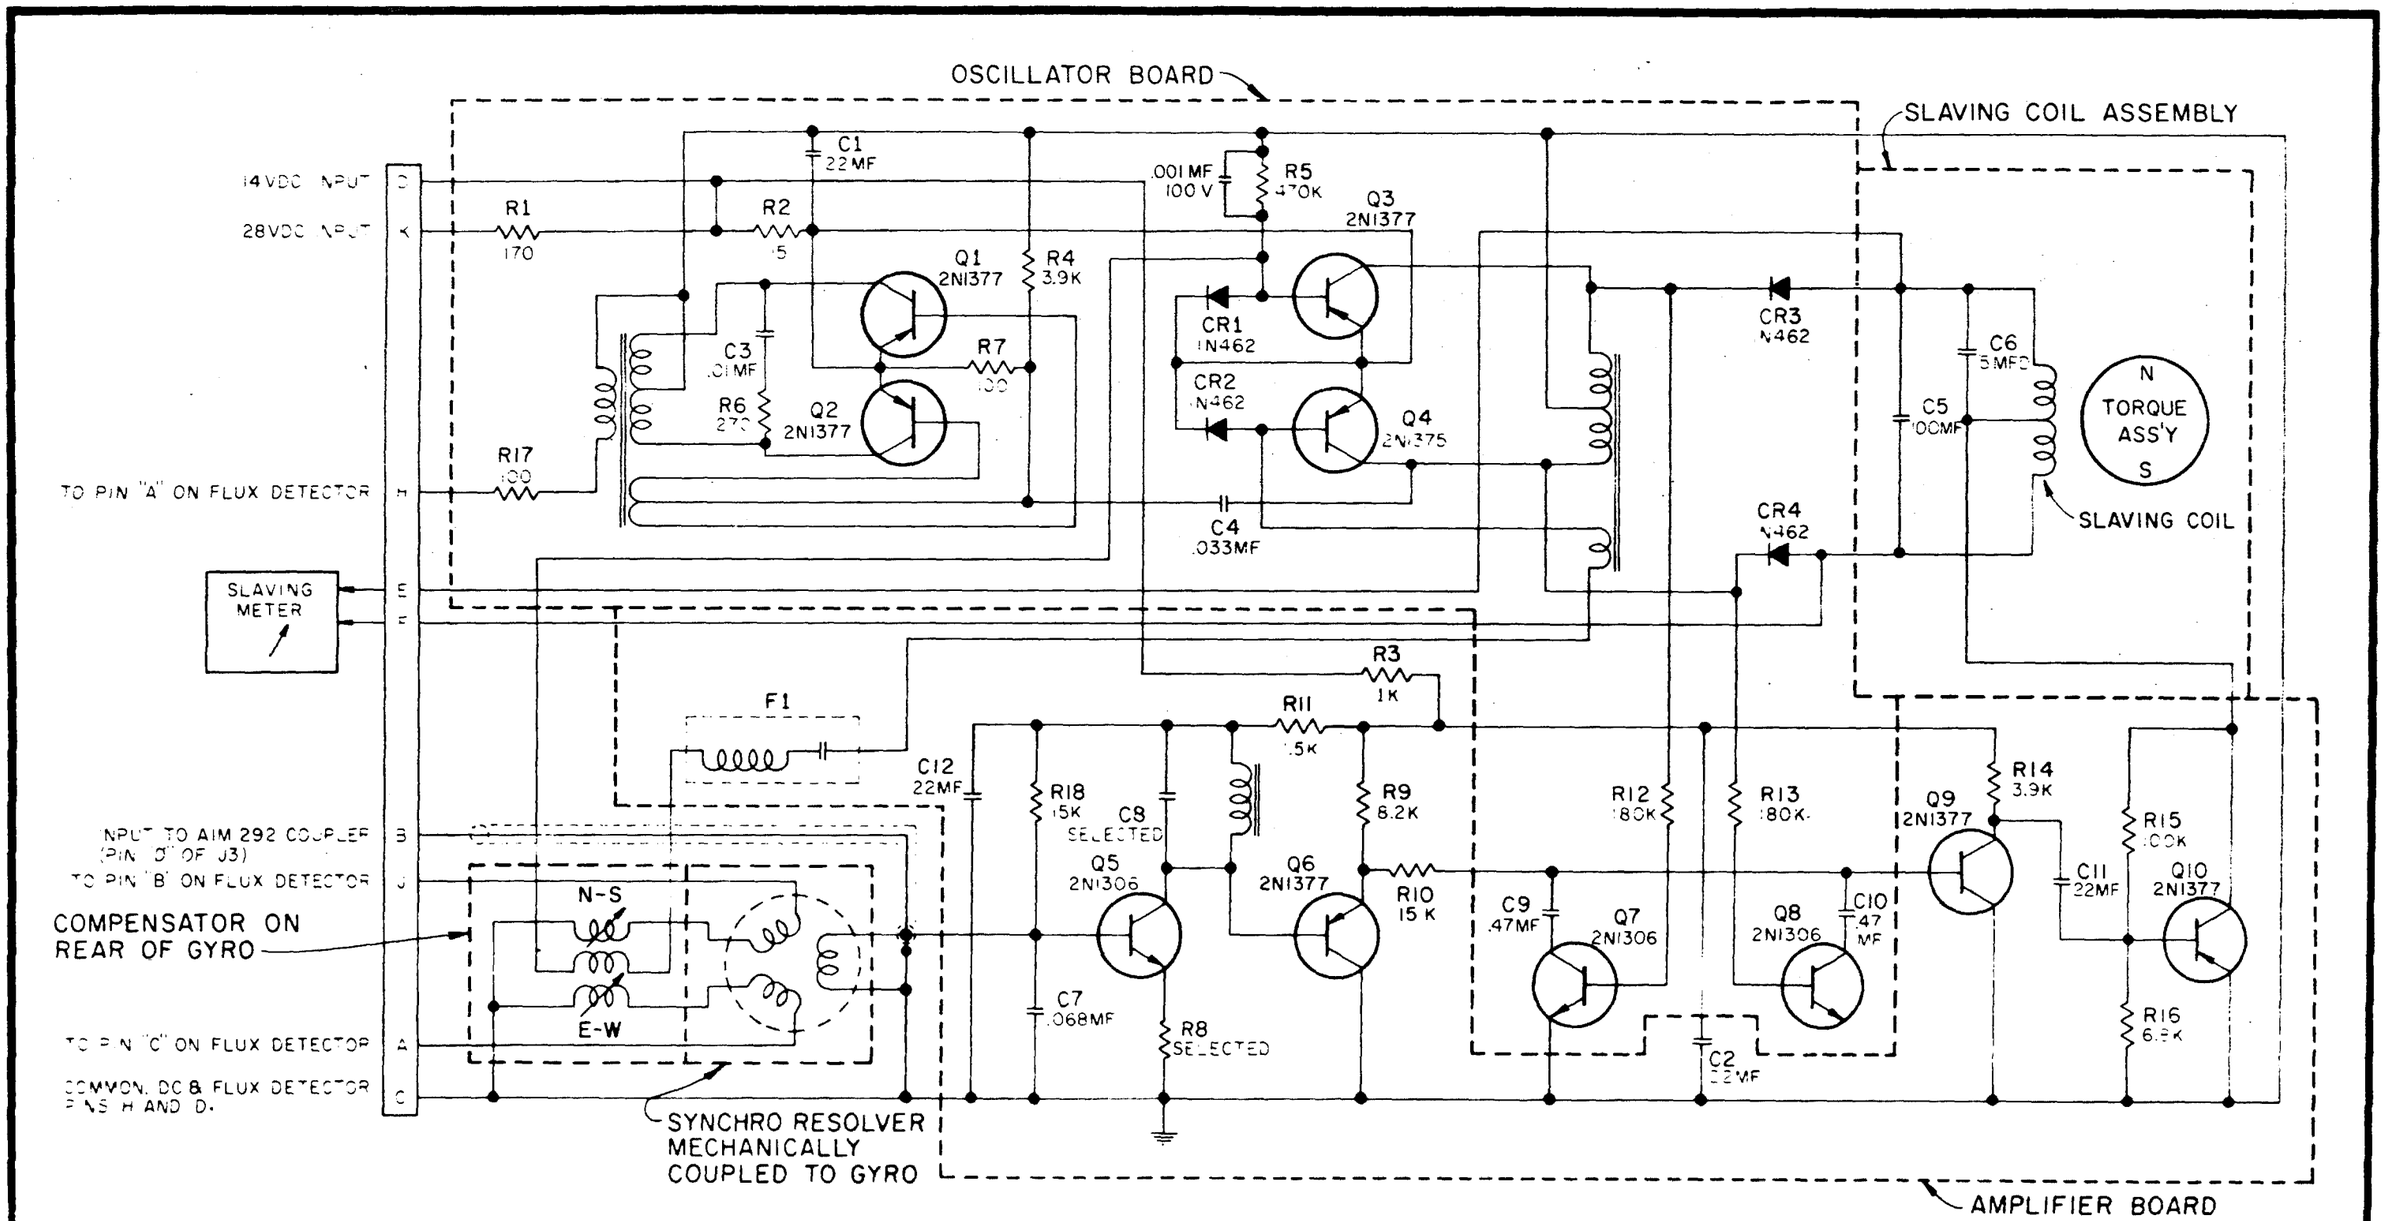
Normal Operating Vacuum	4.5 to 5.2 in. Hg.
Maximum Starting Vacuum	2.25 in. Hg.
Air Consumption	1.8 cubic feet/min.
Stability (free gyro)	Can be used as a temporary heading reference if slaving circuitry becomes inoperative.
Rotor Speed	27,000 RPM
Full Scale Slaving Rate	2°/minute, nominal
ADF/VOR Pointer Synchro (s) (AIM 800 Systems only)	Standard ARINC synchro receiver(s).

1.4.3 Electronic Compass Slaving System

Input Voltage	13.75 or 27.5 vdc (26 volts, 400 cps, 8 VA ac is also required for models used with RMI coupler)
Input Current	0.09 amperes, nominal
Accuracy (fully compensated)	± 1.5 degrees
Heading Drift vs Input voltage Variation	1°/10%
Output	When used with the AIM 292 RMI Coupler, the basic slaved system produces a heading output suitable for driving the heading card of any standard servo-driven RMI.

1.4.4 AIM 254-11 Flux Detector

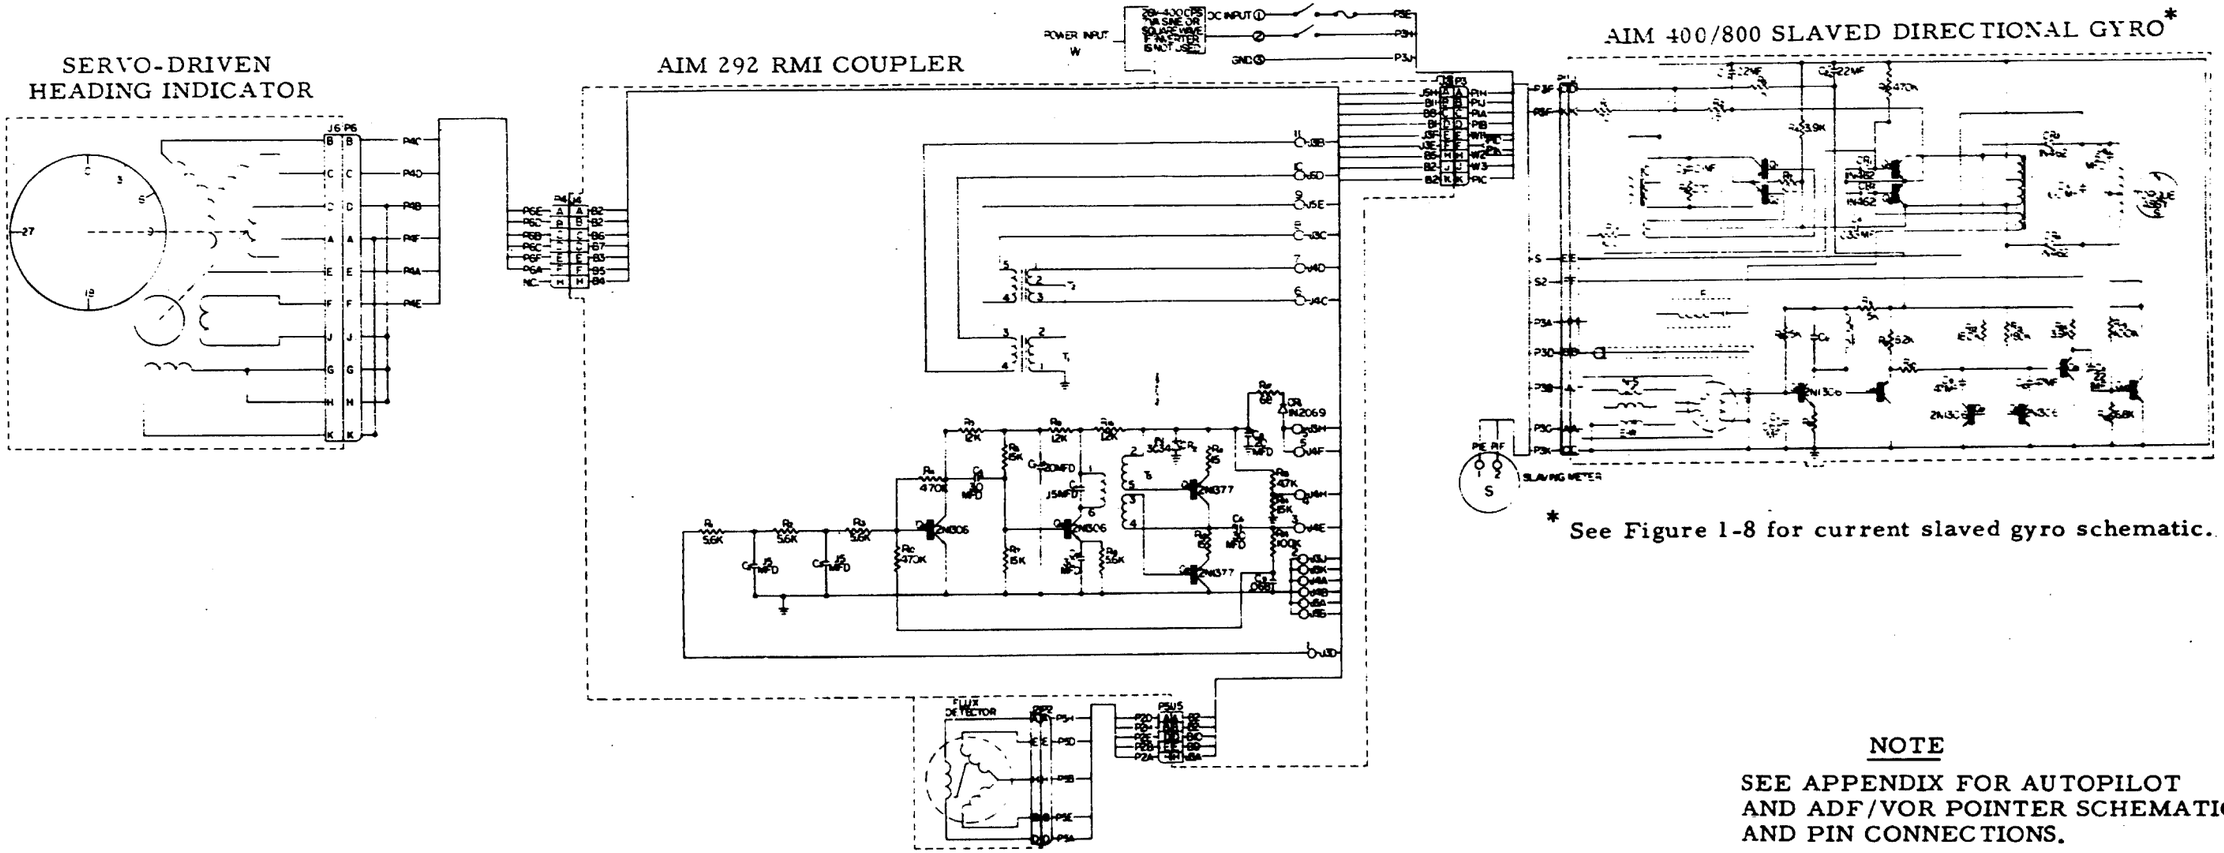
Input	840 cps reference signal from slaved gyro.
Output	1680 cps signal (second harmonic of 840 cps input) the phase of which is shifted in direction and magnitude proportioned to the relative position of the flux detector with respect to magnetic north.



Note

The Flux Detector is a sealed unit and is not repairable in the field. To check for open windings, use a Simpson VOM or equivalent and check for the following DC resistance readings:

Pins "A" to "D" = 0.2 to 5.0 ohms
Pins "H" to "E" = 50 to 200 ohms
Pins "H" to "B" = 50 to 200 ohms



1.4.5 Slaving Indicator

Description	5-0-5 vdc meter with 50,000 ohms across the input terminals.

NOTE:
SEE APPENDIX FOR AUTOPILOT AND ADF/VOR POINTER SCHEMATICS AND PIN CONNECTIONS.

FIGURE 1-8.
SCHEMATIC DIAGRAM, BASIC SLAVED GYRO

* See Figure 1-8 for current slaved gyro schematic.

NOTE

SEE APPENDIX FOR AUTOPILOT AND ADF/VOR POINTER SCHEMATICS AND PIN CONNECTIONS.

FIGURE 1-9.
AIM 400/800 SYSTEM WITH RMI COUPLER

SECTION 2
OVERHAUL AND CALIBRATION
of
ELECTRIC AND VACUUM-DRIVEN GYROS

2.1 GENERAL

This section contains overhaul and calibration procedures for both electric and vacuum driven instruments. Specific procedures which are applicable only to vacuum-driven instruments are identified by "Vacuum Only". Procedures applicable only to electrically-driven gyros are identified by "Electric Only". All steps or procedures not otherwise identified, may be considered applicable to both electric and vacuum driven instruments.

Table 2-1 provides a convenient tabulation of information pertaining to the many gyros covered in this manual. Because of variations in the type, size, and number of synchros used, locations of synchros within the case vary from model to model. The table lists each gyro model number and uses a key letter (A, B, etc.), referenced to the illustration of Figure 2-0, to show the location of each synchro. The functional identification of each synchro is noted in the appropriate column.

Instrument overhaul may be required due to a specific malfunction or merely as a routine step in a periodic maintenance program. Regardless of the reason, the disassembly and overhaul procedures in this section are applicable and should be closely followed.

As each assembly is disassembled, the location of each component should be noted so that it can be replaced in the same position. This is particularly true of bearings, pivots, or jewels. Although the same bearing type may be used in several positions, the bearings are designed to provide different amounts of radial play according to their use and location within the instrument.

When handling the ADF/VOR needles and/or the circular indicator card, care should be taken to avoid soiling the various markings. All bearings, pivots, and jewels should be handled with assembly tweezers

2.1 GENERAL (Cont'd)

to avoid contamination. Iridited, oxided, or passivated parts must be protected against scratching or marring. Self-locking nuts with worn fibers must be replaced. Nuts and screws used for balancing must be secured in final adjusted position by "Glyptal" (G. E. Trademark). Solvents used for cleaning must be high grade such as Chlorothene-Nu (Dow Chemical Co.).

2.2 TOOLS REQUIRED

All routine maintenance or repair work can be accomplished with standard instrument-shop handtools. A pair of assembly tweezers, an eye loupe, a selection of small screwdrivers, a 0.3 gram counterbalance, 1/4" and 3/16" open-end wrenches, #2 and #4 Bristol spline wrenches, and the spanner wrenches of Figure 2-1 are the basic tools which are normally required.

Spanner wrench "A" is used in removing the threaded bearing housing from the gimbal assembly. Spanner "B" is used in conjunction with spanner "A" to simultaneously hold the threaded bearing housing in position in the gimbal and to secure the lock ring (some models only) in place around it.

Spanners "C" and "E" are used in removing the threaded housings from each end of the 34B and R3H rotor housings, respectively. Spanner "D" is used to remove the lock rings securing the threaded housings in place.

2.3 DISASSEMBLY PROCEDURES

2.3.1 General

Before proceeding with disassembly of any component, the degree of wear, end play, backlash, and general physical appearance must be checked and noted as an aid in reassembly.

During disassembly, extreme care must be used in the removal of any component. Use of proper tools is important to prevent damage by scratching or marring. Screws or other attaching parts must be carefully identified during disassembly for correct replacement during reassembly.

TABLE 2-1. SYNCHRO FUNCTIONS AND LOCATIONS (Figure 2-0).

GYRO MODEL NO.	SYNCHRO FUNCTION/LOCATION				
	Position A	Postion B	Position C	Position D	Position E
254-92, 254-1E	Slaving	-	-	-	-
254-1S, 254-1ES	Slaving	1-bar pointer	-	-	-
254-1D, 254-1ED	Slaving	2-bar pointer	-	1-bar pointer	-
289-1, 289-1E	4-power synchro*	Slaving	-	-	-
289-2, 289-2E	4-power synchro	Slaving	1-power synchro	-	-
289-1S, 289-1ES	4-power synchro	1-bar pointer	Slaving	-	-
289-2S, 289-2ES	4-power synchro	1-bar pointer	Slaving	-	1-power synchro
289-1D, 289-1ED	4-power synchro	2-bar pointer	Slaving	1-bar pointer	-
289-2D, 289-2ED	4-power synchro	2-bar pointer	Slaving	1-bar pointer	1-power synchro
289-3, 289-3E	Autopilot	Slaving	-	-	-
289-3S, 289-3ES	4-power synchro	1-bar pointer	Slaving	-	Autopilot
289-3D, 289-3ED	4-power synchro	2-bar pointer	Slaving	1-bar pointer	Autopilot
293-1, 293-1E	Slaving	-	-	-	-
293-1S, 293-1ES	Slaving	1-bar pointer	-	-	-
293-1D, 293-1ED	Slaving	2-bar pointer	-	1-bar pointer	-
297-1, 297-1E	Autopilot	Slaving	-	-	-
297-1S, 297-1ES	Autopilot	1-bar pointer	Slaving	-	-
297-2S, 297-2ES	4-power synchro	1-bar pointer	Slaving	-	Autopilot
297-1D, 297-1ED	Autopilot	2-bar pointer	Slaving	1-bar pointer	-
297-2D, 297-2ED	4-power synchro	2-bar pointer	Slaving	1-bar pointer	Autopilot
299-1, 299-1E	Slaving	1-power synchro	-	-	-
424-1, 424-1E	Autopilot	Slaving	-	-	-
424-1S, 424-1ES	Autopilot	1-bar pointer	Slaving	-	-
424-2S, 424-2ES	4-power synchro	1-bar pointer	Slaving	-	Autopilot
424-1D, 424-1ED	Autopilot	2-bar pointer	Slaving	1-bar pointer	-
424-2D, 424-2ED	4-power supply	2-bar pointer	Slaving	1-bar pointer	Autopilot

*Older models contain a 1-power (size 10) synchro instead of a 4-power (size 11) synchro.

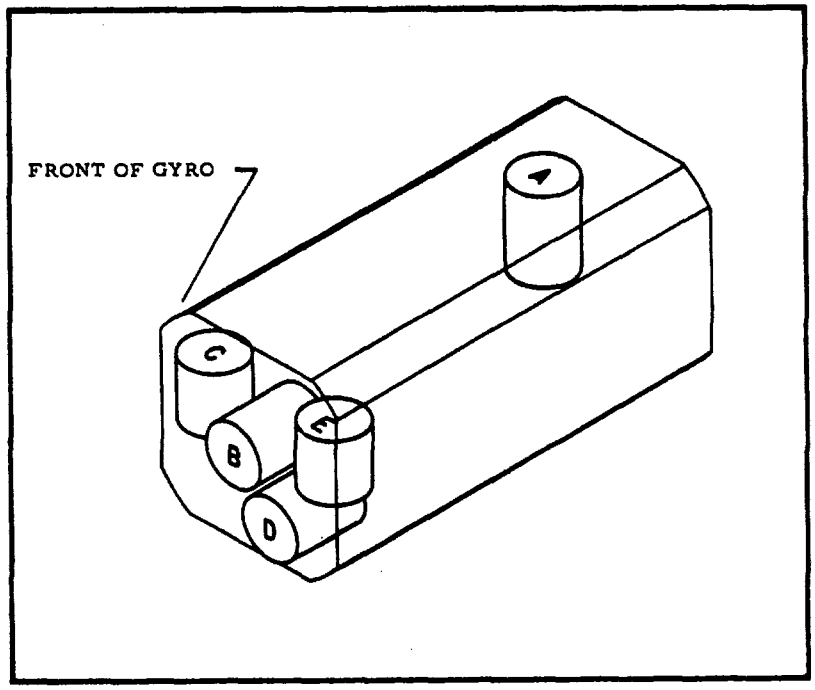


FIGURE 2-0. SYNCHRO LOCATIONS IN THE INSTRUMENT

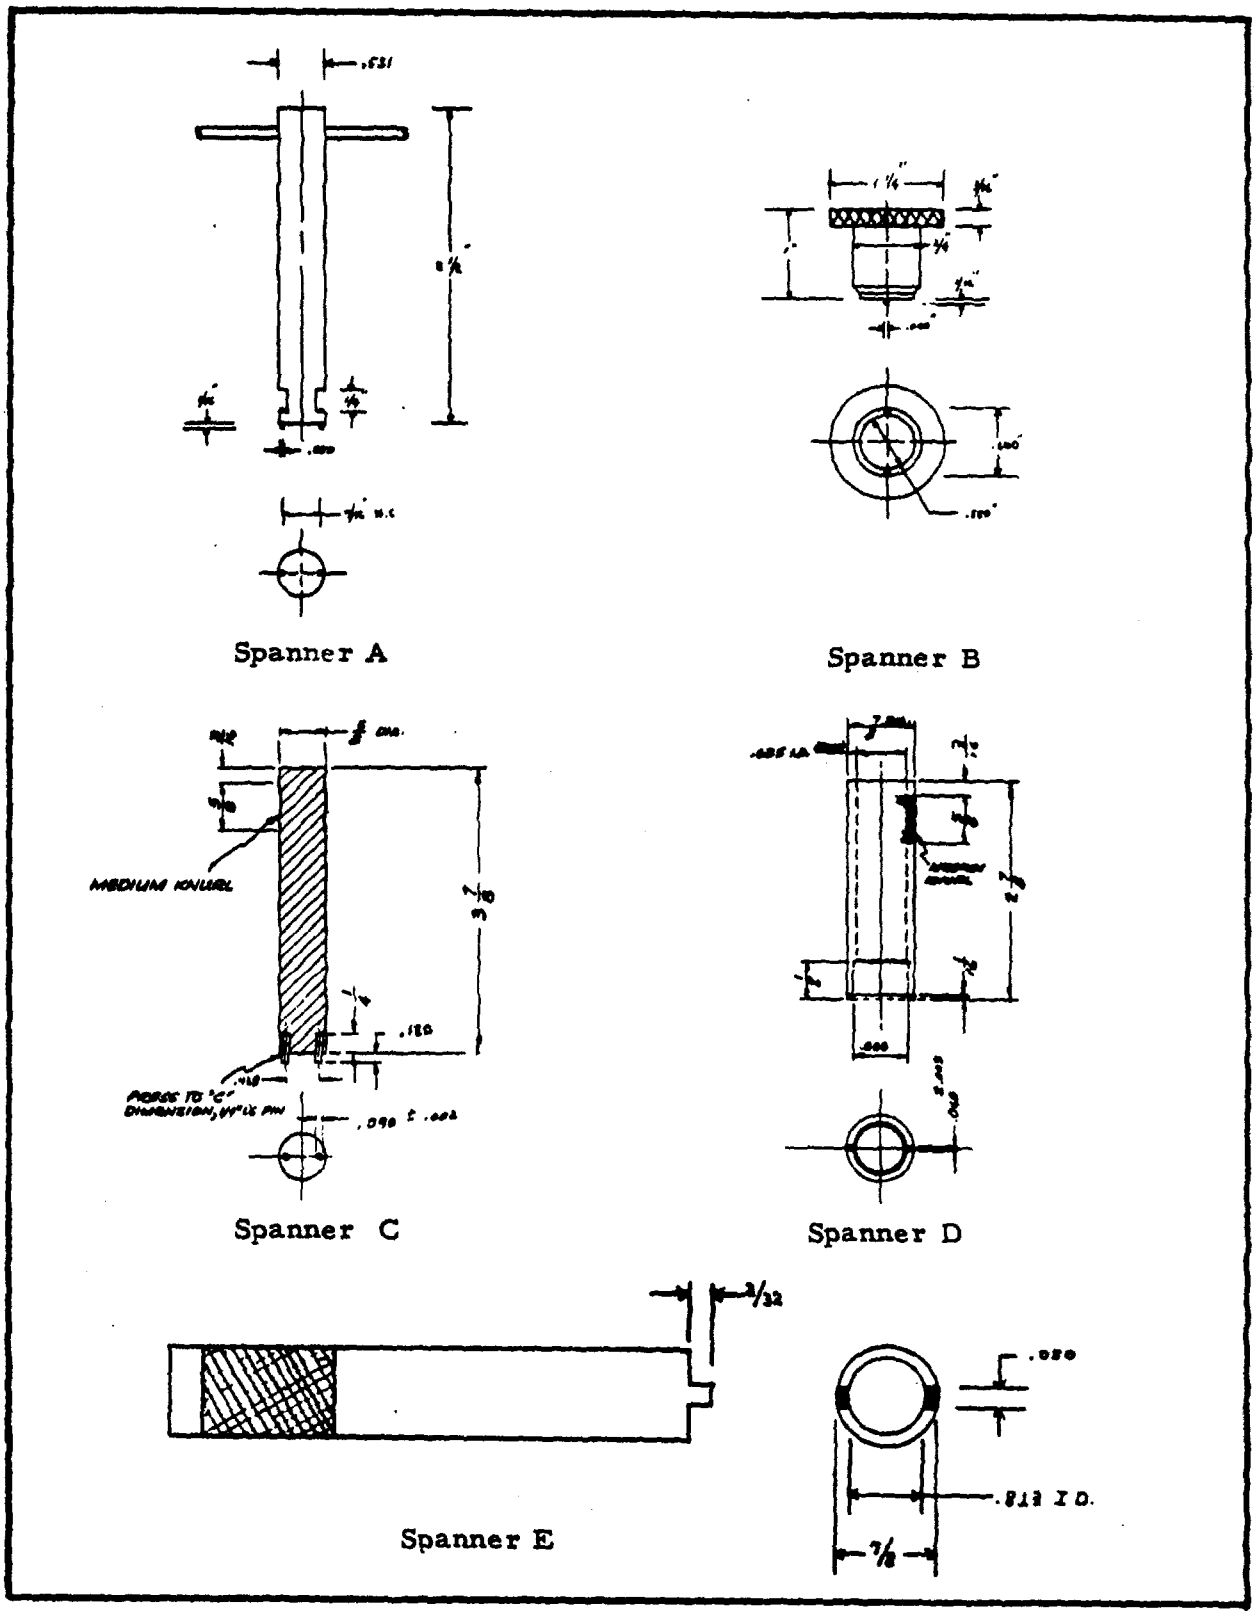

FIGURE 2-1. CONSTRUCTION OF SPECIAL TOOLS

2.3.1 General (Cont'd)

Due to the delicate rebalancing required and the precision parts involved, disassembly and overhaul of the rotor and rotor housing assembly is not recommended. Should the rotor become defective and fail to meet the performance requirements set forth in Section 3, return the used rotor housing and pivot assembly to AIM for an exchange discount on a new replacement assembly.

It should therefore be noted that the following disassembly, cleaning, adjustment, and reassembly procedures do not include provisions for overhaul of the rotor and rotor housing assembly. However, instructions are provided in paragraphs 2.7 and 2.8 for overhaul of the rotor and rotor housing should this become necessary in the field.

If a replacement rotor housing and pivot assembly is secured from AIM, it will be closely balanced and adjusted when received from the factory. Additional balancing or adjustment of the rotor housing may be necessary after assembly in gimbal.

2.3.2 Case Access

(1) Remove the gyro caging knob by loosening the #4-40 spline setscrew which secures the knob to the shaft. A #4 Bristol spline wrench is provided on the rear of the case for this purpose.

NOTE

The #4 Bristol spline wrench is intended to facilitate the rapid installation and removal of the unit from an instrument panel. It should not be used to remove screws inside the instrument due to the possibility of paint flakes contaminating the unit. Instead, an unpainted wrench should be used.

(2) Remove the 7 screws securing the bezel assembly to the main housing. One of the mounting-screw recesses is filled with sealing wax which must be removed. Care should be taken to insure that the front gasket remains in position on the bezel when the bezel is removed. This is done to minimize the possibility of contaminating the unit

2.3.2 Case Access (Cont'd)

with paint flakes from the rubber gasket.

(3) Carefully remove the dust cover, making sure that the rear gasket remains in position on the rear panel of the instrument housing.

(4) When the dust cover has been removed, slip the rear gasket over the rear panel and away from the unit. The front and rear gaskets and the dust cover should be taken to a remote area and thoroughly cleaned of all paint and foreign matter. The gaskets can be cleaned by stretching until the paint cracks and then scraping the flakes away. The same gaskets can be reused when the dust cover is again installed.

2.3.3 Removal of Gimbal Assembly

(1) Remove 3 screws securing the oscillator board to the left rear side of the instrument case.

(2) Using a felt-tip marking pen or similar device, draw an alignment mark across the interface between the gimbal gear and the resolver gear and a second mark between the gimbal gear and the intermediate spur gear. The purpose of these marks is to simplify realignment of the gear train during reassembly.

(3) Remove 4 screws holding the slaving coil to the instrument case.

(4) Place the instrument in its normal position with the caging knob in the lower left corner of the instrument front panel. Remove 3 flat head screws and remove the upper gimbal pivot from the instrument casting (Figure 2-2).

(5) Vacuum Only - Turn the unit over and remove the 2 screws securing the lower (air seal) bearing housing. The housing may contain alignment shims which are used to correctly align the air passage in the housing with the air

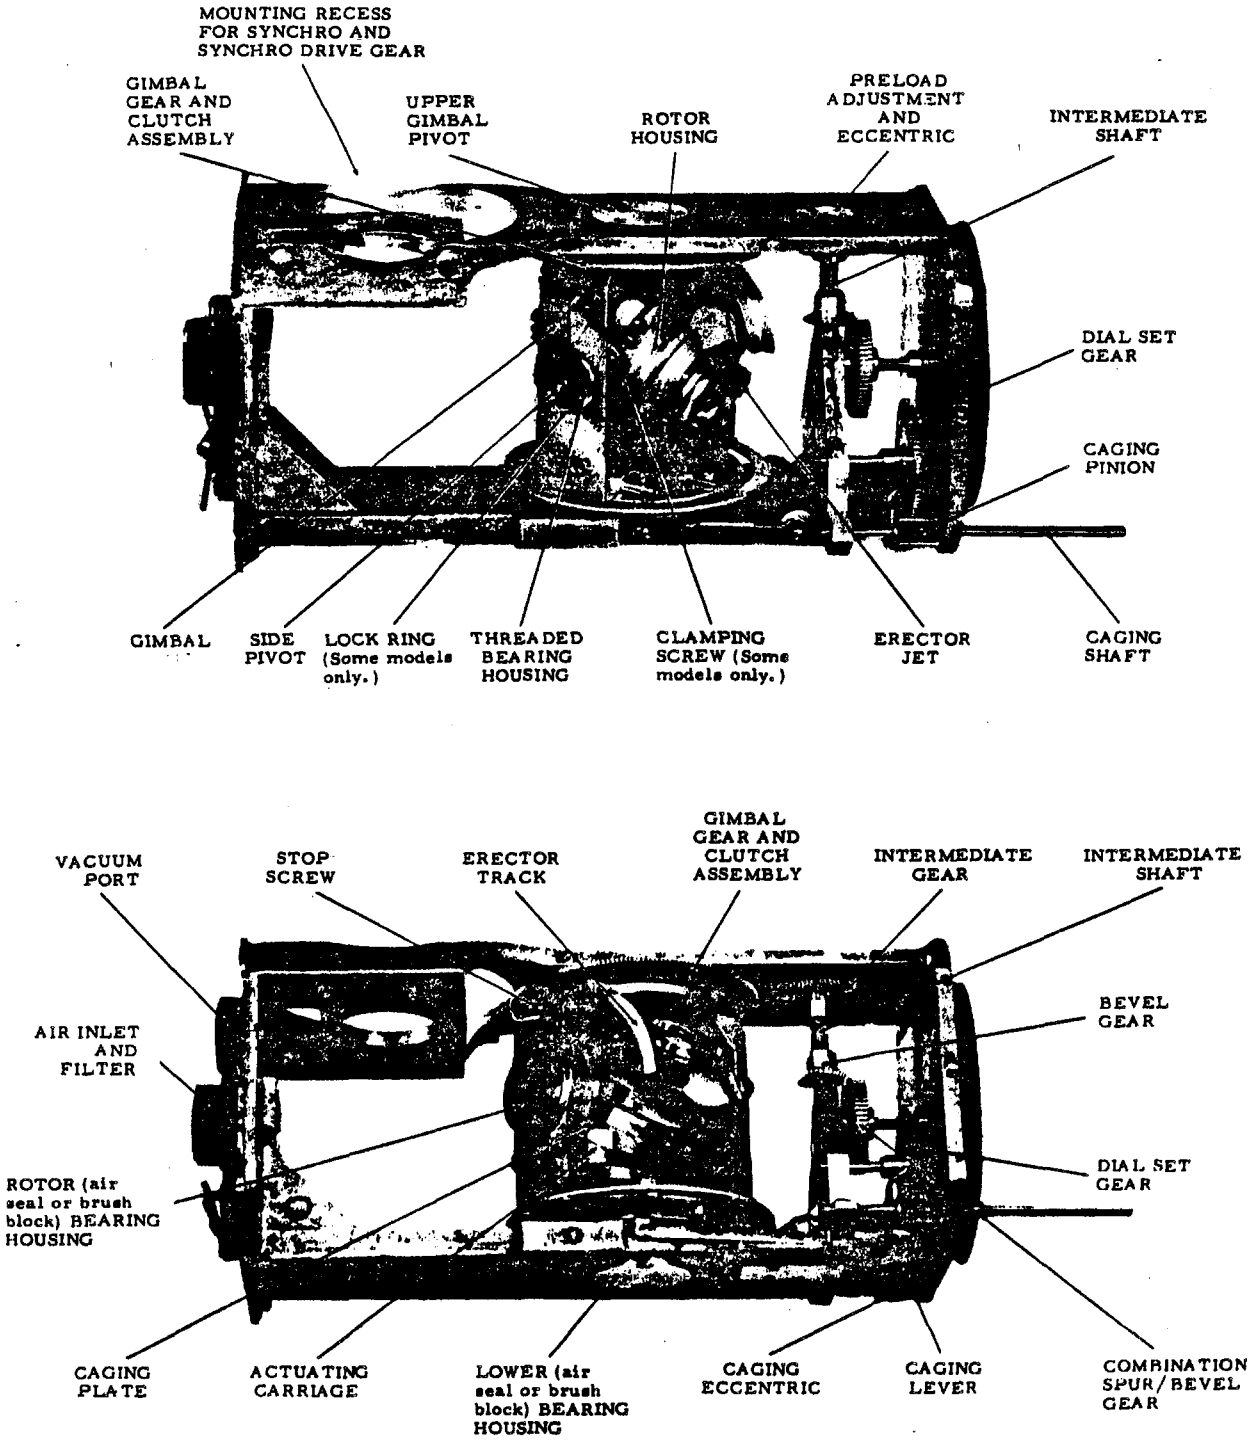

FIGURE 2-2. IDENTIFICATION OF PRIMARY COMPONENTS PARTS

2.3.3 Removal of Gimbal Assembly (Cont'd)

passage in the instrument casting. If shims are included, they should be retained for use during reassembly.

(6) Electric Only - Turn the unit over and remove the gimbal brush block and the two screws securing the lower bearing housing. Remove the lower bearing housing.

(7) Removal of the lower housing permits access to the screws holding the pivot on the bottom of the gimbal. Remove the two pivot screws and lift the pivot off the bottom of the gimbal. When the pivot is lifted into the lower housing recess, the entire gimbal assembly may be removed.

NOTE

The slaving coil must be temporarily removed in order to remove the gimbal. In doing so, care must be taken to avoid unnecessary lead strain which could result in broken electrical connections.

(8) Disassembly of the clutch assembly at the top of the gimbal is not recommended unless specific replacement of component parts is required. If disassembly becomes necessary, proceed as follows:
Remove three screws securing the clutch assembly to the gimbal. During disassembly, notice the order in which the bearing housing, the washer, the gimbal gear, and the friction shim are removed. First comes the bearing housing, then the spring washer, the gimbal gear, and then the friction shim which is mounted between the gimbal gear and the gimbal.

2.3.4 Removal of Rotor Housing

The rotor housing may be removed from the gimbal in much the same manner as the gimbal was removed from the instrument:

(1) Loosen the two #2-56 Bristol setscrews holding the erector track (Figure 2-2) to the gimbal and remove the erector track. Also loosen the binder head stop screw enough to

2.3.4 Removal of Rotor Housing (Cont'd)

permit 360° rotation of the rotor housing.

(2) Vacuum Only - Remove the rotor air seal housing and the two screws which hold the air pivot in place.

(3) Electric Only - Remove the rotor brush block and bearing housing. Also remove the two screws which hold the slip-ring pivot in place.

(4) Remove the slaving magnet by removing the flat head screw holding the magnet to the threaded bearing housing.

(5) Loosen the clamping screw shown in Figure 2-2 and remove the threaded bearing housing from the side of the gimbal.

(6) Remove the three pivot screws and lift the side pivot off the rotor housing and out through the threaded opening. The rotor housing may now be removed from the gimbal.

2.3.5 Disassembly of Gear Trains, General

There are two basic types of gear trains described in the following paragraphs. Paragraphs 2.3.6 (1) and (2) concern the basic gear train used in all AIM 400 gyros. Minor differences in the basic gear train, due to varying output requirements among specific systems, are also explained.

Paragraphs 2.3.6 (3) through 2.3.6 (7) concern the basic gear train used in all AIM 800 single and dual needle gyro/RMI instruments. Minor variations in construction due to varying output requirements, and differences between single and dual pointer instruments are also fully explained.

The purpose of each gear train is the transmission of accurate heading information throughout the instrument. When fully assembled, the gear train maintains the indicator card and all synchros and pointers in a fixed relationship. This relationship is critical and can be lost by loosening a single gear on its shaft. Consequently, before loosening any gear on its supporting shaft, make an alignment mark at the interface between the gimbal gear and its adjacent gears to simplify realignment.

2.3.5 Disassembly of Gear Trains, General (Cont'd)

Under normal operating conditions, the gear train should function in excess of 1,000 hours without defect or loss of efficiency and accuracy. Should a defect occur, and removal of a synchro be required, remove or loosen only that portion of the gear train necessary to obtain access to the defective synchro. Here again, an alignment mark should be placed on adjacent gears to simplify realignment.

Should it become necessary, disassembly or repair of specific drive trains may be accomplished with a minimum of detailed instruction. However, certain areas of disassembly do require some clarification. These areas are fully explained in the following paragraphs. Reference to the associated illustrations will prove helpful in identifying the affected parts.

2.3.6 Disassembly of Specific Gear Trains

1) AIM 254-92 293-1
AIM 254-1E 293-1E

The instrument shown in Figure 2-3 is an AIM 254-92 Slaved Gyro used in the AIM 400 System. For purposes of this discussion, it may be considered identical to AIM 254-1E, 293-1, and 293-1E instruments. The unit contains a synchro resolver which is mounted in the rear of the instrument and is used in the internal slaving circuitry. Both the synchro resolver and the indicator card are driven by the large spur gear at the top of the gimbal assembly. The indicator card is positioned through a simple gear train consisting of the gimbal gear, the intermediate spur gear, the intermediate shaft, the bevel gear, the combination spur/bevel gear, and the card shaft.

To check the drive train for proper operation, loosen the setscrew in the intermediate spur gear (Figure 2-3). Slide the gear down the shaft so that it no longer engages with the gimbal gear. Spin the gear slowly and check for freedom and smoothness of operation.

The intermediate shaft is suspended in two precision bearings. A threaded bearing housing at the top of the shaft permits adjustment of the preload on the shaft bearings. A solvent must be used to

2.3.ó Disassembly of Specific Gear Trains (Cont'd)

1) AIM 254-92 293-1 (Cont'd.)
AIM 254-1E 293-1E

dissolve the Glyptal securing the housing before adjustment can be made. If desired, the eccentric holding the threaded housing may be removed without disturbing the preload adjustment. If the spur gear does not bind with the gimbal gear, and yet the eccentric must be removed, place a mark on the eccentric and a corresponding mark on the instrument casting so that the eccentric can be properly installed with minimum difficulty.

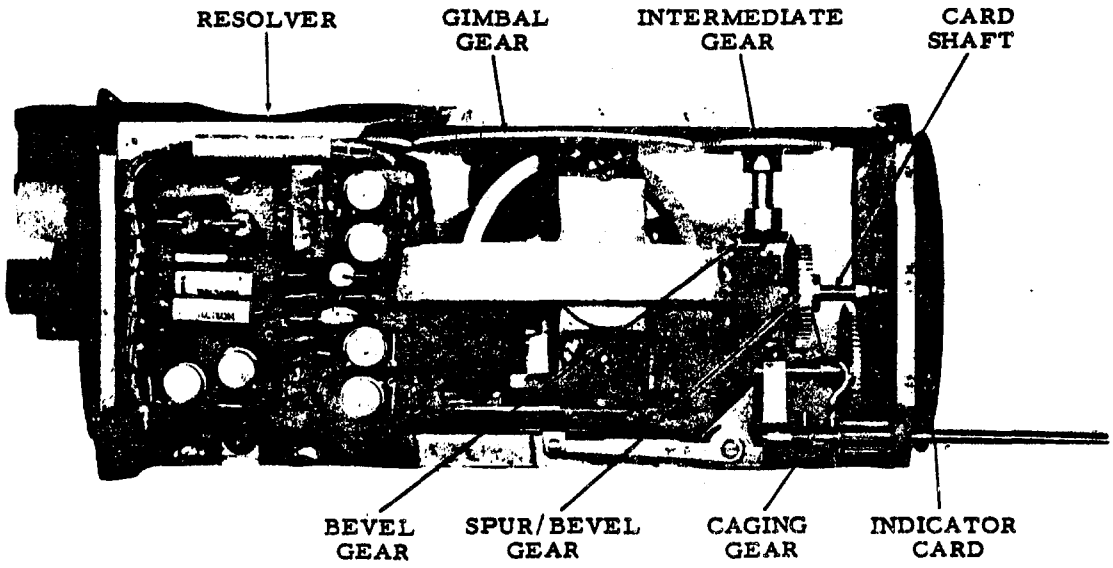

FIGURE 2-3. AIM 254-92 SLAVED GYRO

With the eccentric removed, the intermediate shaft and its associated gears may easily be lifted from the instrument. Care should be taken that the position of the two gears on the intermediate shaft be noted to insure correct replacement. Unless replacement or adjustment of the bevel gear is required, do not loosen the set-screw holding it to its shaft. This simplifies reassembly and eliminates the possibility of reinserting the shaft backwards.

The main horizontal drive shaft may be disassembled by first removing the two securing screws from the front face of the instrument casting. To remove the front bearing, press the combination spur/bevel gear toward the front. If the spur/bevel gear and the

2.3.6 Disassembly of Specific Gear Trains (Cont'd)

1) AIM 254-92 293-1 (Cont'd.)
AIM 254-1E 293-1E

associated shaft collars are to be removed, note their approximate position along the shaft. Also notice that the flanged face of each collar is toward its respective bearing.

Once the spur/bevel gear and the shaft collars are loosened on the shaft, the main bearing which supports the rear of the shaft may easily be removed. Use a small, flat-faced bar, 0.344 inch diameter, and push the bearing from the rear toward the front of the casting.

Removal of the rear bearing permits access to the bearing housing at the base of the intermediate shaft. The housing is secured with Glyptal and a solvent must be used before removal is attempted. By inserting an L-shaped bar into the opening created by removal of the rear bearing, the housing at the base of the intermediate shaft may easily be removed with a slight upward pressure. In turn, the bearing can be removed from the housing in the same way, by pushing through the opening in the bottom and forcing the bearing out of the housing.

The small piece of steel wire attached to the case is designed to ride against the dial shaft and to damp out any oscillation in the dial due to excessive play in the gear mechanism. If the wire is to be removed, notice its position so that it may be properly reinstalled.

2) AIM 289-1 289-3 297-1 424-1 725A Bendix
AIM 289-1E 289-3E 297-1E 424-1E

The instrument shown in Figure 2-4 is an AIM 289-1 Slaved Gyro used in the AIM 400C System. For purposes of this discussion, it may be considered identical to the instruments listed in (2) above. The unit employs one synchro resolver and one synchro transmitter. The resolver is mounted in the front of the unit and is used in the internal slaving circuitry. The synchro transmitter is mounted in the rear of the unit and is used to provide heading information to external systems. Both synchros are driven by the large spur gear at the top of the gimbal assembly. The indicator card and front synchro are positioned through a simple gear train consisting of the gimbal gear, the intermediate spur gear, the intermediate shaft,

2.3.6 Disassembly of Specific Gear Trains (Cont'd)

2) AIM 289-1 289-3 297-1 424-1 725A Bendix (Cont'd.)
AIM 289-1E 289-3E 297-1E 424-1E

the bevel gear, the combination spur/bevel gear, and the double-ended synchro shaft.

The intermediate shaft is suspended in two precision bearings. A threaded bearing housing at the top of the shaft permits adjustment of the preload on the shaft bearings. A solvent must be used to dissolve the Glyptal securing the housing before adjustment can be made. If desired, the eccentric holding the threaded housing may be removed without disturbing the preload adjustment. If the intermediate gear does not bind with the gimbal gear, and yet the eccentric must be removed, place a mark on the eccentric and a corresponding mark on the instrument casting so that the eccentric can be properly installed with minimum difficulty.

With the eccentric removed, the intermediate shaft and its associated gears may easily be lifted from the instrument. Care should be taken that the position of the two gears on the intermediate shaft be noted to insure correct replacement. Unless replacement or adjustment of the bevel gear is required, do not loosen the setscrew holding it to its shaft. This simplifies reassembly and eliminates the possibility of reinserting the shaft backwards.

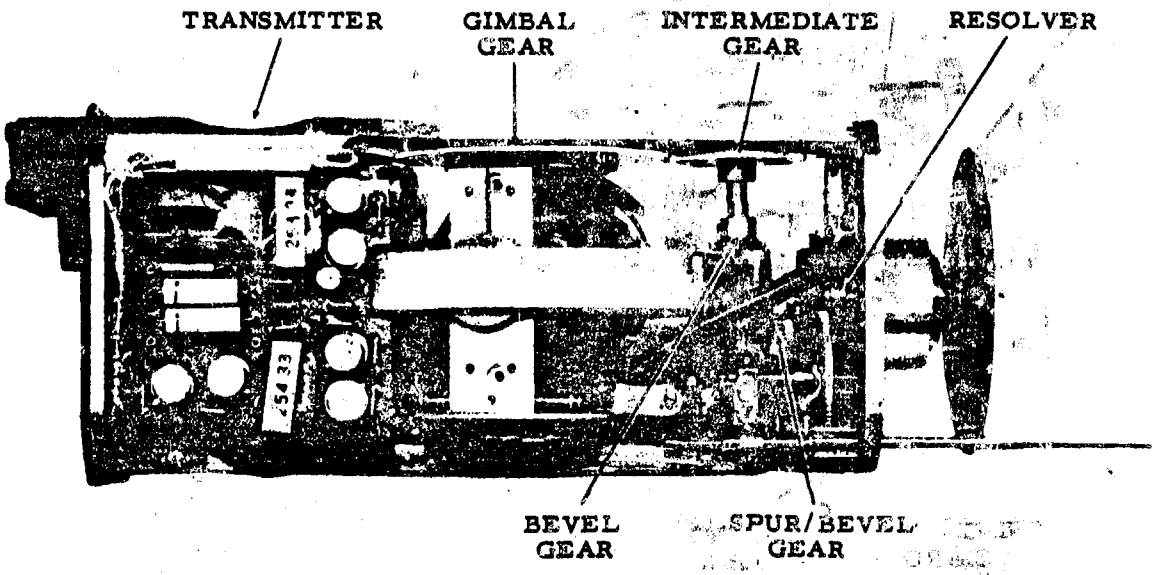

FIGURE 2-4. AIM 289-1 SLAVED GYRO

2) AIM 289-1 289-3 297-1 424-1 725A Bendix *(Cont'd.)*
AIM 289-1E 289-3E 297-1E 424-1E

To obtain access to the front synchro, remove two binder head screws holding the synchro housing to the case. Loosen appropriate cable clamps to permit removal of entire assembly through the front of the case. To further disassemble, remove the indicator card and the combination spur/bevel gear, loosen the setscrew holding the synchro in place and remove the synchro through the rear of the housing.

3) AIM 254-1S 293-1S
AIM 254-1ES 293-1ES

The instrument shown in Figure 2-5 is an AIM 254-1S Slaved Gyro/RMI used in the AIM 808 System. For purposes of this discussion it may be considered identical to the instruments listed in 3) above. The unit employs one synchro resolver and one synchro receiver. The synchro resolver is mounted in the rear of the unit and is used in the internal slaving circuitry. The synchro receiver

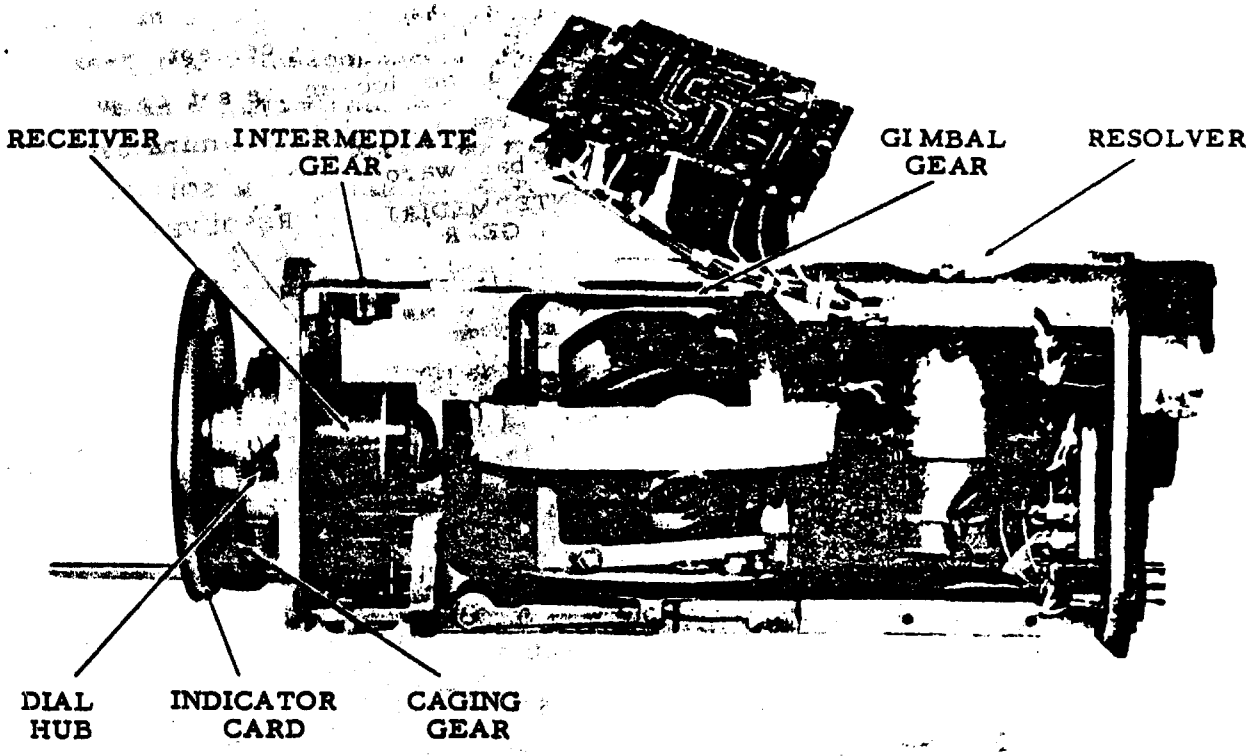

FIGURE 2-5. AIM 254-1S SLAVED GYRO/RMI

2.3.6 Disassembly of Specific Gear Trains (Cont'd)

3) AIM 254-1S 293-1S (Cont'd.)
AIM 254-1ES 293-1ES

is mounted in the front of the instrument and is electrically positioned by signals from an external source.

The synchro resolver and the indicator card are positioned by a simple gear train which runs along the top of the instrument case. The intermediate gear is suspended on two precision bearings on the intermediate shaft. The shaft itself is eccentrically mounted on its base so that by turning the shaft base, gear mesh between the gimbal gear and the intermediate gear may be adjusted. If the intermediate gear does not bind with the gimbal gear, and yet the intermediate shaft must be removed, place a mark on the shaft base and a corresponding mark on the instrument casting so that the shaft can be properly installed with minimum difficulty.

To obtain access to the intermediate gear, the indicator card must first be removed. This is done by removing the press-fitted pointer from its shaft and then removing three flat head screws securing the indicator card to the dial drum.

The shaft on which the dial hub and caging gear are mounted, is attached to the front synchro housing with four binder head screws inserted in slotted holes around the shaft base. These slotted holes permit adjustment of the fore and aft placement of the indicator card to obtain proper gear mesh with the intermediate gear. A screwdriver access hole is provided in the intermediate gear to facilitate adjustment of the top binder head screw.

To obtain access to the front synchro, remove two binder head screws holding the synchro housing to the case. Loosen appropriate cable clamps to permit removal of the entire assembly through the front of the case. To further disassemble, loosen setscrew holding the synchro in place and remove the synchro through the rear of the housing.

The small piece of steel wire attached to the base of the indicator card shaft is designed to ride against the dial drum and to damp out any oscillation in the dial due to excessive play in the gear mechanism. If the wire is to be removed, notice its position so that it may be properly reinstalled.

2.3.6 Disassembly of Specific Gear Trains (Cont'd)

4) AIM 254-1D 293-1D
AIM 254-1ED 293-1ED

The instrument shown in Figure 2-6 is an AIM 254-1D Slaved Gyro/RMI used in the AIM 800 System. This instrument, and those listed in 4) above, are the dual pointer versions of the instruments described in paragraph 3). In each case, one synchro receiver has been added to the front panel to position a second ADF/VOR pointer. The additional synchro is mounted horizontally through the front panel with the shaft toward the rear of the instrument. The rear of the shaft contains a spur gear and the inertial damper which is used to minimize pointer oscillations due to transient external switching. The spur gear engages a second spur gear mounted on the rear of the smaller pointer shaft. This shaft extends through the centrally positioned synchro to the front panel. The shaft is in no way acted upon by the synchro through which it passes.

To obtain access to the intermediate gear and the front bearing assembly, the indicator card must first be removed. This is done by removing the two press-fitted pointers from their respective shafts and removing three flat head screws securing the indicator card to the dial drum.

CAUTION

The inner-most pointer shaft on dual pointer models is extremely delicate and is easily damaged. Exercise extreme care during and after removal of the pointers and indicator card.

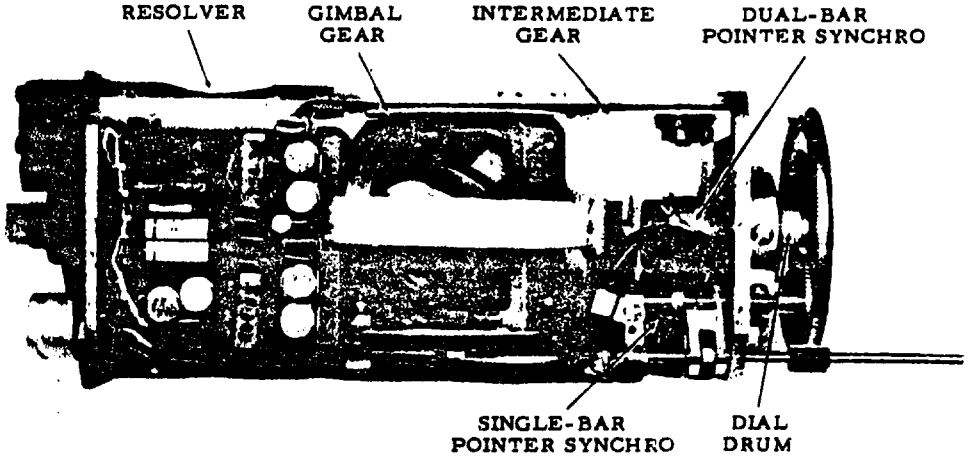

FIGURE 2-6. AIM 254-1D SLAVED GYRO/RMI

2.3.6 Disassembly of Specific Gear Trains (Cont'd)

4) AIM 254-1D 293-1D (Cont'd.)
AIM 254-1ED 293-1ED

Removal of the indicator card permits access to the dial hub, caging gear, and two main bearings mounted on the primary shaft. The entire assembly is held in place by a Truarc ring placed over the end of the primary shaft. The two bearings are fitted inside the hub and may be easily removed.

The primary shaft on which the dial hub and caging gear are mounted, is attached to the front synchro housing with four binder head screws inserted in slotted holes around the shaft base. These slotted holes permit adjustment of the fore and aft placement of the indicator card to obtain proper gear mesh with the intermediate gear. A screwdriver access hole is provided in the intermediate gear to facilitate removal of the top binder head screw.

To remove the single-bar pointer synchro, loosen the #2 Bristol setscrew holding the spur gear and end flange in place on the synchro shaft. Remove the end flange, the damper ring, and the spur gear. The spur gear is secured to the shaft with epoxy. Loosen two #2 Bristol setscrews holding the synchro in its housing on the front panel. Disconnect the appropriate leads from the electrical connector on the rear of the instrument and remove the synchro through the front panel.

To remove the dual-bar pointer synchro, remove both synchro housings from the front panel. Loosen the #2 Bristol setscrew holding the synchro in the housing. An access port is provided for this purpose in the base of the primary shaft. Disconnect appropriate synchro leads and remove the synchro through the rear of the housing. The single-bar pointer shaft which runs through the dual-bar synchro is an integral part of the assembly and cannot be separately replaced.

5) AIM 289-1S 289-3S 297-1S 424-1S
AIM 289-1ES 289-3ES 297-1ES 424-1ES

The instrument shown in Figure 2-7 is typical of AIM 289-1S and 297-1S Slaved Gyro/RMI's used in AIM 800C and 800D systems. For purposes of this discussion, they may be considered identical to the instruments listed in 5) above.

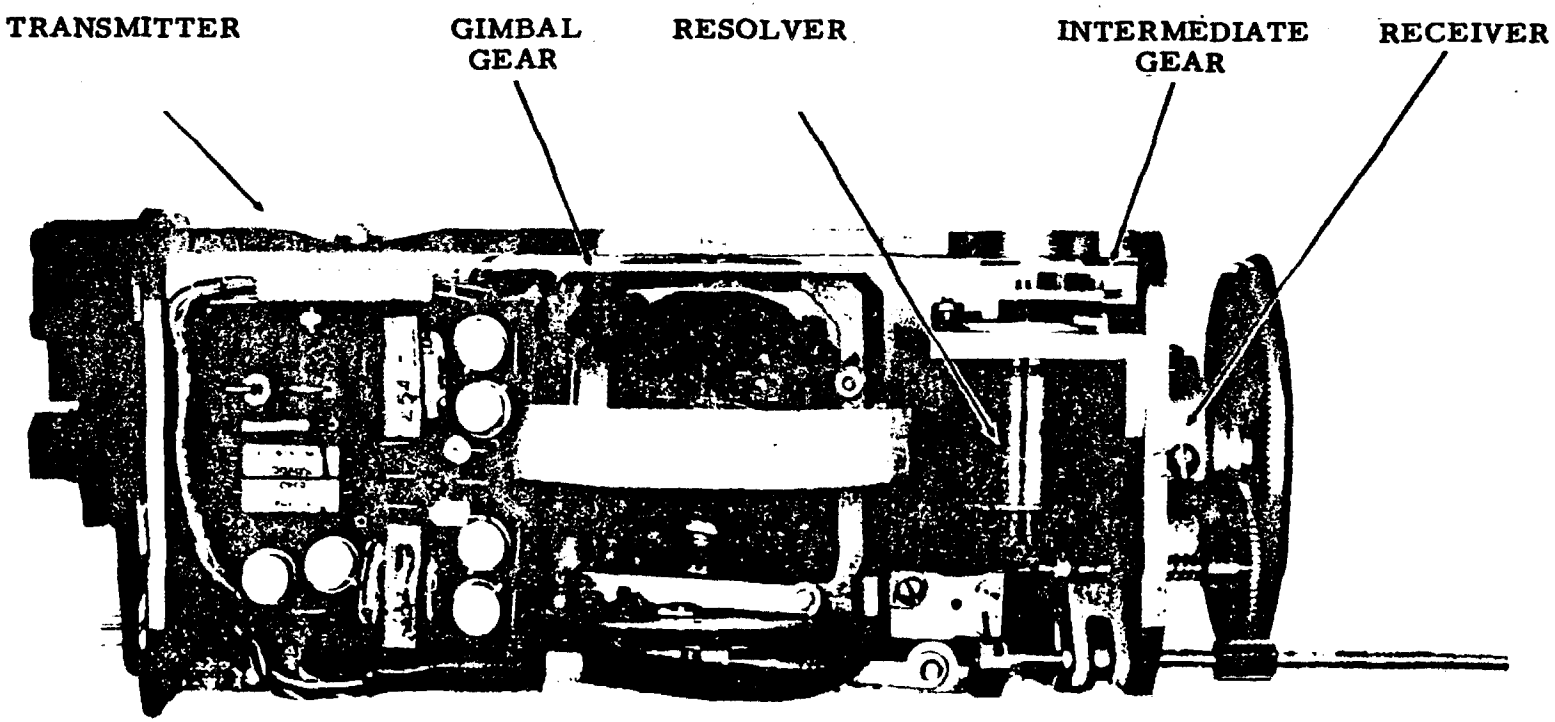

FIGURE 2-7. AIM 289-1S and 297-1S SLAVED GYRO/RMI's

2.3.6 Disassembly of Specific Gear Trains (Cont'd)

5) AIM 289-1S 289-3S 297-1S 424-1S (Cont'd.)
AIM 289-1ES 289-3ES 297-1ES 424-1ES

All of these instruments contain a synchro receiver, resolver, and transmitter. In each case, the synchro receiver is mounted horizontally in the front of the instrument and is electrically positioned by signals from an external source. The synchro resolver used in internal slaving circuitry is mounted vertically in the front of the case and a synchro transmitter which provides heading signals to external systems is mounted in the rear. The AIM 289-3S and 289-3ES instruments employ an additional synchro transmitter (not shown) which is vertically mounted in the front of the case, opposite the slaving resolver.

Note

On earlier models, using size 10 synchros only, synchro functional locations may be found to vary from those indicated.

In all cases, the rear synchro, the indicator card, and the synchro mounted vertically in the front of the unit, are driven by a simple gear train which runs along the top of the instrument case. The intermediate gear is suspended on two precision bearings on the intermediate shaft. The shaft itself is eccentrically mounted on its base so that by turning the shaft base, gear mesh between the gimbal gear and the intermediate gear may be adjusted. If the intermediate gear does not bind with the gimbal gear, and yet the intermediate shaft must be removed, place a mark on the shaft base and a corresponding mark on the instrument casting so that the shaft can be properly installed with minimum difficulty.

To obtain access to the intermediate gear, the indicator card must first be removed. This is done by removing the press-fitted pointer from its shaft and then removing three flat head screws securing the indicator card to the dial hub.

The shaft on which the dial hub and caging gear are mounted, is attached to the front synchro housing with four binder head screws inserted in slotted holes around the shaft base. These slotted holes permit adjustment of the fore and aft placement of the indicator card to obtain proper gear mesh with the intermediate gear. A screw-

2.3.6 Disassembly of Specific Gear Trains (Cont'd)

5) AIM 289-1S 289-3S 297-1S 424-1S (Cont'd.)
AIM 289-1ES 289-3ES 297-1ES 424-1ES

driver access hole is provided in the intermediate gear to facilitate adjustment of the top binder head screw.

To obtain access to the front horizontal synchro, remove two binder head screws holding the synchro housing to the case. Loosen appropriate cable clamps to permit removal of the entire assembly through the front of the case. To further disassemble, loosen set-screw holding the synchro in place and remove the synchro through the rear of the housing.

The small piece of steel wire attached to the base of the indicator card shaft is designed to ride against the dial drum and to damp out any oscillation in the dial due to excessive play in the gear mechanism. If the wire is to be removed, notice its position so that it may be properly reinstalled.

6) AIM 289-1D 289-3D 297-1D 424-1D
AIM 289-1ED 289-3ED 297-1ED 424-1ED

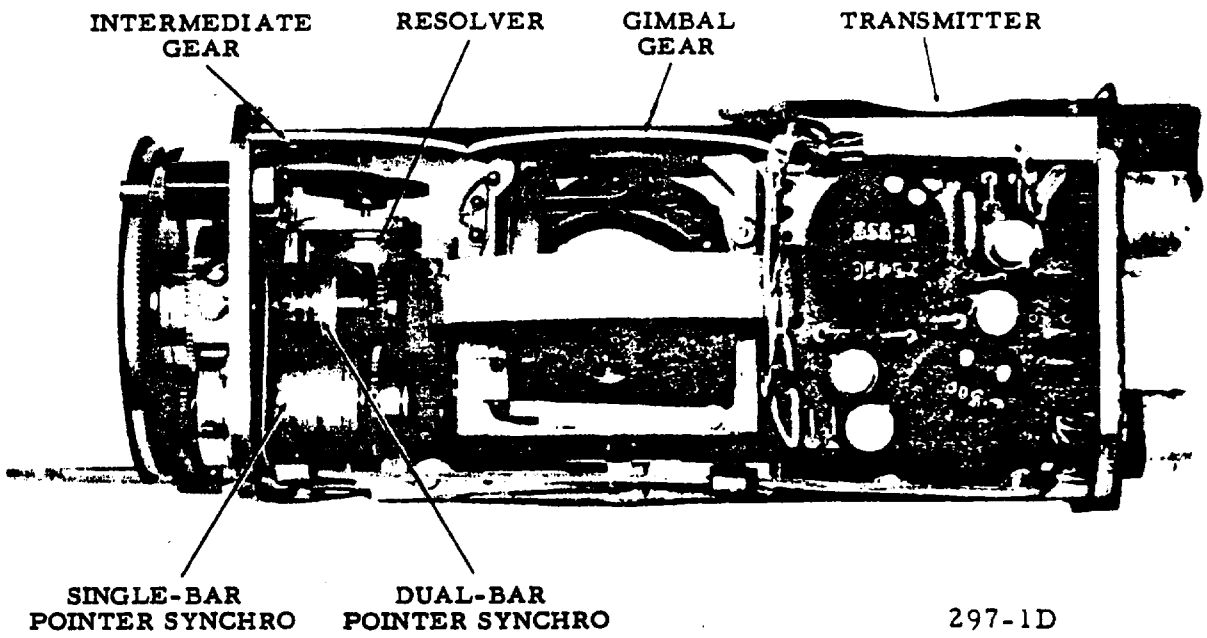
The instruments shown in Figure 2-8 are AIM 289-1D and 297-1D Slaved Gyro/RMI's used in AIM 800C and 800D systems respectively. The instruments are the dual pointer versions of those described in paragraph 5). In each case, one synchro receiver has been added to the front panel to position a second ADF/VOR pointer. The additional synchro is mounted horizontally through the front panel with the shaft toward the rear of the instrument. The rear of the shaft contains a spur gear and an inertial damper which is used to minimize pointer oscillations due to transient external switching. The spur gear engages a second spur gear mounted on the rear of the smaller pointer shaft. This shaft extends through the centrally positioned synchro to the front panel. The shaft is in no way acted upon by the synchro through which it passes.

To obtain access to the intermediate gear and the front bearing assembly, the indicator card must first be removed. This is done by removing the two press-fitted pointers from their respective shafts and removing three flat head screws securing the indicator card to the dial drum.

2.3.6 Disassembly of Specific Gear Trains (Cont'd)

6) AIM 289-1D 289-3D 297-1D 424-1D (Cont'd.)
AIM 289-1ED 289-3ED 297-1ED 424-1ED

CAUTION



The inner-most pointer shaft on dual pointer models is extremely delicate and is easily damaged. Exercise extreme care during and after removal of the pointers and indicator card.

Removal of the indicator card permits access to the dial hub, caging gear, and two main bearings mounted on the primary shaft. The entire assembly is held in place by a Truarc ring placed over the end of the primary shaft. The two bearings are fitted inside the hub and may be easily removed.

The primary shaft on which the dial hub and caging gear are mounted, is attached to the front synchro housing with four binder head screws inserted in slotted holes around the shaft base. These slotted holes permit adjustment of the fore and aft placement of the indicator card to obtain proper gear mesh with the intermediate gear. A screwdriver access hole is provided in the intermediate gear to facilitate removal of the top binder head screw.

To remove the single-bar pointer synchro, loosen the #22 Bristol setscrew holding the spur gear and end flange in place on the synchro shaft. Remove the end flange, the damper ring, and the spur gear. The spur gear is secured to the shaft with epoxy. Loosen two #2 Bristol setscrews holding the synchro in its housing on the front panel. Disconnect the appropriate leads from the electrical connector on the rear of the instrument and remove the synchro through the front panel.

To remove the dual-bar pointer synchro, remove both synchro housings from the front panel. Loosen the #2 Bristol setscrew holding the synchro in the housing. An access port is provided for this purpose in the base of the primary shaft. Disconnect appropriate synchro leads and remove the synchro through the rear of the housing. The single-bar pointer shaft which runs through the dual-bar synchro is an integral part of the assembly and cannot be separately replaced.

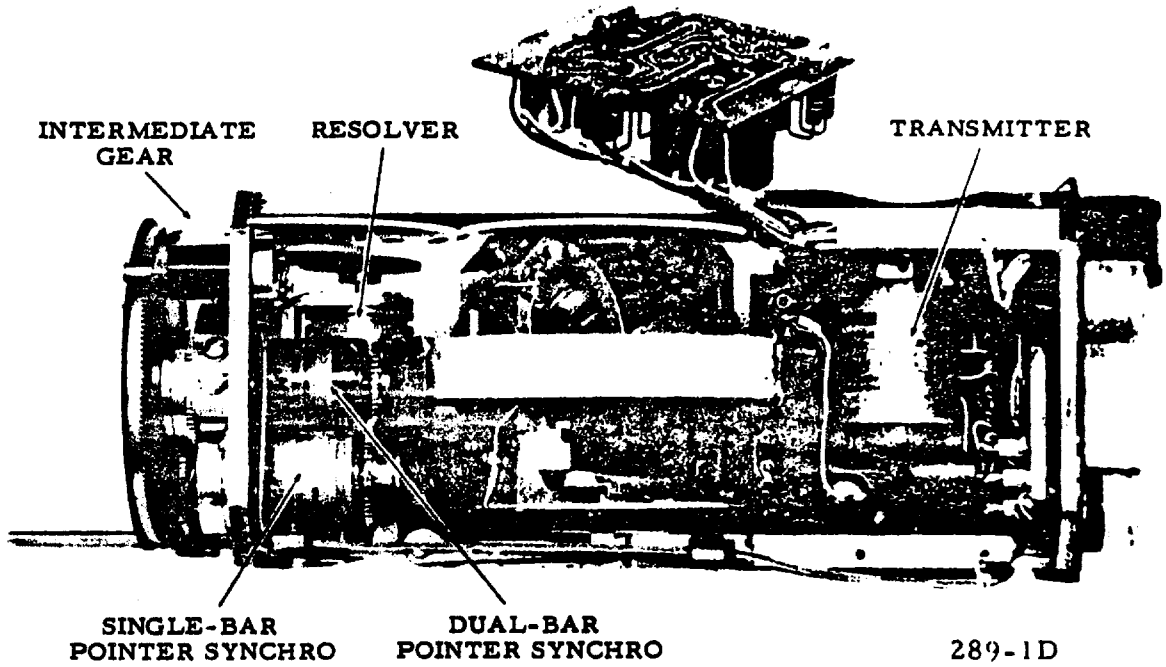


FIGURE 2-8. AIM 289-1D and 297-1D SLAVED GYRO/RMI's

2.3.6 Disassembly of Specific Gear Trains (Con'd)

7) AIM "-2" Instruments

Many of the instruments previously discussed in this section are available in a "-2" configuration, i.e., 297-2D, 424-2ED, etc. These instruments are identical to their counterparts listed in previous paragraphs with the addition of one bootstrap synchro. The additional bootstrap synchro transmitter is vertically mounted in the rear of the instrument case and is driven by the resolver gear. The displaced synchro which is normally mounted in the rear of the unit is then mounted vertically in the front. See Table 2-1 and Figure 2-0.

2.3.7 L-2 Autopilot Pickoff

Instruments designed to provide output signals for use in an L-2 Autopilot are equipped with a specially designed clutch assembly mounted on the synchro transmitter in the rear of the case. The purpose of the unit is to permit the pilot to disengage the L-2 pickoff during turns and to engage the pickoff after the turn is completed. A line drawing of the unit is shown in Figure 2-9.

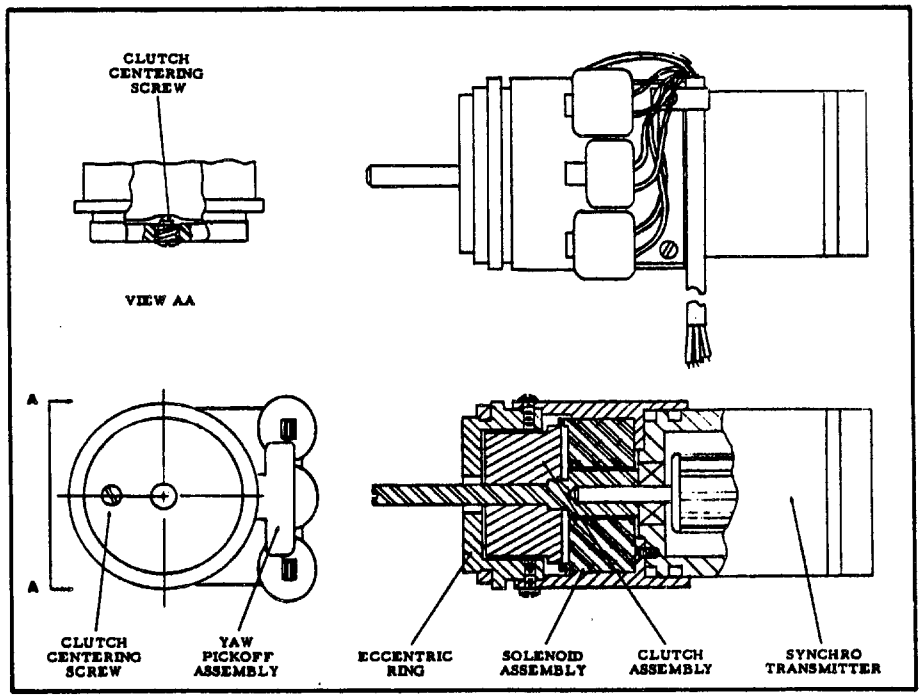

FIGURE 2-9. L-2 AUTOPILOT PICKOFF

2.3.7 L-2 Autopilot Pickoff (Cont'd)

The electrical portion of the L-2 pickoff consists of an armature and three windings which provide an electrical output similar to that of a differential transformer. When the pickoff is engaged, a heading change in one direction will cause an in-phase output and a heading change in the opposite direction will cause an out-of-phase output. These signals are used by the autopilot to initiate corrective action to maintain the selected heading. During turns, power is removed from the solenoid coil inside the clutch assembly to disengage the pickoff. The pickoff is also disengaged by pushing the dial-set knob on the front of the gyro. A normally closed microswitch at the rear of the caging shaft removes power from the solenoid coil when the dial-set knob is depressed.

2.3.8 Disassembly of Caging Mechanisms (Figure 2-2)

Design of the caging mechanism is straight-forward and should require a minimum of specific instructions for disassembly. However, the following phases of the disassembly procedure do require special attention.

On basic slaved gyros (without pointer bars), notice the order in which the single metal washer and the two nylon washers are installed on the caging shaft. From the rear of the shaft, first comes the metal washer, then a nylon washer, then the pinion, then another nylon washer, nearer to the front. Special care should be taken to avoid loss of these parts during disassembly.

On pointer bar models, the sequence of assembly and number of washers is different from that of models without pointer bars. From the rear of the shaft, first come the caging lever, then a metal washer, one arm of an interconnecting bracket, a nylon washer, a setscrew sleeve, a nylon washer, and finally a metal washer.

On pointer bar models, the caging pinion and gear are mounted forward of the front panel. Order of assembly of the caging gear shaft is, from front to back, a lock ring, caging gear, shaft spring, nylon washer, front panel, metal washer, lock ring, interconnecting bracket, nylon washer, shaft spring, nylon washer, and setscrew sleeve.

2.3.8 Disassembly of Caging Mechanisms (Figure 2-2) (Cont'd)

Instruments which provide autopilot outputs are equipped with an extended caging shaft which activates a micro-switch inside the case. The micro-switch automatically disengages the autopilot pick-off when the gyro heading is reset.

Before loosening the caging eccentric on the bottom of the case, notice its approximate position. The purpose of this eccentric is to permit adjustment of the caging mechanism so that the rotor housing is 80 to 90 per cent caged when the dial-set gear engages the caging gear. Observing the position of the eccentric prior to disassembly will permit reassembly with a minimum of trial-and-error adjustment.

2.3.9 Disassembly and Inspection of Air Seal Housings - Vacuum Only

A typical air seal housing assembly is shown in Figure 2-10. It consists of the basic housing, the bearing assembly, the air seal washer, the washer retainer, and a spring type retainer ring.

Two housings of this type are used in the AIM 400 and 800 vacuum driven instruments. One housing is mounted in the instrument casting and serves as a transfer point for the passage of air from the casting to the gimbal assembly. The second housing is mounted in the

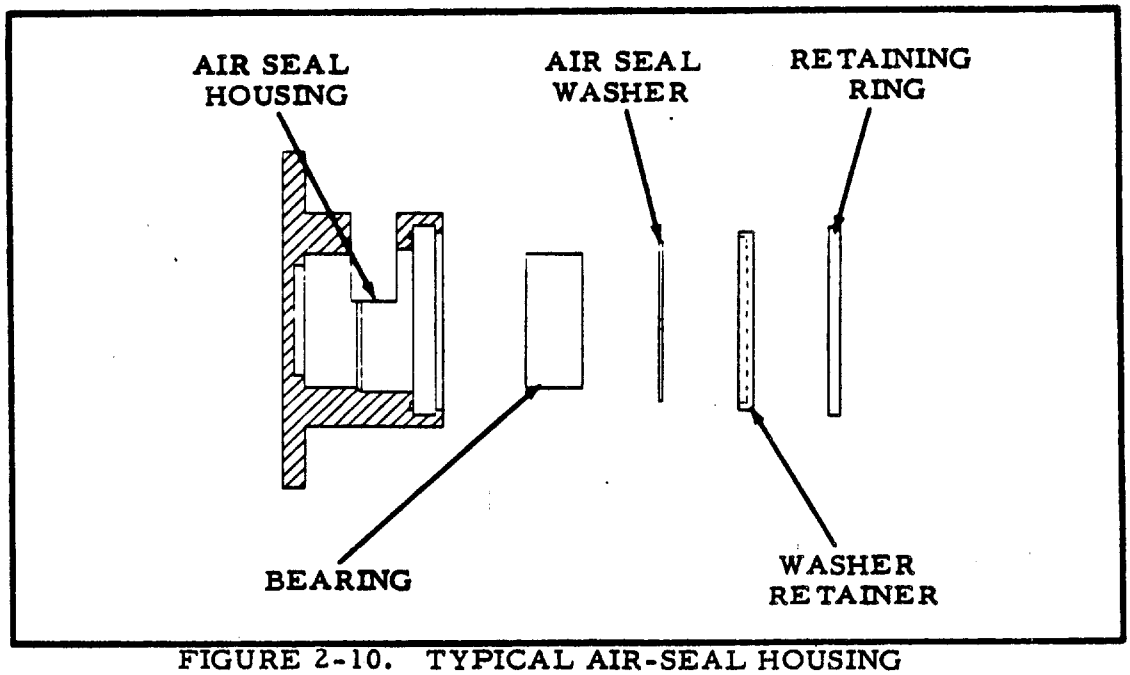

FIGURE 2-10. TYPICAL AIR-SEAL HOUSING

2.3.9 Disassembly and Inspection of Air Seal Housings - Vacuum Only (Cont'd)

gimbal and transfers air from the gimbal to the rotor housing. Although the two housings are similar in appearance, they are not identical. Consequently, extreme care should be taken that each housing is properly identified as to its proper location in the instrument.

Disassemble each air seal housing and check that the air seal washer fits freely over the diameter of its respective pivot assembly without binding. Check that a clean used bearing will fit the diameter of the pivot assembly with no more than finger pressure applied. If difficulty is encountered, refer to the inspection and repair procedures in paragraph 2.5.3.

Remove the used bearing and replace the air seal washer in the air seal housing along with the new bearing to be used. Reassemble the housing and set aside, properly covered, for future use.

2.4 CLEANING

2.4.1 General

Due to the precision components and close tolerances employed in the manufacture of this unit, foreign matter can greatly impair its over-all operating efficiency and service life. It is therefore recommended that every possible step be taken to insure maximum protection of each subassembly during disassembly, repair, and reassembly. As each component is removed during disassembly it should be placed in a dust-free environment and protected with a dust-proof cover.

2.4.2 Air Filters - Vacuum Only

The instrument air filter on the rear of the unit cannot be cleaned by washing and must be replaced when dirty. This should be done routinely at each overhaul of the instrument and the filter should be inspected after each 100 hours of operation. Access to the filter may be gained by removing the four screws in the AIR INLET cover plate at the rear of the instrument. After filter has been replaced, reinstall cover and tighten screws securely.

The amount of dust, lint, tobacco tars, and other foreign matter

2.4.2 Air Filters - Vacuum Only (Cont'd)

reaching the instrument filter may be greatly reduced by the use of an efficient central filter system installed in the aircraft. The Type F-4 Air Filter, available from AIM, is especially designed to filter these undesirable elements from the vacuum system and to effectively extend the service life of any air-driven instrument.

2.4.3 Pivots, Housings, Etc.

During overhaul, all parts should be cleaned carefully to remove oil, dirt, and moisture. If possible, the use of ultrasonic cleaning is highly recommended to insure that all parts with small bores or tapped holes can be effectively cleansed. If this is not possible, component parts such as pivots, bearing housings, shims, etc. should be thoroughly cleaned in a high-grade solvent such as Chlorothene-Nu (Dow Chemical Company), and then thoroughly air dried with clean, low pressure air. If cleaning solvent is used, it must not be allowed to become dirty and must be changed frequently.

Interiors of small holes should be cleaned with pegwood dipped in solvent. The teeth of gears and pinions should be cleaned with a glass fiber brush.

Extreme care should be taken to avoid damage to small or delicate parts during cleaning. In addition, some arrangement must be made to permit identification of each part with respect to its previous location in the instrument. This is particularly true of bearings, pivots, and screws.

After cleaning, some provision must be made to adequately protect the parts from damage and dust while awaiting inspection and reassembly.

2.5 INSPECTION AND REPAIR

2.5.1 General

All parts should be thoroughly examined with an eye loupe for any evidence of excessive wear or damage prior to reassembly. Repair of defective parts is recommended only when it can be done with-

2.5.1 General (Cont'd)

out adversely effecting the proper operation of the instrument. If doubt exists as to the operating condition of any part or assembly, refer to the parts list section of this manual and order replacement parts directly from AIM.

During overhaul, examine each part for evidence of corrosion or breakdown in the plating material. Aluminum parts of the gyro are protected by anodize or iridite treatment and stainless steel parts are passivated. If a crocus cloth is used to remove corrosion or if the plating material appears to be worn through, replate or protect the defective area with a light coat of clear lacquer.

Particular attention should be given to parts which contain internal or external threads. If any evidence of damage to the threads is found, repairs should be made using the correct tap or thread restorer. The part should then be thoroughly re-cleaned and re-examined prior to assembly.

2.5.2 Bearings

The precision bearings used throughout the instrument are designed to provide extremely efficient service over long periods of time. Each bearing should be individually examined for evidence of damage. If defects are noted, the entire bearing should be replaced. No attempt should be made to polish the balls, or otherwise repair the separate bearing parts.

Bearings used in this instrument are precision, instrument grade and must not be replaced with inferior substitutes. Each bearing is lubricated with specific quantities and types of lubricants best suited for its individual function. This lubricant improves the performance of the bearings and substantially increases their service life. It is therefore recommended that replacement bearings be ordered directly from AIM in order to insure maximum operating efficiency.

2.5.3 Pivots

The four pivots used to support the gimbal and rotor housing assemblies are specially designed for specific functional locations

2.5.3 General (Cont'd)

in the instrument. Each pivot is distinctly constructed so that it must not be interchanged with other pivots during reassembly.

Each pivot or support shaft should be examined carefully for evidence of pits and scoring. Due to the precision fit of their respective bearings, the pivots should seldom incur any type of excessive damage. If small scratches are noted, a light polishing should be all that is necessary. However, if scoring or other excessive wear is noted, replacement pivots should be secured from AIM.

For information pertaining to the rotor pivots, refer to paragraphs 2.7.3(2), 2.7.4(2), and 2.8.4 in this manual.

2.6 REASSEMBLY PROCEDURES

2.6.1 General

Throughout the reassembly procedures, extreme care must be taken to prevent damage or contamination of the various component parts and subassemblies. When joining two parts, they must not be forced together. As each subassembly is completed, it must be covered while awaiting further installation to a mating assembly or component.

All adjusting screws must be secured in their final adjusted position by use of Glyptal or a similar sealer.

2.6.2 Installation of Rotor Housing in Gimbal Assembly

(1) Vacuum Only - Remove the side pivot from the rotor housing. Carefully position the rotor housing inside the gimbal by placing the air pivot end into the opening in the gimbal. Install the completed air seal bearing housing with its shim or shims (if originally included) in the gimbal so that the bearing engages the air pivot. Check that the air seal housing is turned properly to permit air flow through the instrument ductwork. Install two mounting screws, then tighten and secure with Glyptal.

(2) Electric Only - Remove the side pivot from the rotor housing.

2.6.2 Installation of Rotor Housing in Gimbal Assembly (Cont'd)

Carefully position the rotor housing inside the gimbal by placing the slip ring pivot into the opening in the gimbal. Install the slip ring bearing housing in the gimbal so that the bearing supports the slip ring pivot. Install two mounting screws and the brush block, then tighten and secure with Glyptal.

(3) Place the side pivot through the threaded port in the gimbal and attach to the rotor housing with three screws. Tighten pivot screws and secure with Glyptal.

(4) Screw the threaded bearing housing into the gimbal until end play is barely perceptible when moderate hand pressure is exerted toward either pivot.

(5) When threaded housing is properly adjusted, insert the clamping screw, washer, and lock nut shown in Figure 2-2. After tightening, check that end play has not changed and secure clamping screw and lock nut with Glyptal.

(6) Position the rotor housing so that the flat side of the air pivot or slip ring pivot flange is toward the caging mechanism at the bottom of the gimbal. When this is done, retighten the stop screw in the top of the gimbal, just above the air seal housing.

(7) Install the erector track so that it is an equal distance from each erector jet on the rotor housing. The ends of the erector track must bisect the erector ports when the spin axis of the rotor is horizontal. The erector track must not touch the erector jets at any point.

(8) Install the slaving magnet on the end of the side pivot with one 2-56 x 3/8" flat head screw. The magnet must be mounted so that the positioning notch is to the right when the rotor spin axis is level.

2.6.3 Installation of Gimbal Assembly in Instrument

(1) Install the gimbal gear and bearing housing on the top of the gimbal assembly in the order described in paragraph 2.3.3. Before securing the bearing housing in place, check that the friction shim is not squeezed between the hub of the bearing housing and the gimbal gear. The inside diameter of the friction shim is large enough so that, when properly installed, the shim will fit over the hub and fill the space between the bearing housing flange and the gimbal gear. When the friction shim is properly positioned, insert the three mounting screws and secure in place with Glyptal.

(2) Insert the air pivot or slip ring pivot into the bearing housing port in the bottom of the instrument case.

(3) Carefully place the completed gimbal and rotor assembly into the instrument with the air pivot or slip ring end centered above the lower bearing pivot.

(4) Turn the entire instrument over, being careful not to drop the gimbal or the pivot.

(5) Mount the air pivot or slip ring pivot to the bottom of the gimbal with two screws inserted through the air seal bearing housing port. Secure the screws with Glyptal.

(6) Vacuum Only - Install the air seal bearing housing with two screws and secure with Glyptal. Check that the air seal housing is properly aligned to permit unobstructed air flow.

NOTE

Shims are sometimes installed at the factory to insure proper alignment of the air passages in the air seal bearing housing. If shims were used prior to disassembly, they should be reinstalled.

(7) Electric Only - Install the slip ring bearing housing with two screws and secure with Glyptal. Install the gimbal brush block.

2.6.3 Installation of Gimbal Assembly in Instrument (Cont'd)

(8) Return the instrument to its normal upright position and install the upper bearing housing. Tighten three screws and secure with Glyptal.

(9) Check that the erector track is properly installed in the gimbal. It must be positioned so that it bisects both erector jets when the gyro is caged. The erector track must not touch the rotor jets at any position.

(10) After the gimbal is fully installed, check that the gimbal gear does not bind with the next gear at any point throughout one complete revolution of the gimbal. If binding is evident, loosen two binder head securing screws and rotate the eccentric on top of the instrument casting until the binding is relieved. When proper adjustment has been achieved, secure the eccentric and the two binder head screws in place with Glyptal.

(11) If the rotor is not properly balanced, refer to paragraph 2.9 before attempting to balance the gimbal.

The gimbal may be balanced by positioning balance screws around the slot in the gimbal base. Provisions have also been made for the installation of additional screws and weights in the #2-56 tapped holes on the side of the gimbal. Repeated trials will be necessary in order to obtain perfect balancing of the assembly. All balancing can be accomplished by adding or subtracting weight from opposing sides of the assembly. Balancing techniques vary according to shop practices. However, it is necessary to point out that trial and error methods are always necessary to obtain near perfect balancing of a precision assembly. During all stages of balancing, assemblies must be vibrated moderately to induce movement and to insure that an absolute minimum of friction between adjacent moving parts is evident.

2.6.4 Reassembly and Adjustment of Gear Train Mechanism

Due to the wide variation in gear train design, no attempt is made to provide specific procedures for reassembly. A full understanding of the information contained in the Disassembly Procedures of paragraph 2.3.6 will be helpful in reassembling the instrument.

If the gear train has been completely disassembled, reassemble the instrument without regard for zeroing synchros at this time. This procedure is fully covered in Section 3 of this manual.

2.6.5 Reassembly and Adjustment of Caging Mechanism

Reassembly of the caging mechanism requires no specific sequence of operations. However, special attention should be given to the following details.

If the caging plate and the nylon actuating carriage (Figure 2-2) are removed during disassembly, care should be taken to insure that the steel wire springs are properly positioned during reassembly. The springs should be tightened down and stressed so that the actuating carriage will be pulled clear of the rotor pivot when the caging shaft is released.

When reassembling the caging shaft, check that the associated pinion and washers are installed in the order described in paragraph 2.3.8. Improper installation of the washers could cause undue wear on the pinion and the related hardware.

After the caging mechanism is properly assembled, adjust the caging eccentric on the bottom of the instrument until the rotor housing is 80 to 90 percent caged before the dial-set gear begins to engage the combination spur/bevel gear on the main horizontal drive shaft. The trial and error method will be necessary until the proper adjustment is obtained.

2.7 OVERHAUL OF VACUUM ROTORS

2.7.1 General

Two types of vacuum rotors and associated housings, designated 34B and R3H, are used interchangeably in both AIM 400 and AIM 800

2.7.1 General (Cont'd)

instruments. Construction of the 34B is shown in Figure 2-11. The two rotors differ primarily in that the 34B utilizes a two part bearing which consists of an outer race assembly mounted in the rotor housing and an inner race which is actually the surface of the rotor shaft. The R3H rotor uses a one piece, non-separable bearing fitted over each end of a stationary rotor shaft and held in place by a knurled preload nut. The inner race and rotor shaft are stationary and the outer race moves with the rotor.

As previously stated in the manual, disassembly and overhaul of the rotor and rotor housing assembly is not recommended. Due to the precision parts involved, and the high speed of the rotor, reassembly and proper adjustment is extremely critical and should not normally be attempted in the field. Should the rotor become defective and fail to meet the performance requirements set forth in this manual, the used rotor housing and pivot assembly should be returned to AIM for an exchange discount on a replacement assembly. However, if

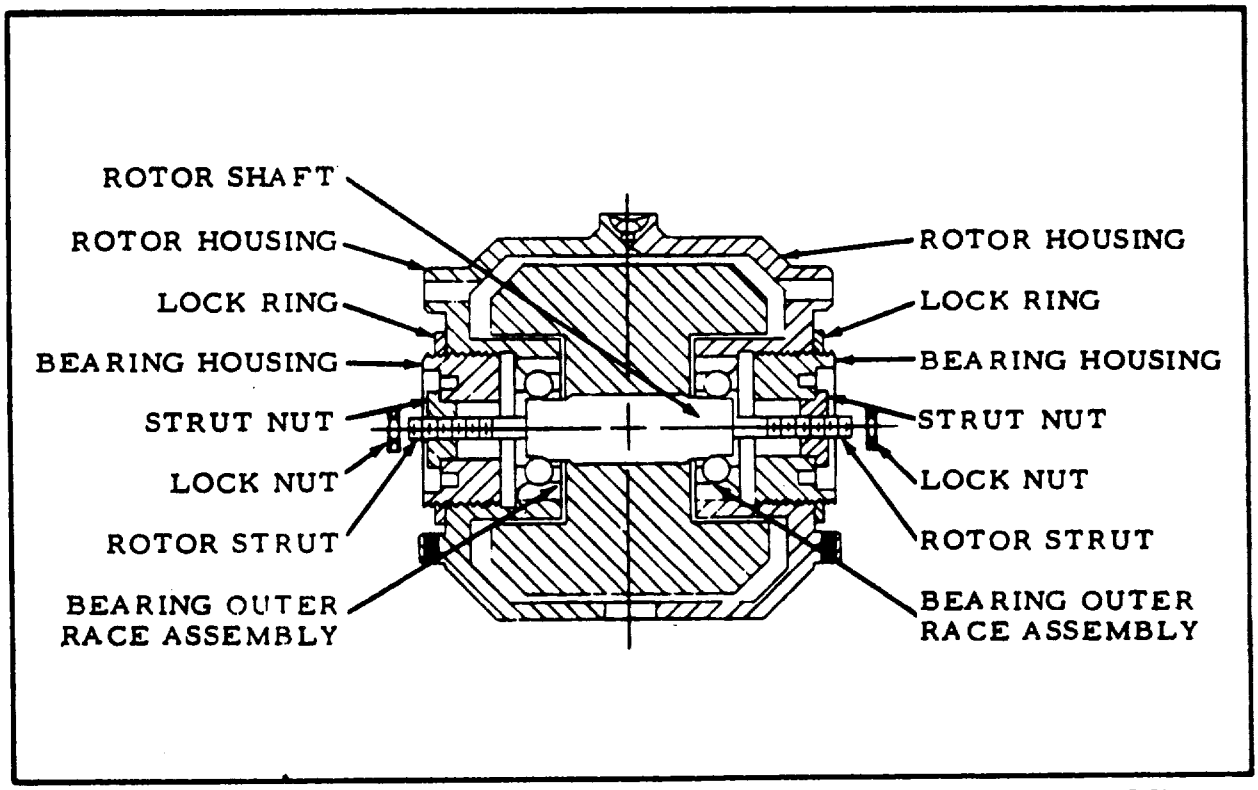

FIGURE 2-11. TYPE 34B ROTOR AND ROTOR HOUSING ASSEMBLY

2.7.1 General (Cont'd)

this is not possible, and disassembly and overhaul does become necessary in the field, the procedures shown in the remainder of Section 2.7 should be followed. Do not attempt to overhaul the rotor unless it fails to meet the operating requirements set forth in Section 3.

2.7.2 Equipment Required

Before disassembling the rotor housing, it should be noted that the following equipment must be available in order to properly readjust the assembly after overhaul. This equipment is in addition to the instrument-shop handtools described in paragraph 2.2.

(1) Mercury monometer capable of reading up to 6 in. Hg.

(2) Pressure source capable of producing a pressure of 4.7 in. Hg. (approximately 2.5 psi). A vacuum source is also recommended but is not required.

(3) Stop Watch.

(4) Clean, dust-free work area.

Additional equipment required for final calibration of the overall instrument is listed in Section 3 of this manual.

2.7.3 Type 34B Rotor and Rotor Housing (Figure 2-11)

1) Disassembly

(1) Remove one strut nut and one lock nut (Figure 2-11) from either end of the rotor strut. Do not disturb the strut nut and lock nut on the opposite end of the rotor strut.

(2) Remove the rotor strut from the rotor housing.

(3) Remove four #3-48 screws securing the front and rear halves of the rotor housing.

(4) The housing may now be opened to expose the rotor. The rotor bearing outer race assemblies are fitted into the housings in each end of the assembly and may be easily removed. The two bearing housings may also be removed by simply

2.7.3 Type 34B Rotor and Rotor Housing (Cont'd)

1) Disassembly (Cont'd)

loosening the respective lock rings (Figure 2-11) and threading the bearing housings out of the rotor housing.

2) Inspection, Cleaning, and Repair

Once the rotor housing is disassembled, check that the buckets in the rotor are free of accumulated dust, tobacco tars, and other foreign matter. Clean the various rotor parts in accordance with the procedures set forth in paragraph 2.4. After cleaning, each part must be adequately protected from dust while awaiting reassembly.

No attempt should be made to clean, re-oil, or otherwise repair the rotor bearings. If the bearings are defective, they should be replaced. In addition, no attempt should be made to polish or lap the rotor pivots on the ends of the rotor shaft. These pivots are actually the inner race of the rotor bearings and are manufactured to a precision geometry to match the bearing outer race assemblies. Any attempt at polishing or lapping could change the curvature of the pivot taper with subsequent damage to the pivot and the bearing. Each pivot should be carefully examined for pits or scoring. If damage is found, a new rotor housing and pivot assembly must be obtained from AIM. The replacement rotor housing and pivot assembly will be completely run-in and ready for installation when received.

3) Reassembly and Adjustment of Rotor Housing

(1) Check the bearing bore in each half of the rotor housing by pressing a clean used bearing into each bore using finger pressure only. Each bearing must be a gauge fit.

(2) Remove the used bearings from the bore in each half of the rotor housing. Apply a small quantity of Threadlube to the threads of each threaded bearing housing.

(3) Thread the bearing housings into their respective halves of the rotor housing approximately three turns.

2.7.3 Type 34B Rotor and Rotor Housing (Cont'd)

3) Reassembly and Adjustment of Rotor Housing (Cont'd)

(4) Apply a small quantity of Threadlube to each lock ring, then thread each lock ring onto its respective bearing housing until finger tight.

(5) Using instrument tweezers or a similar tool, install the new rotor bearings in their respective housings. Check that each bearing is fully seated in the bottom of its respective housing. Do not handle bearings with fingers.

(6) Grasp the rotor with watch paper or other high grade lintless tissue and place in position in one half of the rotor housing. Check that the rotor is positioned so that air entering the housing will strike the rotor buckets in the correct direction to obtain maximum rotation.

(7) Place the opposite half of the rotor housing in place and check that the air inlet ports on each half correspond.

(8) Attach the back half of the rotor housing to the front half with four screws. Tighten screws and secure with Glyptal.

NOTE

The front and back halves of the rotor housing may be distinguished by the four screw-holes used to hold the two halves together. The holes are threaded in the back half and are not threaded in the front half. Consequently, the four screws should be inserted from the front half toward the back.

(9) Position the threaded bearing housings at each end of the rotor shaft so that rotor end play is barely perceptible. Readjust lock rings until finger tight.

(10) Mount the side pivot on the rotor housing and insert three attaching screws. Tighten the screws but do not secure with Glyptal since the side pivot must be removed during installation of the rotor housing into the gimbal assembly.

(11) Hold the rotor housing so that the spin axis of the rotor is

2.7.3 Type 34B Rotor and Rotor Housing (Cont'd)

3) Reassembly and Adjustment of Rotor Housing (Cont'd)

horizontal, the back half of the rotor housing is to the left, the front half is to the right, and the air pivot side is directly visible. Apply Loctite to two attaching screws and mount the air pivot on the rotor housing so that the flat side of the air pivot is toward the bottom.

4) Rotor Bearing Preload Adjustments and Run-in Procedures

(1) Place the rotor housing in a suitable run-in fixture. If none is available, install the rotor in the instrument as described in paragraphs 2.6.2 and 2.6.3.

(2) Adjust the threaded bearing housings (Figure 2-11) at each end of the rotor until the rotor is centered in the over-all assembly.

(3) Apply enough low pressure air at the air pivot or at the AIR INLET port to permit the rotor to start and continue to rotate at approximately 500 rpm. Disconnect air supply hose, then gently shake the assembly to check for excessive rotor bearing end play. If excessive end play is evident, readjust the threaded bearing housings evenly.

(4) Re-attach the air supply hose and recheck end play in the same manner as above. End play is properly adjusted when minutely evident with the rotor spinning at approximately 500 rpm.

(5) When end play is properly adjusted, tighten lock rings and secure with Glyptal.

(6) Insert the rotor strut through the rotor shaft. Install strut nuts and lock nuts on the threaded ends so that equal amounts of threads are showing.

(7) Again attach an air supply hose to the air pivot or AIR INLET port. Tighten strut nuts and lock nuts evenly and sufficiently to permit rotor to start and

2.7.3 Type 34B Rotor and Rotor Housing (Cont'd)

4) Rotor Bearing Preload Adjustments and Run-in Procedures (Cont'd)

(7) continue to rotate at an air pressure of 0.5 to 1.0 in. Hg if the rotor housing is in a run-in rack, or not in excess of 2.25 in. Hg if it is installed in the instrument. Secure strut nuts and lock nuts in their final adjusted position with Glyptal.

(8) Connect air supply hose and allow the rotor to run for 48 hours at its rated pressure of 4.6 in. Hg.

(9) After the 48-hour run-in period, check that the rotor meets the rotor start, rotor speed, and rotor coast performance tests in Section 3 of this manual.

2.7.4 Type R3H Rotor and Rotor Housing (Figure 2-12)

1) Disassembly

(1) Remove the rotor support nut and the four screws holding the two halves of the rotor housing together.

(2) Carefully remove one-half of the rotor housing and thread rotor out of the second half using the screwdriver slot in the upper end of the rotor shaft. Select a screwdriver with a 0.140 maximum face width to avoid damaging threads in the rotor support nut.

(3) To obtain access to the rotor bearings, remove one preload nut from each end of the rotor shaft and six 1-72 x 3/16 binder head screws securing each bearing shield to the ends of the rotor shaft.

2) Inspection, Cleaning, and Repair

Once the rotor is disassembled, check that the buckets in the rotor are free of accumulated dust, tobacco tars, and other foreign matter. Clean the various rotor parts in accordance with the procedures set forth in paragraph 2.4. After cleaning, each part must be adequately protected from dust while awaiting assembly.

2.7.4 Type R3H Rotor and Rotor Housing (Figure 2-12) (Cont'd)

2) Inspection, Cleaning, and Repair (Cont'd)

No attempt should be made to clean, re-oil, or otherwise repair the rotor bearings. If the bearings are defective, they should be replaced.

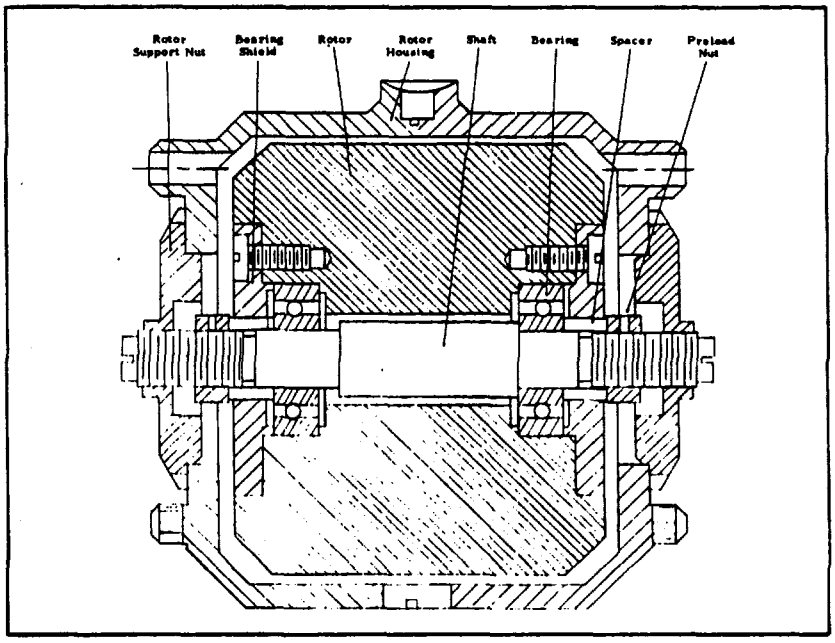

FIGURE 2-12. R3H ROTOR AND ROTOR HOUSING ASSEMBLY

3) Reassembly and Adjustment

(1) If the rotor has been completely disassembled, determine the position in which the rotor must be installed to obtain counterclockwise rotation when viewed from the front of the rotor housing. This may be done by noting the curvature of the buckets in the side of the rotor.

NOTE

The front and back halves of the rotor housing may be distinguished by the four screw holes used to hold the two halves together. The holes are threaded in the back half and are not threaded in the front half. Consequently, the four screws should be inserted from the front half toward the back.

2.7.4 Type R3H Rotor and Rotor Housing (Figure 2-12) (Cont'd)

3) Reassembly and Adjustment (Cont'd)

(2) Slip the rotor shaft through the rotor so that the short bearing surface will be at the front of the housing when the rotor is completely installed.

(3) Install one bearing, one spacer, one bearing shield, and one preload nut over each end of the rotor shaft. The bearings must be installed so that the engraved type numbers are not visible and with the word "thrust" toward the center of the rotor. This is imperative with this type of bearing.

4) Rotor Bearing Preload Adjustment and Run-in Procedures

(1) Set the front preload nut tight against the bearing spacer. This is the end of the shaft with the short bearing surface.

(2) Carefully tighten the nut on the opposite end until the detectable axial end play between rotor and shaft just disappears. This rotor bearing preload adjustment is very critical and must not be exceeded if normal bearing life is to be realized. At the correct setting the rotor shaft will spin freely in the rotor assembly and have no detectable end play. To check for proper adjustment hold the rotor stationary and spin the rotor shaft. If a noticeable roughness is apparent, the preload is set too tight or the bearings are damaged. Do not apply Glyptal to either preload nut at this time.

(3) When preload has been completed, thread the rotor and rotor shaft into the rotor housing and install the rotor support nut.

(4) Install the rotor housing and the air pivot in the gimbal or in a suitable run-in fixture.

(5) Run rotor for 48 hours with 4.5 - 4.7 in. Hg air pressure applied. Recheck the preload setting after run-in and readjust as required in paragraph (2) above.

2.7.4 Type R3H Rotor and Rotor Housing (Figure 2-12) (Cont'd)

4) Rotor Bearing Preload Adjustment and Run-in Procedures (Cont'd)

(6) Run the rotor for an additional 24 hours and check the rotor start and run-down performance. The rotor must start and continue running with 0.4 to 0.8 in. Hg pressure applied to air pivot. The run-down time should be between 5 and 9 minutes. If the rotor fails to start within these prescribed limits, and run-down time is not as required, the rear preload nut should be readjusted. If successive rotor starts vary widely and run-down time will not exceed 5 minutes, the bearings are contaminated or worn and must be replaced.

(7) Check that the rotor attains a speed of approximately 28,000 rpm with 4.5 to 4.7 in. Hg pressure applied to the rotor housing.

(8) After it has been established that the rotor meets the requirements of the above paragraphs, apply a small amount of Glyptal to both preload nuts. Avoid excessive Glyptal on the free threads at each end of the rotor shaft.

(9) Install the rotor housing in a balancing fixture or in the gimbal to properly locate the rotor in the housing. Balance the assembly by turning the rotor shaft as required to center the rotor in the housing. When proper adjustment has been obtained, secure the rotor shaft and the rotor support nuts with Glyptal.

2.8 OVERHAUL AND ADJUSTMENT OF ELECTRIC ROTOR

2.8.1 General

As previously stated in this manual, disassembly and overhaul of the rotor and rotor housing assembly is not recommended. Due to the precision parts involved, and the high speed of the rotor, reassembly and proper adjustment is extremely critical and should not normally be attempted in the field. Should the rotor become defective and fail to meet the performance requirements set forth in this

2.8.1 General (Cont'd)

manual, the used rotor and rotor housing assembly should be returned to AIM for an exchange discount on a replacement assembly. However, if this is not possible, and disassembly and overhaul does become necessary in the field, the procedures shown in the remainder of Section 2.8 should be followed. Do not attempt to overhaul the rotor unless it fails to meet the operating requirements set forth in Section 3 of this manual.

2.8.2 Equipment Required

Before disassembling the rotor housing, it should be noted that the following equipment must be available in order to properly readjust the assembly after overhaul. This equipment is in addition to the instrument-shop handtools described in paragraph 2.2.

(a) 115 vac, 400 cps, single phase power source
(b) 0-150 ma ac milliameter
(c) Voltmeter capable of reading 85 vac to 115 vac
(d) Stop watch
(e) Variac power transformer or similar means of varying supply voltage from 85 to 115 vac
(f) Clean, dust-free work area

2.8.3 Disassembly of Electric Rotor and Rotor Housing (Figure 2-13)

(1) Remove the four screws securing the two halves of the rotor housing.

(2) Carefully separate the two halves and thread the rotor assembly out of the rotor housing using the screwdriver slot in the upper end of the rotor shaft.

(3) To obtain access to the rotor bearings, remove the impellers from each end bell and remove the preload nut and spacer from each end of the rotor shaft. The bearings are protected by a small bearing shield over each end of the rotor shaft.

(4) Care should be taken to avoid loss of the spacers and bearing shields located between the preload nut and the bearing on each end of the rotor shaft.

2.8.3 Disassembly of Electric Rotor and Rotor Housing (Figure 2-13) (Cont'd)

NOTE

Removal of the end bells on each end of the inertia ring is not normally required, and is not recommended. If either end bell is removed, delicate rebalancing of the inertia ring assembly will be required. If the end bells must be removed to obtain access to the stator, it is suggested that a mark be made at the interface between the inertia ring and each end bell to simplify reassembly and minimize rebalancing required.

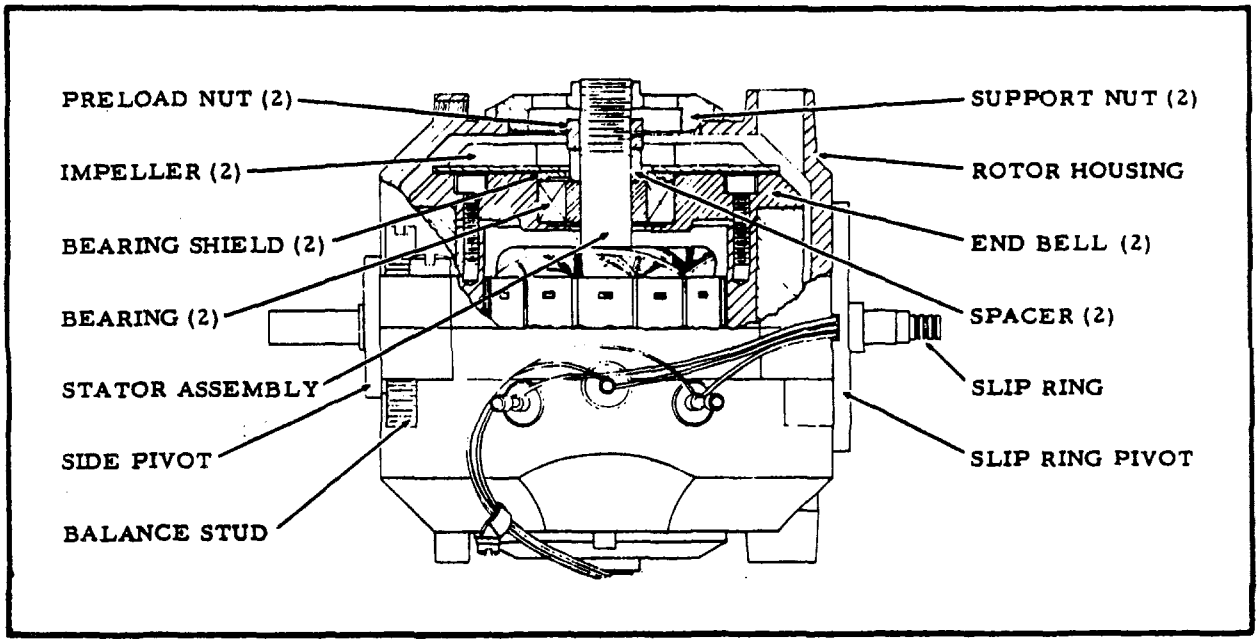

FIGURE 2-13. ELECTRIC ROTOR AND ROTOR HOUSING ASSEMBLY

2.8.4 Inspection, Cleaning, and Repair

Clean the various rotor parts in accordance with the procedures set forth in paragraph 2.4. After cleaning, each part must be adequately protected from dust while awaiting reassembly.

No attempt should be made to clean, re-oil, or otherwise repair the rotor bearings. If the bearings are defective, they should be replaced.

2.8.5 Reassembly and Adjustment

(1) Install the rotor bearings over each end of the rotor shaft with the word "thrust" toward the center of the rotor.

(2) Install the bearing shields with the recessed side toward the center of the rotor.

(3) Reinstall the impellers on each end bell if they were removed during disassembly. Tighten all attaching screws securely.

(4) Install the spacer and preload nut on each end of the rotor shaft.

2.8.6 Rotor Bearing Preload Adjustment and Run-in Procedures

(1) Set the bottom preload nut tight against the bearing spacer. This is the end of the shaft with the short bearing surface.

(2) Carefully tighten the nut on the wire outlet end until the detectable axial end play between rotor and shaft disappears. This rotor bearing preload adjustment is very critical and must not be exceeded if normal bearing life is to be realized.

At the correct setting the rotor shaft will spin freely in the rotor assembly and have no detectable end play. To check for proper adjustment hold the rotor stationary and spin the rotor shaft. If a noticeable roughness is apparent, the preload is set too tight or the bearings are damaged. Do not apply Glyptal to either preload nut at this time.

(3) When preload has been completed, thread the rotor and rotor shaft into the rotor housing and install the rotor support nut.

(4) Install the rotor housing and both pivots in the gimbal or in a suitable run-in fixture.

(5) Run rotor for 48 hours with 115 vac, 400 cps, single phase power applied and using a .18-.22mf, 600 v, phase shift capacitor to shift the phase of one winding by 90°. Recheck the preload setting after run-in and readjust as required in

2-8-6 Rotor Bearing Preload Adjustment and Run-in Procedures (Cont'd)

paragraph (2) above.

(6) Run the rotor for an additional 24 hours and check the rotor start and run-down performance. The rotor must start and continue running with 90 vac, 400 cps applied and run-down time should be between 6 and 10 minutes. If the rotor fails to start at 70 to 90 vac, and run-down time is not within limits, the top preload nut should be readjusted. If successive rotor starts vary more than 15 vac, the bearings are contaminated or worn and must be replaced.

(7) Check that the rotor attains a speed of approximately 23, 500 rpm with 115 vac, 400 cps applied to the rear connector. The rotor should draw approximately 140 milliamperes starting current and 115 milliamperes running current.

(8) After it has been established that the rotor meets the requirements of the above paragraphs, apply a small amount of Glyptal to both preload nuts. Avoid excessive Glyptal on the free threads at each end of the rotor shaft.

(9) Install the rotor housing in a balancing fixture or in the gimbal to properly locate the rotor in the housing. Balance the assembly by turning the rotor shaft as required to center the rotor in the housing. When proper adjustment has been obtained, secure the rotor shaft and the rotor support nuts with Glyptal.

2.9 ROTOR HOUSING STATIC BALANCING

(1) The rotor housing should be statically balanced inside the instrument. Install two balancing screws from the back of the rotor housing toward the front so that the screws are centered horizontally (Figure 2-14).

(2) Turn the instrument on its side and position the rotor housing so that the rotor strut is perpendicular to the earth.

(3) Place a small weight and a piece of tape on a gram scale and

cut the tape until the total weight of the two is 3/10 gram.

(4) Attach the weight to the top of the rotor housing where the two halves come together (Figure 2-14).

(5) Return the rotor strut to the perpendicular position and let go. The rotor should not move from this position. As a further check, a screwdriver handle or similar device should be rattled along the instrument casting to induce vibrations which will assist in determining any imbalance. If the rotor tends to fall, either to the top or to the bottom, appropriate weight should be added at the four #2-56 tapped holes provided for this purpose (A, Figure 2-14).

(6) Set the instrument in the upright position with the air passage or slip ring side of the gimbal toward the back of the instrument. The rotor housing should assume about a 10° tilt to the left when viewed from the front of the instrument. Again, a screwdriver handle or similar device, rattled on

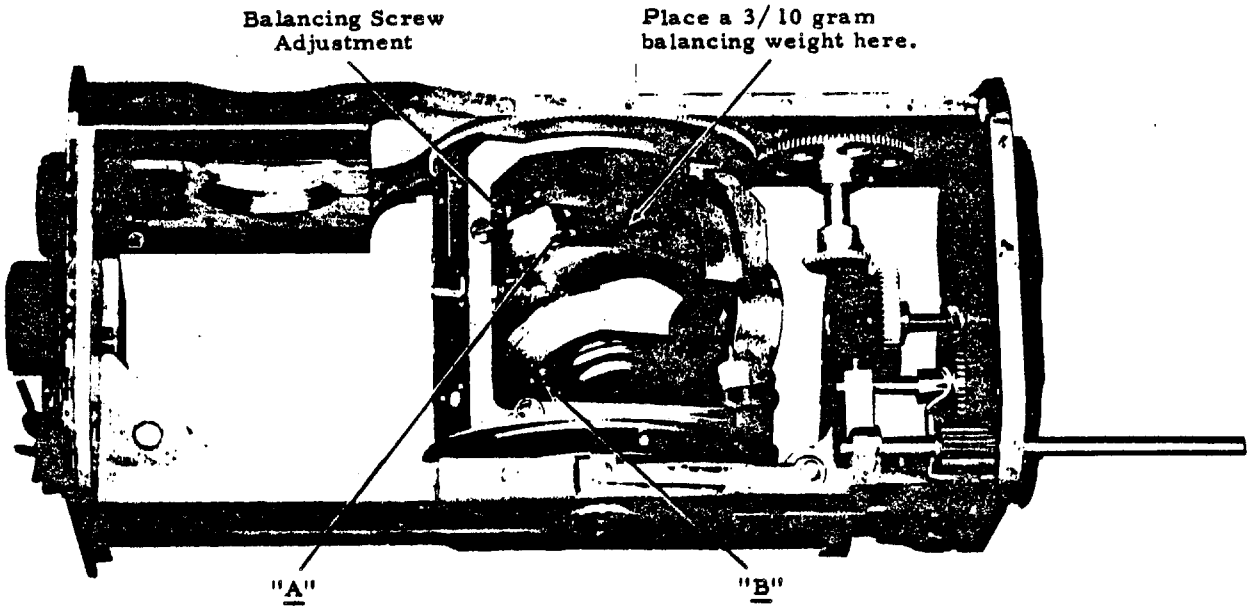

FIGURE 2-14. ROTOR HOUSING BALANCE ADJUSTMENTS

the instrument casting, will cause the rotor housing to seek its stable position.

(7) A rough adjustment may be accomplished by centering the two balancing screws and adding or subtracting weight at the two #1-72 tapped lugs shown in B, Figure 2-14, until the rotor housing is near the correct position. Final adjustment may be accomplished by positioning the two balancing screws as required. Secure the balancing screws with a minimum amount of Glyptal since additional adjustment may be necessary during the drift and calibration tests in Section 3.

SECTION 3

TEST AND CALIBRATION

3.1 TEST AND CALIBRATION

3.1.1 General

The following test and calibration procedures may be used to either isolate malfunctions in the instrument prior to overhaul, or to checkout and recalibrate the instrument after overhaul has been accomplished. Included with each test are suggested corrective measures which should be employed if the instrument fails to meet the required performance specifications.

3.2 TEST EQUIPMENT REQUIRED

3.2.1 General

(a) Scorsby test stand capable of providing roll, pitch, and yaw oscillations with an amplitude of ± 3 degrees about each axis at a frequency of 5 to 7 cycles per minute.

(b) Stop watch

(c) Clean, dust-free work area

3.2.2 Vacuum Only

(a) Mercury manometer capable of reading up to 6 in. Hg

(b) Pressure source capable of producing a pressure of 4.7 in. Hg (A vacuum source is recommended but is not required.)

(c) Either a volumetric flow meter or a similar device capable of measuring approximately 2.0 cfm air consumption

3.2.3 Electric Only

(a) 115 vac, 400 cps, single phase power source

(b) Variac power transformer or similar means of varying supply voltage from 85 vac to 115 vac

3.2.3 Electric Only (Cont'd)

(c) Vacuum tube voltmeter

(d) 0-200 ac milliameter

3.3 MECHANICAL TESTS

3.3.1 Rotor Speed Test - Vacuum Models

This test is an "open" calibration test and should be performed with the instrument dust cover removed. Apply a pressure line of 4.5 to 4.7 in. Hg to the AIR INLET port on the rear panel of the instrument. Allow approximately five minutes for the rotor to gain speed and stabilize.

The rotor should attain a speed of 23,000 rpm or greater if the rotor housing is installed in the instrument and the instrument ductwork is used. If the rotor housing is outside of the instrument, and air pressure is applied directly to the air pivot, rotor speed must be in excess of 29,000 rpm.

If the rotor fails to reach the required speed, a new rotor and rotor housing should be installed. If replacement is not possible, overhaul of the rotor and rotor housing should be accomplished as described in paragraph 2.7 of this manual.

3.3.2 Rotor Speed Test - Electric Models

This test is an "open" calibration test and should be performed with the instrument dust cover removed. Insert a 0-200 ac milliameter in series with 115 vac, 400 cps and apply power to the proper electrical connector on the rear panel of the instrument. Allow approximately five minutes for the rotor to gain speed and stabilize. The rotor should attain a speed of 23,000 rpm or greater.

Check for approximately 115 milliamperes running current. Rotate the instrument horizontally through 360° and check for any variation in current. Also tilt the rotor to its limits of travel and check for current variation. If current does vary, readjust tension on the appropriate brushes so that the brushes do not drop away from their respective slip ring.

3.3.2 Rotor Speed Test - Electric Models (Cont'd)

If the rotor fails to reach the required speed, a new rotor and rotor housing should be installed. If replacement is not possible, overhaul of the rotor and rotor housing should be accomplished as described in paragraph 2.8 of this manual.

3.3.3 Rotor Coast Test

After the conditions described in the Rotor Speed Test have been attained, disconnect electrical power or pressure line from the instrument. Rotor run-down time must be 6 minutes or more for electric models and 4-1/2 minutes or more for vacuum models. If the rotor fails to coast the required length of time, replacement or overhaul of the complete rotor housing should be accomplished.

3.3.4 Still Run Drift and Calibration

(1) Mount the instrument in a panel or secure it on a bench so that the bezel is vertical and the instrument will not change position on the bench.

(2) Apply 115 vac, 400 cps or 4.5 to 4.7 in. Hg air pressure for the remainder of this test. Allow five minutes for the rotor to attain full speed.

(3) Set the dial on 0° or North heading and allow the gyro to run for 15 minutes. At the end of 15 minutes, the dial reading must be between 357° and 3°. If the reading is greater than 3°, turn one of the balancing screws shown in Figure 3-1 counterclockwise. Likewise, if the reading is less than 357°, turn one of the balance screws clockwise.

To correct for a 10° change in drift rate, turn each balancing screw 1-1/2 to 2-1/2 turns. To simplify calibration, the original drift and the correction made should be recorded. This procedure should be repeated and evaluated for the next correction.

(4) Repeat the above procedure for headings of 90°, 180°, and 270°. Maximum permissible drift for any cardinal heading is $\pm 3^{\circ}$ in

3.3.4 Still Run Drift and Calibration (Cont'd)

fifteen minutes.

If the instrument fails to maintain the required performance levels specified in the above test procedures, the following items should be checked for proper assembly.

(a) The gear train which drives the dial must be free throughout its entire range of rotation. If the gimbal gear binds with the intermediate gear, the bearing eccentric on the top of the instrument must be adjusted as described in paragraph 2.6.3 (10).

(b) Check the bearings which support the rotor housing for rough spots or excessive preload. Either replace the bearings or adjust the threaded housing as described in paragraph 2.6.2 (4).

(c) Check the bearings which support the gimbal for proper clearance between the gimbal and the case. The gimbal assembly must move up and down when the gimbal is lifted and released. If the bearings are excessively preloaded, add necessary shims under the lower bearing housing. Refer to paragraph 2.6.3 of this manual.

3.3.5 Erection Test in Still Run

Mount the instrument securely with the frame placed in a level position. Apply 115 vac, 400 cps or 4.5 to 4.7 in. Hg air pressure and allow five minutes for the rotor speed to increase and stabilize. Displace the rotor spin axis 55° from horizontal and check that the rotor housing automatically erects. If the rotor housing fails to erect, the rotor housing is improperly installed or the erector track is improperly adjusted. For proper installation and adjustment refer to paragraph 2.6.2.

3.3.6 Caging

The rotor housing must be 80% to 90% caged before the dial-set

3.3.6 Caging (Cont'd)

gear becomes sufficiently engaged to permit readjustment of the heading card. When the caging shaft is fully in, the rotor housing must be fully caged.

If adjustment is necessary refer to paragraph 2.6.5 in this manual.

3.3.7 Rotor Start Test - Vacuum Only

To perform this test and those following, the instrument must be completely assembled and sealed. Apply a vacuum to the vacuum port on the rear panel. By listening carefully against the case, any rotation of the rotor can be heard. The amount of vacuum required for the rotor to start and continue running should not exceed 2.25 in. Hg.

If the rotor fails to start at the prescribed vacuum, a new rotor and rotor housing should be installed. If replacement is not possible, overhaul of the rotor and rotor housing should be accomplished as described in paragraph 2.7 of this manual.

3.3.8 Rotor Start Test - Electric Only

The rotor must start with 90 vac, 400 cps applied to the rear connector. This check should be repeated several times. If successive starts vary more than 15 vac, the rotor bearings are worn or contaminated and should be replaced.

Check that the starting current is approximately 140 milliamperes and running current is approximately 115 milliamperes. If the rotor fails to conform to the above requirements, a new rotor and rotor housing should be installed. If replacement is not possible, overhaul of the rotor and rotor housing should be accomplished as described in paragraph 2.8.

3.3.9 Scorsby Test

Mount the instrument on a Scorsby test stand which should be set for 5-7 oscillations per minute at an amplitude of ± 3 degrees

3.3.9 Scorsby Test (Cont'd)

about each axis.

For each cardinal heading, the instrument drift must not exceed 3^{o} for 10 minutes. If drift is excessive, check for possible defects and recalibrate as explained in paragraph 3.3.4. Also check freedom of dial and gear train mechanism as described in the appropriate paragraph of section 2.3.

3.3.10 Air Consumption Tests - Vacuum Only

1) General

This test should be performed after the instrument is calibrated because the instrument must be completely assembled and fully sealed. An air volumetric flow meter or similar device must be used to perform the following tests.

2) Leak Test

Block the AIR INLET port and apply a vacuum of 4.5 in. Hg to the vacuum port. Air consumption must not exceed 0.2 cfm. If excessive leakage occurs, check cover gaskets, air filter housing, and glass for leakage.

3) Air Consumption When Running

Apply a vacuum of 4.5 in. Hg to the vacuum port. Air consumption must not exceed 2.1 cfm. If air consumption is greater than 2.1 cfm, check for internal leaks such as omitted air seals, loose bearing housings, loose pivots, etc.

3.3.11 Appearance

There should be no bright surfaces on the face of the dial. The dial, glass, indices, and bezel should be free of scratches or flaking paint. The nameplate and serial number should be clearly legible.

On vacuum instruments, plastic pipe plugs should be installed in both the AIR INLET port and the vacuum port until the instrument is installed in the aircraft.

3.4 ELECTRICAL TESTS AND ADJUSTMENTS

3.4.1 General

Synchro zeroing may be accomplished by either of two methods. The first method is detailed in the following procedures and can be performed using equipment which is readily available in most overhaul shops.

The second method is of particular value where overhaul is performed regularly on a number of different AIM, ARINC instruments. It requires the construction of an ARINC Test Box such as that described in the Appendix of this manual. The test box simplifies synchro zeroing and substantially reduces the amount of time required. Instructions for use of the test box are also included in the Appendix.

3.4.2 ARINC Zeroing Procedures for Synchro Transmitters

1) Null

(1) Connect a vacuum tube voltmeter and a 26 volt, 400 cps power supply to the synchro under test as shown in Figure 3-1.

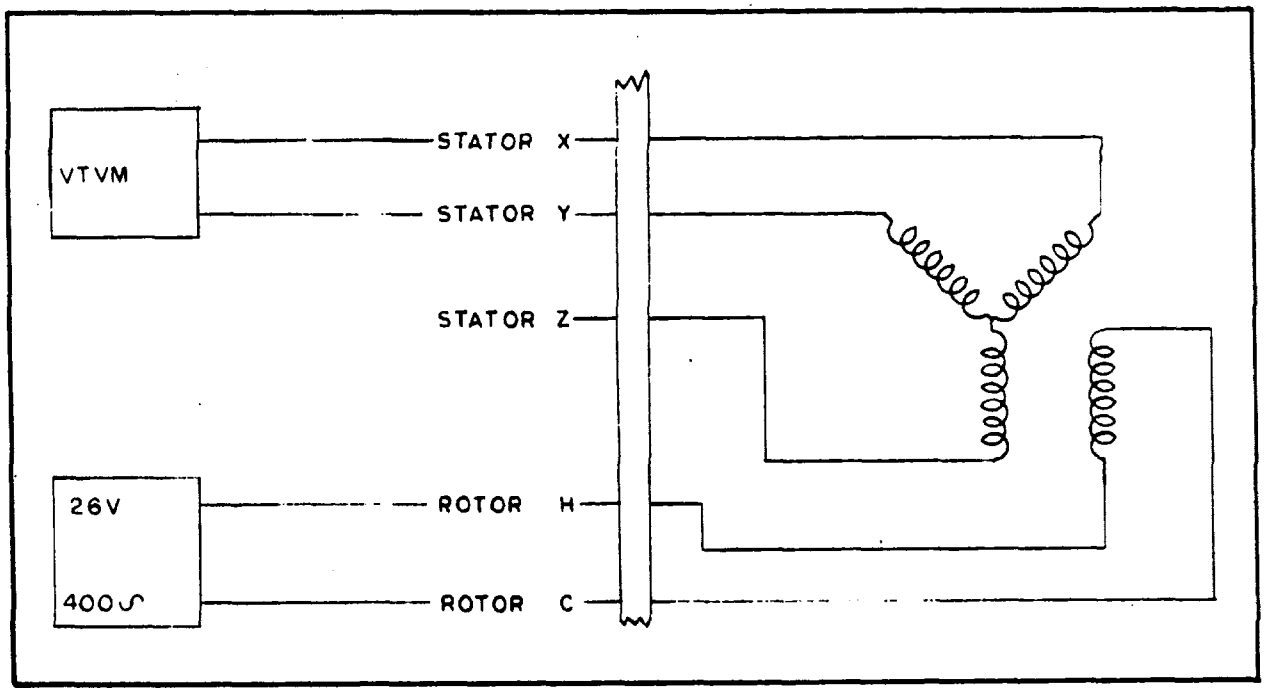

FIGURE 3-1. ARINC ZEROING PROCEDURE, STEP 1

3.4.2 ARINC Zeroing Procedures for Synchro Transmitters (Cont'd)

1) Null (Cont'd)

(2) Rotate the heading gear train until null (minimum voltage) is indicated on the VTVM.

(3) Loosen the gear hub or dial setscrew on the synchro under test.

(4) Hold the synchro shaft and rotate the heading dial to north. Lightly tighten the setscrew.

2) Phase

(1) Change the test circuit to that shown in Figure 3-2.

(2) Rotate the heading card from north to +30° while observing the VTVM. The voltage must be at least 26 volts and must increase from 0° to 30°.

If the voltage is 26 volts or greater at 0°, but decreases from 0° to 30°, reverse the synchro stator x and y leads and repeat steps 1) and 2) above.

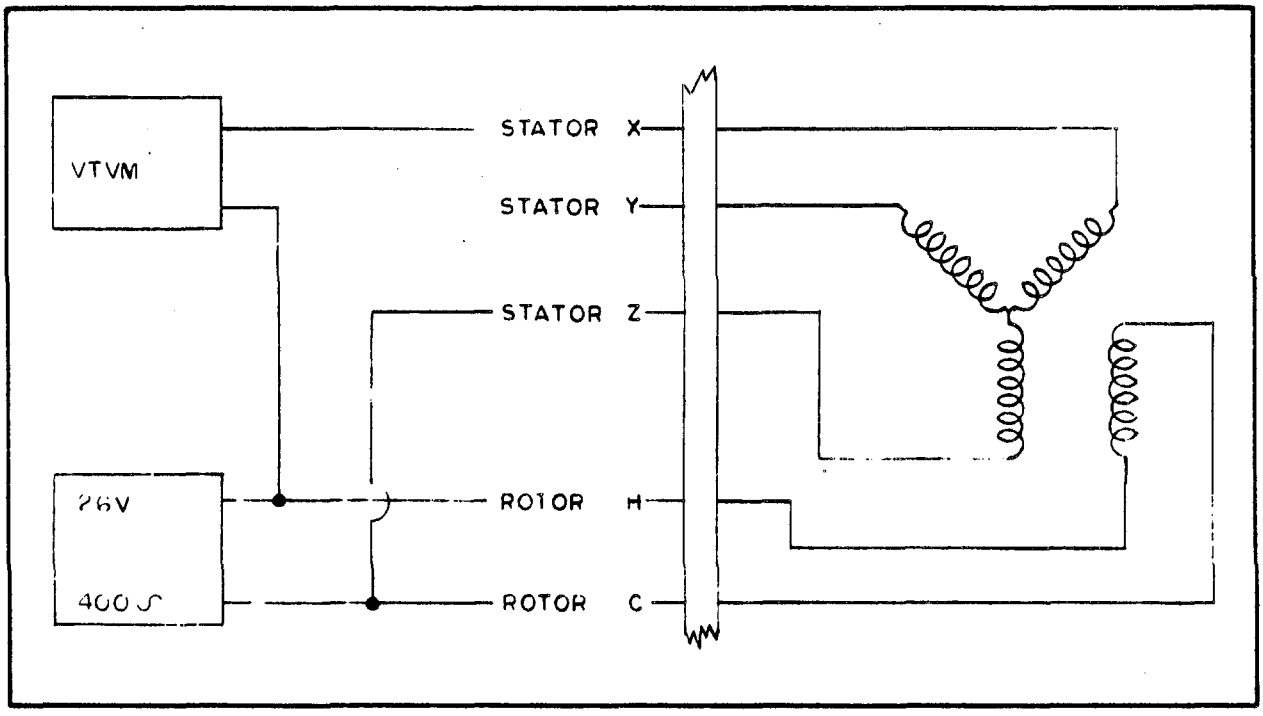

FIGURE 3-2. ARINC ZEROING PROCEDURE, STEP 2

3.4.2 ARINC Zeroing Procedures for Synchro Transmitters (Cont'd)

2) Phase (Cont'd)

(2) If the voltage is less than 26 volts at 0°, loosen the gear hub or dial setscrew and rotate the synchro shaft 180 degrees. Lightly tighten the setscrew and repeat steps 1) and 2) above.

3.4.3 ARINC Zeroing Procedure for Synchro Receivers

Zeroing procedures for ADF/VOR pointers are the same as those for synchro transmitters except that electrical zero is at south instead of north. Consequently, the voltage must be at least 26 volts at 180° and must increase from 180° to 210°.

3.4.4 ARINC Zeroing Procedure for Synchro Resolvers

(1) Construct a test circuit as shown in Figure 3-3.

(2) Set the switch in position 1 and loosen the setscrew which secures the dial to the resolver synchro shaft.

(3) Turn the dial to 0° or north heading.

(4) Hold the dial and turn the shaft until the VTVM reads minimum voltage. Tighten the setscrew holding the dial on the shaft.

(5) Check that null occurs within 1/2 degree of the dial zero.

(6) Set the switch in position 2 and rotate the card and shaft 360°. Observe the VTVM and check that low null (minimum voltage) occurs at north or 0°.

(7) Set the switch in position 3 and rotate the card and shaft 360°. Observe the VTVM and check that low null occurs at east or 90°.

(8) If the low null in step (6) occurs at south, and the low null in step (7) occurs at west, loosen setscrew and turn the synchro shaft 180 degrees while holding the card stationary. Retighten setscrew and repeat steps (6) and (7).

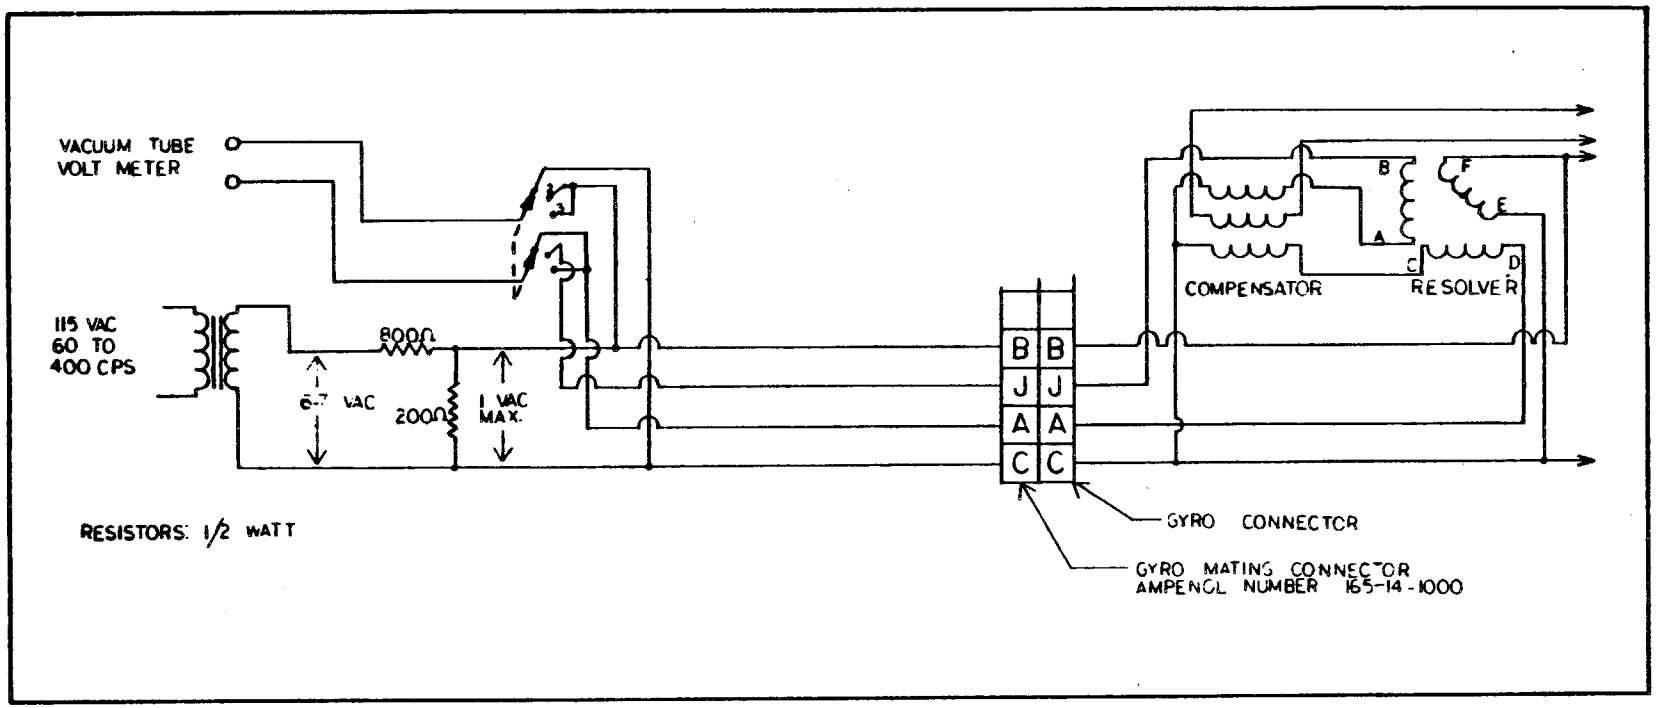

FIGURE 3-3. SYNCHRO RESOLVER CALIBRATION CIRCUIT

3.4.4 ARINC Zeroing Procedures for Synchro Resolvers (Cont'd)

(9) If the low null in step (6) is correct, but the low null in step (7) occurs at 270° or west, reverse wires A and B or blue and yellow on the synchro resolver and repeat steps (6) and (7).

(10) If the corrective measures of steps (8) and (9) fail to bring the desired results, check wiring by reversing pairs of wires as required.

(11) Disconnect wiring to the synchro resolver and use an ohm meter to check continuity between the following pairs of synchro leads:

(a) Black and white

(b) Blue and yellow

(c) Black-white and red-white

Also rotate the shaft while making this check. If continuity exists, check for continuity in the electronic compensator coils. If the continuity fails to check, the synchro must be replaced.

3.5 ADJUSTMENT OF ELECTRONIC COMPENSATOR

3.5.1 Equipment Required

Use a 5-0-5 voltmeter and a magnetic flux detector mounted on a calibrated base as shown in Figure 3-4.

3.5.2 Adjustment Procedure

(1) Set both the gyro card and the flux detector dial to read north.

NOTE

If the gyro is not running, it may be necessary to hold the gyro in the caged position to maintain the desired heading.

(2) Position the flux detector platform until null is obtained on the slaving indicator.

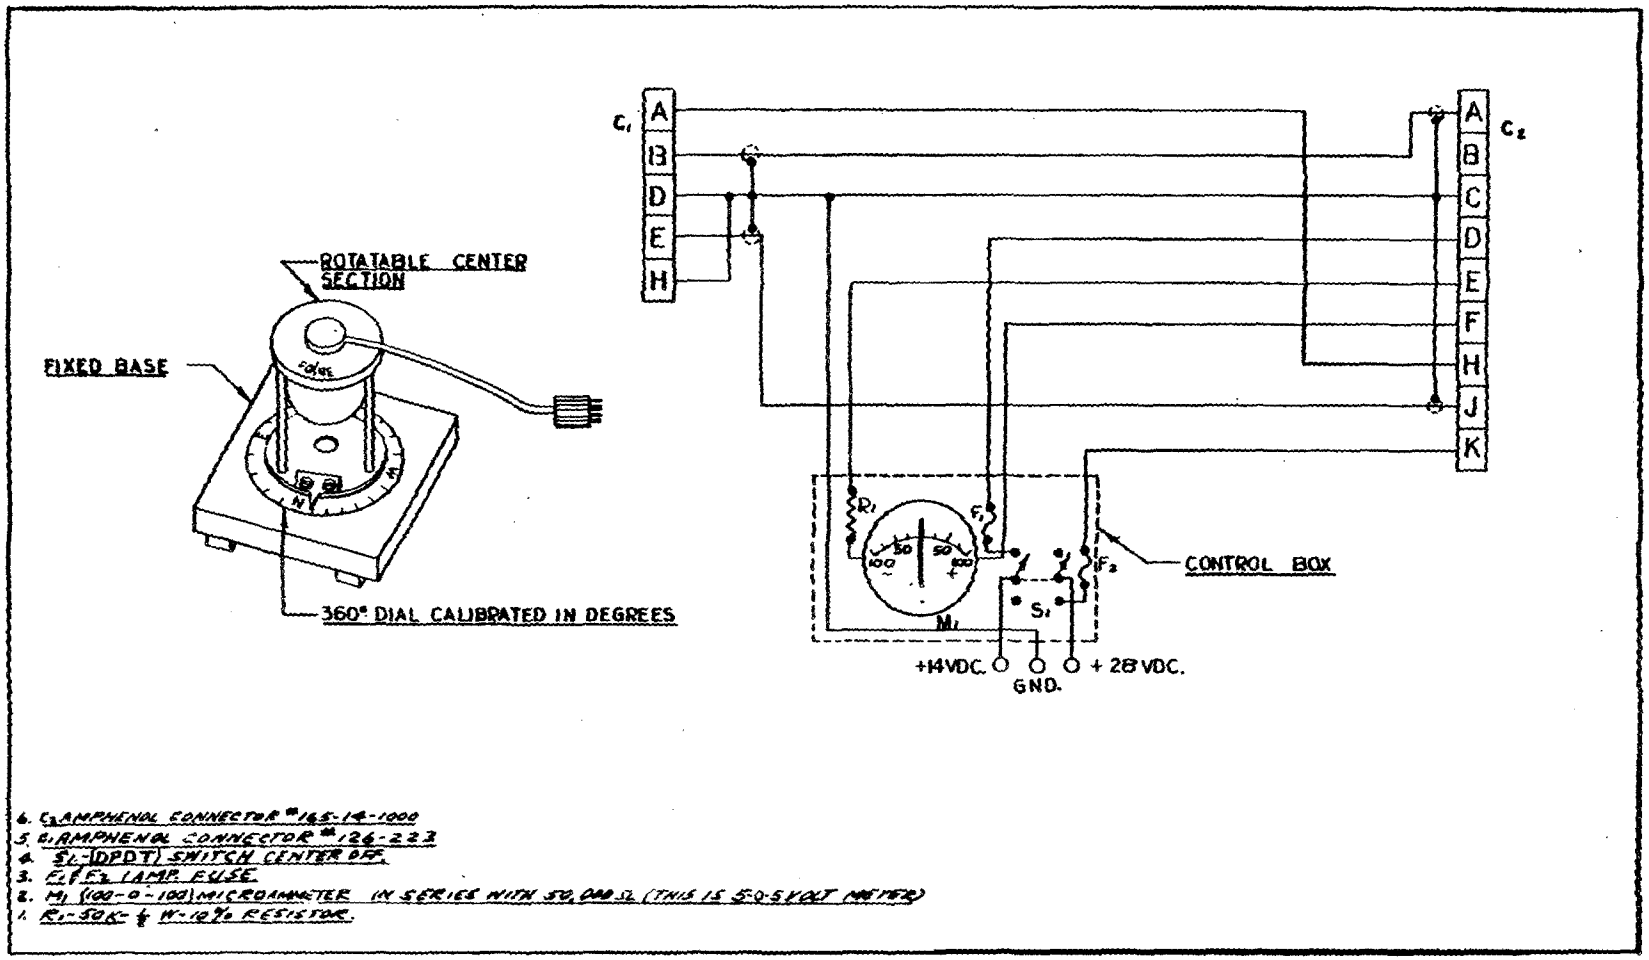

FIGURE 3-4. ADJUSTMENT OF ELECTRONIC COMPENSATORS

3.5.2 Adjustment Procedures (Cont'd)

(3) Rotate the gyro card to 180° and the turntable to the angle near 180° at which null occurs, and note the deviation of the turntable from 180°.

(4) Rotate the turntable to reduce the deviation by 50% and adjust the N-S compensator to again obtain a null on the slaving indicator.

(5) Return the gyro card and flux detector turntable to zero degrees and reposition the platform to obtain null on the slaving indicator.

(6) Rotate the gyro to 180° and the turntable to the angle near 180° at which null occurs, and note the deviation of the turntable from 180°.

(7) Again rotate the turntable to reduce the deviation by 50% and adjust the N-S compensator to obtain a null on the slaving indicator.

(8) Repeat the above procedure until no deviation is noted when the gyro card and flux detector turntable are turned to 180°.

(9) Without moving the flux detector platform, rotate the gyro card and turntable to 270°.

(10) Adjust the E-W compensator to obtain null on the slaving indicator.

(11) Rotate the gyro card to 90° and the turntable to the angle near 90° at which null occurs, and note the deviation of the turntable from 90°.

(12) Rotate the turntable to reduce the deviation by 50% and adjust the E-W compensator to obtain a null on the slaving indicator.

(13) Repeat the above procedures, alternating between 90° and 270° until no deviation is noted.

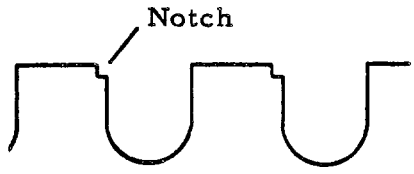
3.6 TROUBLE-SHOOTING

3.6.1 General

Before attempting to trouble-shoot the system, make certain that the trouble is not caused by loose or improper cable connections, inadequate power or vacuum supply or other external conditions. Test and troubleshooting procedures must be performed with all elements of the system operating, in order to insure the validity of test results. The AIM 254-11 Flux Detector is a sealed unit and is not repairable in the field. To check for open windings, refer to paragraph 2.4.1 (page 1-16) of the manaul. The AIM 292 RMI Coupler used with some systems, is a field repairable unit. The schematic is included in Figure 1-9 (page 1-18) and the component layout and parts list is provided on page 4-25. The gyro internal circuitry is shown schematicaly in Figure 3-5, and parts data is provided on pages 4-20 thru 4-23. The P-10A and P-11 Inverter schematics and parts lists are provided on pages 4-26 and 4-27, respectively.

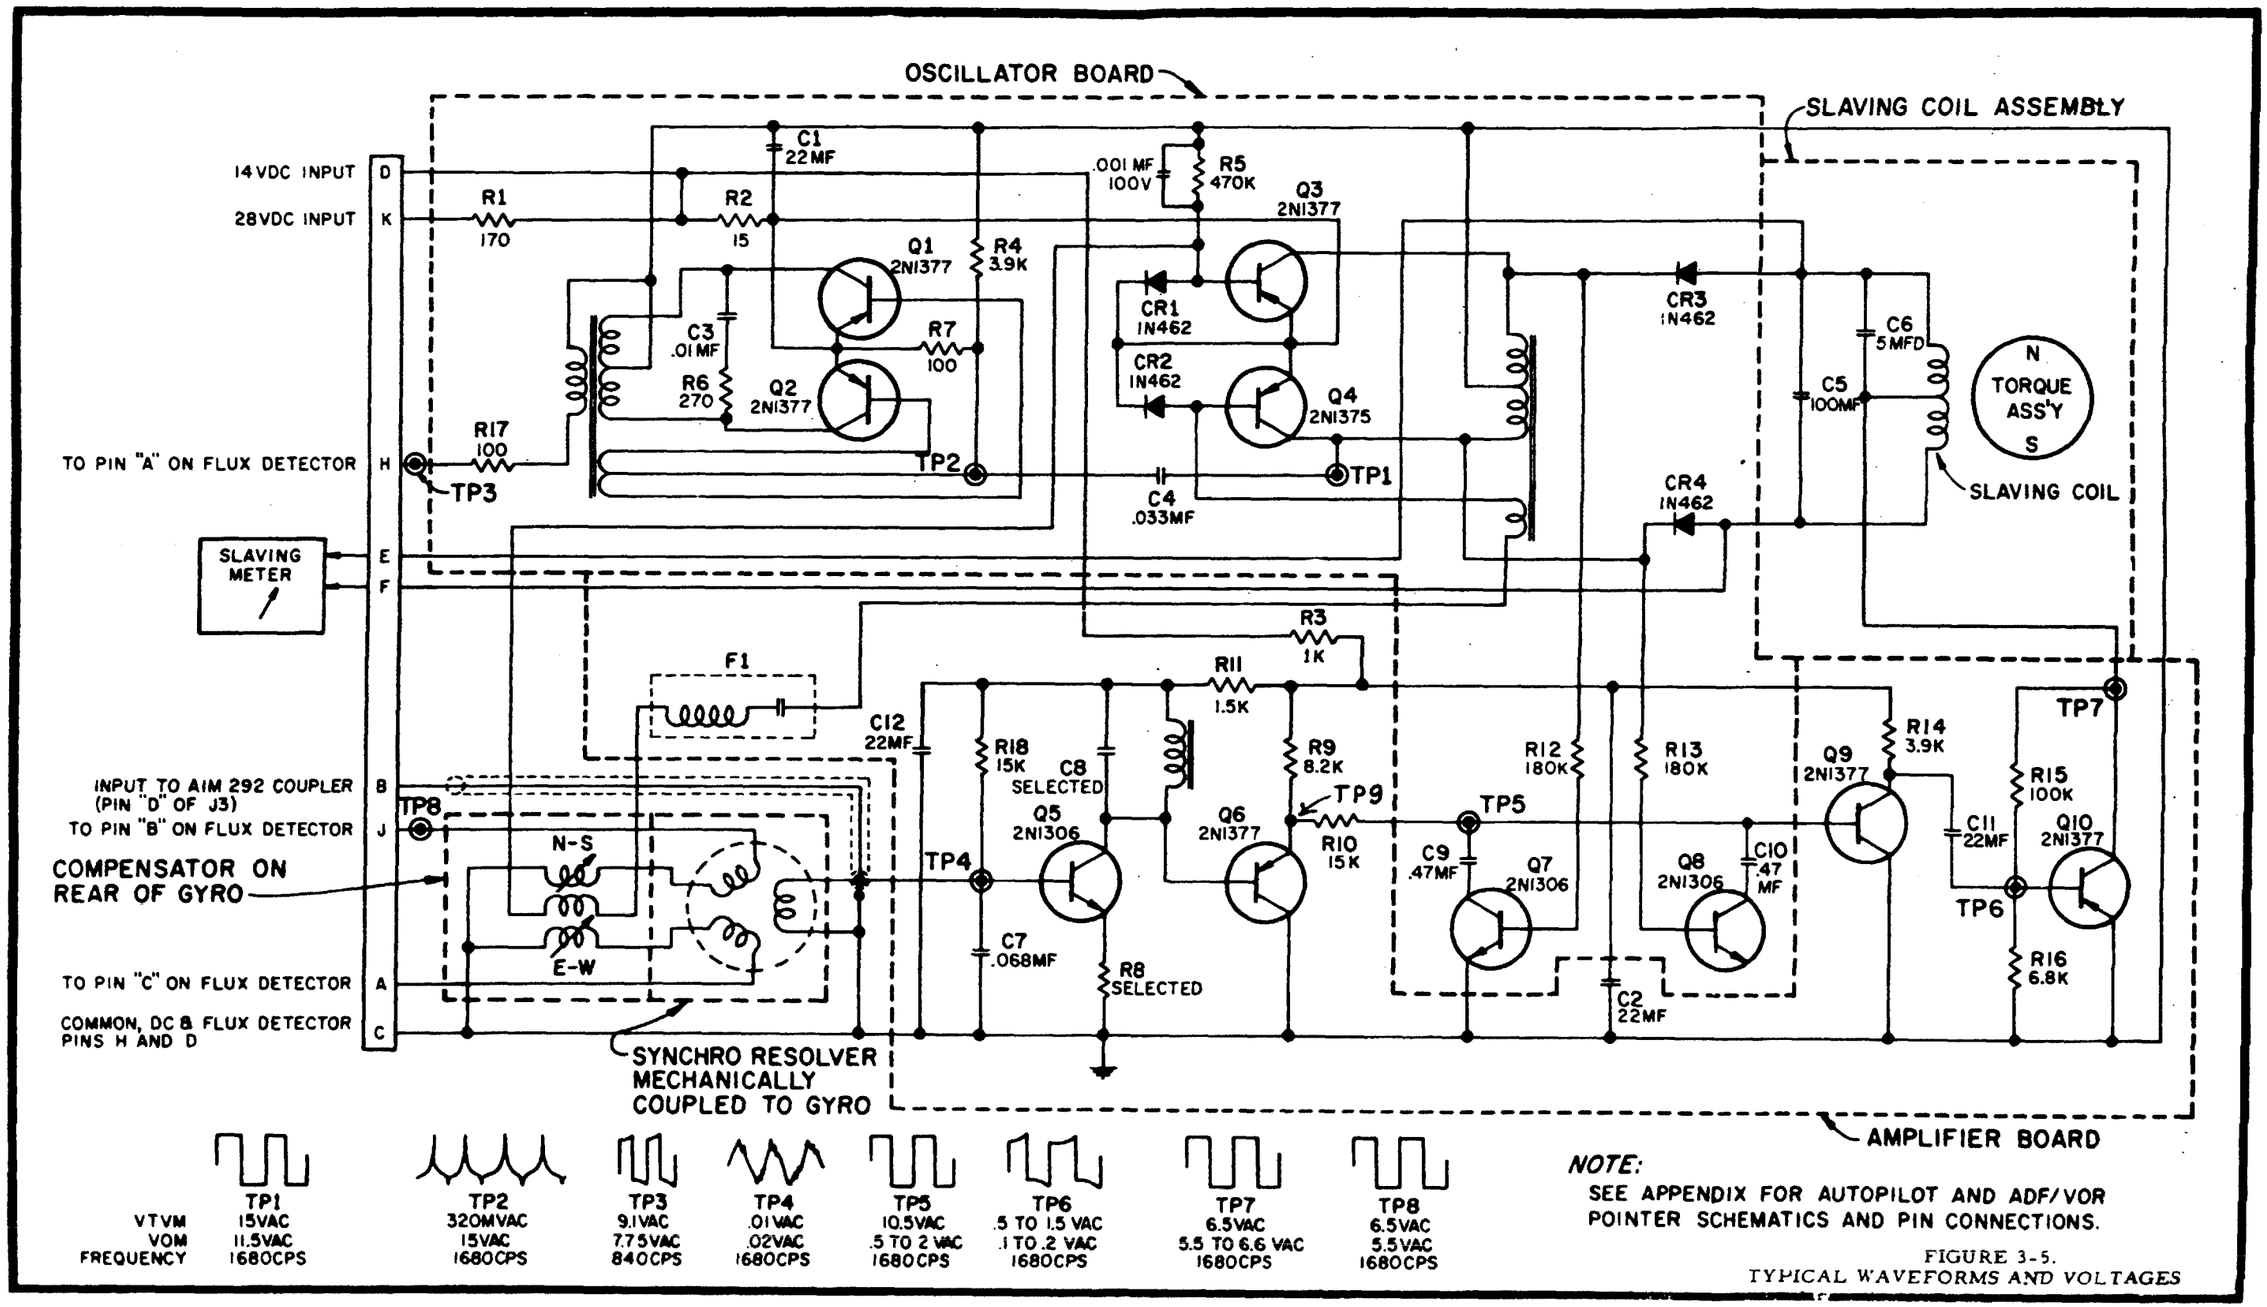
3.6.2 Equipment Required

(1) Adequate power supplies to provide appropriate supply voltages for specific system under test.



(2) Oscilloscope

(3) VTVM or VOM capable of reading ac and dc voltages from 0.01 volts to 50 volts.



3.6.3 Trouble-Shooting Procedure

Using an oscilloscope and either a VTVM or VOM, check for appropriate readings and waveforms at the test points indicated on the schematic of Figure 3-5. The actual location of each test point is shown in Figure 3-6.

To match the amplifier frequency to the oscillator frequency, select capacitor C8 so that the frequency at TP 9 equals the frequency at TP 1 and produces the waveshape shown.

Select R8 to produce full scale slaving indication (5 vdc across pins E and F) when the heading card is offset 4 degrees in each direction from null.

	TP1	TP2	TP3	TP4	TP5	TP6	TP7	TP8
VTVM	15VAC	320MVAC	9.1VAC	.01VAC	10.5VAC	.5 TO 1.5 VAC	6.5VAC	6.5VAC
VOM	11.5VAC	15VAC	7.75VAC	.02VAC	.5 TO 2 VAC	.1 TO .2 VAC	5.5 TO 6.6 VAC	5.5VAC
FREQUENCY	1680CPS	1680CPS	840CPS	1680CPS	1680CPS	1680CPS	1680CPS	1680CPS

NOTE:

TABLE 4-2. TYPE R3H VACUUM ROTOR (Figure 4-2)

NO.	DESCRIPTION	AIM PART NO.
	Note This parts list and the drawing of Figure 4-2 cover several versions of the basic R3H rotor. Where parts are identified by two callout numbers in the illustration, check the part description closely to insure the interchangeability of replacement parts.	
1	Pivot	639-0003-902
2	Screw, 1-72 x 1/8, flat hd., st. st.	—
3	Nut, preload, knurled	605-0012-001
4	Nut, preload, Esna, hex (used only with Item 18)	605-0015-001
5	Rotor Housing (with cast orifice)	652-0005-901
6	Rotor Housing (without cast orifice)	652-0006-901
7	Screw, balance	603-0009-002
8	Nut, rotor support	605-0011-001
9	Bumper, 1/8 x 1/4 I. D. vinyl tubing	—
10	Screw, 3-48 x 3/8, fillister hd., st. st.	—
11	Screw, 1-72 x 3/16, binder hd., st. st. (used only with Item 18)	—
12	Screw, 1-72 x 3/16, flat hd., st. st. (used only with Item 17)	—
13	Retainer, bearing	608-0011-001
14	Plate, bearing (used only with Item 18)	628-0070-001
15	Plate, bearing, with counter-sunk holes for flat-head screws (used only with Item 17)	628-0082-001
16	Spacer, bearing	616-0019-001
17	Rotor, brass, counterbored 3/32 inch to accommodate Items 3, 13 and 15	636-0006-001
	Rotor, heavy metal, counterbored 3/32 inch to accommodate Items 3, 13, and 15	—
	Note If defective, replace with Items 4, 18, and 23 as a set.	
18	Rotor, brass counterbored approx. 5/32 inch to accommodate Items 4, 13 and 14	636-0009-001
	Rotor, heavy metal, counterbored approx. 5/32 inch to accommodate Items 4, 13 and 14	636-0010-901
19	Bearing	637-0011-004
20	Pivot, air (without orifice insert)	639-0005-901
21	Pivot, air (with orifice insert)	639-0009-901
22	Screw, 2-56 x 1/8, binder hd., st. st.	—
23	Shaft, rotor	632-0064-004
24	Weight, lead, as required for balancing	—
25	Screw, 2-56, length as required, binder hd., st. st.	—

NOTES

1. For complete rotor housing assembly, consisting of all parts shown below, order P/N 652-0016-901 (brass rotor) or P/N 652-0016-902 (heavy metal rotor). Assembly will be correctly preloaded and will require only minor balancing when installed.
2. For preloaded rotor assembly consisting of items 4, 11, 13, 14, 16, 19 and 23, order P/N 636-0018-901 (brass rotor) or P/N 636-0018-902 (heavy metal rotor).

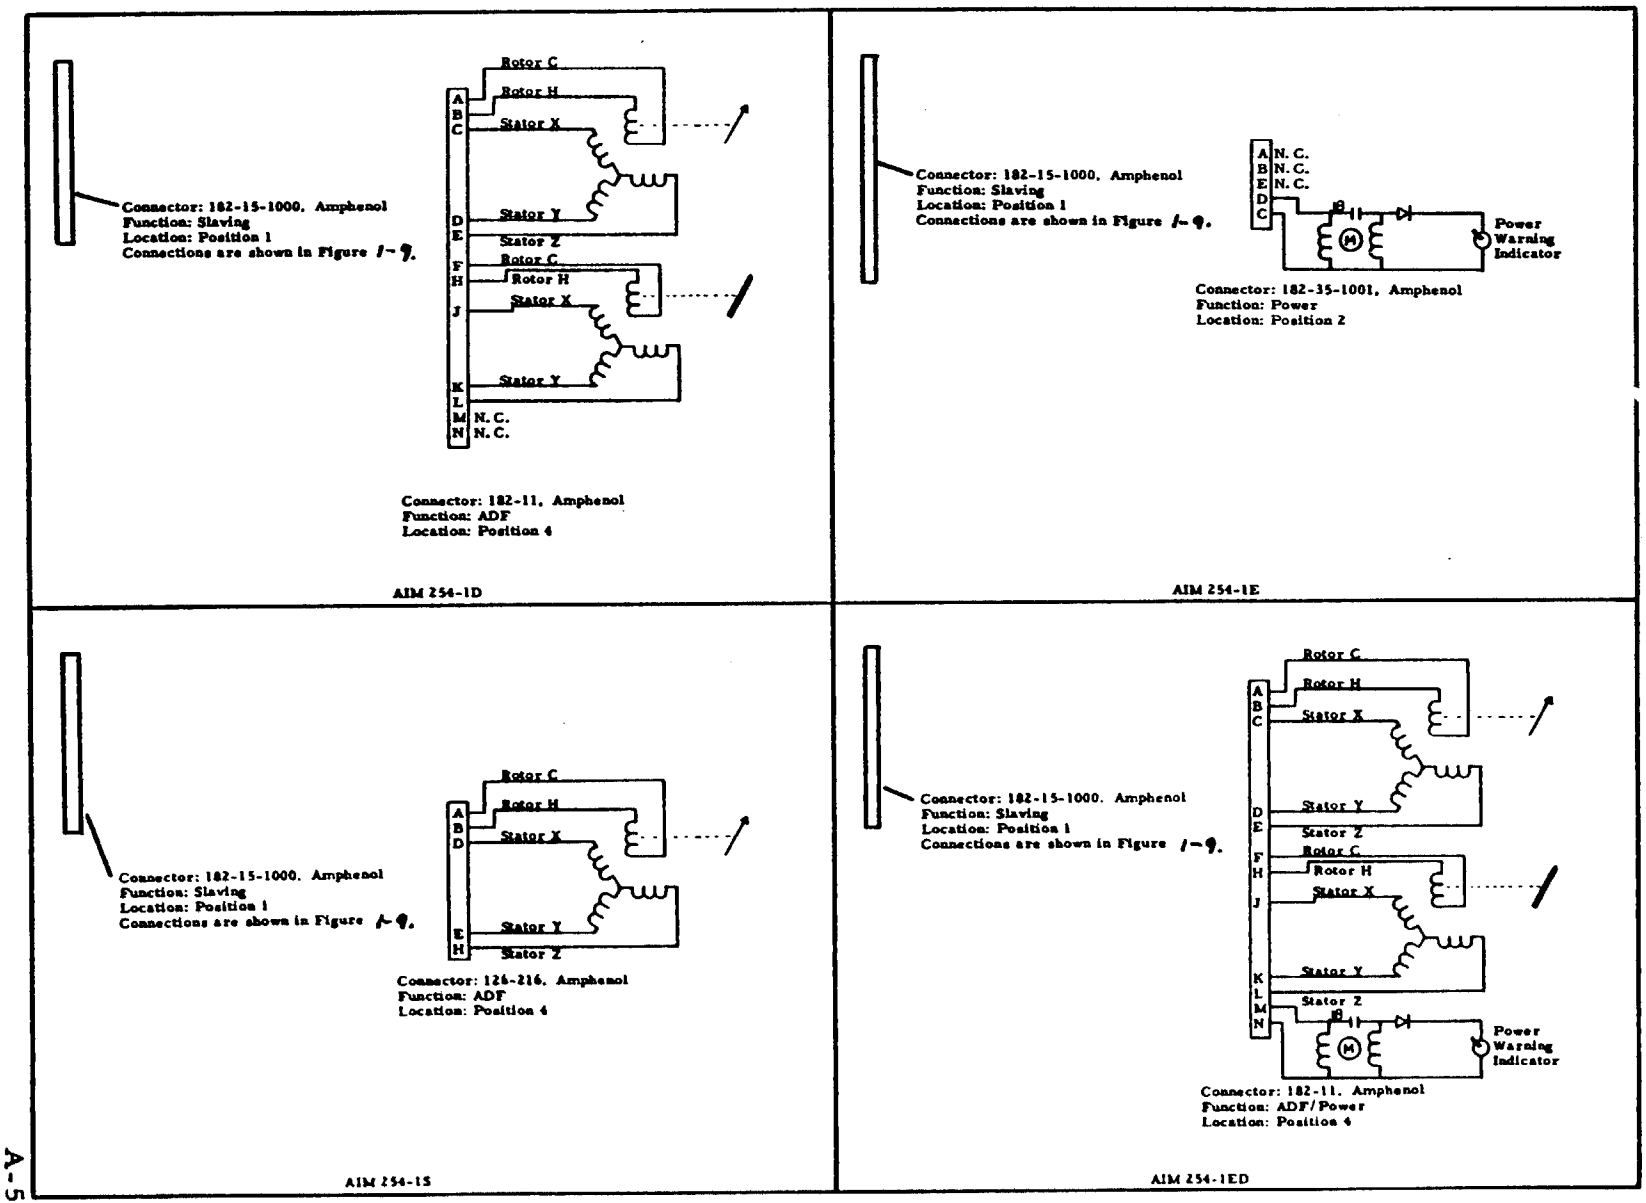
APPENDIX
to the
MAINTENANCE AND
OVERHAUL MANUAL
for
AIM 400 and AIM 800 SYSTEMS

REAR CONNECTOR INFORMATION



The following reference pages provide specific information as to the number, type, location, and function of electrical connectors on the rear of AIM Slaved Gyro Direction Indicators covered in this manual. This information, along with the schematic diagrams contained elsewhere in the appendix, will assist the field technician in troubleshooting the instrument.

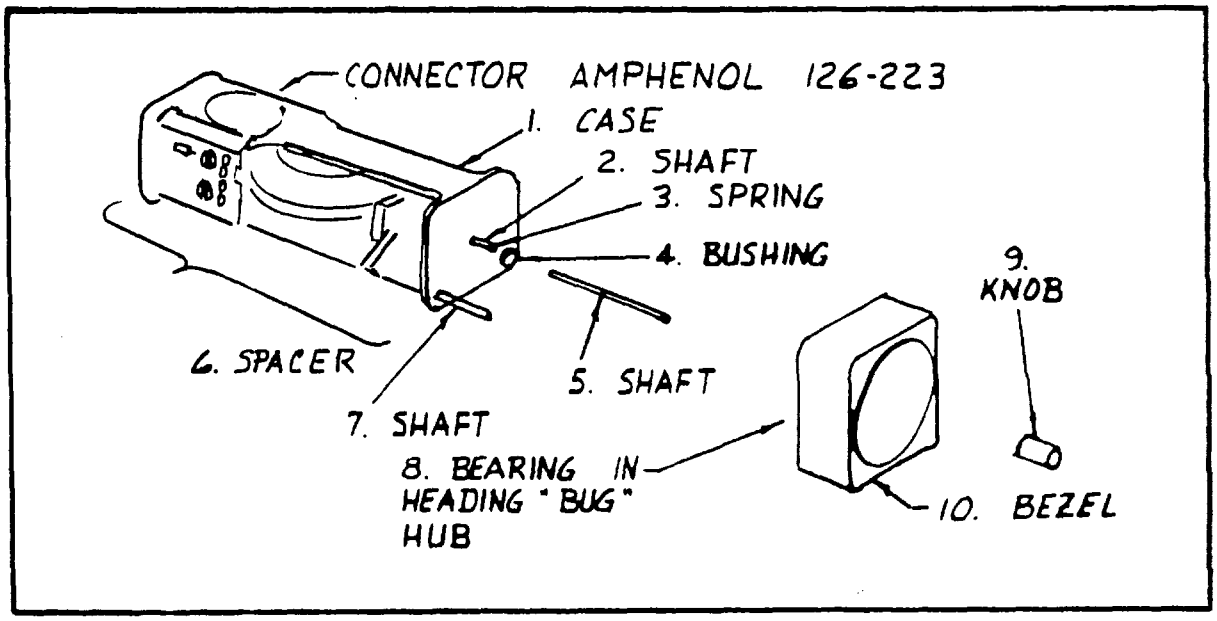
SUPPLEMENTAL DATA SHEET

SUBJECT: Maintenance and Overhaul Manual for AIM 400/800 Slaved Gyro and Slaved Gyro/RMI Systems



EFFECTIVE: October 1969

AIM 400G and 400G EL Slaved Gyro Systems

The AIM 400G and 400G EL Systems are designed for use with Mitchell Industries, Inc. Century II and Century III Autopilots, and with Piper Aircraft Altimatic II and Altimatic III Autopilots. The AIM 400G System employs an AIM 254-2 (vacuum-driven) gyro and the AIM 400G EL uses the AIM 254-2E (electrically-driven) gyro.

The AIM 254-2 and AIM 254-2E are identical to the AIM 254-92 and AIM 254-1E, respectively, except for the autopilot pickoff parts and the parts noted below. The pickoff parts are identical to those used in the Mitchell 52D54 Directional Gyro, and are fully described in Mitchell Industries 52D54 Maintenance and Overhaul Manual.

ITEM	DESCRIPTION	AIM PART NO.	
		254-2	254-2E
1	Case	649-0050-901	649-0124-901
2	Shaft, center	632-0056-002	632-0056-002
3	Spring	657-0022-001	657-0022-001
4	Bushing	624-0005-001	624-0005-001
5	Shaft	632-0058-001	632-0058-001
6	Spacer	616-0024-001	616-0024-001
7	Shaft	632-0014-001	632-0014-001
8	Bearing	637-0004-001	637-0004-001
9	Knob	633-0005-001	633-0005-001
10	Bezel	653-0063-901	653-0063-901

SUPPLEMENTAL DATA SHEET

SUBJECT: Overhaul Manual for AIM 400/800 Slaved Gyro and Slaved Gyro/RMI Systems

EFFECTIVE: January 1970

1. Correction on P-10A Schematic, Page 4-26

115V-400 CPS Output	E	This part is correct as shown
26V-400 CPS Output	H	
115V/26V-400 CPS Common	A	
28VDC Input	D	
DC Ground	B	

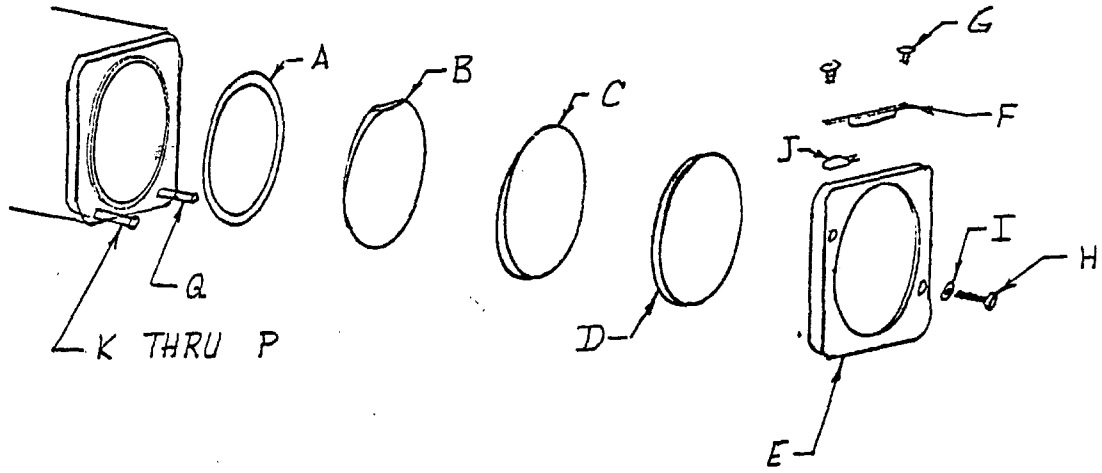
2. Correction on P-11 Schematic, Page 4-27

115V-400 CPS Output	E	This part is correct as shown
26V-400 CPS Output	H	
115V/26V-400 CPS Common	A	
14VDC	D	
DC Ground	B	

3. Additional Information

Subject: Integral Lighting

Integral Lighting is now available on AIM instruments. The parts shown on Page 2 are of interest in overhaul and repair. The "Terminations" shown are typical and vary per Airframe Manufactures requirements.



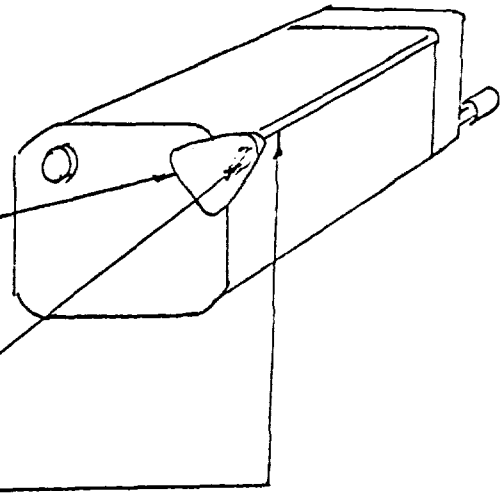


FIGURE 1

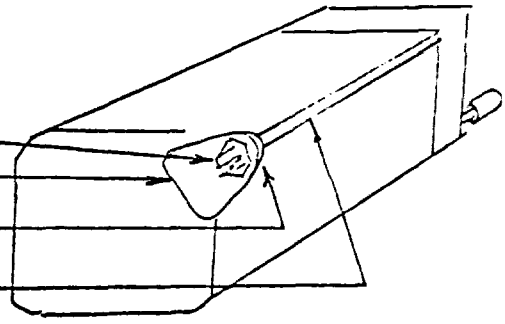
ITEM	DESCRIPTION	AIM PART NUMBER
A	Spacer	616-0049-001
B	Glass (Wedge)	612-0017-001
C	Glass (Wedge)	612-0016-001
D	Glass (Flat)	612-0015-001
E	Bezel	653-0071-901
F	Lighting Insert	622-0015-001 Blue-White 28VDC
	Lighting Insert	622-0015-002 Blue-White 14VDC
	Lighting Insert	622-0015-003 Red 5VDC
G	Screw	#4-40 x 1/4 Flat Hd.
H	Screw	#3-48 x 3/4 Fill. Hd.
I	Washer	606-0026-001
J	Circuit Board	800-0027-001
K	Shaft, Caging	632-0005-002
L	Shaft, Caging	632-0014-004
M	Shaft, Caging	632-0014-004
N	Shaft, Caging	632-0038-006
O	Not used for designation	See Table 1
P	Shaft, Caging	632-0038-004
Q	Shaft, Heading Select	632-0058-002
	Case (Not shown)	Ref., Item 315, 422, 529, 637, Page 4-2. Several of the above models require a new case which has two additional tapped holes for wiring hold down devices depending on Airframe Manufactures requirements.

TYPICAL TERMINATIONS



NOTE: Wires from the lighting bezel go into the back of the case then to the power connector.

641-0020-001 Adapter

*Additional suffixes will designate lighting and terminations per Airframe Manufactures requirements. Most suffixes have not been assigned at this time.

4. ARINC Zero

Delete Paragraph 3.4.1

Figure 3-1 and Figure 3-2. The 26V, 400Hz supply must not have a common to the volt meter. Many 400Hz supplies and volt meters have a common by way of the 3 prong power cords. We recommend an isolation transformer between the 400Hz supply and the test circuit shown.

SUPPLEMENTAL DATA SHEET

SUBJECT: AIM 400/800 Overhaul Manual

EFFECTIVE: April 1970

REFERENCE: AIM Flux Detector

Do not install AIM Flux Detectors or Flux Detector wiring within 2 feet of an ADF loop. Closer installation may result in noise on the ADF.

Do not install Flux Detectors within 2 feet of electrical wiring. Closer installation could result in error while night flying etc.

Use two ground return wires to the Flux Detector as shown on installation diagrams.

CORRECTION ON: Figure 1-8 (page 1-17)

Figure 3-5 (page 3-15)

To Pin "E" on Flux Detector	J
To Pin "B" on Flux Detector	A

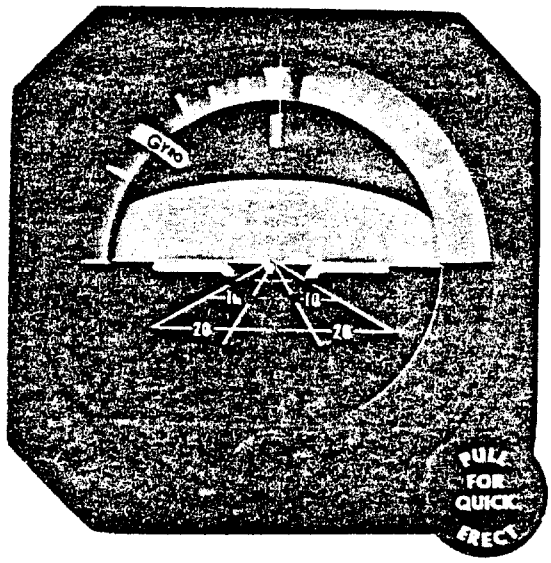

FIGURE 1-1. TYPICAL AIM 510 SERIES, ATTITUDE GYRO

SECTION 1

GENERAL INFORMATION

1.1 SCOPE

This manual contains maintenance and overhaul procedures for electrically operated AIM 510-( ) Series, Attitude Gyros manufactured by Aviation Instrument Manufacturing Corporation. Additional models will be subsequently covered by the inclusion of Supplemental Data Sheets in the front of the manual.

This manual is divided into three basic sections, the first of which is "General Information". This section explains the theory of operation which is common to the instruments covered.

Section 2 contains detailed information pertaining to disassembly, overhaul, reassembly, and checkout of the instruments.

Section 3 contains exploded-view drawings showing the location of each replaceable part. Tables associated with the drawings identify each component or assembly and list the appropriate AIM part numbers by which replacement should be ordered.

1.2 GENERAL DESCRIPTION

Although the instruments described in this manual contain variations from model to model, the basic theory of operation is common to all the units covered.

The AIM 510-( ) Series Attitude Gyros are precise, gyroscopic flight instruments, primarily designed to furnish the aircraft pilot with a visual indication of an aircraft's pitch and roll attitude with respect to the earth.

In order to achieve the desired attitude indication, the instrument must establish and maintain a stabilized datum reference perpendicular to the earth. This is accomplished by a universally mounted, self-erecting, high speed rotor which develops sufficient momentum to overcome normal bearing friction, and thus becomes stable relative to space. This stability, known as "rigidity in space", resists small forces which attempt to displace the axis of rotation, and consequently, its position in space.

The visual presentation displays pitch and roll information by means of a small symbolic airplane, and a horizon pointer bar which is mounted so that it will remain parallel to the true horizon regardless of the aircraft's attitude.

Angular movements of the aircraft in roll are indicated by means of a roll index and circular dial ring which is graduated in both primary and secondary markings. In some series the roll index is attached to the instrument case, and the dial ring moves with the gimbal. In other series the dial ring is attached to the case and the roll index moves with the gimbal. In either application, as the instrument is banked, the degree of bank is indicated by the position of the roll index to the dial ring.

1.3 PRINCIPLES OF OPERATION

Refer to the exploded-view drawings and tables of Section 3 for identification of major subassemblies and components.

The functional center of the instrument is an accurately balanced, high-speed rotor which is mounted on precision bearings inside an enclosed rotor housing. The rotor housing is suspended from bearings mounted in the gimbal assembly and is free to pivot up to $\pm$ 85° in pitch. In turn, the gimbal assembly is suspended from bearings in the rear of the instrument so that the over-all assembly has complete roll freedom about the instrument's longitudinal axis.

The rotor is driven by 400 Hz., single phase power. A capacitor, is electrically connected between the two-phase effect necessary for operation of the rotor.

The rotor drive voltage is applied to leads inside the gimbal support shaft through a brush block and slip ring assembly at the rear of the instrument. Internal wiring is then routed through the gimbal to a second brush block and slip ring assembly at the rotor housing pivot assembly. Three leads carry the drive voltage from the slip ring down through a center shaft in the rotor housing to the stator winding. The rotor and hysteresis armature ring are mounted around the stator on precision bearings so that, when power is applied to the stator, the desired rotor movement is achieved.

Small impellers are affixed to the top and bottom of the spinning rotor to generate the air flow required in order to utilize the self-erection system.

The schematic diagram is shown in Figure 1-2, 1-3 and 1-4

1.4 SPECIFICATIONS

Operating Range:

Pitch	360° freedom through controlled precession
Roll	360° gimbal freedom
Operating Temperature Range:	-30°C(-22°F) to +50°C(+122°F)
Rotor Speed:	22,000 rpm, minimum
Turn Error:	Maximum 3° bank and pitch error resulting from coordinated 180°/minute turn at 180 mph.
Bank & Pitch Indication:	Matte white dial ring & horizon pointer bar marking, arc yellow roll index and symbolic airplane on an earth-sky background.
Intergral Lighting:	Voltage and color for each 510 series instrument is specified on parts list in Section 3.
Mounting:	Standard 3-1/8 in. cut-out in shock mounted panel (See Figure 1-5)
Case Size:	See Figure 1-5.
Weight:	3.0 lbs. nominal
Power Requirements:	21 VA Max.

1.5 GYRO HANDLING

High gyro removal rate can be directly related to rough or improper handling. Gyros are delicate instruments and cannot withstand the shock of being dropped, jarred, or struck by other pieces of equipment.

To preclude damage to the gyro, it should be transported to and from the aircraft in its original container. When this procedure is impractical, the gyro should be hand-carried with special care.

Even though a gyro has malfunctioned and is being removed from the aircraft, the gyro must be handled with the same respect due a new one. It is easy to think of a gyro that has malfunctioned as one destined for the scrap pile. This is not so. It can probably be fixed. It is therefore very important that proper handling procedures also be employed during removal.

TYPICAL OUTLINE DIMENSIONS

SECTION 2

OVERHAUL

2.1 GENERAL

Due to the similarity in construction among all AIM 510 Series instruments, overhaul procedures have been consolidated into a single section describing disassembly, reassembly, and calibration. Most procedures contained in this section are common to all instruments, but some sections are applicable only to certain models.

Instrument overhaul may be due to a specific malfunction or merely as a routine step in a periodic maintenance program. Regardless of the reason, the disassembly and overhaul procedures in this section are applicable and should be closely followed.

Each instrument consists of several distinct subassemblies which may be separately disassembled, cleaned, reassembled and tested. Due to the construction of the instrument case, the sequence of disassembly and overhaul set forth in this section should be followed.

As each assembly is disassembled, the location of each component should be noted so that it can be replaced in the same position. When handling the mask, the horizon pointer bar, the roll index, and the circular dial ring, care should be taken to avoid soiling or scratching the various markings. All bearings, pivots and jewels should be handled with assembly tweezers to avoid contamination. Iridited, oxided or passivated parts must be protected against scratching or marring. Self-locking nuts with worn fibers must be replaced. Nuts and screws used for balancing must be secured in the final adjusted position by "Glyptal", 5 minute epoxy maybe used as an alternate. Solvents used for cleaning must be high grade such as Chlorothene-Nu (Dow Chemical Company).

2.2 TOOLS AND EQUIPMENT REQUIRED

2.2.1 General

Although the instrument can be completely disassembled and reassembled using only the standard instrument-shop handtools listed in paragraph 2.2.2, special attention should be given to the additional equipment required under 2.2.3. This equipment, although not directly used in assembling or disassembling the instrument, must be available to properly calibrate and checkout the instrument's operating characteristics after overhaul.

2.2.2 Handtools

All routine maintenance, repair, claibration and checkout may be accomplished with the following basic handtools:

1. Assembly tweezers
2. Eye loupe
3. Selection of small screwdrivers and nut drivers
4. #2, #4, #6 and #8 Bristol Wrench
5. 3/8, 3/16 and 1/2 open-end wrenches

2.2.3 Balancing, Calibration and Checkout Equipment

The following equipment is required to properly balance, calibrate or check out the instrument.

1. Power source capable of adjustment from 80% to 100% of the rated power.
2. Milliameter capable of reading 80% to 100% of the rated current consumption.
3. Stop watch
4. Gram gauge capable of measuring brush tension of 1-1/2, $\pm$1/2 gram.
5. Ultrasonic cleaning equipment (recommended but not required).
6. Test stand capable of holding gimbal assembly in normal position.
7. Suitable work area free from dust.

8. Strobotac

9. Test stand capable of testing roll and pitch within 1/2° accuracy, and capable of applying between 25 and 33 cycles/second at ±.005 in. total displacement to the instrument.

2.2.4 Expendable Supplies

The following expendable supplies should be available before attempting to overhaul the instrument.

1. Chlorothene-Nu (Dow Chemical Company)

2. Watch paper

3. Blue Glyptal (General Electric Company)

4. 5 min. epoxy (Devon Corp.)

5. Amicon Bonding Compound (Amicon Corp). Used on some rotor assemblies.

6. Sealing Tape, Black "Velvet Coated" plastic (Scotch Brand).

2.3 DISASSEMBLY PROCEDURES

2.3.1 General

Before proceeding with disassembly of any component, the degree of wear, end play, backlash, and general appearance must be checked and noted as an aid in reassembly.

During disassembly, extreme care must be used in the removal of any component. Use of proper tools is important to prevent damage by scratching or marring. Screws or other attaching parts must be carefully identified during disassembly for correct replacement during reassembly.

Due to the delicate rebalancing required and the precision parts involved, disassembly and overhaul of the rotor is not recommended. Should the rotor become defective and fail to meet the performance requirements set forth in paragraph 2.8, the used rotor should be returned to AIM for an exchange discount on a new replacement assembly. However, should field overhaul of the rotor become necessary, appropriate instructions are provided in section 2.6.

If a replacement rotor assembly is obtained from AIM, it will be closely balanced and adjusted when received.

2.3.2 Removal of Dust Cover

Remove two binder head screws and sealing tape holding the dust cover to the case. Separate the dust cover from the case by carefully sliding the dust cover gasket with the dust cover.

2.3.3 Removal of Bezel Insert Assembly

1. Move warning flag back to clear the dial ring and secure.

2. Remove the retainer ring securing the bezel insert assembly in the case.

3. Carefully remove the bezel insert assembly by pulling it forward, holding the miniature airplane knob. Care should be taken not to let the components separate from each other during removal.

4. After removal, hold the components together with a small piece of tape, and set aside for future disassembly.

2.3.4 Removal of circuit board Assembly

1. Remove the two binder head screws securing the brush block to the rear of the case.

2. Loosen the nut, or 2 screws on same series, securing the connector to the rear of the case. Slide the connector down and away from the case.

3. Unsolder the two wires from the flag motor and the two wires from the lighting insert. Take note and tag their locations.

4. Remove two binder head screws securing the circuit board assembly to the rear of the case.

5. Remove the circuit board assembly and set it aside for future disassembly. Protect the brush block in some manner to avoid damage.

2.3.5 Removal of Gimbal Assembly

1. Remove the 5/16 nut and lock washer securing the gimbal assembly to the case.

2. Slip the gimbal assembly forward and out of the case.

2.3.6 Disassembly of Gimbal Assembly

Mount the gimbal assembly in a holding fixture and proceed with the following disassembly.

1. Remove the four binder head screws securing the dial to the gimbal and set it aside.

2. Remove the four binder head screws securing the pointer bar assembly to the gimbal and set the pointer bar aside for future disassembly.

3. Remove the two binder head screws securing the mask to the gimbal and set the mask aside.

4. Remove the binder head screw and lock washer securing the pointer bar actuator to the rotor housing assembly and carefully draw the actuator through the hole in the gimbal. Take care to keep the pointer bar actuator and the bushing together.

5. Remove the binder head screw and lock washer securing the pitch cam and bearing housing to the rotor housing assembly.

6. Unsolder the three wires from the brush block on the terminal board at the rear of the gimbal assembly. Note and tag their locations.

7. Remove the binder head screws securing the brush block to the gimbal and carefully remove the brush block. Protect the brushes from damage and set aside.

8. Remove two flat head screws securing the bearing housing and remove the bearing housing and bearings.

9. Rotate the gimbal assembly so the slip ring is down and hold it in position. Remove the bearing pivot and pitch cam.

10. Remove the rotor housing assembly by very carefully rotating the gimbal so the slip ring is in an up position, thus allowing the rotor housing assembly to move down.

CAUTION

Do not allow rotor housing to
fall and damage the slip ring.

Rotate the rotor housing assembly so the slip ring clears the hole in the gimbal and remove the rotor housing assembly.

11. To remove the gimbal support shaft and slip ring, remove four binder head screws securing the support shaft to the gimbal. Carefully lift the terminal plate and unsolder the three wires from the slip ring. Take note and tag their location.

2.3.7 Disassembly of Case Assembly

1. Remove the caging support shaft through the hole provided in the rear of the case.

2. Remove the caging shaft and caging bracket by first removing the setscrew in the retaining collar closest to the front of the case, then the collar closest to the rear. Remove the two setscrews securing the remaining collars and slide the shaft forward and out of the case. Take care not to let the springs recoil causing damage or loss of parts.

3. Remove the binder head screw that holds the flag indicator motor in place and carefully slip it through the opening.

4. Remove two flat head screws securing the lighting insert to the case and carefully remove the lighting circuit board and wires from the case.

2.3.8 Disassembly of Pointer Bar Assembly

Remove the hex nuts securing the pointer bar shaft, bearing retainer, and bearing to each side of the pointer bar. Take note of the number of shims used and their location.

NOTE

Do not remove balance weights

2.4 CLEANING

2.4.1 General

Due to precision components and close tolerances employed in the manufacture of this unit, foreign matter can greatly impair its over-all operating efficiency and service life. It is therefore recommended that every possible step be taken to insure maximum possible protection of each subassembly. As each component is removed during disassemly, it should be placed in a dust-free environment and protected with a dust-proof cover.

2.4.2 Pivots, Housing, Etc.

During overhaul, all parts should be cleaned carefully to remove oil, dirt, and moisture. If possible, the use of ultrasonic cleaning is highly recommended to insure that all parts with small bores or tapped holes can be effectively cleaned. If this is not possible, component parts such as pivots, bearings, shims, etc. should be thoroughly cleaned in high-grade solvent such as Chlorothene-Nu (Dow Chemical Co.), and then air dried with clean low pressure air. If cleaning solvent is used, it must not be allowed to become dirty and must be changed frequently.

Extreme care should be taken to avoid damage to small or delicate parts during cleaning. In addition, arrangements must be made to permit identification of each part with respect to its previous location in the instrument.

After cleaning, provisions must be made to adequately protect the parts from damage and dust while awaiting inspection and reassembly.

2.5 INSPECTION AND REPAIR

2.5.1 General

All parts should be thoroughly examined with an eye loupe for any evidence of excessive wear or damage prior to reassembly. Repair of defective parts is recommended only when it can be done without adversely affecting the proper operation of the instrument. If doubt exists as to the operating condition of any part or assembly, refer to the parts list section of this manual and order replacement parts directly from AIM. During overhaul, examine each part for evidence of corrosion or breakdown in the plating material. Aluminum parts of the gyro are protected by anodize or iridite treatment and stainless steel parts are passivated. If a crocus cloth is used to remove corrosion, or if the plating material appears to be worn through, replace or protect the defective area with a light coat of clear lacquer.

Particular attention should be given to parts which contain internal or external threads. If any evidence of damage to the threads is found, repairs should be made using the correct tap or thread restorer. The part should then be thoroughly re-cleaned and re-examined prior to assembly.

2.5.2 Bearings

The precision bearings used throughout the instrument are designed to provide extremely efficient service over long periods of time. Each bearing should be individually examined for evidence of damage. If defects are noted, the entire bearing should be replaced. No attempt should be made to polish the balls, or otherwise repair the separate bearing parts.

Bearings used in this instrument are precision, instrument grade, and must not be replaced with inferior substitutes. Each bearing is lubricated with specific quantities and types of lubricants best suited for its individual function. This lubricant improves the performance of the bearings and substantially increases their service life. It is therefore recommended that replacement bearings be ordered directly from AIM in order to insure maximum operating efficiency.

2.5.3 Support Shaft, Bearing Housings, and Pivots

Each pivot or support shaft should be examined carefully for evidence of pits and scoring. Due to the precision fit of their respective bearings, the pivots and support shaft should seldom incur any type of ex-

cessive damage. If small scratches are noted, a light polishing should be all that is necessary. However, if scoring or other excessive wear is noted, a replacement pivot or support shaft should be obtained from AIM.

Disassemble each bearing housing and check that a clean used bearing will fit the diameter of the pivot assembly with no more than finger pressure applied.

2.6 ROTOR OVERHAUL

2.6.1 General

As previously stated in this manual, disassembly and overhaul of the rotor assembly is not recommended due to the precision parts involved, and the high speed of the rotor, reassembly and proper adjustment is extremely critical and should not normally be attempted in the field. Should the rotor become defective and fail to meet the performance requirements set forth in this manual, the used rotor assembly should be returned to AIM for an exchange discount on a replacement assembly. However,if this is not possible, and disassembly and overhaul does become necessary in the field, the procedures shown in the remainder of this section should be followed. Do not attempt to overhaul the rotor unless it fails to meet the operating requirements as set forth in paragraph 2.8.

2.6.2 Disassembly of Electric Rotor and Rotor Housing

1. Remove the vanes, the top rotor support nut, and the four rotor cover screws.

2. Unsolder the three rotor leads (Note their location).

3. Carefully remove cover and thread rotor assembly out of the rotor housing using the hex in the lower end of the rotor shaft.

4. To obtain access to the rotor bearings, remove the impellers from each bearing housing and remove the preload nut and spacer from each end of the rotor shaft. The bearings are protected by a small bearing retainer over each end of the rotor shaft.

5. Care should be taken to avoid loss of the spacers and bearing retainers between the preload nut and the bearing, located on each end of the rotor shaft.

NOTE

Removal of the bearing housings on each end of the inertia ring is not normally required and is not recommended. If either bearing housing is removed, delicate rebalancing of the inertia ring assembly will be required. If the bearing housing must be removed to obtain access to the stator, it is suggested that a mark be made at the interface between the inertia ring and each bearing housing to simplify re-assembly and minimize the rebalancing required.

6. On some rotors the bearing housing are bonded to the inertia ring. On others, the bearing housings are mounted to the inertia ring by retaining screws. To remove bonded bearing housing from the inertia ring, place a sharp tool where the two are joined and tap sharply, repeat this tapping procedure in several places around the inertia ring. On other types, simply remove retaining screws and disassemble.

2.6.3 Inspection, Cleaning, And Repair

Clean the various rotor parts in accordance with the procedures set forth in paragraph 2.4. After cleaning, each part must be adequately protected from dust while awaiting reassembly.

No attempt should be made to clean, re-oil or otherwise repair the rotor bearings. If the bearings are defective, they should be replaced.

2.6.4 Reassembly

NOTE

If bonded bearing housings have been removed, center them to inertia ring with Amicon Bonding Compound.

1. Install the rotor bearings over each end of the rotor shaft with the identification marks on the inner race facing outward.

2. Install the bearing retainers with the recessed side toward the center of the rotor.

3. Re-install the impellers on each bearing housing if they were removed during disassembly. The impeller with the longer blades goes on the bottom.

4. Install the spacer and preload nut on each end of the rotor shaft.

2.6.5 Rotor Bearing Preload and Run-in Procedures

1. Set the bottom preload nut tight against the bearing spacer. This is the end of the shaft with the short bearing surface.

2. Carefully tighten the top preload nut until the detectable axial end play between rotor and shaft just disappears. This rotor bearing preload adjustment is very critical and must not be exceeded if normal bearing life is to be realized. At the correct setting the rotor shaft will spin freely in the rotor assembly and have no detectable end play. To check for proper adjustment, hold the rotor stationary and spin the rotor shaft. If a noticeable roughness is apparent, the preload is set too tight or the bearings are damaged.

3. When preload has been completed, thread the rotor shaft into the rotor housing and install the cover, rotor support nut, and resolder leads.

4. Install the rotor housing and both pivots in the gimbal or in a suitable run-in fixture.

5. Run rotor for 48 hours with rated voltage, single phase power applied and using a phase shift capacitor to shift the phase of one winding by 90°. Recheck the preload setting after run-in and readjust as required in paragraph (2) above.

6. If preload had to be reset, run the rotor for an additional 24 hours and check the rotor start performance. The rotor must start and continue running with 80% rated voltage applied. If the rotor fails to start at 80% rated voltage, the top preload nut should be readjusted.

7. Check that the rotor attains a speed of 22,000 rpm min. within 3 minutes max. with rated voltage applied, and that it coasts for 5 minutes minimum after power is removed. If the rundown time is less than 5 minutes, readjust the top preload nut.

8. Install the rotor housing in a balancing fixture or in the gimbal to properly locate the rotor in the housing. Balancing should be accomplished with the vanes installed. Balance the assembly by turning the rotor shaft as required to center the rotor in the housing. When proper adjustment has been achieved, secure the rotor shaft and the rotor support nuts with Glyptal only.

2.6.6 Rotor Vane Adjustment

The electric rotor employs two non-interchangeable vanes, each of which should be adjusted as follows:

1. Vanes must not drag on the rotor housing.

2. Vane clearance at the rotor erector jet should be .010±.005 inch.

2.7 REASSEMBLY PROCEDURES

2.7.1 General

Throughout the reassembly procedures, extreme care must be taken to prevent damage or contamination of the various component parts and subassemblies. When joining two parts, they must not be forced together. As each subassembly is completed, it must be covered while awaiting further installation to a mating assembly or component.

All adjusting screws must be secured in their final adjusted position by use of Glyptal. Five minute epoxy may be used as an alternate.

2.7.2 Installation of Caging Shaft in Case

1. Insert the shaft through the hole provided until it protrudes into the web area. Compress the long return spring slightly and reassemble it over the shaft. Slide the shaft to within about one inch of the rear web in the case.

Depress the spring and insert the caging shaft collars. Slide the shaft through the rear web and assemble the caging bracket, shaft collars, and spring. Fasten the collars in the web area to the shaft with setscrews. Fasten the collars in the caging bracket area with setscrews.

2. Insert the caging bracket support shaft through the hole provided in the rear of the case and secure.

2.7.3 Installation of Flag Motor

1. Insert the flag motor in the area provided and secure with a binder head screw and lock washer.

2. Feed the wires through to the back of the case and temporarily secure.

2.7.4 Reassembly of Pointer Bar Assembly

Secure the pointer bar shaft, bearing cover, bearings, and their required shims to each side of the pointer bar. Care should be taken to shim the pointer bar shaft in the same manner as previously assembled. Check the static balance of the pointer bar. There should be no axial play between the shaft and the pointer bar.

2.7.5 Reassembly of Gimbal Assembly

1. Insert the slip ring wires from the support shaft through the hole provided.

2. Install the support shaft on the gimbal with four binder head screws, leaving them loose.

3. Solder the three wires from the slip ring to the terminal plate as noted during disassembly, and install the terminal plate in the location provided. Mount the support shaft to the gimbal and tighten the four binder head screws.

4. Install the rotor housing assembly in the gimbal by carefully rotating the rotor housing assembly in the reverse direction from that used during disassembly. Rotate the gimbal while holding the rotor housing assembly so the left side of the gimbal is down. Install the pitch cam and bearing housing, and the bearing, and secure with one binder head screw and lock washer. Insert the right bearing pivot. At this time the pivot should just engage the bearing about half way. Rotate the gimbal so the right bearing pivot is down and install the left bearing and bearing housing and secure with two flat head screws. Rotate the gimbal so the left side is down again and set the end play so you can feel only a slight movement of the rotor housing in the gimbal.

5. Install the brush block in the gimbal with one binder head screw. Depress the leads, and rotate them along the gimbal and through the hole provided in the rear of the gimbal. Solder them to the terminal plate in the proper location. Check that the tension on each brush is 1-1/2 $\pm$ 1/2 grams. Rotate the rotor housing assembly $\pm 85^{\circ}$ and check that the brushes do not drop away from the slip ring at any point.

6. Install the pointer bar drive and bushing with one binder head screw and lock washer. Leave this screw slightly loose.

7. Install the mask to the front of the gimbal with two binder head screws.

8. Install the pointer bar assembly to the gimbal with four binder head screws that secure the two bearings to the side of the gimbal.

9. Install the dial to the front of the gimbal with four binder head screws and adjust the dial to produce .03 min. clearance between the dial and the pointer bar.

2.7.6 Reinstallation of Gimbal in Case Assembly

1. Install one support shaft bearing on the gimbal assembly.

2. Install the gimbal in the case through the case bezel opening.

3. Install the second bearing on the support shaft at the rear of the case.

4. Secure the gimbal assembly in the case with a 5/16 nut and lock ring. Take care to set the end play of the two support shaft bearings at 0 to slight end play. Do not over-torque the nut against the bearings. This will damage the bearings. Lock the 5/16 nut in place by bending two tabs on the lock ring against the flats.

2.7.7 Reinstallation of Circuit Board Assembly

1. Mount the circuit board assembly to the case and secure with two binder head screws.

2. Slide the connector wires through the slot provided at the rear of the case and secure the connector to the case.

3. Install the rear brush block to the case. Check that the tension of the brushes is 1-1/2 ± 1/2 grams. Roll the gimbal 360° and check that the brushes do not drop away from the slip ring.

4. Resolder the two wires from the flag motor to their respective points on the circuit board assembly.

5. Install the lighting insert assembly and secure with two flat head screws. Resolder the two wires to their respective points on the circuit board assembly.

2.7.8 Installation of Bezel Insert

1. Carefully insert the bezel insert assembly in the case opening. Take care that the locator in the case and the bezel line up, and secure with the spring retainer.

2.7.9 Balancing Rotor Housing and Gimbal Assembly

1. Mount the instrument on the test stand.

2. Center all calibration screws prior to balancing. Also center the roll and pitch vanes and secure with tape to prevent movement during balancing.

3. Add a 1.7 gram weight to the top of the rotor housing.

4. Place the test stand so that the instrument longitudinal axis is vertical. Balance the rotor housing to a horizontal position by adjusting the rotor center, by means of the hexagon hole in the rotor shaft.

5. Place the test stand so that the instrument longitudinal axis is horizontal. Rotate the gimbal assembly so the inner gimbal axis is vertical and adjust the gimbal assembly balance by adding weight to the adjustment screw on the bottom of the gimbal.

6. Remove the 1.7 gram weight and allow the inner gimbal axis to return to a horizontal position.

7. Balance the gimbal assembly horizontal position by adding weight to either the right or left side of the gimbal. Secure screws and weights with Glyptal.

2.7.10 Installation of Dust Cover

1. Slide the dust cover forward on the case and secure with two binder head screws. Make sure the dust cover gasket is in place.

2.8 FUNCTIONAL TEST AND ADJUSTMENTS

2.8.1 General

The following test and calibration procedures may be used to either isolate malfunctions in the instrument prior to overhaul, or to check-out and recalibrate the instrument after overhaul has been accomplished. Included with each test are suggested corrective measures which should be employed if the instrument fails to meet the required performance specifications. These tests are "open" calibration tests and are performed with the dust cover removed.

2.8.2 Test Equipment Required

Reference Paragraph 2.2.3

2.8.3 Visual Inspection

The following visual checks shall be made prior to testing and again after calibration has been completed.

1. Check that all screws are tightened securely and staked with Glyptal or 5 min. epoxy.

2. Check that all solder joints are secure and properly soldered.

3. Check that the gimbal assembly is free through 360° roll with the rotor housing in the extreme dive and climb positions.

4. Observe the horizon pointer bar and rotor housing for evidence of drag against adjacent parts through ±85° of pitch travel.

5. Check that clearance between symbolic airplane and pointer bar is .032 ± .016.

6. Verify lights burn evenly at rated voltage.

7. Verify dust, lint, and scratches are not visible on instrument display parts when unit is lighted, and viewed from arm's length.

2.8.4 Rotor Start Test

Check that the power consumption is 21va max. at rated voltage. Running current should be slightly less than the starting current.

If the instrument fails to meet the above requirements, the rotor bearings may be worn, or the circuitry may be malfunctioning. Use a voltmeter to check that proper voltage is being applied to the motor. to check the rotor, disconnect the rotor leads from the circuitry and use a 400Hz. variable power supply to check the rotor starting voltage and run-down time as described in paragraph 2.6.5, step 6. Note that power must be applied to the rotor through a phase shift capacitor in series with one rotor winding.

2.8.5 Rotor Speed Test

Apply rated power to the instrument and allow three minutes for the rotor to gain speed and stabilize. The rotor should attain a speed of 22,000 rpm or greater.

2.8.6 Brush Contact Test

Rotate the instrument through 360° of roll and check for any variation in current. Also tilt the rotor housing to its limits of travel and check for current variation. If current does vary, readjust tension on the appropriate brushes so that the brushes do not drop away from their respective slip ring. The tension on each brush should be between 1 1/2 ± 1/2 grams.

2.8.7 Rotor Coast Test

After the conditions described in the Rotor Speed Test of paragraph 2.8.5 have been achieved, disconnect power from the instrument. The rotor run-down time must be 5 minutes or more.

If the rotor fails to coast the required length of time, replacement or overhaul of the complete rotor should be accomplished.

2.8.8 Erection and Calibration Tests

For this test, vibration shall be applied to the instrument to minimize frictional effects.

The frequency shall be between 25 and 33 cycles per second and amplitude between .002 and .005 inch double amplitude.

1. Apply power, manually erect and allow the instrument to settle.

2. After the instrument has reached operating speed, turn power off and rotate the instrument 180° in azimuth within a 10 second period to check bar rise and bank indication. The bar must rise 0° to 2° for helicopter application and 4° to 6° for fixed wing aircraft application. If it does not, adjust the pitch vane balancing screw as shown in Figure 2-1. If the roll indice does not indicate level ±1°, adjust the roll vane balancing screw as shown in Figure 2-1.

3. Check that the pointer bar aligns with the two 90° roll marks on the dial ±1°, and that the roll index aligns with the zero roll mark on the dial ±1°.

4. Cage the instrument and check that the caged position corresponds with the zero position ±2°.

5. Precess the rotor housing to the extreme dive (pointer bar up) and climb (pointer bar down) conditions. The horizon pointer bar must not touch adjacent parts at any point.

6. With power applied, precess the rotor to a 20° right bank condition with the horizon pointer bar centered in pitch.

7. Note the time required for the rotor to return to 10° right bank.

8. With power applied, precess the rotor to a 20° left bank condition with the horizon pointer bar centered in pitch.

9. Note the time required for the rotor to return to 10° left bank. The erection time shall be between 55 seconds and 2 1/2 minutes. If the difference between the two erection times is 60 seconds or more, an adjustment must be made as shown in Figure 2-1.

10. Repeat the above erection tests in the climb and dive positions.

NOTE

If difficulty is encountered in setting either the roll or pitch rates, check for improper bar balance or excessive bearing drag.

2.8.9 Warning Flag Test

For 115 VAC Gyros

1. Set variable 115 Volt, 400 HZ power supply at 115 VAC sine wave. Plug in non-running gyro. Flag must disappear within 45 to 180 seconds.

2. Let gyro attain full speed by running at 115V for 5 minutes.

3. Reset power supply to 105 VAC and interrupt power momentarily. Flag must appear and disappear again within 5 seconds.

4. Slowly reduce voltage. Flag must appear on or before 80 VAC.

NOTE

If flag does not disappear within 45 to 180 sec. adjust P1. (See Fig. 3-6)

If flag does not appear before 80 VAC adjust P2. (See Fig. 3-6)

Detail Setting:

1. With no power to non-running gyro set P1 fully CCW, set P2 approximately mid range.

2. Set variable 115 Volt, 400 HZ power supply between 85 and 90 VAC. Plug in non-running gyro.

3. Slowly adjust P2 to make flag appear and disappear (adjustment of P2 achieved when flag has disappeared).

4. Set P1 fully CW and variable 115 Volt test box to 115 VAC.

5. Turn off power.

6. After allowing rotor to stop, turn power on and start timing the amount of time required for flag to disappear. (If flag has not disappeared before 90 seconds slowly adjust P1 (CCW).

7. Let gyro attain full speed by running at 115 VAC for 5 minutes.

8. Slowly reduce voltage. Flag must appear on or before 80 VAC. (If flag has not appeared adjust P2).

9. After final setting of P1 and P2, perform final inspection test.

For 28 VDC Gyros and 14 VDC Gyros

1. Apply rated voltage to the gyro. The flag must disappear.

2. Slowly reduce the voltage. The flag will appear at approximately 20 VDC for 28 VDC gyros and approximately 11 VDC for 14 VDC gyros.

2.8.10 Spin Test

Tilt the gyro to 10° climb and disconnect power. The gyro gimbal must not spin in roll. The gyro may precess up to ±80° in roll and pitch but must not roll completely over during run-down.

If the gyro spins in roll, the following possible defects should be checked:

1. Check roll and pitch bearings. Replace bearings if defective.

2. Bearings may be excessively preloaded.

3. Rotor bearing preload may be excessive. Check rotor coast performance as described in paragraph 2.7.9.

4. Rotor housing may not possess enough bottom-heaviness. Refer to the balancing procedures of paragraph 2.7.9.

CAUTION

Do not add excess bottom heaviness. This will result in turn errors in flight which may not be apparent on bench test.

2.9 FINAL OPERATIONAL AND APPEARANCE CHECKS

(Recommended Accemptance Test Procedure)

NOTE

The following tests are performed with the dust cover in place.

2.9.1 Presentation

1. Verify lights burn evenly at rated voltage.

2. Verify dust, lint, and scratches are not visible on instrument display parts when unit is lighted and viewed from arm's length.

2.9.2 Rotor Performance Test

1. With 80% rated voltage applied, the unit shall start and continue to run.

2. With rated voltage applied, power consumption shall not exceed 21va.

2.9.3 Settling Test

1. With rated voltage applied, allow three minutes for it to obtain speed with vibration applied to the stand, and then manually quick erect the unit. The unit shall settle within $\pm$1 degree of level in roll and pitch. The applied vibration shall be between 25 and 33 cycles per second and between .002 and .005 inch double amplitude.

2.9.4 Erection Rate Test

1. The erection rates shall be as follows:

ROLL AXIS		PITCH AXIS	
From Left to Left	20° 10°	From Dive to Dive	20° 10°
Time	0'55" to 2'30"	Time	0'55" to 2'30"
From Right to Right	20° 10°	From Climb to Climb	20° 10°
Time	0'55" to 2'30"	Time	0'55" to 2'30"

Maximum difference between left and right and dive and climb shall not exceed 60".

2. The change in roll indications during pitch erection tests must not exceed $\pm 3^\circ$.

3. *The change in pitch indications during roll erection tests must not exceed* $\pm 3^\circ$.

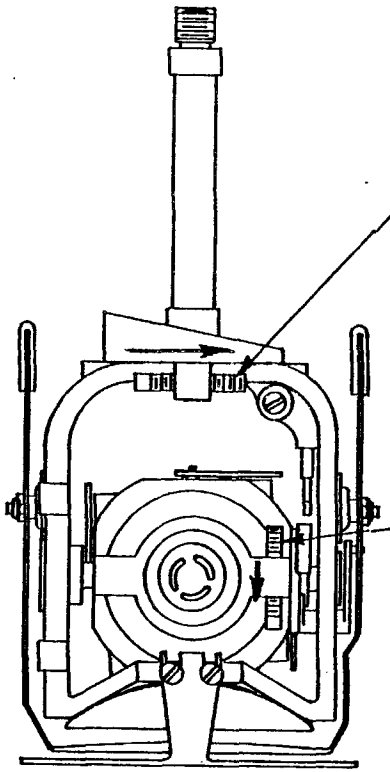
2.9.5 Verticality Test

1. Allowable deviation of bank and pitch indication, directly after azimuth rotation of 180 degrees within 10 seconds shall be as follows:

   (a) Roll shall be $+1^\circ$ of level
   (b) Pitch bar rise shall be 0° to 2° for helicopter application and 4° to 6° for fixed wing aircraft application.

2.9.6 Caging Checks

1. With unit operating at rated voltage, pull quick erect knob, unit shall cage within $\pm 2^\circ$ of its horizontal and vertical 0° position.



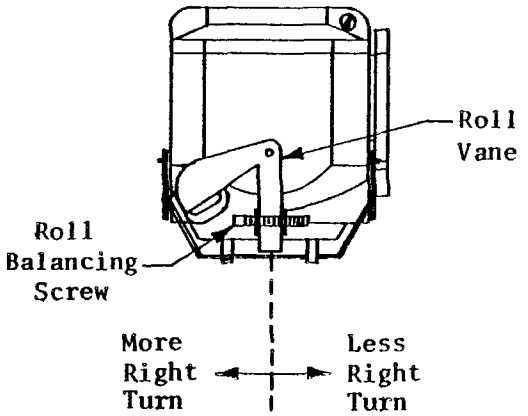
2.9.7 Warning Flag Test

1. Apply rated voltage to the unit. The flag must disappear.

2. Slowly reduce voltage to approximately 20 VDC for 28 VDC Gyros, 11 VDC for 14 VDC Gyros, and 80 VAC for 115 VAC Gyros. Flag must appear on or before stated voltage is reached.

2.9.8 Spin Test

Tilt the gyro to 10° climb and disconnect power. The gyro gimbal must not spin in roll. The gyro may precess up to $\pm 80^\circ$ in roll and pitch but must not roll completely over during run-down.



Pitch Erection Rate Adjustment Screw

If dive erection time exceeds climb erection time, adjust screw in direction shown. Reverse adjustment if climb erection time exceeds dive erection time.

Roll Erection Rate Adjustment Screw

If right bank erection time exceeds left bank erection time, adjust screws in direction shown. Reverse adjustment if left bank erection time exceeds right bank erection time.

SUPPLEMENTAL DATA SHEET

AIM 510 ( ) Series Horizon Reference Indicator

SUBJECT: 510-7A

EFFECTIVE: 5/16/78

This Supplemental Data Sheet adds the 510-7A to the list of instruments covered by this manual.

The 510-7A is similar to the 510-1A with the exception of the rotor assembly, pointer bar, miniature airplane adjustment, connector, pin connections and circuit-board. Therefore, in the manual where 28VDC is referenced, substitute 115AC, 400 Hz, and where 28VAC, 400 Hz is referenced, substitute 115VAC, 400 Hz.

The tables and figures noted below change for the 510-7A as shown:

Figure 1-2	Schematic/Wiring Diagram	Figure 1-2(B)
Figure 3-2	Bezel Insert Assembly	Figure 3-2(B)
Figure 3-3	Gimbal Assembly	Figure 3-3
Figure 3-6	Circuit Board Assembly	Figure 3-6(A)

SUPPLEMENTAL DATA SHEET

SUBJECT: ADDITIONAL MODELS ADDED FOR 510 SERIES/LIGHT REGULATOR CIRCUIT

EFFECTIVE: JANUARY, 1980

MANUAL EFFECTED: 510 SERIES ATTITUDE GYROS

ADDITIONAL MODELS TO BE ADDED

510-10A
510-10B
510-10C
510-17A
510-17B

DISCLOSURE

510-10A

The 510-10A is the 28VDC input version of the 510-7A. All part listings are identical to the 510-7A, with the following exceptions:

Ref. Table 3.1 CALLOUT NUMBER	DESCRIPTION	NEW AIM P/N
10	Circuit board assy. 28VDC	800-0111-903
13	Connector	821-0047-001
22	Label 28VDC, pin connection	600-0076-001
25	Seal, rear	610-0092-001

8	Rotor assy. 26VAC	236-0041-902

Ref. Table 3.5 CALLOUT NUMBER		
3	Ring assy. 28VDC gyros	611-0074-902
9	Stator 28VDC gyros	827-0017-001
11	Screw, 1-72x5/16 Binder hd, st.st.	603-1172-110

510-10B

The 510-10B is identical to the 510-10A with the following exceptions:

Ref. Table 3.1 CALLOUT NUMBER	DESCRIPTION	NEW AIM P/N
7	Insert assy, lighting	622-0015-008

510-10C

The 510-10C is calibrated for a 9° forward tilt panel. All part listings are identical to the 510-10A.

510-17A/510-17B

The 510-17A/510-17B are replacement models for the 510-7A/510-7B. All part listings are identical to the 510-7A/510-7B with the following exceptions:

OVERHAUL MANUAL

ALTIMETER PRESSURE SENSITIVE

A35-MA-10L-1
A35-MA-10L-2

This manual covers all A35-MA-10L-1 and A35-MA-10L-2 Altimeters manufactured by either Aerosonic Corporation or Aero-Scotia Limited with the exception of Altimeters bearing serial numbers NS 348 to NS 431 inclusive. Instruments bearing these serial numbers have a slightly different mechanism and should be returned to the manufacturer for overhaul. This difference in no way affects the operation, serviceability or reliability of the instruments.

SECTION I

INTRODUCTION

1-1. **Identification** — The Aerosonic and/or Aero-Scotia instrument part number and serial number are obtained from the nameplate and are required for the complete identification of the equipment.

1-2. **Purpose** — The altimeter measures the existing atmospheric pressure. Since the atmospheric pressure varies with altitude this pressure is indicated on the dial of the instrument in feet of altitude.

1-3. **Description** — The case of the altimeter is of two-piece construction to ensure an airtight seal. The mounting flange of the case is supplied with three mounting openings.

1-4. There are three concentrically arranged pointers. These indicate on a common scale in units of 100 feet, one thousand feet and ten thousand feet respectively. In moving through the entire range of 35,000 feet the long pointer makes thirty-five revolutions, the intermediate pointer performs three and one-half revolutions, and the inverted pointer makes three and one-half tenths of a revolution.

1-5. The outer dial is graduated into single divisions of twenty feet of altitude when measured by the long pointer and estimations can be conveniently made to five feet.

1-6. A Barometric Scale (sub-dial), which is visible through a window on the outer dial, indicates the barometric pressure. The A35-MA-10L-1 model indicates pressure in inches of mercury with a range of 28.1 to 31.0 inches. The A35-MA-10L-2 model indicates pressure in milibars of mercury with a range of 950 to 1050 milibars.

1-7. The adjustment knob, located at the lower left corner of the case provides a means of adjusting the hands and barometric scale simultaneously to correct for changes in atmospheric pressure resulting from changing conditions.

1-8. The pointers, numerals and graduations are painted with white material. Under average conditions of night flying the instrument will be sufficiently luminous to be legible.

SECTION II

OVERHAUL INSTRUCTIONS

2-1. **Special Tools:** None

2-2. Repair, assembly and testing shall be accomplished in a controlled area, Ref. T. O. 00-25-203 of latest date and FED STD-209 of latest issue. The work space requires better than normal housekeeping and segregation from excessive dirt generating operations.

2-3. **Disassembly.**

2-4. Disassembly of Components. (See Figure 2-1).

2-5. **Removal of Bezel.**

a. Wrap a piece of friction tape around the knurled part of knob (2). Hold knob (2) with a pair of pliers and loosen lock nut (3) with a 5/16 inch wrench. Remove knob (2) and lock nut (3) from the adjustment knob stem (32).

b. Back off locking stud screw (4) until the head clears the top flange of bezel (7). Push screw (4) to the left. This disengages locking stud (5) which rides in a recess in adjustment knob stem (32). It is not necessary to remove screw (4) or stud (5).

c. Turn the instrument over and remove the lead seal (6), eight screws (8 and 9) and lock washers (10). Carefully lift the bezel (7) from the case (39).

d. Remove glass (12) and paper gasket (11) from bezel (7).

2-6. **Pointer and Dial Removal**

a. Remove the bezel gasket (13) and spacer ring (14) from the case (39).

b. Pull pointers (16 and 17) and pointer assembly (18) off the front of the transmission mechanism (24).

c. Remove dial (19) by removing two dial screws (20). Lift barometric dial assembly (21) off of transmission mechanism (24).

NOTE: Do not further disassemble barometric dial assembly (21).

2-7. **Transmission Mechanism Removal**

a. Lift barometric setting gear assembly (23) from transmission mechanism (24).

b. Remove tension wire (15). With a sharp pointed instrument, pry free both ends of snap ring (22) and remove.

c. Turn case (39) upside down and allow transmission mechanism (24) and mechanism assembly (25) to fall into the hand. A formed spring ring (26) is also removed.

2-8. **Completing Disassembly of Case**

a. Using a sharp pointed instrument pry both ends of snap ring (36) free and remove snap ring from case (39).

b. From the well at the inside corner of case (39) remove snap ring from *the groove of adjusting knob stem (32). Use a screwdriver to facilitate re*moval.

c. Remove pin (31) from adjusting knob stem (32) and zero setting pinion gear (35) by pressing out part way with tweezers. turn knob a half turn and remove pin.

d. Pull adjusting knob stem (32) out of the front of case (39). Remove from slot at the inside of case (39) a compression spring (33) and zero setting pinion gear (35). Remove "O" ring (34) from the front of case.

e. Install a round punch, 5/16 inch in diameter, through the rear of case (39) and press out filter screen washer (37) and filter screen (38), if damaged.

* CAUTION * Care must be taken to prevent damage to static line inlet connector threads.

2-9 **Transmission Mechanism Disassembly**

a. Remove transmission mechanism (24) from the front of mechanism *assembly (25).*

b. Pull the wheel assembly (1, Figure 2-2) from gear bushing (5).

c. Remove pivot plate assembly by taking out three shouldered screws (3). Separate stem pinion (2) from wheel assembly (7) and remove both.

d. Remove gear assembly (4) from gear bushing (5). The gear bushing is now free of pivot plate sub-assembly (6).

e. Remove gear assembly (8) from the gear plate assembly (9).

NOTE: Inspect gear stud (10) carefully before removing. Do not remove the stud unless bent or excessive wear is detected.

2-10. **Mechanism Disassembly** (See Figure 2-3).

NOTE: Do not remove jewels uless damaged, see paragraph 2-25.

a. From the hub of gear plate (14) remove center pinion (1) with a suitable pinion remover being careful not to damage the handstaff pinion (2).

b. Loosen set screw (12). Remove jewel bushing (3) and handstaff pinion (2).

c. Work the aneroid spring clip (19) from the aneroid and pull the aneroid pin (20). Remove the special screw (22) and diaphragm support nut (23). Remove two screws (49) and slide the diaphragm support plate (48) with diaphragm from the casting. Separate the aneroid assembly (21) from the plate (48).

* CAUTION * Do not separate the two aneroid halves as they are a matched set. Replace with new assembly if damaged.

d. Pull the bearing pin (24) from the bi-metal assembly (27) and remove the mechanism link assembly (25).

e. Loosen two screws (52) and remove two pivot screws (26). Lift the bi-metal support assembly (28) with sector and rocking shaft assembly (30) out of the casting.

f. Loosen screw (29) and pull bi-metal assembly (27) from the bi-metal support assembly (28). Remove the bi-metal support assembly from the sector and rocking shaft assembly (30) by loosening screw (33).

g. Remove counterweight (32) from the crown gear of the sector and rocking shaft assembly (30) by removing a screw (31). Remove a screw (33) and remove the bi-metal counterweight (34).

* CAUTION * Do not further disassemble the sector and rocking shaft assembly.

h. Loosen a screw (52) and withdraw the jewel bushing assembly (39) from the frame (57). Remove crown pinion assembly (43).

i. Remove five bodyfit screws (7) and lift the gear plate assembly (6) from the casting.

j. Lift the transmission gear assembly (15) from the casting.

k. Press the taper pin (16) from the hairspring post (56) and lift the hairspring wheel assembly (17) from the casting. The hairspring (18) may be pressed from the wheel assembly if damaged.

l. Remove a sector guide screw (50) from the sector guide post (51). Do not remove the sector guide post (51) from the frame (57).

m. Loosen a set screw (52) and withdraw the remaining jewel bushing assembly (44) from the frame (57).

n. It is not recommended that the hairspring post (56) be pressed from the frame (57).

o. Do not remove teflon bearings (58) unless damaged.

2-11. **Cleaning, Inspection, Test and Repair**

2-12. General. Examine all the pinion teeth and pivots for wear and corrosion. The jewel setting assemblies should be examined for loose or broken jewels. The aneroid link should be inspected for burrs or out-of-round (ovalized) pivot holes. If the hole is oval shaped or the jewel damaged, replace the link.

2-13. **Cleaning**

2-14. General. All parts should be put in a small wire mesh basket and washed in a watch type cleaning solution then rinsed thoroughly in benzine, Federal Specification VV-B-231, and dried.

2-15. Pinions. The cleaning of pinions both handstaff and intermediate may be facilitated by using a pair of tweezers with a hole in each of the pointed ends. The pinions may be placed in these holes and the teeth brushed satisfactorily.

2-16. Wheel and Hairspring Assemblies. The teeth of the wheel and hairspring assembly and the sector teeth should be brushed. Next transfer the parts to a box containing boxwood sawdust, and there shaken to dry thoroughly. Another brushing must follow this treatment, this time with a dry and clean watchmaker's brush No. 3, which is occasionally rubbed across a piece of prepared chalk.

2-17. Pivots. Pivots are cleaned by pressing them into the end grain of a piece of dry featherwood and twirling the wood between the fingers.

2-18. Pivot Holes. All pivot holes are to be cleaned with care using the pointed end of an orangewood (pegwood) stock which is to be scraped clean frequently. A last touch in the cleaning of pivots is sticking them into dry elder pitch.

2-19. **Inspection**

a. After brushing, the parts are to be looked over with a magnifying glass to make certain that they are truly clean.

b. Inspect all pivots, they should be highly polished and free from scratches. If any damage is apparent, the pivot must be replaced.

c. Inspect all jewels. If a chipped or cracked jewel is found, replace with a new mounted jewel.

d. Inspect the case for cracks or chipped spots.

e. Inspect the hairspring. It should be free from sharp bends or kinks, other than at the ends, and should lie in a level plane.

f. Inspect both ends of link. They should be smooth and free from scratches.

g. Inspect the aneroid assembly. If any damage is detected in the aneroid assembly such as dents, misalignment, lost parts or general wear, replace the assembly as a unit.

2-20. **Storage**

2-21. After inspection, place the parts at once under a small bell jar where they are to be kept for assembly.

2-22. **Testing**

2-23. There is no testing required for dismantled parts.

2-24. **Repair or Replacement**

NOTE: Replacement of parts such as diaphragm, pivots, handstaffs, sectors and gears during overhaul, may disturb the original alignment of the Altimeter and cause erratic altitude readings and excessive friction during initial calibration. Custom or hand fitting replacement parts, plus additional calibration may be required to correct these conditions.

2-25. **Removal and Replacing of Press Jewels**

a. Use a scribe to break out a broken jewel from mounting. Drill out the mount with a No. 53 Tap with a No. 1-72 bottoming tap until jewel works itself out.

NOTE: Use the above method on bushings and rocking shaft. See method outlined in paragraph b. for removing jewel from plate.

b. Using watchmakers bench block for support a round flat nose punch of a diameter slightly smaller than the jewel and press out.

2-26. Replacement of Rocking Shaft Jewels

a. On the sector gear end of the sector and rocking shaft (Figure 2-3) press in the cap jewel (36) and then the hole jewel (35) until flush with the end of the shaft. Stake bushing to shaft.

b. On the large diameter end of the rocking shaft insert rocking shaft spring (38) and cap jewel (37) and then press in the hole jewel (35) until flush with the end of the shaft. Stake the bushing to the shaft.

2-27. Jewel Bushings. The jewel bushing assembly (39) used with the crown pinion assembly (43) and the transmission gear assembly (15) are assembled in the following manner: Insert cap jewel (41), face up, and then press the hole jewel (40) countersunk face up, in until flush with face of bushing. Stake the mounting to the jewel pinion bushing (42). Frame bushing (55) with its hole jewels (53) and cap jewel (54) are assembled in the same manner.

2-28. Frame Center Jewels

a. Frame center jewels (53 and 54) are removed from the gear plate end of the frame (57) with a round flat nose punch slightly small than the diameter of the jewel mount.

b. Replace the jewels (53 and 54) from the gear plate end of the frame by pressing one hole jewel (53) with countersunk side up, one cap jewel (54), and one hole jewel with countersunk side down. Press jewels until first hole jewel is flush with inside surface of frame (57).

2-29. Jewel Bushing. Jewel bushings are assembled by pressing in cap jewel (46) and then hole jewel (45) with countersunk face down until flush with end of jewel bushing (47). Replace the larger mounted jewel (4) by pressing into jewel bushing (5).

2-30. Eccentric Jewel Bushings

a. Press cap jewel (10) and then hole jewel (9), with countersunk face toward the slot in the eccentric jewel setting (11). Press until hole jewel (9) is flush with smaller diameter of jewel setting (11). Stake jewel mountings at both sides of the setting.

b. Eccentric jewel assemblies (8) are set at assembly to obtain correct height and position to insure correct mesh of gear teeth.

2-31. **Lubrication**

2-32. No lubrication is required.

2-33. **Reassembly**

2-34. Reassembly of Mechanism Assembly (See Figure 2-3).

a. Press the assembled frame bushing (55) into the frame (57) with the flush jewel side toward the inside of the frame. Stake the bushing.

b. Install the jewel bushing assembly (39) in the extended arm section of the frame (57). Set the screw (52) to retain the bushing. Refer to paragraph 2-34 j. for adjustment.

c. Work the remaining jewel bushing assembly (39) into the extended arm section of the frame (57), until it is flush with the open side of the arm. Install a screw (52) to secure in position.

d. Install sector guide screw (50) in the sector guide post (51)

e. Assemble mechanism link (25) into the slot of the aneroid assembly (21) and install aneroid pin (20). Lock the pin in position with aneroid spring clip (19).

f. Press the hairspring (18) on the hairspring wheel assembly (17) until it bottoms on the shoulder.

g. Position the hairspring wheel assembly (17) in the jewel of jewel bushing assembly (44) with hairspring side next to the frame. Rotate hairspring wheel assembly (17) until the bent portion of the hairspring is in line with the hole in the hairspring post (56). Install 1/8 inch end of spring in the post and insert taper pin (16). Taper pin must be installed in the same direction as the spring. Cut the taper pin so that approximately 1/8 inch extends beyond each side of the post.

* CAUTION * There should be no sharp bends or kinks in the hairspring (18) where it is pinned, as this weakens leaf and it may break in service. See that hairspring is in a rounded and flat condition.

h. If hairspring (18) is not in position as described, it may be adjusted. Adjustments to correct misalignment of the hairspring should be made with tweezers at point of pinning.

i. Position the transmission gear assembly (15) in the jewel bushing assembly (39).

j. Align the gear plate assembly (6) with the pivots on the wheel gears and assemble the gear plate to the frame (57). Secure the plate with five bodyfit screws (7).

k. Reverse the frame in the holding cup.

l. Adjust jewel bushing assemblies (39) and (44) for proper end shake .003 inch. Tighten the screws (52) on the bushings.

m. Install the crown pinion assembly (43) and adjust jewel bushing assembly (39) for proper end shake, .003 inch. Tighten screw (52) on bushing.

n. Adjust eccentric bushings located in the gear plate assembly (6) for proper mesh of teeth.

o. Assemble the sector and rocking shaft assembly (30) in the following manner: Assembly bi-metal counterweight (34) to the end of the rocking shaft pin and secure with a screw (33). Install two more screws (33) loosely in the rocking shaft (30). Assemble counterweight (32) to the crown gear and secure with screw (31).

p. Install the bi-metal support assembly (28) in the sector and rocking shaft assembly (30). Tighten the set screw (33).

q. Position the sector and rocking shaft assembly (30) in the frame (57) between the pivot screws (26). Use the new pivot screws (26) if they appear to be damaged. Adjust the pivot screws to hold the crown gear in mesh with crown pinion assembly (43). Set the end shake to approximately .0015 inch.

r. Install aneroid assembly (21) in the opening of the diaphragm support plate (48). Assemble diaphragm support nut (23) and special screw (22) to the diaphragm support plate (48). Install this assembly in the frame (57) and secure with two screws (49).

s. Install the bi-metal assembly (27) in the bi-metal support assembly (28). Snug up the screw (29).

t. Mechanism hook-up. Disengage the crown gear, of the sector and rocking shaft assembly (30), and crown pinion assembly (43) by running the sector gear out. Turn the crown pinion assembly (43) gear one and one half revolutions clockwise and engage the crown gear.

NOTE: Care should be taken to keep the gear train in position for the next step in the hook-up.

u. Assemble the mechanism link (25) in the slot of the bi-metal assembly (27) with a bearing pin (24). Adjust the bi-metal so that mechanism link (25) pin opening is aligned with the hole in the aneroid assembly (21) opening. Slide aneroid spring clip (19) between aneroid pin (20) and aneroid assembly (21).

NOTE: Adjust the bi-metal assembly (27) to insure alignment of linkage. Tighten the bi-metal support assembly (28) clamp screw (33).

v. Reverse the frame (57) in the holding cup so that it is positioned gear plate end up.

w. Install the handstaff pinion (2) in the hole jewel (53). Position the jewel bushing assembly (3) into the center bushing (13), with large mounted jewel (4) and jewel bushing (5). Mounted jewel is mounted up. Adjust the bushing (5) to obtain .003 inch end shake of the handstaff pinion (2). Tighten jewel bushing set screw (12).

x. Pinch the hub of center pinion (1) lightly to insure positive fit. Press the center pinion (1) on the shaft of the handstaff pinion (2). There should be .002 to .003 inch clearance between center pin pinion and hub of gear plate assembly.

2-35. Transmission Mechanism (See figure 2-2).

a. Press a new gear stud (10) in the cut-away sector of the gear plate assembly (9), if removed.

NOTE: The top side of the gear plate assembly (9) is the side with the greatest amount of machining and recesses. The bottom is relatively smooth in appearance.

b. Position gear assembly (8) in the gear plate assembly (9) located next to the plate assembly. The gear assembly (8) is located in the small hole, next to the large opening in the center of the pivot plate sub-assembly (6), on the side opposite the locating pin.

NOTE: The top of the pivot sub-assembly (6) is distinguished by the three countersunk holes around the outer edge.

c. Install gear bushings (5), from the top, through the bushing of the pivot plate sub-assembly (6) and press the gear assembly (4) onto the gear bushing (5). Use .003 inch shim between gear bushing and pivot plate. Remove the shim. Note the position of gears with respect to the plate sub-assembly.

d. Install stem pinion (2) through the top of pivot plate sub-assembly (6) and hub of wheel assembly (7). There are two small holes in the inner part of the pivot plate sub-assembly (6). These two holes, one countersunk hole and the center bushing assembly are in line. The hole on the side opposite the aligned countersunk screw hole is the hole on the plate (6) used to install stem pinion (2).

e. Position pivot plate assembly, install wheel assembly (7) in gear plate assembly (9), on the gear stud side of the gear plate. Make sure all pinion stems and staffs are located in their respective pivot points. The three screw hloes should already be aligned. Install three shoulder screws (3). Install wheel assembly (1) on hub of pivot plate.

f. Assemble the bottom opening of the transmission mechanism (24, Figure 2-1) over the center bushing of the gear plate of the mechanism assembly (25).

NOTE: Care must be taken to properly mesh center pinion (1, Figure 2-3) with the gear assembly located inside mechanism assembly (25, Figure 2-1). Rotate transmission mechanism several times to insure meshing of all gears and pinions. Press pointer (16) into handstaff pinion (2, Figure 2-3). Rotate the mechanism in relationship to the transmission mechanism. When properly seated the pointer will turn with the mechanism assembly without binding, sticking, or any irregular motion.

2-36. **Calibration and Checking** (See Figure 2-3)

2-37. Checking for Balance

a. The sector counterweight (32) controls position error at 90 degrees and 270 degrees from the normal operating position.

b. Mount the mechanism in a suitable calibration stand so that wheel assembly is at zero position and place the stand, dial up, on the bench. Lightly press a balanced pointer on handstaff pinion (2) so it indicates zero. With mechanism in the calibration stand and pointer pressed onto the handstaff at an indication of zero, hold the instrument dial vertical with the "0" on top. Tap the stand and note the reading. Turn instrument 180 degrees (this places "0" at bottom) and, after tapping, note indication of pointer. If pointer was moved clockwise (or counterclockwise) by more than 20 feet, check rocking shaft (30) for too much end shake.

c. Hold mechanism dial vertical with "0" on top. Tap stand and note reading. Turn instrument 90 degrees counterclockwise. This places "0" at left (9 o'clock). After tapping, note indication of pointer. If pointer has moved clockwise (plus error) by more than 20 feet, correct error by shifting position of sector counter-weight (32) toward rocking shaft. If error is minus by more than 20 feet, the sector counterweight should be moved away from rocking shaft (30).

2-38. **Temperature Compensation**

NOTE: The instrument without provisions for temperature compensation would read plus in going from room to cold. The aneroid may be considered a spring under load. (The atmospheric pressure being the load.) When the temperature is reduced, the aneroid material becomes stiffer, and stronger and thus resists the load more easily. Since the load remains constant, the aneroid expands and a plus indication is obtained. The rocking shaft, hairspring, and wheel hairspring also tend to become stronger in cold and increase the plus indication. To compensate for this action, a bi-metallic strip is interposed between the aneroid and linkage to rocking shaft. The bi-metal assembly (27) used in this instrument has a "fast" side of brass. Under a change in temperature; the brass side will become either longer or shorter than the other side causing a point on the free end of the bi-metal to swing through an arc. For proper compensation, plane of the bi-metal is approximately 60 degrees to the surface of the aneroid assembly with the brass side down and inclined toward the left, when viewing the mechanism from the rear.

2-39. **Test Equipment**

a. Air chamber. Controlled temperature capable on an overall change of 80 degrees C (144 degrees F) in temperature. This allows testing adjustment of altimeter temperature compensation with the desired degree of accuracy.

b. The mechanism must be placed in suitable calibration stands equipped with four Edward Buzzers. This vibration should be used during all compensation tests.

2-40. Individual Tests

2-41. Place the mechanism in the calibration stand and set pointer to "0".

NOTE: Fluctuations in atmospheric pressure during compensation testing must be taken into account. These changes in pressure may be noted in terms of feet of altitude from another standard altimeter. For instance, if the standard altimeter indicates 500 feet at the start of the compensation test and 530 feet when the test is completed, the mechanism undergoing the compensation test will also have changed plus 30 feet during the same time.

This error must be subtracted algebraically from the reading obtained from the test instrument in order to arrive at true compensation. Record zero reading of instrument(s) and place instrument(s) in cold chamber set at -35 degrees C (-31 degrees F) for a period of 1½ hours. Record scale reading of instrument making correction or changes of atmospheric pressure, indicated by standard altimeter. The instrument is then removed from the cold chamber to room temperature condition and then placed in a dryer for one hour before adjustment. No test readings will be taken until a minimum soak period of 1½ hours has been established.

2-42. Adjustment

a. *If the difference in room and cold reading exceeds the tolerance shown* in Table 2-1, temperature compensation is necessary.

b. Should the mechanism indicate a plus reading in going from room to cold temperature, the mechanism is under compensated and the bi-metal support screw (29, Figure 2-3) should be loosened slightly. Rotate the bi-metal assembly (27) counterclockwise and tighten screw.

c. Should the mechanism indicate a minus reading in going from room to cold, the adjustment is made in a similar manner, but in a clockwise direction. Re-zero pointer and repeat test procedure. To maintain a minimum error at various altitudes it is important to compensate the mechanism as near to zero as possible.

2-43. **Calibration Procedure**

a. The calibration points listed in Table 2-2 are the primary check points to be used during calibration.

b. Either a change of aneroid assembly (21, Figure 2-3) position or a change in the length of the bi-metal support assembly (28) "speeds up" or *"slows down" the mechanism with a corresponding increase or decrease* in the rate of hand rotation between zero and maximum altitude.

c. Shifting the aneroid assembly (21) position changes the speed of rotation at high altitudes more than at low altitudes. Shifting the aneroid toward the shaft of sector and rocking shaft assembly (30) "speeds up" the mechanism while shifting it away from the rocking shaft "slows down" the mechanism.

d. If the aneroid is shifted so that the hand indicates a change of 1000 feet, the change in indications at different altitudes will be approximately as shown in Table 2-3.

e. An increase in bi-metal support assembly (28) length slows down, and a decrease in length speeds up the mechanism througout the entire range. Calibration adjustments for the middle range (10,000 to 25,000 ft.) can be made by raising the support bar (48) to speed up the readings and lowering the bar to decrease the readings.

f. If the bi-metal support assembly (28) length is changed equivalent to 0.005 inch, the change in indications at different altitudes will be approximately as shown in Table 2-4.

g. By using both adjustments, ıe speed of rotation can be selectively increased or decreased in the l , middle, or high ranges.

h. Observe the point where tl crown pinion assembly (43, Figure 2-3) meshes with the crown gear (sector and rocking shaft assembly (30). The point of mesh should be proximately 6-8 teeth, from the end of the crown gear arc at sea le pressure. It is important to have this starting position in order to ha the altimeter reach its maximum range of operation. To adjust the pc ion of the sector gear; hold the sector gear with hand and turn the roc ıg shaft with a pair of pliers as required.

2-44. Mechanism Temperature ımpensation and Calibration Procedure

a. Place the mechanism in th calibration stand and install the 100 ft. pointer at the existing ambient ırometric pressure of the day. (No pressure or vacuum applied).

b. Calibration at this point is ıncerned with the primary check points listed in Table 2-2. If all the pri ry check points are approximately within the tolerances listed, then the ıchanism is considertd to be within the established range and calibrati curve. At this point proceed to temperature compensation under para ıph 2-42.

c. The next step is to place the ıechanism in the test chamber and apply pressure to minus 200 feet or)0 feet below zero feet (29.92 inches of mercury).

d. Decrease pressure to zero ıt (29.92 inches of mercury) and record error. (Room temperature 25 de ıes C). Also record error of other check points in Table 2-2.

e. The next step is to record ı pointer error at -35 degrees C utilizing the procedures outlined in prec ding sub-paragraphs (c) and (d).

NOTE: While a ± 30 fo change is allowable for room to cold reading at zero fe it is recommended that the change be limited, if possible, ± 15 feet or less.

f. If the difference in room and ıld readings exceed the allowable change in Table 2-1, then temperature ıompensation is necessary. Utilize paragraph 2-42 b and 2-42 c. Prior changing the position of the temperature compensator, consideration shou be given to the scale error curve recorded when utilizing Table 2-2. In a event, if adjustment of the temperature compensator is necessary, rec ık the primary check points and/or recalibrate utilizing Table 2-2. Fur r adjustment of the mechanism should be made as required until all rec ngs come within the allowable changes and tolerances specified.

g. In the event that the differe ı in room to cold readings do not exceed the allowable change, proceed th final calibration.

NOTE: The preceding step are considered critical. Make certain the test chamber and ırometer with associated tubing, valves, etc. are free from ıks.

2-45. Adjustments

a. Mount the mechanism in the calibration stand so the aneroid is on the same side as "0" and place it in a pressure chamber so "0" is at the top. By means of knob on the calibration stand, set the hand of the test mechaism so that it will read "0" when the master altimeter or barometer reads "0".

NOTE: If the pointers of the master altimeter are below "0", close the chamber and reduce the pressure until the pointers indicate "0". Note the position of the pointer of these test instruments. If it is not on "0", open the chamber to atmosphere and turn the adjustment knob to reposition the pointers. Repeat the procedure until reading of "0" is obtained. If the pointers of the master are above "0", the procedure is similar to that described above except that the instruments must be subjected to pressure.

b. Close the pressure chamber and slowly decrease the pressure until the master altimeter or barometer indicates a reading equivalent to 10,000 feet.

c. If the mechanism shows a plus or minus indication, remove it and adjust the effective length of the bi-metal support assembly (28) to which the mechanism link (25) is connected. If the mechanism reading is too high move the bi-metal support (28) out of the rocking shaft. If the mechanism readings are too low, move the adjusting arm into the rocking shaft.

d. When the altimeter mechanism reading agrees with that of the master altimeter or barometer at 0 and 10,000 feet, increase pressure to that of room pressure, remove the instrument and stand from the chamber and recheck balance as described previously. When the instrument is balanced within the limits listed above, place the mechanism in a chamber and recheck instrument error at 0 and 10,000 feet. If the error is within tolerance specified, further reduce pressure and record errors at the succeeding check points (20,000 and 30,000 feet).

e. If the mechanism indicates a reading at 35,000 feet above or below that of the master altimeter (after applying the allowed tolerance) remove the mechanism from the chamber and adjust the position of the aneroid assembly (21) in the mechanism body. If the mechanism reading is too high, move the aneroid out (away) from the rocking shaft. The position of the aneroid assembly (21) in relation to distance of the rocking shaft assembly (30) is adjusted in the following manner: To move the aneroid away from the rocking shaft, turn the diaphragm support nut (33) clockwise. To move the aneroid toward the rocking shaft first loosen the aneroid clamping screw (22) with an Allen wrench, then back off the diaphragm support nut the desired amount, move the aneroid assembly toward the rocking shaft and tighten the clamping screw.

f. Shifting the aneroid assembly (21) to correct the indicator at 35,000 feet altitude alters both the "0" position and the setting at 10,000 feet. Therefore, the mechanism must be adjusted again so that it indicates 0 and 10,000 feet in accordance with the steps outlined above.

g. Further adjustment of the mechanism should be made as required until all readings come within the tolerances specified above.

h. Check the backward movement of the mechanism by slowly increasing the pressure until the altimeter indicates a minimum of -2,000 feet, maximum -3,000 feet. The sector and rocking arm shaft assembly (30) must be shifted with pliers and wrench as described above.

2-46. **Case Assembly** (See Figure 2-1)

a. If removed, position the filter screen (38) over the inside of the opening in the bottom of the case (39). Assemble the washer (37) over the screen and press into position and stake.

b. Position the case (39) on its side with the corner well down. Place the snap ring (36) on the upper hub of the pinion gear (35). Position pinion gear with hub facing out in the well of the case. Place compression spring (33) in the well of the case (39) around the neck of gear (35) and also around the snap ring (30).

c. Use a new "O" ring (34) at reassembly.

d. Align the center hole of the pinion gear (35) with the hole in the case (39). Install the unthreaded end of the adjustment knob stem (32) in the case.

e. Align the hole in the pinion gear (35) with the hole in the stem (32) and install the pin (31). Fasten in position by dropping the snap ring (30) in the groove in the neck of the gear (35).

f. Position the snap ring (36) in the innermost groove at the inside of the case (39). The snap ring (36) fits in the vertical groove next to the well corner of the case (39).

g. Install formed spring ring (26) in the case (39) on top of snap ring (36).

2-47. **Reassembly of Major Components**

a. Place the case (39) on the bench with the open end facing up.

b. Install a No. 6-40 x 1 inch screw in the threaded hole of the transmission gear plate (14, Figure 2-3). Suspend the transmission mechanism (24, Figure 2-1) and mechanism assembly (25) by the screw and lower the assembly into the case (39). The locating pin must be in line with the groove adjacent the case well for proper assembly.

c. Compress the transmission and mechanism assembly in the case and install the snap ring (22) in the second groove. The locater of the snap ring fits in the groove opposite the case well.

d. Insert the tension wire (15) between the transmission mechanism and the case in the transmission mechanism slot located diagonally opposite the case well.

e. Remove the pointer (16).

f. Assemble barometric setting gear assembly (23) over the gear stud (10, Figure 2-2) with wheel gear against gear plate.

2-48. Dial Assembly (See Figure 2-1)

a. Position barometric dial assembly (21) on the front of transmission and mechanism assembly.

b. Assemble dial (19) with the opening at the side opposite the gear assembly (23) to the pivot plate assembly of the transmission mechanism with two dial screws (20).

c. Press pointer assembly (18) on the bushing of wheel assembly (1, Figure 2-2) with the inverted arrow pointing to zero.

d. Press pointer assembly (17, Figure 2-1) on the gear bushing (5, Figure 2-2) with the pointer toward zero.

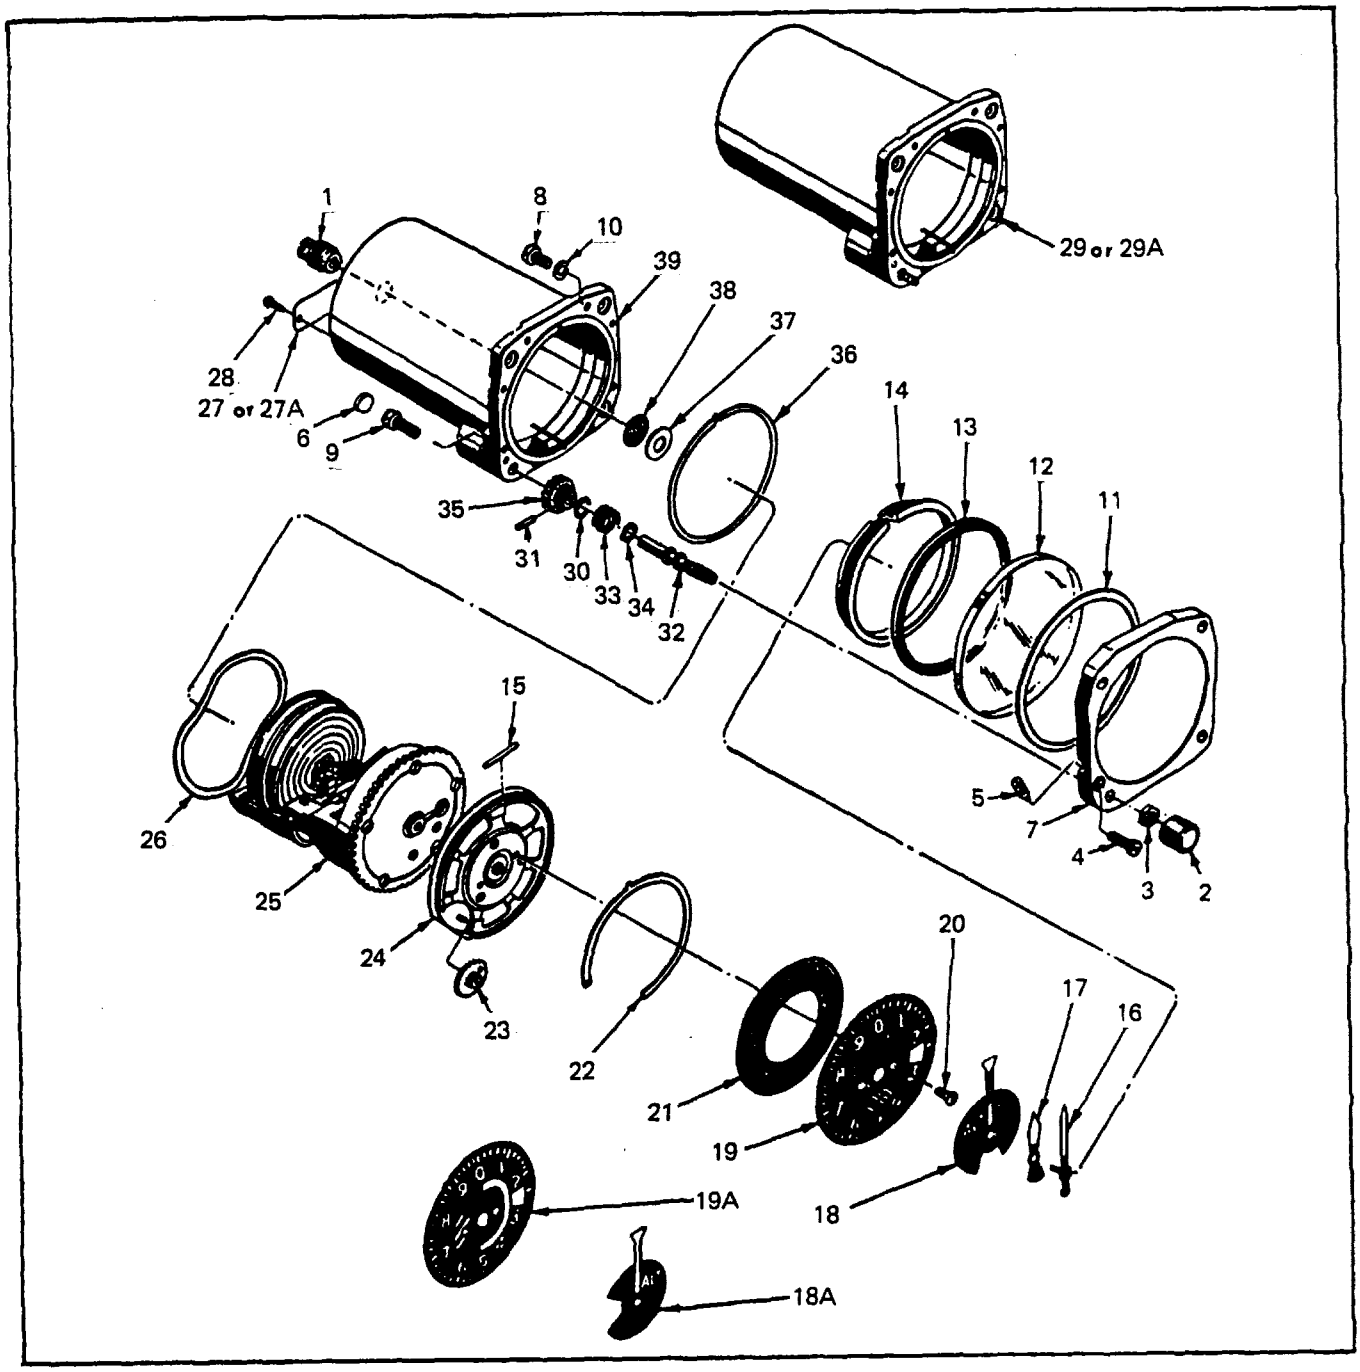
e. Press the center bushing of pointer (16, Figure 2-1) over the handstaff pinion (2, Figure 2-3). This pointer also points toward zero.

f. Install spacer ring (14, Figure 2-1) in the case (39) with the lip of spacer ring resting on the outer edge of case. Make sure the lock at the side of spacer ring is located in the outermost groove of the case.

g. Carefully assemble new bezel gasket (13) around the outer edge of spacer ring (14).

h. Clean and position glass (12) on the gasket (13) place paper gaskets (11) and bezel (7) on the glass.

i. Place one hand over the bezel to prevent it and the glass from falling off. While holding it thus, turn the instrument face down.



j. Install two diametrically opposite lock washers (10) and screws (8) to hold the bezel to the case. Install the remaining screws (8) each with a lock washer (10) around the case. Install two screws (9), on either side of adjustment knob stem. Tighten all screws by selecting screws in directly opposite positions and bring them up evenly to the tight position. Press a new lead seal (6) into mounting flange.

2-49. Completing Assembly

a. Replace lock nut (3) and the knob (2) on the adjustment knob stem. Hold the knob by covering knurled section with friction tape and grasping with pliers. Tighten knob lock nut against the knob with a 5/16 inch end wrench.

b. Lightly tap the instrument glass to remove friction Note the barometric pressure and compare it with the reading from a standard barometer. If it is necessary to adjust the barometric dial, pull the adjustment knob forward and while holding it in this position turn it to reset the barometric dial. When the desired barometric pressure is indicated, release the knob.

c. Push the locking stud screw (4) to the right to engage the pin, of locking stud (5), that rides in the recess of the knob stem. Screw down the locking screw (4).

10,000 Ft.	100 Ft.
20,000 Ft.	150 Ft.
30,000 Ft.	350 Ft.

SECTION III
TEST PROCEDURES

Specification Requirements

Instrument shall be in accordance with FAA TSO-C10b (AS392C).

	Paragraph
Scale Error Room Temperature	3-1
Scale Error Low Temperature	3-2
Hysteresis	3-3
After Effect	3-4
Friction	3-5
Case Leak	3-6
Position Error	3-7
Barometric Scale Error	3-8

3-1. **Scale Error** — With the barometric pressure scale at 29.92 inches of mefcury, the altimeter shall be subjected successively to pressures corrospoding to the altitude specified in Table I up to maximum normally expected operating altitude of the airplane in which the altimeter is to be installed. The reduction in pressure shall be made at a rate not in excess of 20,000 feet per minute to within approximately 2,000 feet of the test point. The test point shall be approached at a rate compatable with the test equipment. The altimeter shall be kept at the pressure corresponding to each test point for at least one minute, but not more than ten minutes, before the reading is taken. The error at all test points must not exceed the tolerance specified in Table I.

3-2.. **Low Temperature** — The instrument shall be exposed to a temperature of -30 degrees C for three hours and while at the temperature shall be tested as described in paragraph 3-1. The change in reading of the indicator from room temperature reading at any tese point shall not exceed the value specified in Table I.

3-3. **Hysteresis** — Not more than 15 minutes after the altimeter's initial exposure to the pressure corresponding to the upper limit of the scale (per paragraph 3-1), and while the subject instruments are still at this pressure the hysteresis test shall commence. Pressure shall be increased at a rate simulating a descent in altitude approximately (but not exceeding) 20,000 fpm until within 3,000 feet of the first point (50% of the maximum altitude). Then the test point shall be approached at a rate of approximately 3,000 fpm. Within ten seconds after the pressure has been stabilized at the test point, the instrument indication shall be within 75 feet of the scale error (paragrph 3-1) reading. The altimeter shall remain at this pressure for at least five minutes, but not more than 15 minutes before pressure shall be further increased at the above rate until the pressure corresponding to the second test point (40% of the maximum altitude) is reached. The Altimeter shall remain at this pressure for at least one minute but not more than ten minutes before the test reading is taken. After the reading has been taken the pressure shall be further increased as specified above, until atmospheric pressure is reached. The reading of the Altimeter at either of the two test points shall not differ from the reading of the Altimeter for the corresponding altitude in the scale error test by more than the tolerance specified in Table II.

3-4. **After Effect** — Not more than five minutes after the completion of the hysteresis test, the pointers shall have returned to their original reading, corrected for any chage in atmospheric pressure within the tolerance specified in Table II.

3-5. **Friction** — The Altimeter shall be subjected to a steady rate of decrease of pressure equivalent to about 750 feet per minute. The change in reading of the pointers due to a light tapping of the instrument noted at the altitude specified in Table III shall be recorded as friction and shall not exceed the tolerance listed in Table III.

3-6. **Case Leak** — A pressure equivalent to 18,000 feet within the case shall not result in leakage exceeding the tolerance shown in Table II during a period of one minute.

3-7. **Position Error** — With atmospheric pressure applied to the instrument, the difference between the pointer indication when the instrument is in normal operating position and when it is in any other position shall uot exceed the tolerance specified in Table II.

3-8. **Barometric Scale Error** — With the ambient pressure constant, various settings of the barometric pressure scale within its range shall cause the pointer to indicate the equivalent altitude differences shown in Table IV within a tolerance of 25 feet.

TABLE I

ALTITUDE PRESSURE

(Ref: U. S. Standard Atmosphere 1962)

Altitude (Feet)	Equivalent Pressure (Inches of Hg.)	Tolerance (Feet)
-1,000	31.02	± 20
0	29.92	20
500	29.38	20
1,000	28.86	20
1,500	28.33	25
2,000	27.82	30
3,000	26.82	30
4,000	25.84	35
6,000	23.98	40
8,000	22.22	60
10,000	20.58	80
12,000	19.03	90
14,000	17.58	100
16,000	16.22	110
18,000	14.94	120
20,000	13.75	130
22,000	12.64	140
25,000	11.10	155
30,000	8.89	180
35,000	7.04	205

TABLE II

TEST TOLERANCES

Test	Tolerance (Feet)
Case Leak Test	± 100
Hysteresis Test	
First Test Point (50% Maximum Altitude)	75
Second Test Point (40% Maximum Altitude)	75
After Effect Test	30

SECTION I

INTRODUCTION

1. This handbook is issued as the basic parts breakdown for Pressure Altimeter, Part Number A35-MA-10L-1 manufactured by Aerosonic Corporation, Clearwater, Florida, and/or Aero-Scotia Limited, Amherst, Nova Scotia.

2. In the parts numbering system the prefix letter indicates: (A) assembly, (SA) sub-assembly, (M) and (P) have no special significance. The first numerical digit indicates the drawing size: (1) A, (2) B, (3) C, (4) D.

3. Abbreviations used are in accordance with MIL-STD-12.

SECTION II

GROUP ASSEMBLY PARTS LIST

Figure & Index No.	Part Number	Description	Units Per Assy
1 -	A35-MA-10L-1	Altimeter	1
1	1604 - 600	Plug, Plastic Black	1
2	P1396	Knob	1
3	P1295	Nut, Lock	1
4	P1294	Screw, Locking Stud	1
5	P1293	Stud, Locking	1
6	P1297	Seal, Lead	1
7	M2098	Bezel	1

AEROSONIC CORPORATION
OVERHAUL MANUAL
ALTIMETER INDICATOR
(SERIES 101720 AND 101730)

DESCRIPTION AND OPERATION

1. INTRODUCTION

This manual contains all information required for the overhaul and testing of the Three-Pointer Pressure Altimeters (Series 101720 and 101730) manufactured by Aerosonic Corporation, Clearwater, Florida 33518. Refer to table 1 for altimeter part numbers and leading particulars. Detailed instructions and procedures are given wherever required. When no specific instructions are given in this manual, standard shop practices should be used. Repairable parts are listed in the ILLUSTRATED PARTS LIST section.

2. GENERAL

A. HOW TO USE THIS MANUAL

This manual covers 12 different pressure reporting altimeter units which are dissimilar in each of three respects. To use this manual properly, first determine which of the 12 units is being subjected to overhaul. These units differ as follows:

- Barometric Readout -- Millibar (Mb) Readout, Inches of Mercury (In. Hg) Readout, or Dual (Mb or In. Hg) Readout
- Maximum Range -- 20,000 or 30,000 Feet
- Bezel -- Lighted or Unlighted

After determining the type of unit to be serviced, refer to that section of this manual and proceed with repair. Differences in disassembly/assembly procedures, altitude test points, tolerances and parts as applicable to the different altimeter configurations are noted in the text, tables, and illustrated parts list.

3. PURPOSE OF THE ALTIMETER

These altimeters measure atmospheric pressure as varied with altitude above ground level and provide a readout of that altitude on the dial face.

4. DESCRIPTION

A. Leading Particulars

Leading particulars of the 12 altimeter configurations covered herein are shown in table 1.

B. Electro-Mechanical

(1) The case of the altimeter is of two-piece construction, the case sub-assembly and the bezel assembly. It is airtight when assembled except for a static pressure port at rear of case. The bezel assembly has three counterbored holes for mounting the altimeter to the instrument panel.

Table 1. Leading Particulars

ALT. INDICATOR PART NUMBER	RANGE (FEET)	BAROMETRIC DIAL RANGE		BEZEL ASSY
		IN. OF Hg	MILLIBARS	
101720-01354	-1000 to +20,000	28.1 to 31.0		Unlighted
101720-01355	-1000 to +20,000		946 to 1050	Unlighted
101730-01356	-1000 to +30,000	28.1 to 31.0		Unlighted
101730-01357	-1000 to +30,000		946 to 1050	Unlighted
101720-01383	-1000 to +20,000	28.1 to 31.0	946 to 1050	Unlighted
101720-11384	-1000 to +20,000	28.1 to 31.0		Lighted
101720-11385	-1000 to +20,000		946 to 1050	Lighted
101720-11386	-1000 to +20,000	28.1 to 31.0	946 to 1050	Lighted
101730-01387	-1000 to +30,000	28.1 to 31.0	946 to 1050	Unlighted
101730-01388	-1000 to +30,000	28.1 to 31.0		Lighted
101730-11389	-1000 to +30,000		946 to 1050	Lighted
101730-11390	-1000 to +30,000	28.1 to 31.0	946 to 1050	Lighted

Maximum overall length: 5.367 inches
Maximum width: 3.260 inches
Maximum weight: one pound, two ounces
Lamp Voltage: 5 VDC

(2) Altitude is indicated on the front dial face of the instrument by three concentrically arranged pointers. These indicate on a common scale units of 100 feet, 1,000 feet, and 10,000 feet. (See figures 1 through 4).

(3) The outer dial is graduated into single divisions of twenty feet when measured by the 100-foot pointer, 200 feet with respect to the 1,000-foot pointer and 2,000 feet with respect to the 10,000-foot pointer.

(4) A barometric dial located between dial numerals 2 and 3 indicates and can be corrected to local ground level barometric pressure in inches of mercury or millibars (figures 1 and 3). Altimeters which provide dual barometric readout have a dial assembly that indicates pressure in In. Hg between numerals 2 and 3 and pressure in Mb between numerals 7 and 8 (figures 2 and 4).

(5) A barometric adjusting knob located at the lower left corner, when rotated, will adjust the altimeter pointers and barometric dial(s) simultaneously to correct for changes in ground level pressure.

(6) Power for the lamps in altimeters with lighted bezels is brought in on two leads through the top of the bezel (figures 3 and 4).

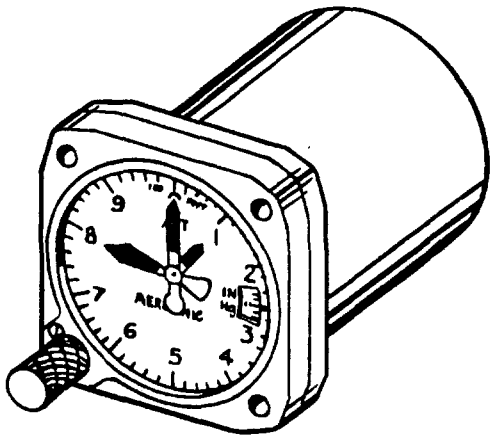

Figure 1. Unlighted, Single Barometric Readout Altimeter

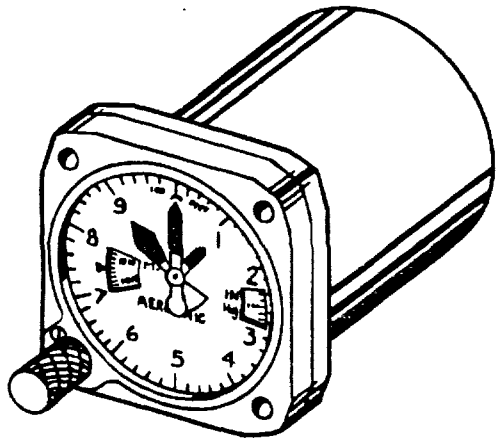

Figure 2. Unlighted, Dual Barometric Readout Altimeter

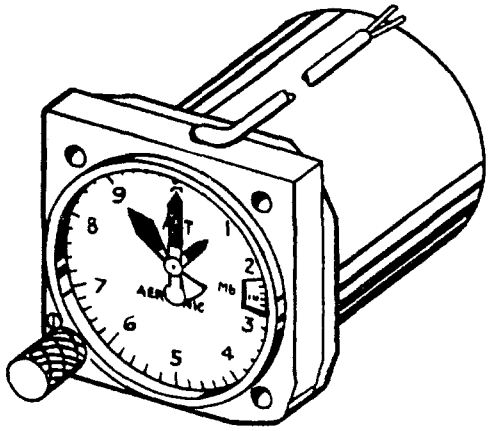

Figure 3. Lighted, Single Barometric Readout Altimeter

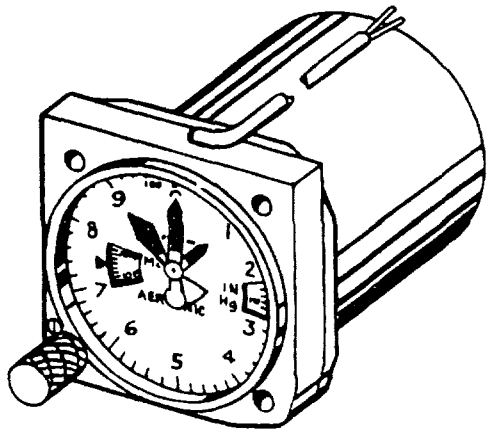

Figure 4. Lighted, Dual Barometric Readout Altimeter

5. THEORY OF OPERATION

Atmospheric pressure exerted upon surfaces of aneroid at zero altitude is greater than the pressure within aneroid. This unequal distribution of pressure causes aneroid to contract. An increase in altitude decreases atmospheric pressure, thereby exerting less pressure upon surfaces of aneroid allowing it to expand. This motion is transferred through mechanism to the transmission assembly, thereby actuating radial movement of instrument pointers.

DISASSEMBLY

1. GENERAL

This section provides instructions for the disassembly of the Pressure Altimeters. These altimeters should be disassembled only when repair is necessary. Unless the altimeter has obviously been damaged to the extent that testing is impossible, perform the tests given in the TESTING section prior to disassembly and determine the degree of repair required.

NOTE: When disassembling, keep parts together and protected from dust and dirt. Handle glass parts using white cotton gloves on edge surface only.

2. DISASSEMBLY PROCEDURES

A. Disassembly of the Altimeter Major Components (See figure 1101).

NOTE: Place appropriate end of altimeter in a suitable support block to protect parts during disassembly.

NOTE: Do not disturb position of aneroid and thermometal assembly (figure 1102-36), or angular relationship of rocking shaft assembly (figure 1102-17) to the aneroid and thermometal assembly unless absolutely necessary for repair. Disturbing the setting of these parts will necessitate recalibration of the unit.

(1) Wrap friction tape around knurled adjusting knob (figure 1101, 2). Hold knob stationary with pliers and loosen knob locknut (3) with a 5/16-inch wrench. Remove knob and locknut from adjustment knob stem (62).

(2) Back off locking stud screw (4) until head clears front face of bezel (7 or 15). Slide screw to the left in its slotted passage to disengage locking stud (5) from adjustment knob stem (62). It is not necessary to remove either screw or stud from bezel unless damaged.

(3) Remove lead seal (6), screws (8), screws (9) and lockwashers (10).

(4) Remove bezel (7) or bezel assembly (-11).

NOTE: Steps 5 and 6 apply only to lighted altimeters (items 15 through 23, shown in the inset in figure 1101).

(5) Separate black paper gaskets (16), bezel spacer (17) and lens (18) from the bezel (15).

(6) Remove screws (20) and light tray assembly (-19). Unless it is necessary to replace one or both of the lamps (22), do not remove filters (23) or unsolder lamps (22) from printed circuit board (21).

NOTE: Step 7 applies only to unlighted altimeters.

(7) Separate lens (25) and paper gasket (24) from bezel (7).

(8) Remove bezel gasket (26) and ring spacer (27) from case (68).

(9) Lift off 100-foot pointer (28), 1,000-foot pointer (29), and 10,000-foot pointer (30).

(10) Remove dial screws (32) and lift off altimeter dial (31) and barometric dial assembly (33).

(11) Remove tension wire (34). Pry both ends of snap ring (35) until free, and remove from case. Remove gear assembly (52) and dial washer (53).

(12) Remove transmission mechanism assembly (-36 or -44) from case.

NOTE: Steps 13 and 14 apply only to altimeters with single barometric readout.

(13) Remove screws (39), gear assembly (40), wheel assembly (41), pinion (42), wheel assembly (43) and pivot plate assembly (38), from gear plate assembly (37).

(14) Remove wheel assembly (41) and pinion from pivot plate assembly.

NOTE: Steps 15 and 16 apply only to altimeters with dual barometric readout.

(15) Remove screws (47), transmission cover assembly (46), gear assembly (48), wheel assembly (49), pinion (50), and wheel assembly (51) from transmission housing assembly (45).

(16) Remove wheel assembly (49) and pinion from transmission cover assembly.

(17) It is not necessary to remove vent plug (54) from vent unless the vent insert is damaged.

(18) Remove mechanical mechanism assembly (55) from case.

(19) Lift spring ring (56) from case.

(20) Washer (66) and filter screen (67) are staked parts and should not be removed unless they have been damaged. Press them from the case and smooth off stake marks in case before replacing washer and filter screen.

(21) Remove lock pin (61) and snap ring (60).

(22) Pull adjustment knob stem (62) from its socket and remove "O" ring (63). Remove compression spring (65) and pinion gear (64) from the case when pulling adjustment knob stem clear.

B. Disassembly of Mechanical Mechanism Assembly (See figure 1102).

(1) Remove pinion (5), screw (7), jewel bushing assembly (6), and hand-staff pinion (8).

(2) Remove pin (18), screw (37) and aneroid and thermometal assembly (-36).

(3) Remove screw (42), two screws (41), clamp bar (39) and thermometal (40).

(4) Remove screws (45 and 46), clamp bar (43) and thermometal support (44) from aneroid assembly (47).

(5) Remove screws (39) and diaphragm support plate (35).

(6) Remove taper pin (19).

(7) Remove screws (4) and gearplate assembly (3).

(8) Remove nut (24), screw (23), pin (21), link (20) and link arm (22).

(9) Remove screw (26), counterweight (25), screw (28) and rocking shaft pin (27).

(10) Remove screw (30) and counterweight (29).

(11) Do not remove pivot pins (31), sector gear (32), or sector gear hair-spring (33) from rocking shaft (34).

(12) Remove taper pin (10) and lift out gear assembly (9).

(13) Remove screw (12), eccentric jewel bushing assembly (11), screw (14), jewel bushing unit (13), screw (16), and eccentric jewel bushing assembly (15) from frame (2).

CLEANING

1. GENERAL

This section gives instructions and recommended procedures for cleaning the altimeter after disassembly.

2. MECHANICAL PARTS

A. General Procedure

CAUTION: DO NOT IMMERSE THE ANEROID ASSEMBLY OR JEWEL ASSEMBLIES CONTAINING HOLE AND CAP JEWELS IN CLEANING OR RINSE SOLUTIONS. (SEE 2C BELOW.) CLEAN ELECTRICAL PARTS AS DESCRIBED IN 3.

(1) Refer to table 201 for solvents and cleaners and their use.

Table 201. Cleaners and Solvents.

SOLVENT/CLEANER	USE
L and R Nofome Cleaning Solution	Cleaning Mechanical Parts
L and R Rinsing Solution L and R Manufacturing Co. Kearney, New Jersey 07032	Rinsing Mechanical Parts
Featherwood (Pithwood)	Cleaning Pivots and Pinions
Watchmaker's Paper	Cleaning Gears and Pinions
Prepared Chalk	Cleaning Gears and Pinions
Tissue, Lint Free, Optical Grade	Cleaning Lenses
Alcohol, Ethyl	Cleaning Lenses
Detergent, Liquid	Cleaning Lenses

(2) Wash parts and hardware in a wire mesh basket immersed in cleaning solution. Rinse the parts and hardware in rinsing solution. (See CAUTION above.) Dry with low pressure air: approximately 25 psi.

(3) Store the cleaned and dried parts under a bell jar until ready for reassembly.

B. Pinions and Pivots

(1) Clean pinions by pressing them into end grain of Featherwood.

(2) Clean pivots by pressing them in the end grain of Featherwood and twirling the wood between the fingers.

C. Jewels

Do not attempt to clean jewels. If they are soiled, replace them with new assemblies. To determine if they are soiled, view them through at least 2X magnification.

D. Gears and Pinions

Brush the gear and pinion teeth with a No. 3 watchmaker's brush occasionnally rubbed across a piece of prepared chalk. Hold the parts being brushed in a piece of watchmaker's paper to keep the brush and the parts from contacting bare skin. Use a clean portion of paper for each part.

3. LIGHT TRAY ASSEMBLY

The light tray assembly is not normally cleaned. If cleaning is required use a brush and low pressure compressed air.

4. LENS

Clean lens with soft lint free tissue moistened with ethyl alcohol. If lens surface is very dirty, clean with a mild solution of liquid detergent and water. Rinse thoroughly and dry with clean low pressure compressed air.

CAUTION: DO NOT RUB OR POLISH LENS SURFACE OR TOUCH WITH BARE FINGERS, SINCE THIS MAY DAMAGE THE OPTICAL COATING. DO NOT STORE COATED LENS IN OR NEAR POLYETHYLENE.

INSPECTION/CHECK

1. GENERAL

This section gives instructions for inspecting the altimeter prior to disassembly, and the individual components after disassembly.

2. INSPECTION PROCEDURES

A. Altimeter Assembly

Inspect the unit prior to disassembly for physical evidence of damage. Check for dents, cracks, broken or damaged indicator parts or electrical wiring defects.

B. Major Components

When the unit has been broken down into its four major assemblies (bezel, transmission, case, mechanism), check for obvious damage. Check movable parts for indication of damage to bearings, bushings and shaft ends.

C. Assemblies

Refer to table 301 for specific assemblies and parts to be inspected.

Table 301. Inspection Chart

NOMENCLATURE	PROCEDURE
Bezel Assembly	Inspect lenses and filters for scratches or other damage.
Light Tray Assembly	Inspect for damaged wires, cracked P.C. board, bad solder connections, and cracked or defective lamps.
Rocking Shaft	Inspect as applicable for distorted or broken link arm, bent or kinked hair-spring, broken or worn teeth on sector gear, chipped or broken jewels, and damaged pivot. This assembly should be replaced as a unit if damaged.
Aneroid Assembly	Check for dents, bent pressure pin and puncture or seal defects. Replace damaged portion of assembly.

Table 301. Inspection Chart (Continued)

NOMENCLATURE	PROCEDURE
Handstaff Pinion	Inspect for worn or damaged teeth and bent or broken handstaff. If damaged, replace with new handstaff pinion.
Pressed-fit Parts (Jewel Assemblies)	Check for chips, broken jewels and for distortion of parts. Replace if damaged. See paragraph 2, ASSEMBLY section, for replacement.

REPAIR

1. GENERAL

This section gives instructions for repair of damaged or defective parts of the equipment.

2. REPAIR PROCEDURES

Electrical and mechanical parts should not be repaired except for the replacement of lamps and for normal realignment, adjustment, and polishing procedures.

NOTE: Replacement of parts such as aneroids, pivots, handstaffs, sectors and gears during overhaul may disturb the original alignment of the altimeter and cause erratic altitude readings and excessive friction during initial calibration.

3. LUBRICATION

No lubrication of parts is recommended.

ASSEMBLY

1. GENERAL

Refer to the figures in the Illustrated Parts List and assemble the altimeter in accordance with the following instructions.

NOTE: Place appropriate end of altimeter in a suitable support block to protect parts during disassembly.

NOTE: Do not disturb position of aneroid and thermometal assembly (figure 1102-36) or angular relationship of rocking shaft assembly (figure 1102-17) to the aneroid unless absolutely necessary for repair. Disturbing the setting of these parts will necessitate recalibrationof the unit.

2. ASSEMBLY PROCEDURES

NOTE: If any jewels, pins, bearings, bushings, gears, or other pressed parts have been disassembled, they should be reassembled using appropriate new parts. Assembly of these parts should be accomplished before other assembly procedures begin.

A. Assembly of Mechanical Mechanism Assembly (See figure 1102).

(1) If previously removed, mount eccentric jewel bushing assembly (11) in frame (2) and secure with screw (12).

(2) If previously removed, mount large jewel bushing unit (13) in frame and secure with screw (14).

(3) If previously removed, mount eccentric jewel bushing assembly (15) in frame and secure with screw (16).

(4) Mount clamp bar (43) and thermometal support (44) on aneroid assembly (47) with screw (45) and screw (46).

(5) Mount clamp bar (39) and thermometal (40) on thermometal support (44) with screws (41) and screw (42).

(6) Insert aneroid and thermometal assembly (-36) into diaphragm support plate (35) and secure with screw (37).

(7) Attach aneroid and thermometal assembly with diaphragm support plate to mechanism frame (2) with screws (38). Make sure aneroid assembly does not touch frame.

(8) Mount crown gear counterweight (29) to partially disassembled rocking shaft assembly (31, 32, 33 and 34) and secure with screw (30).

(9) Insert rocking shaft pin (27) in rocking shaft (34) and secure with screw (28).

(10) Mount rocking shaft counterweight (25) on rocking shaft pin and secure with screw (26).

(11) Insert link arm (22) in rocking shaft and secure with screw (23) and nut (24).

(12) Attach aneroid link (20) to link arm with bearing pin (21). Bend the rear end of the pin.

(13) Insert pivot on opposite side of hairspring of intermediate gear assembly (9) into eccentric jewel bushing assembly (11). Using work plate T21306 to hold gear in place, adjust spring so that is is centered between hairspring guards and wheel moves freely.

(14) Straighten approximately 1/2 inch of the end of intermediate gear assembly (9) hairspring and insert into hole in lower left of frame (2). Pin hairspring to frame with taper pin (10). Cut taper pin and hairspring so they are flush with outside diameter of frame.

(15) Insert forward pivot of intermediate gear assembly (9) into jewel bearing assembly in gearplate assembly (3).

(16) Position gearplate assembly on frame (2) and secure with four screws (4).

(17) Set rocking shaft assembly (-17) in frame with rear pivot pin (31) inserted in eccentric jewel bushing assembly (15) and the forward pivot pin (31) into jewel bearing assembly in gearplate assembly.

(18) Straighten approximately 1/2 inch of the end of sector gear hairspring (33) and insert into hole in upper left side of frame. Pin hairspring to frame with taper pin (19). Insure that coils of hairspring are concentric with rocking shaft (34).

(19) Set endplay of intermediate gear assembly (9) to 0.0005 to 0.001 inch and endplay of rocking shaft assembly (-17) to 0.005 to 0.001 inch by adjusting eccentric jewel bushing assemblies.

NOTE: To obtain proper alignment of intermediate gear assembly (9), loosen screw (12) and rotate eccentric jewel bushing assembly (11). Tighten screw. To obtain proper alignment of rocking shaft assembly (-17), loosen screw (16) and rotate eccentric jewel bushing assembly (15). Tighten screw.

(20) Drop handstaff pinion (8), short journal first, through center hole of gearplate assembly (3) and into jewel bushing (13).

(21) Place jewel bushing assembly (6) onto exposed journal of handstaff pinion (8). Set jewel bushing unit 0.005 to 0.007 inch below face of center bushing in gearplate assembly (3). Set handstaff pinion (8) endplay to 0.0003 to 0.0005 inch. Secure in place with screw (7).

(22) Press hub of 12T center pinion (5) onto handstaff pinion (9) until 0.003 to 0.005 inch clearance from jewel bushing assembly (6) remains.

(23) Calibrate and adjust mechanism assembly as outlined in TESTING section, paragraphs 14 and 15.

B. Assembly of Major Components (See figure 1101).

(1) Insert filter screen (67) with washer (66) into bottom port inside case (68). Stake washer to case.

(2) Slide "O" ring (63) onto unthreaded end of adjustment knob stem (62) until flush with shoulder of stem.

(3) Press snap ring (60) onto pinion gear (64) so snap ring is below pin hole in gear.

(4) Place in order; pinion gear (64) and compression spring (65) into gear well in lower left corner of case. Align center holes of these parts.

(5) Insert adjustment knob stem through aligned center holes of parts in preceeding step. Pin pinion gear (67) to adjustment knob stem with lock pin (61).

(6) Place spring ring (56) into case.

NOTE: Steps 7, 8 and 9 apply only to altimeters with single barometric readout. The front of gear plate assembly (37) is the face with the greatest amount of machining and recesses. The rear face is relatively smooth in appearance.

(7) Position 13T and 40T gear assembly (40) into gear plate assembly. The 13T and 40T gear assembly is located in the small hole, next to the large opening in the center of pivot plate assembly (38) on the side opposite the location pin.

NOTE: The front of pivot plate assembly is distinguished by three countersunk holes around the outer edge.

(8) Install 12T stem pinion (42) through the front of pivot plate assembly and hub of 48T wheel assembly (41). There are two small holes in the inner part of the pivot plate assembly. These holes (one countersunk) and the center bushing assembly are in line. The hole on the side opposite the aligned countersunk screw hole is the hole on the pivot plate assembly used to install stem pinion.

(9) Position pivot plate assembly, and install 48T wheel assembly (41) into gear plate assembly (37) on the gear stud side of the gear plate. Make sure all pinion stems and staffs are located in their respective pivot points. The three screw holes should already be aligned. Install three screws (39). Install 60T wheel assembly (46) on hub of pivot plate assembly.

NOTE: Steps 10, 11 and 12 apply only to altimeters with dual barometric readout. The front of the transmission housing cover (45) is the face with the greatest amount of machining and recesses. The rear face is relatively smooth in appearance.

(10) Position 13T and 40T gear assembly (48) into the transmission housing cover. The gear assembly is located in the small hole, next to the large opening in the center of the transmission housing cover on the side opposite the location pin.

(11) Install 12T stem pinion (53) through the front of transmission housing cover and hub of 48T wheel assembly (52). There are two small holes in the inner part of the transmission housing cover. These holes (one countersunk) and the center bushing assembly are in line. The hole on the side opposite the aligned countersunk screw hole is the hole on the transmission housing cover used to install stem pinion.

(12) Position transmission cover assembly (46), and install 48T wheel assembly (52) into transmission housing assembly on the gear stud side of the gear plate. Make sure all pinion stems and staffs are located in their respective pivot points. The three screw holes should already be aligned. Install three screws (50). Install 60T wheel assembly (54) on hub of pivot plate.

(13) Position transmission mechanism assembly (-36 or -47) on to front of mechanical mechanism assembly (55).

NOTE: Care must be taken to properly mesh 12T center pinion (figure 1102, 5) with 13T and 40T gear assembly (figure 1101, 40 or 48). Rotate transmission mechanism assembly several times to insure meshing of all gears and pinions. Press pointer (28) onto handstaff pinion (figure 1102, 9). Rotate the mechanical mechanism assembly (figure 1101, 55) in relation to the transmission mechanism assembly. When properly seated, the pointer will turn with the mechanical mechanism assembly without binding, sticking, or any irregular motion.

(14) Place the case on the bench with the open end facing up.

(15) Suspend the transmission mechanism assembly and mechanical mechanism assembly over the case, and lower the assembly into the case. The locating pin must be in line with the groove adjacent the case well for proper assembly.

(16) Compress the transmission mechanism assembly and mechanical mechanism assembly in the case, and install snap ring (35) in second groove.

(17) Insert two tension wires (34) between transmission mechanism and case in transmission mechanism assembly slot located diagonally opposite the case well.

(18) Remove 100 foot pointer (28).

(19) Place barometric setting gear assembly (52) with dial washer (53) over the gear stud in gear plate assembly or transmission housing assembly with wheel gear against gear plate assembly and stop, oriented toward center of mechanical mechanism assembly.

(20) Position barometric dial assembly (33) on the front of transmission mechanism assembly with grads for 29.92 IN. Hg, or 1013 Mb. at 12 o'clock.

(21) Assemble altimeter dial (31) with two dial screws (32) and the opening at the side of barometric setting gear assembly (52) opposite the pivot plate assembly or transmission housing cover of the transmission mechanism assembly.

(22) Press 10,000-foot pointer (30) onto the bushing of 60T wheel assembly (46 or 54) with the inverted arrow pointing to zero.

(23) Press 1,000-foot pointer (29) onto the bushing of the pivot plate assembly or transmission housing assembly with the pointer toward zero.

(24) Press the center bushing of 100-foot pointer (28) over handstaff pinion (figure 1102, 9). This pointer also points toward zero.

(25) Install ring spacer (figure 1101, 27) into case with the lip of ring spacer resting on the outer edge of case. Make sure the lock at the side of the ring spacer is located in the outermost groove of the case.

(26) Carefully assemble new bezel gasket (26) around the outer edge of ring spacer (27).

NOTE: Steps 27 and 28 apply to unlighted altimeters only.

(27) Clean and position lens (25) on bezel gasket. Place gasket (24) and bezel (7) on the lens.

(28) Install two diametrically opposite lock washers (10) and screws (9) to hold bezel to the case assembly (-59). Install the remaining four screws (9), each with a lock washer (10), around the case assembly. Install two screws (8), on either side of adjustment knob stem (62). Tighten all screws evenly.

NOTE: Steps 29 through 32 apply to lighted altimeters only. Refer to TESTING section, paragraph 13 for lighting test.

(29) If removal of one or both of the lamps (22) was necessary, position new lamp(s) on printed circuit board (21) and solder the lead to board. Install filter(s) (23).

(30) Attach light tray assembly (-19) to bezel (15) with two screws (20).

(31) Position, in order, one paper gasket (16), bezel spacer (17), paper gasket (16) and lens (18) in bezel.

(32) Place bezel assembly (-11) on case assembly (-59) and install two diametrically opposite lockwashers (10) and screws (9) to hold the bezel assembly to the case assembly. Install the four remaining screws (9), each with a lock washer (10), around the case assembly. Install two screws (8), on either side of adjustment knob stem (62). Tighten all screws evenly.

(33) Install locknut (3) and adjusting knob (2) on adjustment knob stem. Hold the knob by covering knurled section with friction tape and grasping with pliers. Tighten knob locknut against the knob with a 5/16-inch end wrench.

(34) Lightly tap the instrument glass to remove friction. Note the barometric pressure, and compare pressure with the reading from a standard barometer. If it is necessary to adjust the barometric dial assembly (33), pull adjusting knob forward and while holding knob in this position, turn to reset the barometric dial. When the desired barometric pressure is indicated, release knob.

(35) Slide the locking stud screw (4) to the right in its slotted passage to engage the pin of locking stud (5) that rides in the recess of the adjustment knob stem. Screw down the locking stud screw.

Table 501. Paints and Adhesives

ITEM	PAINT/ADHESIVES	USE ON
1	Paint, Dull Black, Color No. 37038, FED STD-595	Dial and pointer base
2	Paint, Matte White, Color No. 37875, FED STD-595	Pointer needles and dial markers
3	Alcoa Thread Lubricant, Aluminum Co. of America Pittsburgh, Pa.	One threaded insert in case sidewall
4	Locktite, Grade EV	All screws on mechanism
5	Glyptal, red General Electric Co. Code Ident 08800	All parts that will vibrate loose

FITS AND CLEARANCES

1. GENERAL

This section tabulates the settings, adjustments and tolerances of movable or mating parts. Refer to table 601 for the listing of movable or mating parts which have specific clearances, end play, or backlash.

Table 601. Clearance, End Play, and Backlash Tolerances

ITEM	INDEX NO.	NAME	CLEARANCE	END PLAY	BACKLASH
1	1102,10	Intermediate Gear Assy	--	.0005-.001	*
2	1102,-17	Rocking Shaft Assy	--	.005-.001	.0004-.0006
3	1102,6	Large Jewel Bushing Unit	.005-.007	--	--
4	1101-38	Pivot Plate Assy	.003	--	--
5	1102,9	Handstaff Pinion	.003-.005	.0003-.0005	**

* By locking rocking shaft, the backlash of intermediate gear assembly must be 30'-50' as measured at tip of pointer.
** By locking intermediate wheel, the backlash of handstaff must be 5-10 feet when measured at the pointer.

TESTING

1. GENERAL

The following procedures are set forth in this section.

Barometric Scale Error Test (Zero Setting Scale Test)
Barometric Scale Adjustment Knob Disengagement Test
Position Error Test
Case Leak Test
Scale Error Test
Hysteresis Test
After Effect Test
Friction Test
Lighting Test
Calibration
Adjustments

Paragraphs 5 through 13 give instructions for testing the altimeter. Test equipment, test specifications, and test conditions are described in paragraphs 2 through 4. These following tests should be performed prior to conducting an overhaul to determine the extent of repair that will be necessary. After the assembly of the altimeter, perform another complete sequence of tests to determine that the altimeter performs as specified.

2. TEST EQUIPMENT

Test equipment required is listed in SPECIAL TOOLS, FIXTURES AND TEST EQUIPMENT. The typical test setup for the altimeter is shown in figure 701.

3. TEST SPECIFICATIONS

Tolerances for major tests are given in table 701.

Table 701. Specific Tolerances for Major Tests

TEST	TOLERANCE FEET
Case Leak	100 per minute
Position Error	±20
Hysteresis	
First test point 25,000 feet	75
Second test point 20,000 feet	75
After Effect Test	30

4. TEST CONDITIONS

Unless otherwise specified, the indicator shall be tested in its normal operating position with the dial vertical. All tests shall be conducted in an environment as follows:

Ambient Temperature	$23^{o}C \pm 5^{o}C$
Atmospheric Pressure	28 to 32 inches of mercury
Relative Humidity	no greater than 55 percent

A typical test configuration is shown in figure 701.

5. BAROMETRIC SCALE ERROR

A. Test shall be conducted with indicator subjected to a constant ambient pressure.

B. Rotate adjustment knob (figure 1101, 2) until the barometric dial(s) (figure 1101, 33) indicate(s) each of the various settings in accordance with table 702. While barometric dial(s) is (are) being adjusted to test setting, the hundred-foot pointer will simultaneously adjust to setting. Record pointer readings at each setting.

C. When pointer reading at each setting has been recorded, determine the difference in altitude between each reading and zero. The differences shall not exceed tolerances listed in table 702.

Table 702. Barometric Scale Error

EQUIVALENT PRESSURE		ALT. DIFFERENCE FROM ZERO (FEET)		TOLERANCE (±FEET)
INCHES OF Hg	MILLIBARS	IN Hg	Mb	
28.10	950	-1727	-1773	25
28.50	964	-1340	-1344	25
29.00	982	- 863	- 920	25
29.50	998	- 392	- 364	25
29.92	1013	0	0	
30.50	1033	+ 531	+ 589	25
30.90	1047	+ 893	+ 856	25
30.99	1049	+ 974	+ 989	25

6. BAROMETRIC SCALE ADJUSTMENT KNOB DISENGAGEMENT TEST

A. Pull out firmly on knurled adjustment knob.

B. Rotate barometric scale with continuous outward pressure applied from 29.92 (1013) to minimum and maximum points on scale and return to 29.92 (1013).

C. Observe that 100-foot pointer moves in conjunction with the barometric scale(s). Failure of pointer to move indicates a defect in mechanism assembly of altimeter.

7. POSITION ERROR TEST

A. Mount altimeter in a position error test stand.

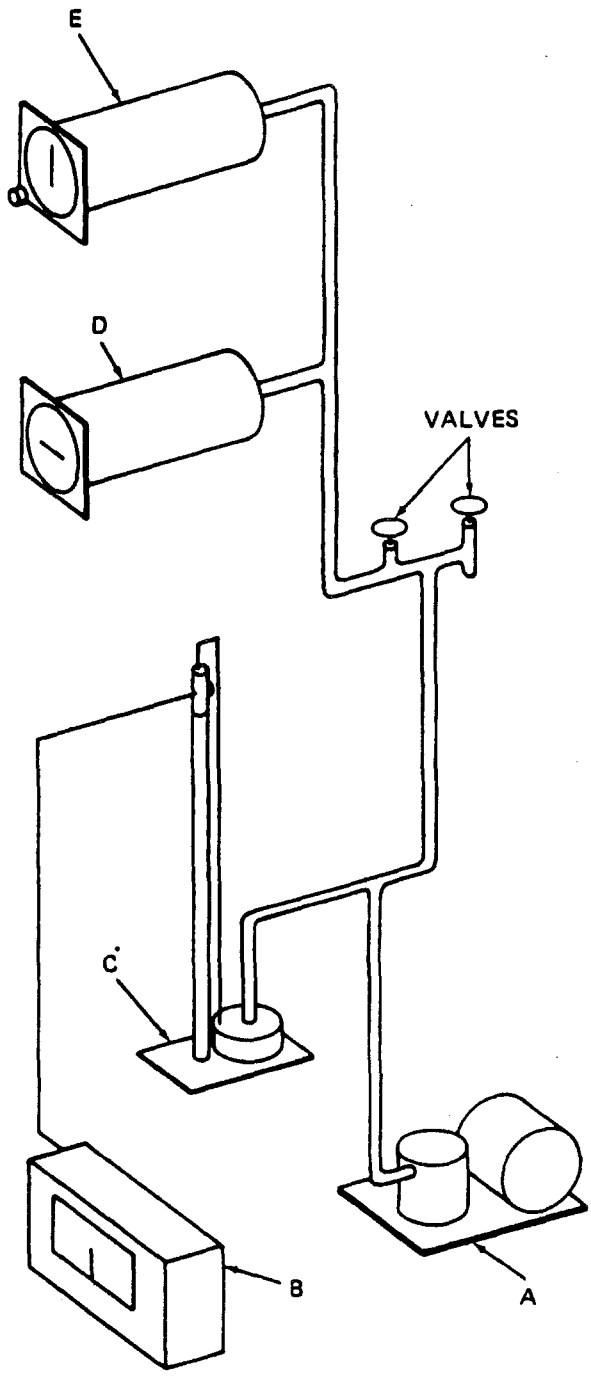
B. Place altimeter in normal operating position and rotate 100-foot pointer to 0-foot indication. Record reading. Rotate altimeter so pointer is at 3, 6, and 9 o'clock indications. Record readings.

C. The difference between pointer indications with indicator in normal operating position and in 3, 6, and 9 o'clock positions, as described above, shall not exceed ±20 feet.

8. CASE LEAK TEST

A. Install a 1/8-27 ANPT male pipe fitting properly lubricated in altimeter static port and connect to vacuum source. Test setup is as shown in figure 701.

B. Depressurize altimeter 18,000 feet and allow to stabilize for one minute. Then clamp hose off and time for 1 minute, using stop watch. Maximum loss must not exceed 100 feet.



9. SCALE ERROR TEST

NOTE: For a period of not less than twelve hours prior to this test, the altimeter shall not have been exposed to pressures other than those pressures specified in paragraph 4 test conditions.

A. Room Temperature Test

(1) Set the zero setting system for standard sea level pressure (29.92 and/or 1013 on the barometric dial). Be sure the pointers indicate within ±20 feet of the altitude pressure that exists at the location of the tests. Record reading at ambient or atmospheric pressure.

(2) Place the altimeter in an altitude chamber connected to a barometer and a source of vacuum and pressure. Without changing the zero setting, subject the altimeter to pressures specified in table 703. The reduction in pressure shall be made at a rate not in excess of 20,000 feet per minute to within approximately 2,000 feet of each test point. From this point, the test point shall be approached at a rate compatible with the test equipment.

A VACUUM PUMP
B PHOTO SCANNER
C BAROMETER
D RATE OF CLIMB INDICATOR
E ALTIMETER (UNDER TEST)

Typical Test Configuration
Figure 701

(3) The altimeter shall remain at the pressure specified for each test point in table 703 for at least one minute (but not over ten minutes) and be lightly tapped or vibrated before a test reading is taken: scale errors shall not exceed the tolerances specified.

(4) Movement of pointer shall be observed for any irregular motion. From 0 to 20,000 feet or 30,000 feet, depending on the series altimeter under test, the pointer shall not jitter more than 20 feet.

Table 703. Altitude Versus Pressure (As Per NACA Report 1235)

EQUIVALENT PRESSURE			ALTITUDE	TOLERANCE (FEET)	
MM	IN	Mb	FEET	ROOM TEMP.	LOW TEMP.
787.87	31.0185	1050.41	-1,000**	± 20	--
760.00	29.9213	1013.25	0**	20	±40
746.37	29.3846	995.08	500**	20	--
732.93	28.8557	977.17	1,000	20	--
719.70	28.3345	959.52	1,500	25	--
706.65	27.8210	942.13	2,000	30	--
681.14	26.8167	908.12	3,000	30	--
656.38	25.8418	875.10	4,000**	35	--

320.96	12.6363	427.91	22,000	140	--
282.04	11.1035	376.01	25,000**	155	155
225.69	8.8854	300.89	30,000**	180	--

*Allowable change from room temperature scale error test indication

**See paragraph 14A.

B. Low Temperature Test

(1) Condition altimeter to -30°C temperature for 3 hours.

(2) At this temperature, repeat test described in paragraph A, steps 1 through 4. The change in reading from room temperature reading obtained at any test point shall be within tolerance specified in table 703.

(3) If difference between room temperature and cold readings exceeds tolerances, temperature compensation is necessary. Refer to paragraph 15.E.(4).

10. HYSTERESIS TEST

A. Not more than 15 minutes after altimeter has been first subjected to pressure corresponding to the upper limit of its scale and while it is still at this pressure, the hysteresis test shall be started. Increase pressure at a rate equal to decreasing the altitude approximately (but not exceeding) 20,000 feet per minute until pressure indicates altitude is within 3,000 feet of first test altitude shown in table 704. Then approach test point at approximately 3,000 f.p.m. and stop. Within 10 seconds after the pressure has stabilized, the altimeter shall read within 100 feet of the scale error recorded for the first test point. The altimeter shall read within the tolerance specified in table 704.

B. After taking the first reading, increase pressure further at the rate of 3,000 feet per minute until pressure corresponding to second test point altitude is reached. Hold altimeter at this pressure at least one minute, but not longer than ten minutes before taking test reading. The altimeter reading shall not differ from the recorded reading in the scale error test by more than the tolerance specified in table 704.

Table 704. Hysteresis

TEST POINT	ALTITUDE (FEET)	EQUIVALENT ATMOSPHERIC PRESSURE		TOLERANCE (±FEET)
		INCHES OF Hg	MILLIBARS	
*First	14,000	17.5773	595.24	75
*Second	10,000	20.5769	696.81	75
**First	25,000	11.1035	376.01	75
**Second	20,000	13.7501	465.63	75

*101720 Series Altimeters
**101730 Series Altimeters

11. AFTER EFFECT TEST

A. This test procedure shall be performed not more than five minutes after the completion of hysteresis test.

B. With the return of pointers to original ambient readings the error shall not exceed ±30 feet after correction for any change to ambient atmospheric pressure has been made.

12. FRICTION TEST

A. The indicator shall be subjected to a steady rate of decrease in pressure equivalent to about 750 f.p.m. in accordance with table 705. At each test point two readings are to be recorded; the first before tapping instrument and the second after tapping instrument. Friction error shall not exceed tolerance listed in table 705.

Table 705. Friction Error

ALTITUDE (FEET)	TOLERANCE (FEET)
1,000	70
2,000	70
3,000	70
5,000	70
10,000	80
15,000	90
20,000	100
25,000*	120
30,000*	140

*101730 Series Only

13. LIGHTING TEST

The altimeter lighting circuit shall be tested as follows. Connect to five volts dc and see that both lamps light and that all connections are secure. Refer to figure 801, schematic diagram, lighting system, for any necessary information concerning internal circuitry. Replace defective parts.

14. CALIBRATION

A. General

Calibration consists of testing to determine indication errors and preparing calibration charts to denote deviations in pointer readings from dial markings. Adjustments are made when deviations exceed tolerances. Primary calibration check points are shown by double asterisks in the altitude column of table 703.

B. Calibration Procedures

NOTE: Subassembly tests required for calibration are denoted in the adjust procedures when they differ from unit testing techniques.

(1) Perform tests outlined in paragraphs 5, 7 and 9 in this section.

(2) Record test results and denote out-of-tolerance conditions.

(3) Perform required adjustments, then retest to assure in-tolerance conditions.

15. ADJUSTMENTS

A. General

Adjustments are performed with the internal mechanism removed from the case and bezel assemblies but with dial and 100-foot pointer installed. The unit should be mounted in a stand suitable for the test being performed.

B. Preparation for Adjustments (see figures 1101 and 1102).

(1) Position barometric setting gear on stud of transmission mechanism assembly (figure 1101-36 or -44) with setting gear stop centered over bottom of nearest screw on pivot plate assembly (38) or transmission housing assembly (45).

(2) Position barometric dial assembly (30) on shoulder of transmission mechanism assembly with 29.92 (1013) marking in line with center at 3 o'clock position dial plate screw hole.

(3) Position altimeter scale dial (31) over barometric dial with zero marking at 12 o'clock position (top) and secure with two dial screws (32).

(4) With pointers balanced and needles at zero dial indication, sequentially install 10,000-foot pointer (30), 1,000-foot pointer (29) and 100-foot pointer (28) on handstaff pinion (figure 1102, 9).

(5) Observe point-of-mesh between sector gear of rocking shaft assembly (-17) and intermediate gear assembly (9). Point-of-mesh should be approximately 4 teeth from end of gear arc at sea level pressure to permit maximum operating range.

C. Zero Setting Adjustment

Using tweezers, carefully position pointer(s) in line with zero dial marking.

D. Position Error Adjustments (see figure 1102).

(1) This procedure shall be conducted with mechanism subject to vibration.

(2) Position calibration fixture with mechanism assembly in a normal operating position with zero indication of dial at 12 o'clock. Rotate mechanism within fixture until pointer indicates zero.

(3) Lightly tap mechanism and record reading. Rotate calibration fixture clockwise until pointer is at 6 o'clock position. Tap mechanism and record reading. The difference between readings shall not exceed ±20 feet.

(4) If a plus error is indicated, loosen screw (28) and position rocking shaft counterweight (25) away from rocking shaft (34); then tighten screw. If a minus error is indicated, position counterweight toward rocking shaft; then tighten screw. Balance mechanism to specified tolerance.

(5) Rotate calibration fixture until pointer is at 9 o'clock position; then lightly tap mechanism and record reading. Rotate calibration fixture clockwise until pointer is at 3 o'clock position. Tap mechanism and record reading. The difference between readings shall not exceed ±20 feet.

(6) If a plus error is indicated, loosen screw (30) and position crown gear counterweight (29) toward rocking shaft. If a minus error is indicated, position counterweight away from rocking shaft. Tighten screw when mechanism is balanced within specified tolerance.

NOTE: Remove excessive pointer oscillation, if necessary, by increasing tension of sector gear hairspring (33).

(7) Position the calibration fixture with mechanism dial facing up. With pointer at zero lightly tap mechanism to remove friction. If pointer indicates an error, loosen screw (16) and rotate eccentric jewel bushing assembly (15) to correct for excessive endshake of rocking shaft assembly. Tighten nut when mechanism is balanced within specified tolerance.

(8) Repeat procedures as outlined in paragraph D. to insure that mechanism is balanced to within specified tolerance.

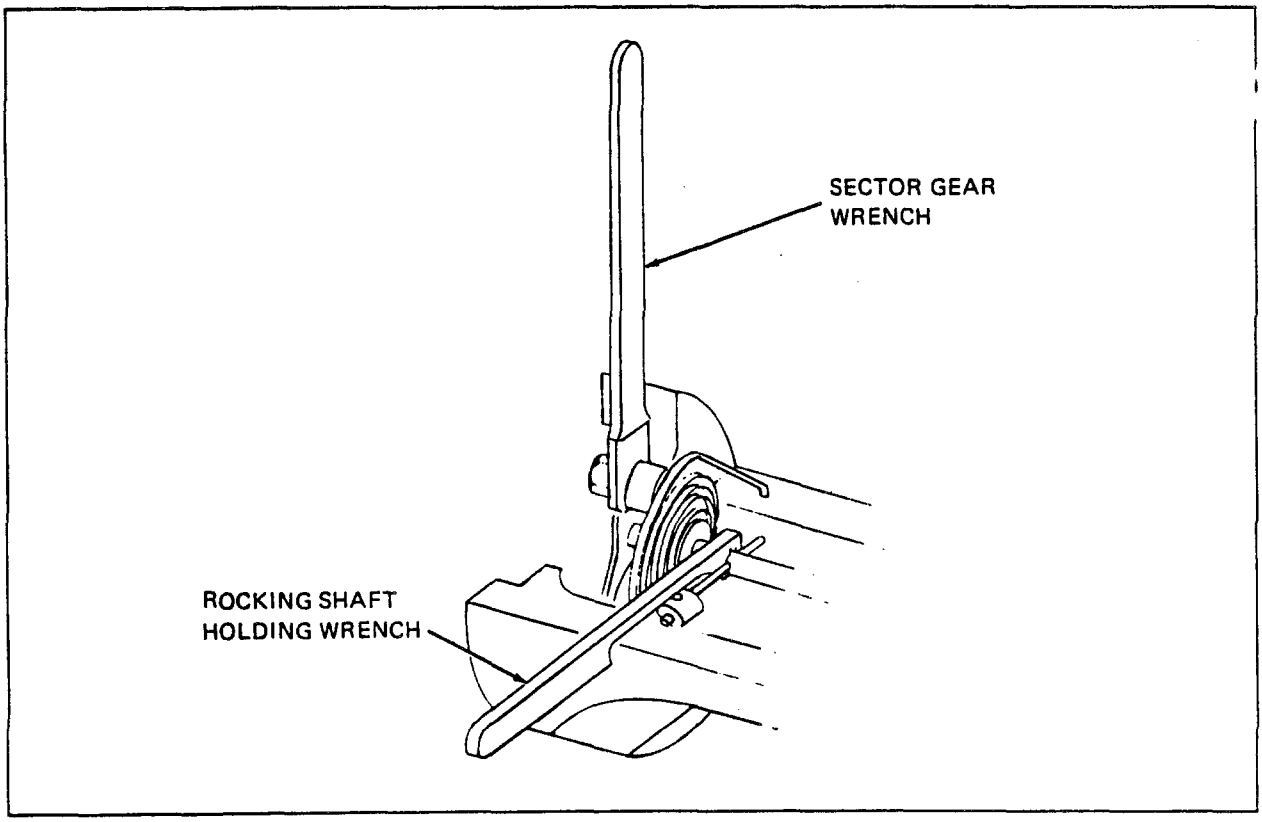
E. Scale Error Adjustments

(1) Scale errors at room temperature which exceed tolerance, require adjustments in calibration. Out of tolerance readings between room temperature and cold tests normally require compensation.

(2) Sector Gear Adjustment (see figures 702 and 1102).

(a) The point-of-mesh between the sector pinion and the sector gear of the rocking shaft assembly (figure 1102-17) should be approximately four teeth from the end of the sector gear arc at sea level pressure.

(b) Adjust position of sector gear by holding rocking shaft with rocking shaft holding wrench and turn sector gear with sector gear wrench as required (see figure 702).



(3) Aneroid and thermometal assembly (figure 1102-35) adjustment notes.

(a) A change in position of either the aneroid assembly or the link arm causes a change in response to the mechanism, and a corresponding change in the rate of pointer rotation between zero and maximum altitude.

(b) The location of the aneroid assembly affects speed of rotation at high altitudes more than at low altitudes. Moving the aneroid toward the rocking shaft assembly increases mechanism reaction speed. Conversely, moving the aneroid assembly toward its support plate slows mechanism response.

(c) Changing link arm settings will cause a change in the speed of rotation throughout the entire range.

(d) Speed of rotation and amount of change can be controlled by use of both adjustments.

Rocking Shaft Sector Gear Adjustment
Figure 702

(4) Temperature Compensation

(a) Altimeters that are not correctly temperature compensated react to lowering temperatures by showing increased or decreased altitude readings on the indicator, depending on length of thermometal on aneroid.

(b) As its temperature is lowered, the metal in the aneroid stiffens. Since the "load" of ambient atmospheric pressure remains constant, the aneroid expands and the transmission gear and the rocking shaft react, causing the indication to change.

(c) To provide a means of temperature compensation, two thermometals (figure 1102, 40) are provided. One "U" shaped pre-adjusted thermometal is on the arm. This one compensates for high range (10,000 to 35,000 ft.). No adjustment should ever be made on this thermometal. One flat thermometal is mounted on the aneroid with means of adjustment provided. This one compensates for low range (0 to 10,000 ft.).

(d) If the mechanism indicates a plus reading when transferred from room temperature to cold temperature, the mechanism is undercompensated. To correct this, loosen two screws (41) in clamp bar (39) and turn screw (42) clockwise. One turn of the screw will cause an approximate 50-foot change in indication. Tighten two screws (41).

(e) If the mechanism indicates a minus reading when transferred from room temperature to cold temperature, the mechanism is overcompensated. To correct this, loosen two screws (41) in clamp bar (39) and turn screw (42) counterclockwise. Then apply force to the thermometal (40) at the link and push toward screw (42). Tighten two screws (41).

(f) The link pin hole in the thermometal should remain as close as possible on the center of the support button on the aneroid assembly (47) at all times. If it is moved off center because of compensation adjustments, screws (45 and 46) in clamp bar (43) should be loosened and the thermometal should be moved in either direction to position the link pin hole in the thermometal at the approximate center of the support button. Tighten screws in clamp bar.

(5) Link Arm and Aneroid Assembly Adjustments (see figure 1102).

(a) Mount the mechanism in the calibration stand so the aneroid is on the same side as "0". Then, place calibration stand with mounted mechanism in a pressure chamber with "0" at top. Set the pointer of the test mechanism, using the knob on the calibration stand, so it will read "0" when the master altimeter or barometer reads "0".

NOTE: If the pointers of the master altimeter are below "0", close the chamber and reduce the pressure until the pointers indicate "0". Note the position of the pointers of these test instruments. If not on "0", open the chamber to atmosphere, and turn the adjustment knob to reposition pointers. Repeat procedure until a reading of "0" is obtained. If the pointers of the master altimeter are above "0", the procedure is similar to that described above, except that the instruments must be subjected to pressure.

(b) Close the pressure chamber and slowly decrease the pressure until the master altimeter or barometer indicates a reading equivalent to 10,000 feet and check the calibration point shown in table 706.

(c) If the mechanism shows a plus or minus indication, remove it and adjust the effective length of the link arm assembly. If the mechanism reading is too fast, move the adjustment arm out of the rocking shaft. If the mechanism readings are too slow, move the adjusting arm into the rocking shaft.

(d) When the altimeter mechanism reading agrees with that of the master altimeter or barometer at zero and 10,000 feet, increase pressure to ambient pressure. Remove mechanism and stand from chamber and recheck balance. When balanced within limits, place mechanism in chamber and recheck error at zero and 10,000 feet. If the error is within tolerance specified, reduce pressure and record errors at the check points of 15,000 and 20,000 feet.

NOTE: Do not use slide on aneroid for calibration purposes unless absolutely necessary, since any change will affect compensation.

(e) If the mechanism indicates a reading at 25,000 feet above or below that of the master altimeter (after applying the allowed tolerance), remove the mechanism from chamber and adjust the position of the aneroid assembly in the mechanism body. If the mechanism reading is too high, move the aneroid away from rocking shaft.

(f) Further adjustment of the mechanism should be made as required until all readings come within the tolerances specified.

(g) Check the backward movement of the mechanism by slowly increasing the pressure until the altimeter indicates a maximum of -1,000 feet.

(h) Repeat scale error test and position error tests to assure altimeter is within tolerance.

Table 706. Link Arm and Aneroid Assembly Calibration Points

ALTITUDE (FEET)	ADJUSTMENT
0	Link Arm
1,000	Link Arm
4,000	Link Arm
8,000	Link Arm
14,000	Aneroid Assembly
20,000	Aneroid Assembly
25,000	Aneroid Assembly
30,000	Aneroid Assembly

TROUBLESHOOTING

1. GENERAL

This section presents general troubleshooting information to assist in locating and correcting any malfunctions in the altimeter.

2. TROUBLESHOOTING PROCEDURES

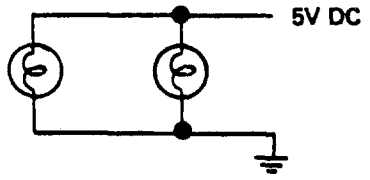
A. General

Troubleshooting should begin after testing and careful observation of the altimeter's performance. Pointer readings and response times should be recorded for reference. Based on the altimeter's performance, attempt to isolate the malfunctions to altimeter mechanism or case assembly. Malfunctions, probable causes and remedies are listed in table 801.

B. Mechanical Malfunctions

When the malfunction has been isolated, perform a visual inspection of the moving mechanical parts. Typical malfunctions would be gears loose on shafts, binding gears on shafts, defective bearing surfaces, foreign matter, loose pointers, broken or damaged gear teeth.

C. Lighting Malfunctions



When the malfunction is determined to be the lighting system, first check electrical circuit for loose solder connections, cold solder joints, defective wiring. Refer to schematic diagram (figure 801).

Table 801. Troubleshooting Chart

TROUBLE	PROBABLE CAUSE	REMEDY
Pointer deviates beyond tolerance at constant altitude	Case leaks due to defective or improperly positioned bezel gasket	Reposition or replace gasket
	Defective packing around adjusting knob stem	Replace packing
	Loose static port	Replace or restake port
Pointer not on zero dial indication at ground level	Pointer slipped on shaft	Adjust pointer to zero (per TESTING section, para. 15)

Table 801. Troubleshooting Chart (Continued)

TROUBLE	PROBABLE CAUSE	REMEDY
Pointer fails to return to zero from altitude	Improper balance	Balance (per TESTING section para. 15)
	Binding gears	Inspect and free gears
	Improper gear mesh	Adjust (per TESTING section para. 15)
Pointer travel is erratic	Binding or slipping gears, foreign matter in gear teeth or bearing surfaces	Clean gears and bearing surfaces, adjust end clearances or replace defective parts
Lamps do not light	Lamp burned out. Corroded or defective solder connection at PC board. Defective wiring.	Replace lamp. Remove corrosion or resolder connection. Replace wiring.

Schematic Diagram, Lighting System
Figure 801

STORAGE INSTRUCTIONS

1. GENERAL

This section gives storage instructions and time limits.

2. STORAGE PROCEDURES

Requirements for packaging and storage conform to U.S. Government Specification (MIL-P-116D). A summary of the most often used methods of packing for storage is included.

A. Packaging for Storage

(1) Packaging for immediate use (for mechanical and physical protection only). The instrument shall be enclosed in wrappings, boxes, bags, cartons or other containers as applicable to the extent necessary to provide protection from hazards of contamination and physical damage encountered in general handling, shelf storage and issue. When bags, wraps or other flexible barriers are used, cushioning shall be applied as required to protect the enclosing media. If packed in a rigid container, this container shall be supported by rigid or resilient dunnage as necessary to prevent free movement. Materials in contact with the surface of the instrument shall be as dry as practicable and in accordance with commercial practice.

(2) Packaging for Short Term Storage. (Up to six months.)

The instrument shall be wrapped or padded so that all projections or sharp edges that might damage a barrier bag are covered sufficiently to avoid damage to the bag. The usual method for accomplishing this is to pack the instrument in dunnage in a corrugated paper carton. The corners of the carton should be crushed so that they will not damage the barrier bag.

The dunnage should be either Kim-Pak, rubberized hair, or fiber.

The barrier bag shall be constructed of one or more plies in any manner which will insure water vapor proofness and flexibility. The material must have low water characteristics for use in packaging. Lapping or butting of the component materials of the finished product is

not permitted except in the direction perpendicular to the rolling direction. The lapped areas shall be plainly externally flagged to prevent use of that portion of the roll when a lap or butt weld is made on the finished product, the foil component (if present) or cloth backing (if present). The barrier bag is usually made of canvas covered foil and can be heat sealed airtight.

SPECIAL TOOLS, FIXTURES AND EQUIPMENT

1. GENERAL

This section lists special tools and test equipment necessary for the disassembly, assembly, calibration, and testing of the Series 101720 and 101730 altimeters.

2. SPECIAL TOOLS, FIXTURES, AND EQUIPMENT (refer to table 1001)

Table 1001. Special Tools, Fixtures, and Equipment

EQUIPMENT	USE
Barometer - Haas Type A-1 w/PRS Photo Scanner	Case Leak Test Scale Error Test Position Error Test
Vacuum Pump - Welch Model 1400B and 1402	Case Leak Test Scale Error Test
Rate of Climb Indicator Aerosonic P/N RC-60-MS-10-3 (0-60000 FPM)	Scale Error Test
Stop Watch, 1/10 second	Case Leak Test
Chamber, Vacuum, Aerosonic P/N 9210052	Calibration
Sector Gear Wrench, Aerosonic P/N 9200072	Calibration
Rocking Shaft Holding Wrench, Aerosonic P/N 9200073	Calibration
Screw, hex hd, brass P/N 201806	Calibration
Work Plate, Aerosonic P/N T21306	Intermediate Gear Assembly Hairspring Adjustment

3. PHYSICAL AND ENVIRONMENTAL CONDITIONS

A. Physical Conditions

It is recommended that overhaul be performed on a laminar flow - clean bench, or equal. If this is not available, overhaul is possible in a high grade instrument shop.

B. Environmental Conditions

Work shall be performed at a temperature of 25° C (77°F) and a relative humidity of 85%. Correct for any change from an atmospheric pressure of 29.92 in.Hg or 1013.3 Mb.

ILLUSTRATED PARTS LIST

1. GENERAL

This section lists and illustrates all repairable parts in the altimeters. Parts which are not broken down are not considered repairable. Order parts directly from Aerosonic Corporation or from the appropriate vendor.

2. INTRODUCTION

A. How to Use Parts List.

The Illustrated Parts Breakdown consists of two parts: Numerical Index and Group Assembly Parts List. Use these as follows:

If the part number is known.....Find number in the numerical index and use the cross referenced figure and item number to find the part in the Group Assembly Parts List.

If the part number is not known. Find the appropriate illustration and look up item number in tabular list in Group Assembly Parts List.

B. Numerical Index

The Numerical Index is an alphanumerical list of all parts contained in the Group Assembly Parts List. The list is arranged in the following order by digits from left to right:

First digit:
Letters A - Z
Numerals 0 - 9

Second and succeeding digits:
Space (blank column)
Diagonal (slant)/
Point (period).
Dash (-)
Letters A - Z
Numerals 0 - 9

The Numerical Index is cross-referenced to the Group Assembly Parts List by figure and item number:

C. Group Assembly Parts List:

(1) Part Number Column. The Group Assembly Parts List is a complete, illustrated breakdown of the unit arranged in approximate disassembly order. The part number column contains the part number assigned by the actual manufacturer of the part. Government Standard numbers are used where applicable.

(2) Nomenclature Column. The nomenclature column contains the nomenclature of the item and any amplifying information. The relationship of assemblies, subassemblies, and detail parts is shown by an indentation system. Detail parts are listed beneath their assembly and indented one space to the right. Attaching parts have the same indent as the assembly they attach and are identified by the phrase (ATTACHING PARTS) at the beginning of the listing and the symbol ---*--- at the end of the listing. If a part is a vendor item, a five-digit vendor number preceded by a "V" is given in parentheses. Parts without vendor codes are Aerosonic parts or standard parts.

(3) Units per Assembly Column. The units per assembly column lists the quantity of parts used at that particular location in the assembly.

D. Vendor Codes

Vendor Codes are five-digit numbers identifying manufacturers as listed in Federal Cataloging Handbook H4-1. The following list is a key to these codes:

V11824 MacLeod Instrument Corp.
1212 N. Hercules Ave.
Clearwater, Fla.

3. NUMERICAL INDEX

NUMERICAL INDEX

AEROSONIC CORPORATION
Clearwater, Florida

March 31, 1976

Difference Data Sheet
for Pressure Altimeter
Part No's. 101730-01398
and -01399
Using Manual for 101720 and 101730 Series

1. GENERAL

The 101730-01398 and -01399 Altimeters are identical to the 101730-01356 and -01357 respectively in the above noted manual except for the dial and 10,000 ft. pointer.

2. PART DIFFERENCES

The following part numbers apply to the noted altimeters, in place of those showin in the illustrated parts list:

Ref.	Part No.	Name
1101-30	21684	Pointer, 10,000 Ft.
-31	21053	Dial

3. TEST REQUIREMENTS

Ref: Pg. 702, para. 5 Barometric Scale Error
After completing the requirements in para's A, B and C, repeat the tests at settings of 29.50 and 30.50 on the baro dial.

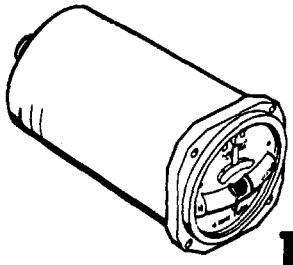
AEROSONIC CORPORATION
Clearwater, Florida

March 31, 1976

Difference Data Sheet
for Pressure Altimeter
Part No. 101730-01419
Using Manual for 101720 and 101730 Series

1.0 GENERAL

The 101730-01419 Altimeter is identical to the 101730-01387 in all respects, except for testing. Additional Testing is required for Barometric Scale error.



2.0 TEST REQUIREMENTS

Ref: Pg 702, para 5. Barometric Scale Error

After completing the requirements in para's A, B and C, repeat the tests at settings of 29.50 and 30.50 on the baro dial.

R. C. A. Publication No. 1200

SERVICE MANUAL

MODEL RCA 30
TURN AND BANK INDICATOR

R.C.Allen Aircraft Instrument Division

GRAND RAPIDS, MICHIGAN 49503

DESCRIPTION

R. C. Allen Turn and Slip (Turn and Bank) Indicator is a gasket sealed, direct-reading, lateral attitude reference component. The indicator meets the requirements of F.A.A. Specification TSO-C3a and SAE Standard AS395B. The basic instrument is DC operated, inverting 28 VDC or 14 VDC into AC voltage for use by a hysteresis type synchronous motor. Variations include dial color, dial presentation, calibration, connectors, and power failure indication. The coding system is defined in Figure 4.

LEADING PARTICULARS

Operating Voltage	12-14 Vdc or 26-30 Vdc	Overall Length	Code "A" . . 5.860 in. Max. Code "B" . . 5.860 in. Max.
Max Current Drain	260 ma at 28 Vdc or 320 ma at 14 Vdc	Required Mounting Hole Size	2-9/32 in. Max.
Connector Type	Code "A" . . AN3102-10SL-3P (Integral with inverter assembly) Code "B" . . (2) NC terminal lugs	Operating Temperature Range	-54°C (-65.2°F) to 71°C (160°F)

OVERHAUL INSTRUCTIONS

1. Special Tools.

   No special tools are required for the performance of the procedures contained in this publication.

2. Disassembly

   a. Disassembly is accomplished in the same order as the index numbers assigned to the exploded view illustrations (See figures 2 and 3) and as outlined in the following steps.

   Note

   It is recommended that soldered assemblies shall not be unsoldered unless absolutely necessary to replace defective parts.

   b. Unsolder and remove lead wires where necessary for disassembly purposes. When lead wires are to be removed, first make careful note of lead lengths, color coding, and wire routing.

   c. Removal of pivot lock nut (63, figure 2) may be expedited by the use of suitable spanner wrenches.

   d. Maintain all parts of damping assembly (40, 41, figure 2) as a matched set. Do not intermix any of these parts with like parts of other indicators.

   Note

   It is recommended that rotor and bearing assembly (13-22, figure 3)

not be disassembled unless necessary to replace damaged or worn parts. This assembly is dynamically balanced and disassembly of any part will require rebalancing of the assembly.

3. Clean the parts of the indicator in accordance with the following procedure:

CAUTION

The indicator is a precision instrument requiring careful handling. It is recommended that cleaning operations be conducted in an area not subject to excessive temperature variations or high humidity. Following cleaning operations, reassemble parts whenever practicable. When cleaned parts must be set aside pending reassembly, place them under a dust cover or in a clean, covered container.

a. Wash all attaching parts such as screws, nuts, and washers using perchloroethylene, Federal Specification O-P-191. Dry parts with a vacuum source.

b. Do not attempt to clean bearings (49, figure 2, 14 and 19, figure 3). These bearings are double-shielded and should be replaced at each overhaul period.

c. All solder connections which have been subjected to unsoldering operations should be thoroughly cleaned and brushed with perchloroethylene, Federal Specification O-P-191 to remove all traces of solder flux.

d. Polish the glass face of cover assembly (4, figure 2) using a clean, lint-free cloth.

e. Castings, housings, and other like parts may be cleaned with a soft cloth or brush dipped in perchloroethylene, Federal Specification O-P-191 and dried with a vacuum source.

4. Perform the inspection procedure in accordance with the following steps:

a. Visually

Visually inspect all covers, housings, and cast parts for cracks, marred mating surfaces, deformed openings, and stripped threads on studs and tapped holes.

b. Examine all surfaces subjected to friction for excessive wear and surface damage.

c. Inspect all ball bearings for roughness and binding.

d. Check all screws, nuts, washers, and retaining rings for acceptable re-usability.

e. Examine all springs for uniform spacing between loops and overall symmetry. Spring (21, figure 2) shall have a free length of 0.329 inch. Spring (62) shall have a free length of 0.599 inch.

f. Inspect the connector part of inverter assembly (16) for stripped threads and bent pins.

g. Inspect cover assembly (11) for evidences of irreparable damage and punctures.

h. Check the glass (4, figure 2) for scratches, chips, cracks, and discoloration.

i. Check dial (26) and pointer assembly (29) for chipped paint.

j. Inspect the inclinometer (25) for general condition. The enclosed glass ball should roll smoothly from side to side as the inclinometer is tilted and should show no evidence of sticking at the ends.

5. Repair or Replacement

Generally, repair should be limited to the replacement of parts found to be defective during the performance of the inspection procedure outlined in the preceding procedure outlined in the preceding paragraph and as follows.

a. Slightly bent pins on the connector of the inverter assembly (16, figure 2) may be straightened.

b. If any part of the rotor and bearing assembly (13 through 22, figure 3) is found to be defective, and the defective part is replaced, the assembly must be dynamically balanced on its bearings.

c. Replace all deformed attaching parts.

d. Replace gasket (51, figure 2) at each overhaul period.

6. Lubrication. None required.

7. Reassembly (See figures 2 and 3)

Generally, reassembly is accomplished in the reverse order of the index numbers assigned to the exploded view illustrations (figure 2 and 3) and as follows:

a. In the event that motor assembly (13 through 22, figure 3) has been disassembled, it will be necessary to dynamically balance the assembly on its bearings to within a maximum unbalance of 100 micro-ounce inch.

Note

Motor shall be run-in for a minimum of forty-eight hours after preload check.

Micronamic Type EU-2 (or equivalent) balancing machine manufactured by Micro Balancing, Inc, Long Island City, N. Y., is suitable for accomplishing the preceding check.

Preload of motor assembly (13 through 22) shall be adjusted to 0.0012 to 0.0018 inch of movement when a reversing two pound load is applied.

Recheck preload after run-in period and adjust, if required, to original deflection tolerance with screw (17, figure 3). Motor speed shall not be less than 7800 rpm with power from inverter. Secure screw (17) with screw (16) after completing deflection adjustment.

Hand form spring assemblies (23) approximately as shown in figure 3.

Assemble bearings (49, figure 2) and motor and gimbal assembly (78) into frame (72). Adjust trunnion to obtain 0.002 inch endplay as checked with a feeler gauge.

Set spring assembly (23, figure 3) contacts to produce a pressure of 20 ± 5 grams against trunnions (48, figure 2).

Position arm assembly (65) on trunnion (71) as shown in figure 2 and lock in place using bushing (63). Lock remaining trunnion with nut (46).

Note

Bushing (63) and nut (46) securing trunnions (71) and (48) shall be tightened to a torque reading of between five and six inch pounds.

b. When reassembled, apply durable, dull black paint to heads of screws (18, 20, and 33, figure 2).

c. Wire (23) shall be twisted a minimum of two turns at rear of retainer (24).

d. Use one spacer (28) as required for thickness to maintain minimum endplay without binding of pointer pivot (30).

Note

Prior to reassembly of cover assembly (11, figure 2) perform Test Procedures, as outlined in paragraph 8.

8. TEST PROCEDURE

Note

The test procedures described in steps a. thru l. following shall be conducted both prior to and following the reassembly of the cover assembly (11, figure 2).

a. Mount the indicator to be tested on a balancing and leveling fixture capable of simulating the roll characteristics of an aircraft.

b. With the indicator in a leveled position, zero the pointer by adjustment of screw (66). Rotate the instrument 180 degrees about its longitudinal axis. Readjust pointer to zero by noting amount of error and removing half with adjusting screw (66) and half by adjusting trimmer screw (77, figure 2).

c. Rotate the indicator 90 degrees about its longitudinal axis both clockwise and counterclockwise. Check the pointer for zeroing in these positions. If adjustment is required, move trimmer nuts (73) on stud (74).

d. Displace the indicator to the right about its roll axis until the glass ball in the inclinometer (25, figure 2) is just short of its limit. The angle of displacement shall be ± 2 degrees. Repeat the test, displacing the indicator to the left. The same angle shall be noted.

e. Place the indicator in a leveled position with the lower mounting holes in a horizontal plane. Note that the ball rests at the zero mark within 1/32 inch.

Note

Be sure the lower mounting holes, rather than bottom flat of bezel (5), are used as level reference.

f. Displace the indicator about its roll axis so that the ball is at rest at either end of the inclinometer. Not less than one-half of the ball shall be visible when the ball is viewed from a position 12 inches directly in front of the zero mark.

Note

Unless otherwise specified on individual procedural steps following, the indicator shall be gently tapped before a test reading is recorded.

g. The indicator shall be placed in any stationary position. The deviation of the pointer from zero shall not exceed 0.010 inch.

h. Apply voltage stamped on the nameplate of the indicator to the pins of the connector on the inverter assembly (16, figure 2), noting polarity as indicated in figure 1. Repeat step g.

i. With the indicator mounted in a normal leveled flight position and the operating voltage applied to the connector, check the rpm of the gyro rotor using a stroboscopic tachometer. The recommended speed for optimum indicator performance is between 7800 and 8000 rpm.

j. By means of a calibrated milliammeter and a voltmeter, connected between the d-c power source and the indicator, check the current drain of the gyro motor. With 28 V dc applied, the current drain shall not exceed 260 milliamperes; with 12 - 14 V dc applied, the current drain shall not exceed 320 milliamperes.

k. With operating voltage stamped on the nameplate applied, the indicator shall be mounted in a normal position on the turn table and rotated about its vertical axis at a speed suffi-

l. With operating voltage applied, the indicator shall be mounted in a normal position on a turn table and turned on its vertical axis at the rates specified in table I. The comparative pointer deflection shall be as indicated for the listed rates of turning.

Table I. Pointer Sensitivity Data

Rate of Turning (Degrees)	Pointer Tip Deflection (in.)	
	4 Min. Turn	2 Min. Turn
36	1/16 ± 1/64	1/32 ± 1/64
90	5/32 ± 1/64	5/64 ± 1/64
180	5/16 ± 1/64	5/32 ± 1/64
360	5/8 ± 1/16	5/16 ± 1/64
1080	1.0 ± 1/8	11/16 ± 1/16

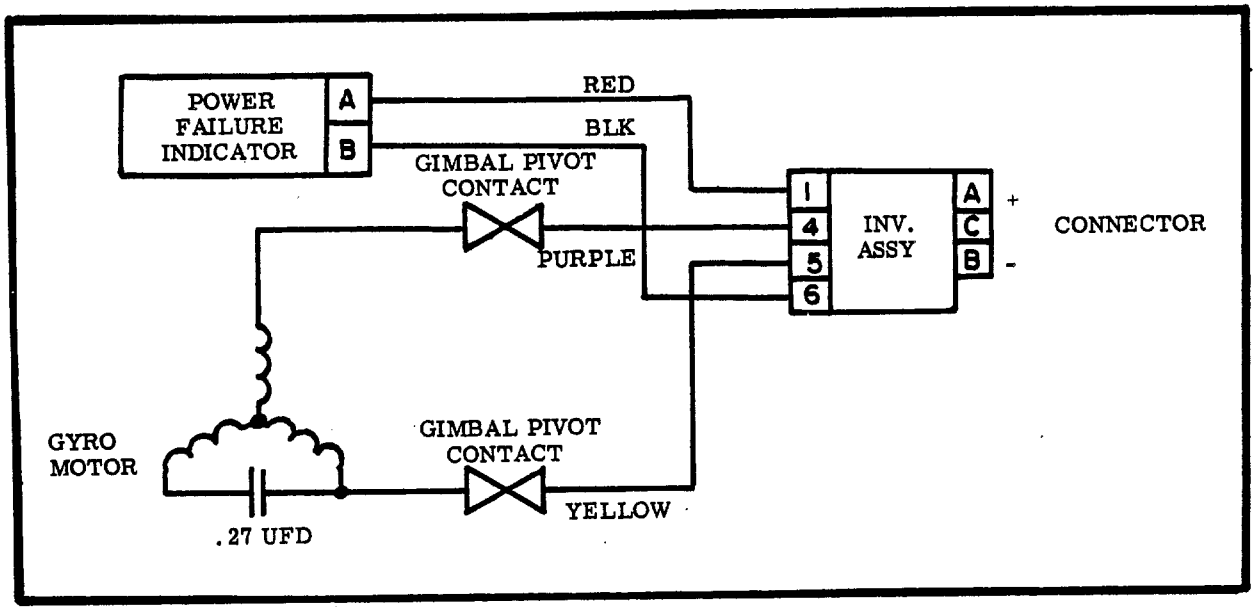


FIGURE 1 WIRING DIAGRAM

9. TROUBLE SHOOTING

Table II outlines troubles, their probable causes, and remedies which may be encountered during the performance of the procedures contained in this publication.

TROUBLE	PROBABLE CAUSE	REMEDY
INDICATOR DRAWS EXCESSIVE CURRENT	Excessive friction in bearings (19 and 14, figure 3).	Replace defective bearings.
	Excessive preloading on bearings (19 and 14).	Adjust motor preload to remove trouble.
BALL REACTION SLUGGISH OR ERRATIC	Defective inclinometer (25, figure 2).	Replace inclinometer.
APPARENT STATIC UNBALANCE OF GIMBAL	Improper adjustment of nuts (73 and 77, figure 2).	Adjust nuts as required.
INDICATING POINTER APPEARS UNSTABLE	Loose linkage to pointer assembly (29, figure 2).	Disassemble, replace faulty parts, and reassemble.
	Insufficient damping.	Disassemble, and check arm assembly (40) and cylinder assembly (41) for cleanliness. Reassemble, checking adjustment.
INDICATING POINTER SLUGGISH (LOW SENSITIVITY)	Insufficient gyro rotor speed. due to excessive friction or preload of rotor bearings.	Replace and/or adjust preload of motor bearings.
	Excessive friction in gimbal bearings (49).	Inspect and replace bearings if required.
	Excessive friction in damper.	Disassemble, and check arm assembly (40) and cylinder assembly (41) for cleanliness. Reassemble, checking adjustment.
NOISY OR VIBRATING ROTOR AND BEARING ASSEMBLY	Improperly balanced assembly.	Rebalance (Step a. under 7.)

1400 SERIES

EA-1400 SERIES

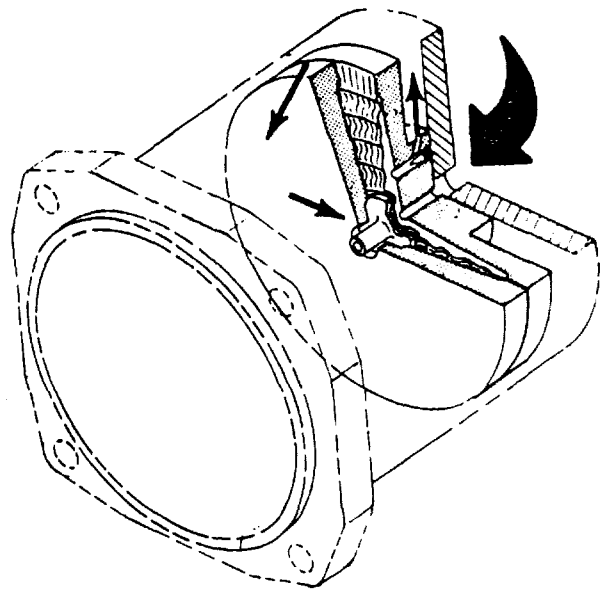
VERTICAL SPEED INDICATOR

DESCRIPTION

The EA-1400 series vertical speed indicators covered by these instructions are manufactured by Edo-Aire Wichita Division, Wichita, Kansas. All instruments in the series conform to the requirements of FAA TSO-C8b.

The indicators are direct-acting sensitive differential pressure instruments that measure the rate of change in atmospheric pressure. A metal diaphragm in a sealed capsule is deflected by changing pressure through a calibrated orifice. Diaphragm deflection moves the pointer through a system of levers driving a conventional sector gear, pinion, and hairspring movement. One of the levers is of thermostatic bimetal, to compensate for temperature changes.

The instrument has only four moving parts and nine points of moving contact. The sector gear shaft and pinion shaft run in jewel bearings.



INSTALLATION DATA

Mounting	Bezel, 4 holes for No. 6 screws on 3.50 inch diameter circle; No. 6-32 spring nuts optional.
Case dimensions	Bezel, 3.25 inches square; panel aperture, 3.12 inches minimum diameter; total depth, 1.90 inches.
Weight	0.5 pound
Static pressure connection	Port, 1/8 inch NPT.

HOW IT WORKS

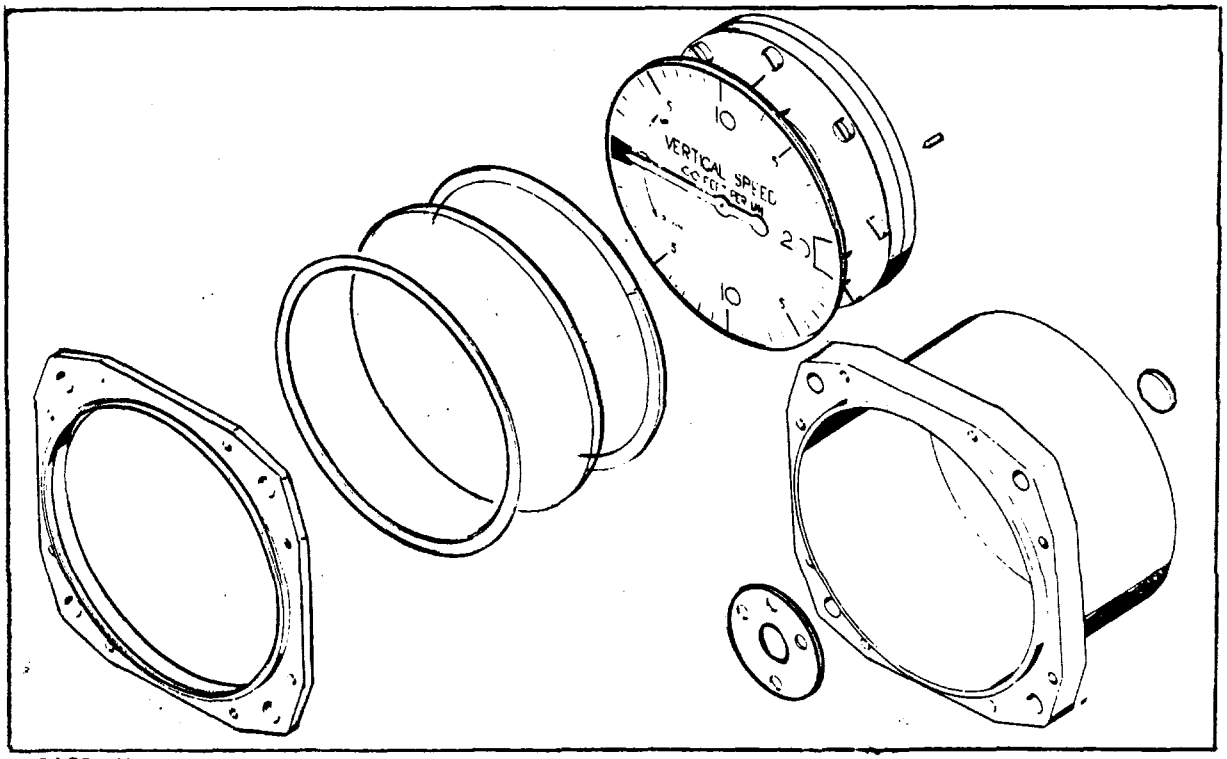
The sketch at right illustrates the function of the diaphragm capsule in sensing vertical speed.

Changes in atmospheric pressure cause air flow through the back of the capsule and the calibrated bleed orifice to the inside of the case until pressure on each side of the diaphragm is equalized. On the ground or in level flight, these changes are slow and cause no deflection of the diaphragm. Climbing or descending, however, produces rates of change in barometric pressure that are greater than the orifice will accommodate. These rapid changes cause pressure differentials on either side of the diaphragm that are proportional to the difference between the rate of barometric pressure change and the rate of equalization through the bleed orifice. The unequal pressures deflect the diaphragm and drive the pointer.

SERVICE INSTRUCTIONS

Unless there is obvious damage to the case or pointer, usually only cleaning and recalibration will be required to restore full serviceability. Disassemble the instrument no farther than necessary to clean and inspect it.

NOTE



Rocking shafts must be kept with their diaphragm capsules, since the diaphragm lever is selected for proper temperature compensation.

The case should be opened only in an air-conditioned, controlled-access area with temperature not exceeding 80 F and humidity not over 50 percent at 80 F. Personnel should wear lintfree caps and smocks and the disassembled instruments should be protected from contamination by polyethylene bags.

DISASSEMBLY

To remove the case, unscrew the eight screws holding the case to the bezel. Remove the bezel, gaskets, and glass. Then unscrew the three screws, which secure the frame to the case. A slight twist of the assembly in the case may be required to break loose the mechanism from the gasket and case.

The disassembly sequence is essentially as shown in the exploded view illustration. Unless it is necessary to reset a bearing or replace parts, do not separate the rocking shaft and adjusting plate assembly from the post and plate assembly or loosen the hex-head screws that

CASE AND MECHANISM ; SHOWN INITIALLY DISASSEMBLED

fasten the plates together. The position of the adjusting plate on the lower plate is set so that the angle which the rocking shaft makes to a line running through the sector pivot and the handstaff is 15 degrees.

DO NOT DISASSEMBLE THE DIAPHRAGM CAPSULE:

Alignment of the diaphragm is critical and even a slight shift in its position will destroy the linearity of its response.

The purple Glyptol used to secure the attaching screws in the movement assembly and the zero adjust screw in the diaphragm capsule may be released by heating the screws with a miniature soldering iron.

Discard the gaskets, filter, and needle valve.

CLEANING

Clean the case, dial glass, dial, and pointer with a soft cloth moistened in soap and water; soap is preferable to synthetic detergents, some of which will attack polycarbonate plastics. Do not use solvents, particularly chlorinated hydrocarbons, that may attack the plastic case and the lacquer finish on the dial and pointer.

Ultrasonic cleaning using standard cleaning solvents is preferred for the movement. The rocking shaft always should be removed before cleaning the movement and should require cleaning only if the instrument has been grossly contaminated. The movement also may be cleaned in an instrument cleaning machine using alkaline cleaning solutions such as L & R No Fome and L & R Rinsing Solution.

Do not attempt to clean the diaphragm capsule with solvents. If the orifices become clogged, they may be cleaned with suction.

INSPECTION

Visually inspect the case, diaphragm capsule, and movement for damage, particularly damage to the case and backplate that would permit air leaks. Check the hairspring for kinks and sagging; the coils must not touch the plate when the movement is held with the pointer shaft horizontal.

Inspect the pinion gear and sector gear for damaged teeth. There must be no perceptible runout in the pinion shaft or sector gear shaft. Check the mating surfaces of the sector gear actuating lever and the rocking shaft lever for corrosion.

REPAIR

Replacement of defective parts or assemblies is the only authorized repair.

SPECIAL TOOLS AND TEST EQUIPMENT

No special tools are required to service the vertical speed indicators. Test equipment listed in the following table is recommended for calibration and functional test.

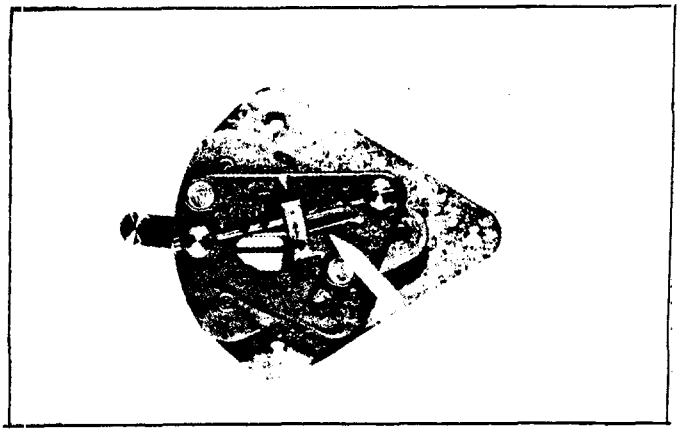
NUMBER	NOMENCLATURE
A338A	Manometer, Meriam Instrument Co., Cleveland, Ohio
16-11-2	Altitude Chamber, Ideal-Aerosmith, Cheyenne, Wyoming
--	Certified sensitive altimeter
89C001-001	Calibrating Screwdriver Edo-Aire

DIAPHRAGM CAPSULE REPLACEMENT

To properly compensate for variations in high and low temperature behavior of the diaphragm, three different diaphragm levers are used, one of stainless steel and two of thermostatic bimetal. The correct lever to use with a replacement capsule must be determined after the instrument is assembled, by placing the uncased instrument in an oven at 160 F for one hour and observing the pointer shift. For the test, install the 2100839 stainless steel lever. If the shift is 100 fpm or less, use the 4000 (2101337) bimetal lever. If the shift is 100 to 200 fpm use the 6100 (2101103) bimetal lever. Make sure the bimetal levers are installed so the identification marks etched on the surface will face the zero-adjust screw in the diaphragm hub.

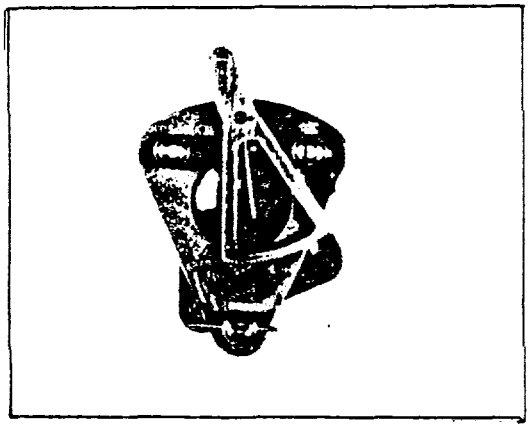
REASSEMBLY

Reassembly is generally in the reverse order of disassembly, except final installation of the case, which is delayed until after calibration. As the instrument is reassembled and adjusted, place a drop of Purple Glyptol or equivalent on each screw.



After calibration, seal calibrating hole with RTV 732 or equivalent.

ORIENTATION



On reassembly, align the backplate, diaphragm capsule, movement, and dial as follows: use the casting number, EA13677, on the diaphragm capsule as a reference. Align the backplate with the capsule so that both the casting number and the backplate placards read alike. Install the movement with the sector gear counterweight over the casting number. Install the dial so the up scale is over the sector gear counterweight.

ROCKING SHAFT INSTALLATION

Before reassembling the movement, make sure the diaphragm lever and rocking shaft lever are perpendicular to each other and that the etched characters on the diaphragm lever face away from the rocking shaft lever. If the diaphragm lever requires adjustment, loosen the clamp screw only enough to permit rotation of the clamp. Take care to avoid transverse movement of the clamp on the rocking shaft, which may alter the temperature compensation and amplification rate. Secure the clamp screw with Purple Glyptol. Set the pivot post adjusting screw that was backed off to remove the rocking shaft so that the shaft moves freely under its own weight and end play does not exceed 0.00025 inch.

BIMETAL DIAPHRAGM LEVER - CHARACTERS ETCHED ON ITS SURFACE IDENTIFY THE SIDE OF THE BI-METAL LEVER THAT MUST COANTACT THE DIAPHRAGM ADJUSTING SCREW FOR CORRECT TEMPERATURE COM-PENSATION.

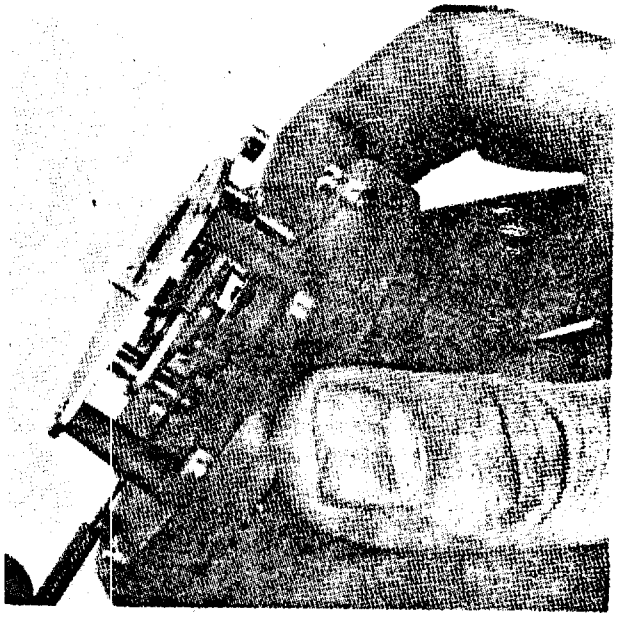
SECTOR GEAR ENGAGEMENT - THE SECTOR GEAR IS SET AGAINST THE RIGHT-HAND SUPPORT POST AND ENGAGED WITH THE HAIRSPRING FULLY RELAXED.

PINION AND SECTOR GEAR INSTALLATION

Install the pinion gear and spring assembly with the free end of the spring to the left. Before engaging the gears, secure the loose end of the hairspring to the support post. Engage the sector gear and pinion from the left, with the rocking shaft lever in the right hand space between the gear web and the center pin, and the sector gear against the right hand post. If necessary, press the sector gear and pinion shaft bearings in or out to bring end play to 0.001 inch or less with no binding.

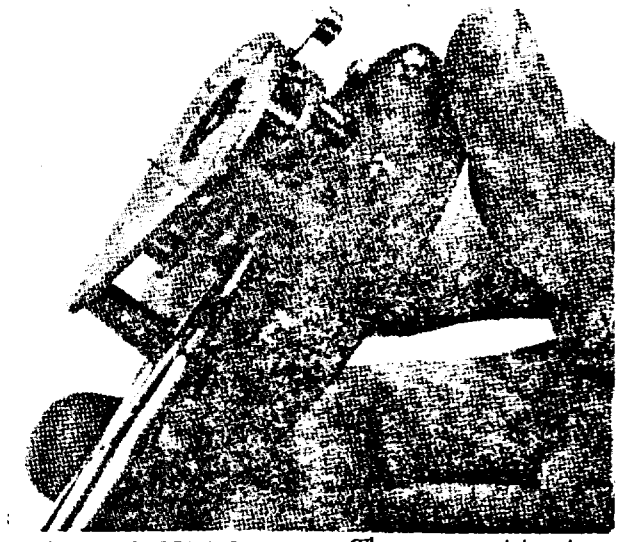
TEMPERATURE COMPENSATION ADJUSTMENT

If the adjusting plate and rocking shaft assembly was separated from the plate and post assembly or new assemblies were installed, adjust the temperature compensation as follows:



1. Loosen the two hex-head screws on the adjusting plate sufficiently to permit relative motion between the two plates.

2. Insert the shank of a No. 52 drill (0.0635-in. diameter) between the two rocking shaft support posts and the diaphragm adjusting screw.



3. Move the adjusting plate until the drill is a snug fit, then tighten the hex-head screws.

ZERO ADJUSTMENT

Adjust the zero setting by turning the diaphragm adjusting screw until the sector gear is centered (14 teeth on each side of the pinion). Secure the adjusting screw with Purple Glyptol.

CHECKING TEMPERATURE COMPENSATION *A No. 52 drill shank should be a snug fit between the diaphragm adjusting screw and the rocking shaft support posts.*

ADJUSTING ZERO POSITION *The zero position is set by turning the diaphragm adjusting screw to center the sector gear with respect to the pinion.*

TEST PROCEDURES

Four tests are required for acceptance of the instrument: a position test, performed without the case installed; calibration and natural lag tests, performed with the case and backplate installed; and a leak test, performed after the assembly is complete and the case sealed. The natural lag test may be performed during calibration if desired.

POSITION TEST

When the instrument is held in various positions other than normal; i.e., inverted, dial face up, dial face down, etc., the pointer must not shift more than 50 fpm. Probable causes for failure are pointer unbalance, particularly if it was refinished, and excessive end play in the rocking shaft or pinion. The pointer may be rebalanced by removing or adding paint to the underside.

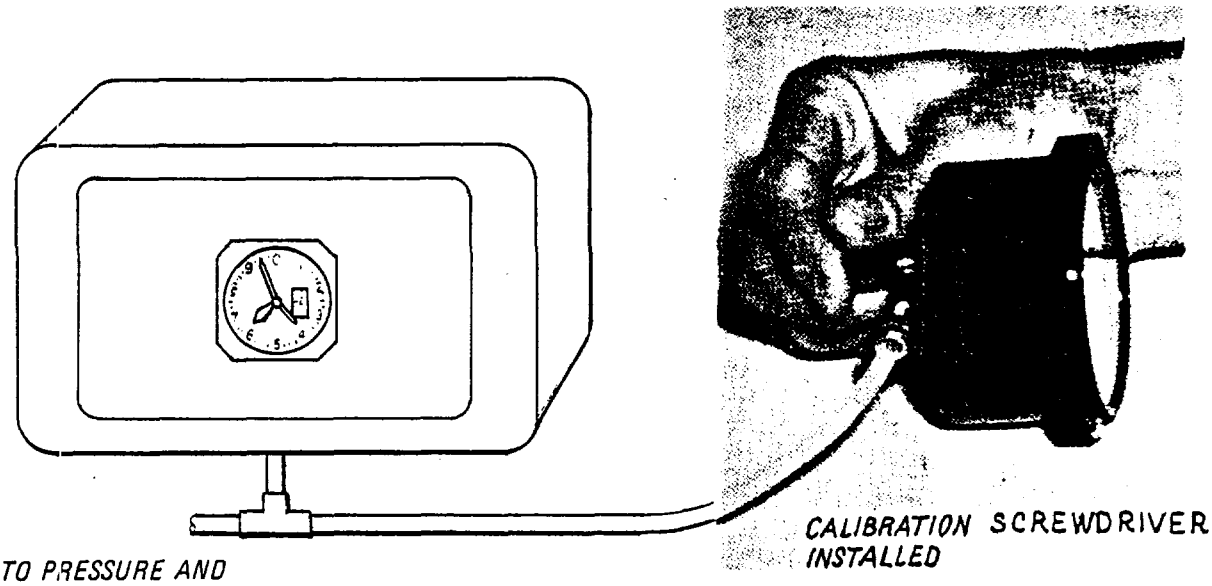
CALIBRATION

Calibration of the vertical speed indicator requires a special backplate with a screwdriver in a sealed gland to adjust the needle valve, a case, and a certified sensitive altimeter in an altitude chamber.

To calibrate the indicator, assemble and install calibrating screwdriver. All connections must be airtight. Connect the backplate port to the altitude chamber and a suitable source of vacuum and air pressure. Connections should be made with polyethylene tubing such as Imperial-Eastman Poly-Flow.

NOTE

To prevent leaks past the O-rings in the calibrating screwdriver, keep them lubricated with high-vacuum silicone grease.



All indicators of the series are calibrated by adjusting the needle valve on the back of the capsule to obtain the vertical speed rates shown in the table on page 6. Set each rate by the instrument under test, start the stopwatch as each starting altitude is crossed, and stop it as each ending altitude is crossed. The elapsed times in the table correspond to the rate tolerances specified in FAA TSO-C8b.

If desired, the altimeter may be read after one minute at each rate and altitude and the tolerance in feet per minute given in the table may be used.

To increase the indicated rate of change, for a low indication, close the valve; to decrease the indicated rate, open the valve. During calibration check that the pointer moves smoothly and responds without undue delay. Jerky pointer motion indicates binding in the movement, usually due to dirt, or a defective hairspring.

After the final assembly and leak test, the calibration should be rechecked at several rates and altitudes, to make sure that the needle valve setting was not disturbed.

CALIBRATION SETUP

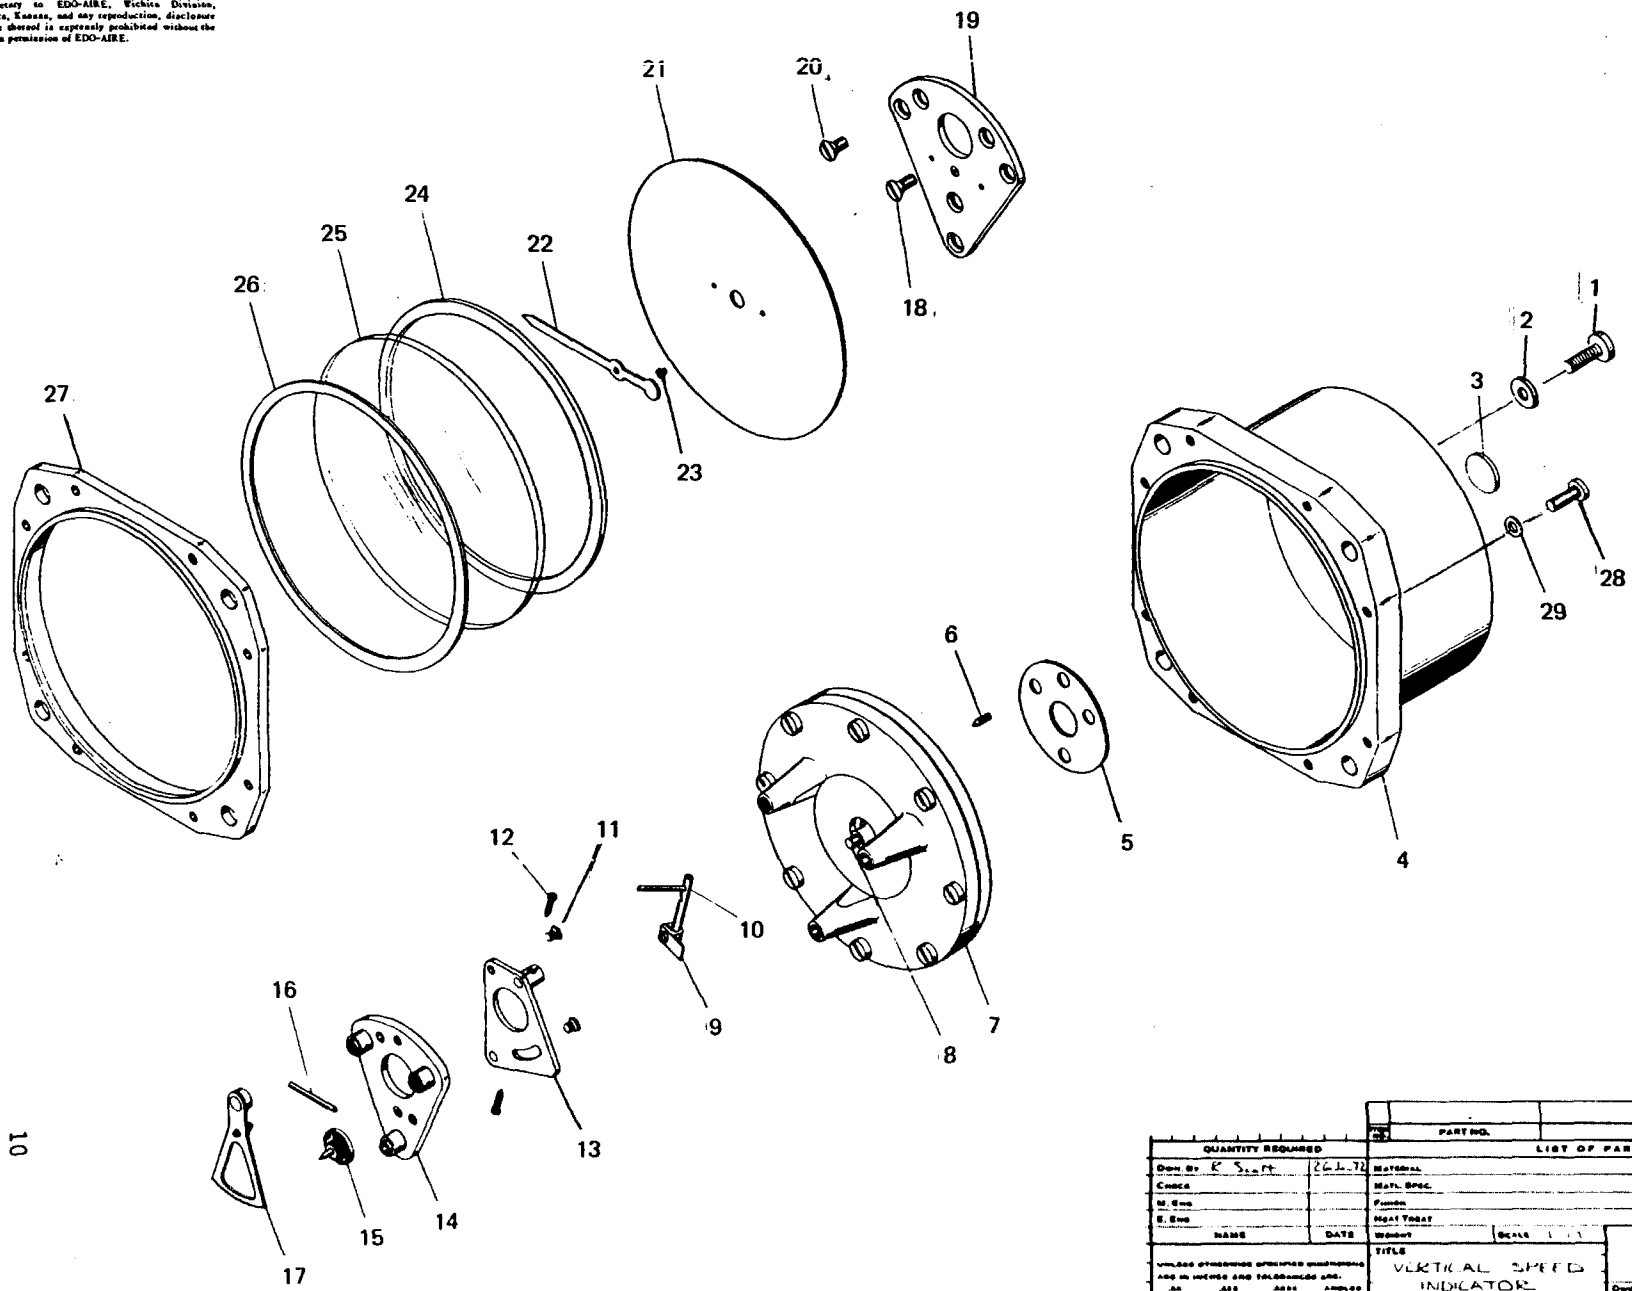
4000	28000	32000	32000	28000	54.0/66.0	400

NATURAL LAG TEST

With the indicator connected to an altitude chamber, or to a properly calibrated manometer, set up a climb or descent of 1800 fpm for 2000 fpm and 3000 fpm instruments or 2000 fpm for 4000 fpm and 6000 fpm instruments. Suddenly reduce the rate to 0 and simultaneously start the stop watch. The indicator should pass through 200 fpm in 3 to 15 seconds. Repeat in the opposite direction. Lag greater than 15 seconds probably is due to over-tight pivot bearings; sector gear, pinion, or rocking shaft pivot misalignment; or reduced amplification.

To increase amplification and decrease lag, adjust the diaphragm lever toward the sector gear by backing off the rocking shaft pivot nearest the *sector gear and tightening the opposite pivot.*



LEAK TEST

The leak test is performed with the instrument completely assembled and the case drive screws installed and sealed, by applying first vacuum and then pressure through the static port and observing pressure changes on a manometer. *Both pressure and vacuum must be applied slowly,* to avoid exceeding full-scale deflection of the indicator.

Apply 15 in. Hg vacuum and hold for 1 minute, then apply 10 in. Hg pressure and hold for one minute. Pressure change indicated by the manometer must not exceed 0.05 in. Hg for either test. If necessary to locate a leak, the instrument may be submerged briefly in mineral spirits or water.

Test Specifications	7 & 8
Parts Section	9, 10 & 11

DESCRIPTION

The Garwin G991 series vertical speed indicator is a temperature compensated instrument. It has a range of from 0 to 3,000 feet per minute, with a zero adjustment screw at the bottom of the case to zero the pointer for diaphragm seasoning. Mounting nuts will not be supplied with the instrument unless the dash number includes an "N". (Example, G991-01N.) The dial color is indicated by the second dash group in the part number as follows:

G-991-01-1A	Dull black with white context
G-991-01-1B	Dull black with yellow fluorescent context (ANLIA)
G-991-01-1C	Dull black with pale green phosphorescent context (14102A)

The weight of the G991 is 17 ounces and the operational and functional test specifications are in accord with CAA-TS0C8a.

Section I

Disassembly, Inspection, Cleaning, Repair and Reassembly.

1. General
   The following special tools and fixtures are required in connection with the work described in this section:
   (1) Vibrating Stand
   (2) Jewelers Stake Set
   (3) Inclined Manometer Test Stand
   (4) Test Dial
   (5) Connection Nipple
   (6) Rocking Shaft Adjustment Tool

2. Disassembly
   A. Removal of Mechanism from the Case
      1. Remove the fitting from the rear of the case.
      2. With a sharp tool, remove the lead seal covering one of the flange mounting screws at the back of the flange.
      3. Remove the eight flange mounting screws, being careful to prevent the flange and glass from dropping off.
      4. Lift the flange, paper gasket, glass and sealing gasket from the case.
      5. Remove the spring and two washers from the adjustment stem.
      6. Remove the hand with a suitable hand remover.
      7. Pry up the retaining ring with a small screw driver and remove it.

8. Remove the two dial screws and lift out the dial.
9. Remove the spring bar.
10. To remove the snap ring, insert a pointed object in the hole of the snap ring and pull away from the case and up.
11. Loosen the three screws at the rear of the case. Set rear of the case on a bench and apply pressure with hand. This will break seal on the diaphragm connector and case and allow mechanism to drop free of the case.

CAUTION

Be extremely careful not to break the pointer staff when removing the mechanism.

12. Remove the loosened screws and with the hand held over the case opening, turn the case upside down. The mechanism will drop out into the hand.

B. Disassembly of the Mechanism Body Assembly
1. Remove the capillary and screw assembly and washer.
2. Remove two screws attaching the diaphragm plate.
3. Remove the shims, if present.
4. Remove the diaphragm assembly from the body. Use extreme care not to injure the diaphragm.
5. Remove the taper pin from the rocking shaft.
6. Back out the pivot screw from the body and lift the shaft assembly out of the mechanism body. Be very careful not to bend either the long or short rocking shaft levers.
7. Remove the taper pin from the sector spring assembly.
8. Remove the three screws from the plate and body.
9. Lift the plate from the body.
10. Lift the sector assembly from the body.
11. Lift the pinion handstaff from the body.
12. Further disassembly of the mechanism body assembly should not be necessary unless the stationary pivot is to be repaired.
13. To remove and replace the stationary pivot, proceed as follows:
    (a) Place the mechanism body casting over a bar with a hole in its end, held in a vise. Drive the pivot out with a pin punch.
    (b) Replace the new pivot to the same depth as the one removed.
14. Instrument is now disassembled for close inspection of pivots, jewels, springs, bushing and diaphragm. Replace necessary parts.

C. Removal of Adjusting Mechanism from Case.

1. It should not be necessary to remove the adjusting mechanism from the case unless a part is broken or unless there is a leak at this point which will affect the operation of the instrument. The case is tested for leaks in accordance with the test specifications in the rear of this manual.
2. A seal washer on the adjustment acts as a seal. If a case leak is indicated here, the washer must be replaced with a new one which has been soaked in castor oil. (AN-JJJ-0316.)
   (a) Push the snap ring from the recess in the adjustment stem pinion. Push out the pin which is found under the snap ring. This will permit removal of the adjustment stem.
   (b) Replace the seal and re-install the adjustment stem and pinion in the case in reverse procedure of disassembly.

3. Inspection, Cleaning, and Repair

A. General - Examine all pinions, sector teeth and pivots for wear and corrosion; jewel setting assemblies for loose or broken jewels; bearing holes and bushings for ovalization (out-of-round); and all other parts for wear or corrosion.

1. Replace all worn and broken or badly corroded parts with new parts. Replace worn bushings. Replace broken or crushed jewels.

B. Cleaning

1. All mechanism parts may be cleaned by washing them in KLEEN-ZIT and rinsing in RINZIT, using any good commercial cleaning machine. Dry with clean, dry, warm air. The diaphragms should not be immersed in the cleaning fluid as some moisture may be retained on the inside. After drying, a light blast of air from a compressed air source may be used to blow off loose dust that may have fallen on the parts. Hairsprings should not be subjected to air from an air hose. All parts, after cleaning, should be placed in a dust-proof container until ready for reassembly.
2. Pinion and sector teeth should be brushed carefully with a No. 3 watchmaker brush, rubbed occasionally across a piece of chalk. The parts being brushed should not come in contact with the hands so should be held in a piece of watchmaker paper which will prevent contact of the parts being brushed with the bare skin and also keep the brush clean. This paper will soil very rapidly so a clean piece should be used with each part.

(a) While brushing, the pinion is best held in a pair of tweezers which has holes drilled in the pointed ends to receive the pivots.

(b) The sector must be handled carefully to avoid bending it. Brushing should always be done in one direction, the same direction which the tool took when cutting the teeth, so any burrs which may have been left by the cutting operation will not be forced into the spaces between the teeth.

3. Pivots are best cleaned by pressing them first into the end grain of a piece of pithwood and twirling the wood between the fingers, then pressing them into a piece of pithwood and twirling them again. If the pivots are corroded, they should be cleaned with a very fine abrasive such as Levigated Alumina mixed with water placed on the end of a pegwood stick and held against the pivot as it turns in a jeweler's lathe. This process should be followed by a thorough washing in clean Naptha and cleaning with pithwood.
4. Jeweled bearings, bushings and bearing holes are best cleaned by twirling the sharpened end of a piece of pegwood in each hole. The stick should be kept clean by sharpening and the twirling process continued until discoloration of the stick is no longer apparent.
5. The capillary assembly cleaning may be accomplished by immersing the entire unit in Naptha and drying with a blast of air. Inspect the assembly to see that the passages through it are unrestricted by holding it up to the light and looking through it with a magnifier.

4. Reassembly

A. Mechanism Plate and Bridge Assembly

1. Replace the sector assembly in the lower jewel.

(a) Secure the hairspring to its post with the tapered pin, adjusting it to have a tension equal to 1 1/2 to 1 3/4 turns. The hairspring should lie in a single plane and the convolutions should not touch.

(b) Adjust the end play of the sector assembly so it is just detectable. Test the mesh of the pinion and handstaff pinion to see if they run freely. See that the sector tracks correctly; that it is not bent or twisted. The teeth end of the sector should ride approximately midway in the handstaff pinion.

2. Replace the handstaff.
   (a) When the plate is screwed on tight, the handstaff must have .001 to .002 end play.

B. Mechanism Body Assembly
1. Replace the rocking shaft assembly. Adjust the pivot so the end play is just detectable. The shaft should move freely when the instrument is moved from side to side.
2. Secure the hairspring to its post with the tapered pin. This should place from 3/4 to 7/8 of a turn tension on the hairspring. The hairspring should lie in a single plane and the convolutions should not touch.

C. Diaphragm Assembly
1. Insert the diaphragm assembly into the body.
2. Insert shims as required under the diaphragm plate and secure them with the two screws.
3. To check the pointer swing, a test pointer should be installed and a check made to see that the pointer swing up and down is equal. This adjustment is made by turning the hexagonal adjusting screw on the diaphragm plate. Turning this screw in or out will equalize the pointer swing.

D. Static Balancing of the Mechanism.
1. Set the pointer on zero with the mechanism in the normal vertical position. Turn the mechanism 180 degrees and check the pointer position. The error shall not exceed fifty feet. To correct an "up" error, move the balance weight on the long rocking shaft lever toward the rocking shaft. To correct a "down" error, move the weight away from the rocking shaft.

5. Calibration
A. Ranging and Zero Adjustment Setting
1. Place a test dial and pointer on the mechanism.
2. Place the hand on zero and check its travel by turning the zero adjustment wheel. The pointer should move through equal angles in both directions. If it does not, remove it and replace it in approximately the center of travel. Continue this procedure until the hand shows an equal deflection on either side of zero. Make certain the hand is perfectly balanced by checking it on a balancing fixture. The pointer deflection should exceed 400 feet minimum on both sides of zero.

3. A check should be made using an inclined manometer to see if the "up" readings are in agreement with the "down" readings.

NOTE

If the reading at 1,000 feet up is equal to the 1,000 feet down reading, all other check points will be satisfactory.

(a) After this check is made, all other calibration will be accomplished after the instrument is assembled, from the outside of the case.

4. Calibration of the assembled instrument is accomplished by installation of the capillary screw assembly, cut to the proper length. Shortening the capillary will result in lower scale reading. In case the readings are too low it will be necessary to install a new capillary screw assembly, and shortening as necessary to secure the proper calibration.
   (a) When shortening the capillary, it is necessary that the following procedure be followed:
      (1) File a small amount from the tube on the capillary.
      (2) Insert a pivot broach in the tube to clean out the hole closed by the filing process.
      (3) Clean the capillary and assemble it for a calibration check.
      (4) Repeat the process until the correct calibration is reached.

B. Case Leak Check
   1. Assemble the instrument in the case and install the dial, pointer, gaskets, glass, and bezel.
   2. Insert a solid plug in the port hole in the rear of the case.
   3. Place in a chamber and apply vacuum to 15,000 feet. The case leak must not be more than 50 feet per minute.
   4. To locate a case leak, connect the instrument to a pressure source, and apply pressure at a rate not to exceed 1,500 feet per minute. Pressurize the case to a maximum of 5 P.S.I. (10.2 in. Hq.) Immerse instrument in water and check for air bubbles.
      (a) A gasket seal compound should be used on the gasket when assembling the mechanism in the case. This assumes an airtight seal at the port.
      (b) A leak at the stem adjustment will necessitate gasket replacement.

6. Tests
   A. Use all the following tests and specifications and tolerances for the functional test.

Table I

Altitude Test Interval Feet	Rate, feet per minute	25°C Ft. /Min. Scale Error	Tolerance Seconds Min.	Max.
2000/3000	500	35	112.1	129.0

OVERHAUL WITH PARTS

D22061 10 012

INTRODUCTION

A. General

This manual contains overhaul instructions and the illustrated parts list for Pressure Altimeter D22061 10 012, manufactured by Kollsman Instrument Corporation, Elmhurst 73, New York, U.S.A.

B. Additional Models

Similar models are included on difference data sheets. Overhaul procedures for these additional models are the same as those recommended in this basic manual except for the specific differences noted by the applicable difference data sheets. Difference data sheets will be issued as available, and should be attached to and filed with, this basic manual.

O. DESCRIPTION AND OPERATION

A. Purpose

The altimeter indicates height of an aircraft above a reference point, assuming normal conditions of temperature and pressure prevail.

B. Description

(1) General

The altimeter is a pressure actuated indicator enclosed in an airtight case. It contains dual, pressure sensing aneroids connected to two rocking shafts, each having its own bimetallic compensator.

(2) Leading Particulars

OPERATING ALTITUDE:	-1000 to 50,000 feet
BAROMETRIC SCALE:	28.1 to 31.0 inches Hg
TEMPERATURE RANGE:	-30°C (-22°F) +25°C (+77°F)
WEIGHT:	Approximately 23 ounces
MOUNTING:	Flange mounted

C. Operation

(1) When installed in the aircraft, static air pressure from the pitot-static system is admitted into the airtight case. The aneroid diaphragms respond to changes in pressure by expanding and contracting. Movement of both aneroid diaphragms is transferred to two similar rocking shaft assemblies whose sectors are mutually engaged with a main pinion. Movement from this point is traced to an intermediate pinion, a handstaff pinion, and to the large pointer. Movement of the intermediate pointer and pointer disk is provided by a gear train located in the top plate assembly which is actuated by a pinion on the handstaff assembly. Backlash is eliminated by a hairspring attached to an intermediate shaft assembly in the main gear train below the top plate assembly.

(2) Two pointers and a disk with pointer extension, rotate concentrically about a single, uniformly scaled dial providing an indication in foot altitude. The larger pointer indicates in hundreds of feet, making one revolution for each 1000 foot altitude change. The intermediate pointer indicates in thousands of feet and the disk with pointer extension indicates tens of thousands of feet.

(3) Since meteorological conditions cause variations from the standard atmosphere to which the altimeter has been calibrated, an adjustment is provided to correct for these variations. An external knob,

located in the lower left corner of the mounting flange, engages the barometric dial assembly and the mechanism plate which supports the entire mechanism. Adjustment is made so that the barometric dial assembly will correspond to the actual barometric condition of the area in which the aircraft is located, or will be located upon landing. In this manner, mechanism and pointers will be repositioned to indicate a corrected reading for variations in local barometric pressure.

1. DISASSEMBLY

A. General

Disassembly procedures generally follow the order of index numbers assigned to the exploded views. Disassemble only to the extent necessary for cleaning, adjustment, repair or replacement.

B. Removing Mechanism Assembly From Case (See figure 1101)

(1) Remove knob (3) and knob locknut (4). Remove screws (6 through 8) and lockwashers (9).

(2) With altimeter in dial up position, lift off mounting flange (5), locking plate (11) and items (13 through 15). Carefully remove pointer assemblies (16 and 17) and dial pointer assembly (18).

(3) Remove centering ring (19) and dial screws (21). Lift off center dial (20), spacer (22), spacer ring (23) and shutter (24). Pry out top plate mounting spring (12) and remove snap ring (33). Carefully remove top plate (48) and parts (25 through 32) and (34 through 47). Disassemble items (25 through 32) and (34 through 48) if required.

(4) Carefully slide mechanism assembly (50) from case (64). Lift off center pinion (49).

C. Disassembly of Case Assembly (See figure 1101)

Remove spring ring (52) and snap ring (53). To extract adjustment knob stem (58), remove snap ring (56) and slide out pin (54), lift out pinion (55) and sealing ring (57). Remove items (1 and 2) and (59 through 63) if required.

D. Disassembly of Mechanism (See figure 1102)

(1) Remove taper pin (20) to release tension on hairspring (35). Remove link pin locking springs (1) and link pins (2). Loosen set screws (3) to allow pivot mount assemblies (4) to be backed out, thereby releasing each rocking shaft assembly (5 through 15).

(2) Disassemble rocking shaft assemblies (5 through 15) only if replacement of parts is required. Disturbing the settings of the compensator assemblies (8) and calibration spring and arm assemblies (11) will complicate calibration procedures. If no

adjustments are required, identify each rocking shaft assembly so that it will be reassembled to its individual diaphragm assembly.

(3) Remove set screws (16) and diaphragm assemblies (17).

CAUTION: HANDLE DIAPHRAGMS CAREFULLY AS THEY ARE EASILY DISTORTED. STORE EACH DIAPHRAGM ASSEMBLY WITH ITS INDIVIDUAL ROCKING SHAFT ASSEMBLY.

(4) Remove screws (21), separate mechanism plate (30) from mechanism body (46) and remove interposing parts (31 through 39).

(5) Remove items (40 through 45) from mechanism body (46) and items (18, 19 and 22 through 29) from mechanism plate (30), if necessary.

2. CLEANING

A. General

After mechanism has been disassembled to the extent required, use the following information for cleaning of parts when applicable.

(1) Clean mechanical parts with Eng Sol Spray Type Cleaning Equipment BC-2S and Eng Sol Solution No. 16 as described in paragraph B.

(2) Remove dirt on dial and pointer assemblies using a soft artgum eraser.

(3) Clean glass with lens tissue.

B. Eng Sol Cleaning Procedure

Eng Sol Spray Type Cleaning Equipment BC-2S includes an electrically driven air pump, a pressure gage, a pressure regulator, and an atomizing gun.

(1) Preheat parts to be cleaned for a period of two to five seconds by applying air pressure at a temperature of +69°C (+154°F).

(2) Thoroughly wash surfaces with cleaning fluid. Hold cleaning gun nozzle about one-half inch from part.

(3) Dry parts using warm air under pressure of about 80 PSI from the gun.

3. INSPECTION

A. General

Inspect parts for wear or damage. If defective, determine whether the part is repairable or should be replaced. When damage or excessive wear is found, always check mating parts to determine the source and extent of damage or wear.

B. Visual Inspection

(1) Check pivots and handstaff pinion for excessive wear and protrusion.

(2) Check jewels for chips, cracks or loose settings.

(3) Check hairspring for non-concentric windings and kinks.

(4) Check gear teeth and pinions for excessive wear and damage.

(5) Inspect rotating wheel assemblies and pointers for balance.

(6) Inspect gaskets and sealing rings for tears and deterioration.

(7) Check diaphragm assemblies for perforations and distortions.

(8) Check static connection for loose or torn screen, and dirt accumulation.

(9) Check dial window for chips or scratches.

(10) Ascertain that ends of links have a high polished finish.

(11) Check painted areas, especially dials and pointers, for scratched or chipped finish.

4. REPAIR

A. General

Repair, for the most part, shall constitute replacement with new parts.

B. Painting Mounting Flange and Case

Repaint chipped or scratched surfaces as follows:

(1) Clean grease, oil, and other residue from surface to be painted.

(2) Spray on one coat of zinc chromate primer. Prepare zinc chromate primer by mixing one part by volume of zinc chromate primer with two to 2-1/2 parts of zinc chromate reducer.

(3) Bake freshly primed parts for 30 minutes at +121°C (+250°F).

(4) Remove parts from oven and allow to cool to room temperature.

(5) Spray parts with dull black baking enamel. Prepare dull black baking enamel by mixing two parts by volume of Black Enamel EM393 with one part of Reducer RU-114.

(6) Bake parts in oven for one hour at +171°C (+350°F).

(7) Remove from oven and cool to room temperature.

5. ASSEMBLY

A. General

Reassembly generally follows the reverse order of index numbers assigned to exploded views; details are given below. Fits, clearances and dimensions specified in the following paragraphs apply to those parts and assemblies which required disassembly to effect repair, replacement, or calibration.

B. Lubrication

(1) Lubricate pivots with Univis P-38 low volatility aircraft instrument lubricating oil. The following procedure is recommended:

(a) Fill a standard wooden oil cup, No. 18-504 with lubricant to a level approximately one-half the height of the tip of a No. 67K and D gold tipped oiler. (Oil cup and oiler are manufactured by Hensinger and Gray, New York, N.Y.)

(b) Dip oiler into oil cup and wipe knife edge along pivot toward the rounded edge.

(2) Apply Alcoa thread lubricant to threads of setscrews (16, figure 1102).

(3) Apply a thin film of silicone grease (DC-33) to the three high spots of spring ring (52, figure 1101).

(4) Apply a thin film of Celvacene Medium Vacuum Grease to sealing ring (57, figure 1101).

C. Mechanism Assembly (See figure 1102)

(1) Press jewels (44) and jeweled endstones (45) into mechanism body (46). Stake jeweled endstones at six places equally spaced.

(2) Insert jewel setting assemblies (42 and 43) into mechanism body (46) and secure temporarily with setscrews (41).

(3) Press fit taper pins (40) into mechanism body (46) so that taper pins protrude 0.125 ± 0.025 inch.

(4) Press fit wheel (38) onto intermediate pinion (39), and press fit wheel (31) onto main pinion (32). Wheels shall be concentric within 0.005 inch after assembly.

(5) Press fit parts (33 through 36) onto intermediate shaft (37). Direction of hairspring (35) winding shall be as shown in figure 1102.

(6) Insert intermediate shaft assembly (33 through 37) and pinion assemblies (31 and 32) and (38 and 39) into their respective settings.

(7) Press fit jeweled endstone (29), jewel (28), hairspring post (27) and jewel housing assembly (24) into mechanism plate (30). Stake bearing (26) to mechanism plate. Insert jewel setting assembly (25) into mechanism plate and secure temporarily with screw (22). Assemble setscrew (23) to mechanism plate.

(8) Carefully position mechanism plate (30) onto mechanism body (46) and secure with screws (21). Adjust endplay of pinion assemblies and intermediate shaft assembly as specified in Section 6.

(9) Position eccentric jewel setting assembly (42) as illustrated in figure 501 to allow for proper mesh between wheel (31, figure 1102) and intermediate pinion (39). Rotate gear train manually to check mesh. Adjust jewel setting assembly as necessary to obtain a mesh which is free of binding or excessive backlash. Check endplay of intermediate pinion after adjustment.

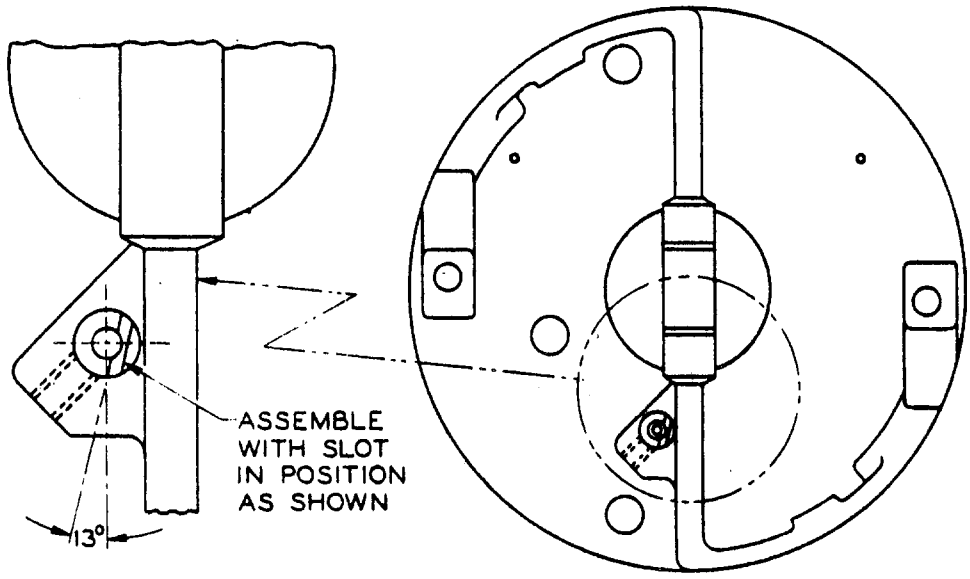

Figure 501. Eccentric Jewel Position

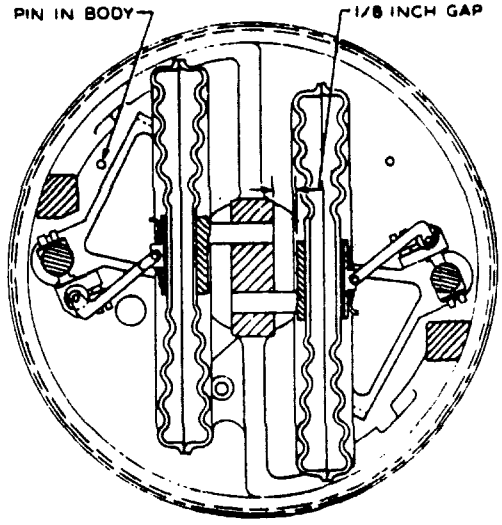
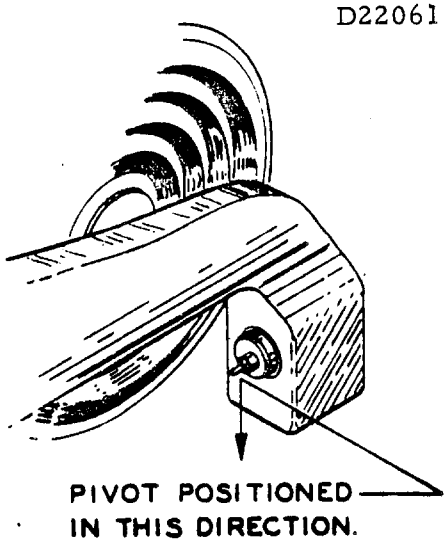
(10) Install handstaff pinion (19) adjusting endplay as specified in Section 6.



(11) Secure hairspring (35) to hairspring post (27) with the flat side of taper pin mating with the tail of the hairspring. Adjust position of taper pin until the convolutions of hairspring are in a flat plane, parallel to hairspring disk (34). If a new taper pin has been used, clip off any excess material after securing hairspring.

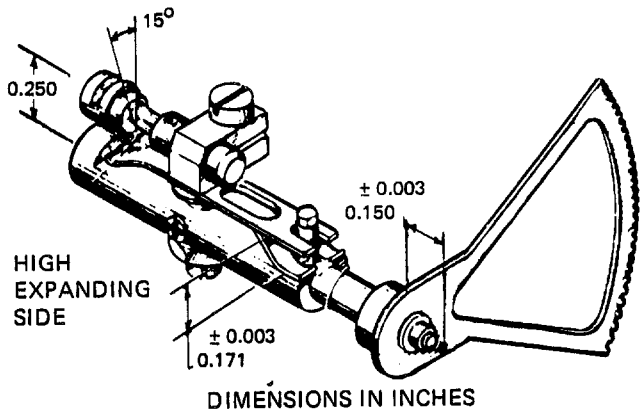
(12) Insert diaphragm assemblies (17) into mechanism body (46) and secure with setscrews (16). Maintain dimensions of diaphragm assemblies as shown in figure 502.

(13) Install pivot mount assemblies (4, figure 1102) and setscrews (3). Position pivot mount assemblies as shown in figure 503.



(14) Reassemble rocking shaft assemblies (5 through 15, figure 1102). Refer to figure 504 for dimensions.

(15) Install each rocking shaft assembly (5 through 15, figure 1102) and connect links (6) with link pins (2) and link pin locking springs (1). Adjust endplay of shaft and sector assemblies (15) as specified in Section 6. Set sectors for about a five tooth override on main pinion (32) using Sector Wrenches TE2600-5007 as shown in figure 505. Maintain position of rocking shaft with upper wrench, shifting sector with lower wrench.

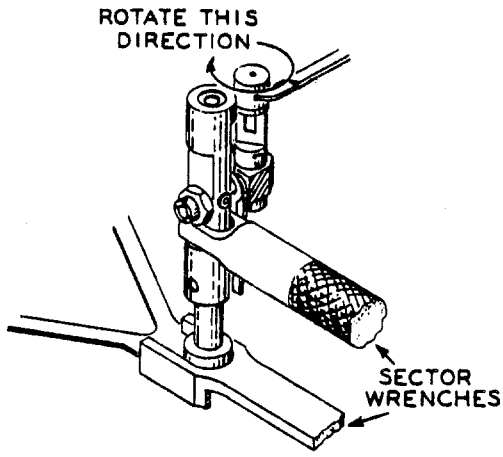


P3936

Figure 502. Diaphragm Position

P1508

Figure 503. Pivot Mount Positions



P3096

Figure 504. Rocking Shaft Assembly

(16) Wedge a round toothpick under each sector, lifting each sector out of mesh with main pinion (32, figure 1102). Rotate wheel (36) 1-1/2 to 1-5/8 turns, applying tension to hairspring (35). Holding wheel (36), remove both toothpicks, reengaging the sectors with main pinion (32).

(17) Season mechanism for three hours at -54°C (-65°F) and three hours at +100°C (+212°F) prior to calibration.

P2085

Figure 505. Fitting Sector Wrenches

D. Calibration

(1) General

(a) Unless otherwise specified, conduct calibration procedures at room temperature between +23 and+27°C (+73.4 and +80.6°F) with a relative humidity not exceeding 85 percent.

(b) Unless otherwise specified, the altimeter shall be vibrated or tapped gently prior to taking test readings.

(c) Due to the nature of the mechanism, calibration procedures have been subdivided into specific steps. A initial calibration of each diaphragm is followed by final calibration and temperature compensation. Satisfactory completion of each step determines the accuracy upon which final results depend.

(d) A standard mercurial barometer calibrated to WADC Model Atmosphere 1952 is required. A suitable pressure chamber, temperature test chamber, sources of suction and pressure, and control valves, complete the requirements.

(e) Clamp mechanism into Calibration Stand TE1357-5003.

(2) Initial Calibration

(a) The mechanism assembly has two sections, each having its own diaphragm and rocking shaft assembly. Each section must be calibrated individually. Identify the sections by marking a numeral "1" on one side of the mechanism assembly and numeral "2" on the other side.

(b) To calibrate side 1, remove link pin locking spring (1, figure 1102) and link pin (2) holding link (6) to the diaphragm of side 2. Tie link (6) of side 2 close to shaft and sector assembly (15) so that the link (6) cannot touch the diaphragm.

(c) Attach test pointer onto handstaff pinion (19) to indicate the prevailing atmospheric pressure in foot altitude.

(d) Insert mechanism assembly into pressure chamber and adjust pressure to zero foot altitude. Indication shall be zero; adjust as necessary, using knob on calibration stand.

(e) Apply test altitudes listed in table 501 and record readings.

TABLE 501

INITIAL SCALE ERROR CALIBRATION

Test Altitude (Feet)	Calibration Tolerance (Feet)
0	± 5
3000	20
6000	30
10000	60
20000	90
25000	120
30000	150
35000	155
40000	160
45000	210
50000	230

NOTE: Since only the 1000-foot indicating pointer is used when calibrating, it becomes necessary to count each pointer revolution to keep account of the actual indications.

(f) Correct errors, in excess of the specified tolerances, by shifting position of diaphragm assembly or by altering the effective length of the calibration spring and arm assembly (11). Altering the effective length of the calibration spring and arm assembly will affect the whole range of the mechanism linearly. Shorten the effective length to increase pointer movement (make indications plus); to decrease movement (make indications minus) extend the effective length. Repositioning of the diaphragm assembly is done mainly to affect the high range. Shifting the position of diaphragm assembly inward (towards center of mechanism body) will decrease movement in high range, while slightly increasing movement in the low range (3,000 and 6,000 feet). Moving diaphragm assembly outward will have the opposite affect. The amount of diaphragm assembly movement can be monitored by noting the amount of pointer movement.

NOTE: Whenever a diaphragm assembly or calibration spring and arm assembly move is made, the sector must be repositioned as specified in paragraph C. (15). Pointer indication must also be reset to indicate the prevailing atmospheric pressure.

(g) Reset zero indication at zero foot altitude. Carefully apply pressure to the mechanism to obtain an indication of minus 1,500 feet. If mechanism will not respond sufficiently, adjust sector positions and recheck calibration.

(h) After completing calibration of side 1, pin link (6) of side 2 to its diaphragm assembly (17) and disconnect and tie back link (6) of side 1. Repeat calibration procedures outlined for side 1, keeping in mind that the calibration curves of the two diaphragm assemblies should be calibrated as much alike as possible to avoid difficulties during final calibration.

(3) Upon completion of calibration of sides 1 and 2 adjust load balances as follows:

(a) With link (6) of side 1 disconnected from its diaphragm assembly (17), use sector wrenches on side 1 to align the hole in link (6) with the link pin hole in diaphragm assembly. Link pin (2) of side 1 shall fall into the holes without forcing, and there shall be no pointer movement when the link pin is removed.

(b) With both links (6) connected to their diaphragm assemblies (17), while watching the pointer, carefully push side 1 diaphragm assembly inward until pointer indication has shifted plus 150 feet.

(c) Test load balance by removing link pin of side 1 and noting amount of pointer shift, reinsert link pin, then remove link pin of side 2 noting pointer movement. Amount of pointer shift for both sides shall be approximately equal and shall be between 150 and 300 feet in clockwise direction. Assemble link pin locking springs (1) to each diaphragm assembly.

CAUTION: MOVING THE DIAPHRAGM ASSEMBLIES AT THIS STAGE OF CALIBRATION MUST BE HELD TO A MINIMUM. ASCERTAIN THAT PERPENDICULARITY OF LINK IS MAINTAINED AFTER DIAPHRAGM ASSEMBLY ADJUSTMENT.

(d) Position pointer at zero with altimeter held in normal operating position. Rotate altimeter about its longitudinal axis in 90-degree increments and note pointer indications. Indications shall not vary from the normal position reading in excess of 20 feet. Readjust load balance if requirement is not fulfilled.

(4) Final Calibration

(a) Apply test pressures specified in table 501 and note altimeter indications. With proper initial calibration, adjustments required at this time should be minor and confined to the calibration spring and arm assembly (11, figure 1102) of the side which is causing the error. Recheck position error, and readjust load balance as required.

(b) Check back movement by applying pressure to cause an indication of minus 1,500 foot altitude. If mechanism does not respond sufficiently, failure can be traced to inaccurate positioning of sectors; adjust as necessary and recheck calibration.

TABLE 502

FRICTION TEST

Test Altitude (Feet)	Tolerance (Feet)
1000	± 70
2000	70
3000	70
5000	70
10000	80
15000	90
20000	100
25000	120
30000	140
35000	160
40000	180
50000	250

(c) After tolerances are met, perform friction test using test altitudes listed in table 502. The altimeter shall be subjected to a steady decrease in pressure at a rate of 3000-feet per minute until within approximately 500 feet of each test point. At this point, rate shall be adjusted to 600 feet per minute until test altitude is reached. Hold pressure constant at each test point and note the pointer indication. Vibrate the mechanism assembly and again note pointer indication. The difference between the two indications constitutes friction and shall not exceed the tolerances specified in table 502.

(5) Temperature Compensation

(a) If original setting of compensator assemblies (8, figure 1102) was disturbed, ascertain that compensator assemblies are present to the angle shown in figure 504.

(b) Record pointer indication and ambient pressure. Insert mechanism assembly into a temperature chamber and subject unit to a temperature of +70°C (+158°F) for a period of one hour. Note pointer indication and ambient pressure. Pointer shift shall not exceed +20 feet corrected for any change in ambient pressure.

(c) Allow unit to cool to room temperature. Pointer shall return to original indication corrected for any change in ambient pressure.

(d) Correct compensation error by adjusting angular setting of compensator assemblies. Rotate compensator assemblies in direction shown in figure 505 for excessive plus reading; turn compensator assemblies in the opposite direction for excessive minus reading. Make small adjustments using Compensation Gage TE2953-5017 and recheck compensation.

(e) After compensation errors have been corrected, recheck scale error in accordance with table 501 and recheck position error.

E. Reassembly of Top Plate Mechanism Assembly (See Figure 1101)

(1) Press fit center pinion (49) onto handstaff pinion (19, figure 1102) allowing 0.003 inch clearance from mechanism plate (30).

(2) Press fit locating pins (42, figure 1101) and stake stud gears (43 and 44) to top plate (48).

(3) Assemble wheel assembly (41) to top plate (48).

(4) Assemble items (36 through 39) to plate and bushing assembly (40). Press fit spur gear assembly (34) onto handstaff (39).

(5) Assemble bearing plate assembly (36 through 40) to top plate screws (35).

F. Closing (See figure 1101)

(1) Assemble items (1 and 2) and items (54 through 63) to case 64.

(2) Assemble snap ring (53) and spring ring (52) to case (64).

(3) Slide mechanism assembly (50) into case (64).

(4) Assemble top plate (48) with attached parts, snap ring (33) and

top plate mounting spring (12) to case (64). The three high spots on spring ring (52) shall be opposite the three pads of top plate (48).

(5) Press fit gears (31, 29, and 27) onto pinions (32, 30, and 28) respectively, and assemble to top plate (48).

(6) Manually rotate gear (29) counterclockwise until gear (31) hits stop lever attached to top plate (48).

(7) Assemble setting marker gear (26) and barometric dial assembly (25) to top plate (48), aligning the 31.0 inches of Hg indication with the dial, locating pin-hole at the 3 o'clock position on top plate (48).

(8) Manually rotate gear (29) fully clockwise and check that 28.1 inches of Hg indication of barometric dial assembly (25) aligns with dial, locating-pin hole specified in step (7).

(9) Position barometric dial assembly (25) so that the range is not restricted by stop lever.

(10) Assemble shutter (24), ring spacer (23) and spacer (22).

(11) Assemble center dial (20) and secure to top plate (48) with dial screws (21).

(12) Assemble centering ring (19) to case (64). Position barometric dial assembly (25) to indicate 29.92.

(13) Assemble dial pointer assembly (18) and pointer assemblies (17 and 16) to indicate the prevailing atmospheric pressure.

NOTE: Pointer assembly (16) shall not make contact with a straight edge when it is placed on centering ring (19).

(14) Insert unit in pressure chamber and apply zero foot altitude pressure. Pointer assemblies (16 and 17) and dial pointer assembly (18) shall align with zero indication on center dial (20). Adjust until required indication is obtained.

(15) Assemble sealing gasket (15) and glass (14) to case (64).

(16) Assemble paper gasket (13), locking plate (11) to mounting flange (5) and assemble to case (64) securing with lockwashers (9) and screws (6, 7, 8 and 10). Select thickness of paper gasket (13) to prevent possible leak.

(17) Assemble knob locknut (4) and knob (3) to adjustment knob stem (58) allowing approximately 1/10 of an inch gap between knob locknut (4) and case (64).

(18) Using knob (3) adjust altitude indication to the prevailing atmospheric pressure. Loosen locking screw (10) sufficiently to pull knob (3) outward. Rotate knob (3) until barometric dial assembly (25) indicates 29.92 inches Hg. Push knob (3) back in, securing it into position by tightening locking screw (10).

(19) Rotate knob (3) to ascertain that movement is smooth throughout entire range of barometric dial assembly, and reset to 29.92 inches Hg.

G. Materials Used During Overhaul

Material	Manufacturer or Distributor
(1) Lubricants	
Calvacene Medium Vacuum Grease	Consolidated Electrodynamics Corp., Rochester, New York.
Univis P-38	Esso Standard Oil Co., Pelham 65, New York.
DC-33 Silicone Grease	Dow Corning Corp., Misland, Michigan.
Alcoa Thread Lubricant	Aluminum Co. of America, Pittsburgh, Pa.
(2) Solvents	
Zinc Chromate Primer Zinc Chromate Reducer	Hilo Varnish Corp., Everett, Mass.
Black Enamel EM 393 Reducer RU-114	Egyptian Lacquer Mfg. Co., South Kearney, N.J.

6. FITS AND CLEARANCES

Fits and clearances to be attained during repair and reassembly are listed in table 601. These requirements are applicable to only those parts which were disassembled during overhaul.

TABLE 601

FITS AND CLEARANCES

Nomenclature	Figure	Index No.	
Pins	1102	40	0.125 ± 0.025 inch protrusion
Wheels	1102	31 and 38	Concentric within 0.005 inch
Intermediate Pinion Assy	1102	38 and 39	0.002 to 0.003 inch endplay
Main Pinion Assembly	1102	31 and 32	0.002 to 0.003 inch endplay
Intermediate Shaft	1102	37	0.002 to 0.003 inch endplay
Handstaff Pinion	1102	19	0.002 to 0.003 inch endplay
Shaft and Sector Assy	1102	15	0.002 to 0.003 endplay
Knob Locknut	1101	4	1/10 inch clearance

7. TESTING

A. General

Unless otherwise specified, tests are to be conducted at room temperature between +23 and +27°C (+73.4 and +80.6°F) with relative humidity not exceeding 85 percent. The altimeter shall be tested in normal operating position and, unless otherwise specified, shall be lightly tapped or vibrated prior to taking test readings. Test pressures are in accordance with WADC Model Atmosphere 1952.

B. Zero Setting Scale

Adjust barometric dial assembly to indications specified in table 701. At each setting the altitude reading shall be as specified in table 701 within listed tolerances.

TABLE 701

ZERO SETTING SCALE

Barometric Dial Setting (Inches Hg)	Altitude Reading (Feet)	Tolerance (Feet)
28.13	-1700	± 25
28.54	-1300	± 25
28.96	- 900	± 25
29.49	- 400	± 25
29.92	0	± 25
30.36	+ 400	± 25
30.91	+ 900	± 25

C. Case Leak

Slowly apply suction sufficient to produce indication of 18,000 foot altitude to the static connection. At this point, the connecting tubing shall be completely sealed off. Change in indication observed for a period of 30 seconds shall not exceed 100 feet.

D. Scale Error Test at Room Temperature

NOTE: The altimeter shall not have been subjected to any test involving operation at other than ambient atmospheric pressures for a minimum period of 12 hours prior to the start of this test. The test altitude being set, shall at no time exceed the specific test point.

(1) Set barometric scale to 29.92 inches Hg.

(2) Subject the altimeter to the test altitudes listed in table 702 for not less than one or more than five minutes before applying vibration. Change of pressure shall be made at a rate not exceeding 3000 feet per minute. Scale errors shall not exceed the tolerances specified in table 702.

TABLE 702

FINAL SCALE ERROR TEST

Test Altitude (Feet)	Tolerance (Feet) Room Temperature	*-30°C (-22°F)
0	± 20	± 40
500	20	-
1000	20	-
1500	25	-
2000	30	-
3000	30	-
4000	35	-
6000	40	60
8000	60	-
10000	80	-
12000	90	90
14000	100	-
16000	110	-
18000	120	120
20000	130	-
22000	140	-
25000	155	155
30000	180	-
35000	205	205
40000	230	-
45000	255	-
50000	280	280

* -30°C tolerance represents the allowable change from room temperature readings.

E. Hysteresis and After Effect

Within 15 minutes after altimeter has been subjected to a pressure equal to 50,000 feet, increase pressure at a rate of approximately 3000 feet per minute. Hold pressure at the test altitudes listed in table 703 and read altimeter within time specified. Compare these readings with readings obtained during room temperature scale error test. Readings shall be within the variance specified in table 703.

TABLE 703

HYSTERESIS AND AFTER EFFECT TEST

Altitude (Feet)	Time Before Reading	Permissible Variation (Feet)
50,000	Maintain pressure not longer than 15 minutes	(No Reading)
25,000	Maintain pressure between 5 and 15 minutes	75
20,000	Maintain pressure between 5 and 15 minutes	75
0	Maintain pressure between 1 and 10 minutes	30

F. Position Error

Position pointer at zero with altimeter held in normal operating position. Rotate altimeter about its longitudinal axis in 90-degree increments and note pointer indications. These indications shall not vary from the normal position indication in excess of 20 feet.

G. Friction Test

Perform friction test as specified in Section 5, paragraph D. step (4) (c).

H. Scale Error at -30°C (-22°F)

Place altimeter in a temperature test chamber and subject it to the prescribed temperature for three hours. Repeat procedures specified in paragraph D. Test altitudes and tolerances are listed in table 702.

8. TROUBLESHOOTING

Table 801 lists troubles which may be encountered, their probable cause and suggested remedies.

TABLE 801

TROUBLESHOOTING

Indication	Cause	Remedy
Room temperature scale errors not within tolerances	Incorrect calibration, pointers not properly set	Recalibrate or reset pointers.
Scale error excessive at low temperature	Compensator assemblies not properly set	Adjust compensator assemblies.
Excessive after effect, hysteresis or failure to pass friction test	Excessive friction or defective diaphragm	Check mechanism for excessive friction. Replace diaphragm, if necessary.
Pointer oscillation	Incorrect hairspring tension	Readjust hairspring tension.
Case Leak	Defective gasket, Loose screws	Replace gasket, tighten screws.

9. STORAGE INSTRUCTIONS

A. Preparation

Clean and lubricate parts and subassemblies, as required, before storing.

B. Storing Parts

Store delicate parts in suitable individual containers, preferably plastic, so that no damage will be incurred in handling. Wrap delicate parts in tissue or lintless packing material before packing them in containers.

C. Storing Subassemblies

Store subassemblies in individual containers or boxes. Handle them carefully and wrap and pack them so as to avoid possible damage through shifting in the containers.

D. Storing Complete Units

Place plastic plug into static port and insert unit in separate container with a bag of commercially available desiccant (silica gel).

E. Marking Containers

Mark or tag containers clearly as to contents and condition of the equipment. Containers holding delicate parts should be marked "FRAGILE - DELICATE INSTRUMENT". Complete instrument containers should bear the type number and serial number of the unit and should be dated.

10. SPECIAL TOOLS AND TEST EQUIPMENT

The following tools and fixtures are required for overhaul.

Kollsman Part No.	Nomenclature	Application
TE2953-5017	Compensation Gage and Pointer	Temperature Compensation
TE1357-5003	Calibration Stand	Holding mechanism during calibration
TE2600-5007	Sector Wrenches	Adjusting rocking shaft assembly

11. ILLUSTRATED PARTS LIST

A. General

The illustrated parts list is used for requisitioning, storing, issuing, and readily identifying replaceable parts during maintenance and overhaul operations.

B. Numerical Parts List Index

The numerical parts list index enumerates all parts and assemblies contained in the group assembly parts list. Numbers are arranged in alpha-numerical sequence.

C. Group Assembly Parts List

(1) The group assembly parts list illustrates and lists all parts contained in the unit. Assemblies and their components are listed in the order of disassembly, except for attaching parts. Attaching parts follow immediately the part or assembly being detached, and precede any components of said item. These parts are captioned "Attaching Parts" and the symbol (-*-) separates them from subsequent parts or assemblies in the listing.

(2) Numbers listed are those of Kollsman parts unless otherwise identified as standard MS, AN or NAS, or by manufacturer's identification given parenthetically in the description column. The vendor's code is in accordance with Catalog H4-1, Federal Supply Code for Manufacturers, and is preceded by the letter "V".

(3) All parts are assigned figure and index numbers. The figure number identifies the illustration in which the listed part is contained. The index number references the part on the illustration.

(4) The symbol "AR" appearing in the Units Per Assembly column means "As Required". The symbol "Ref" signifies a second or subsequent listing of the part or assembly.

(5) "No Number" assigned as a part number indicates a part of an assembly shown for illustration purposes only. It is impractical to further breakdown due to manufacturer's assembly procedures and replacement of said items must be made of the next higher assembly as parts of this nature are not procurable.

D. Usage Code

(1) Master coding is used where a breakdown of more than one type instrument is made in one illustrated parts list. Each type instrument is listed with an assigned alphabetical capitalized code letter. The code letter applicable to each type is shown at the beginning of the first parts list and below.

Usable on Code	Part Number
A	D22061 10 012
B	E22061 04 018

(2) All parts and assemblies which are components of the listed types bear the same code letter as that type. The code letter will appear in the Usage Code Column (column 4).

(3) Detail parts are coded to agree with the assembly on which they are used. The code letter assigned to each assembly is shown at the beginning of the parts list involved.

(4) Parts common to both assemblies are listed with the quantity required for one assembly only. They carry no code letter in column 4, indicating that they are identical parts, applicable to all assemblies on that listing.

NOTE

OVERHAUL AND TEST PROCEDURES FOR THE MODELS INCLUDED IN THIS SECTION ARE THE SAME AS PROCEDURES FOR THE PRESSURE ALTIMETER D22061 10 012 EXCEPT FOR THE SPECIFIC DIFFERENCES NOTED BY THE APPLICABLE DIFFERENCE DATA SHEET.

Kollsman Part Number	Page
E22061 04 018 ✓	1203
D22061 04 021	1209

DIFFERENCE DATA SHEET

E22061 04 018

THE INSTRUCTIONS CONTAINED IN PRECEDING SECTIONS OF THIS MANUAL APPLY, EXCEPT FOR THE DIFFERENCES LISTED ON THIS SHEET.

SECTION 0. DESCRIPTION AND OPERATION

B. Description

(2) Leading Particulars:

Operating Altitudes: -1000 to 80,000 ft
Barometric Scale: 952 to 1050 MB
Temperature Range: -35°C (-31°F) to +45°C (+113°F)

SECTION 1. DISASSEMBLY

B. Removing Mechanism Assembly from Case

(3) Omit reference to shutter (24), setting marker gear (26), gear (27) and pinion (28).

C. Disassembly of Case Assembly

Add: Remove mylar gasket (51)
Omit reference to items (59 through 61)

SECTION 5. ASSEMBLY

D. Calibration

(2) Initial Calibration

(e) Use table 1201 in lieu of table 501

TABLE 1201

INITIAL SCALE ERROR CALIBRATION

Test Altitude (Feet)	Calibration Tolerance (Feet)
0	10
3000	30
6000	45
10000	60
20000	90
25000	120
30000	150
35000	155
40000	160
45000	210
50000	230
60000	600
70000	900
80000	1125

(2) Adjusting Load Balance

(d) Additional position error test altitude: Dial up position.

(4) Final Calibration

(a) Use table 1202 in lieu of table 501.

(b) Use table 1202 in lieu of table 502.

TABLE 1202

FRICTION TEST

Test Altitude (Feet)	Tolerance (Feet)
1000	70
2000	70
3000	70
5000	70
15000	90
20000	100
25000	120
30000	140
35000	160
40000	180
50000	250
60000	450
70000	650
80000	850

(5) Temperature Compensation

(e) Use table 1201 in lieu of table 501.

E. Reassembly of Top Plate Mechanism Assembly

(2) Assemble items (42 through 47, figure 1101) as shown in figure 1201.

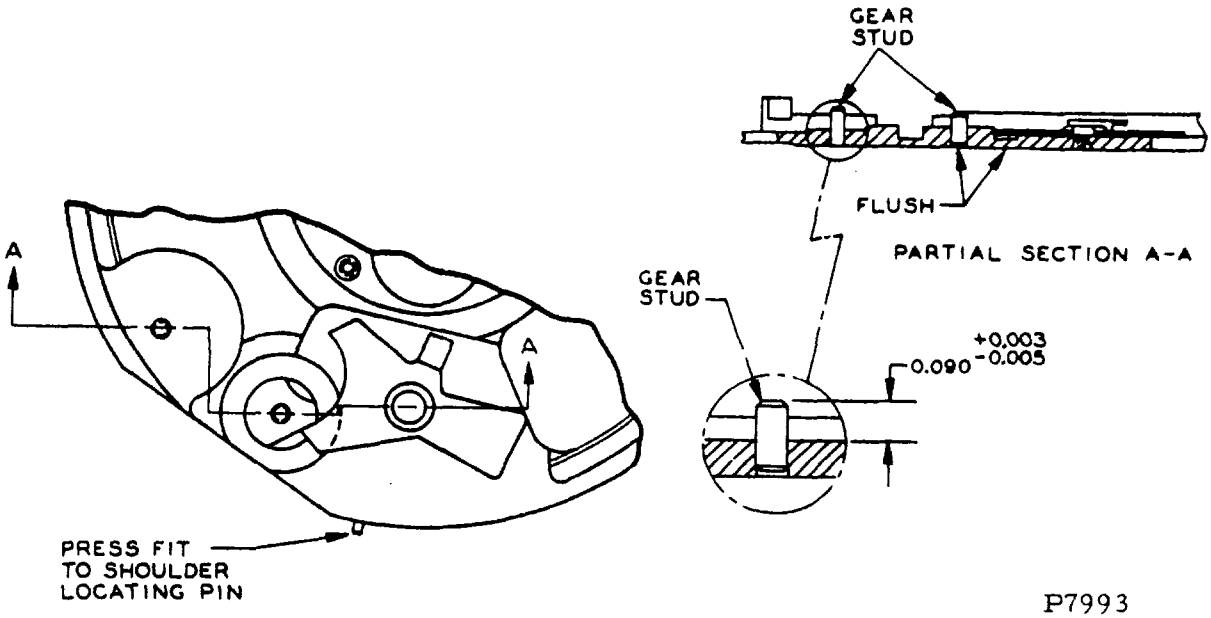

Figure 1202. Top Plate Assembly

F. Closing (See figure 1101)

(1) Omit reference to items (59 through 61).

(2) Add mylar gasket (51).

(5) Omit reference to gear (27) and pinion (28).

(7) Omit reference to setting marker gear (26). Align 1050MB indicator.

(8) Align 952.5MB indication.

(10) Omit reference to shutter (24).

(12) Position barometric dial assembly to indicate 1013.25MB.

(18) Position to 1013.25MB.

(19) Position to 1013.25MB.

SECTION 7. TESTING

B. Zero Setting Scale

Use table 1203 in lieu of table 701.

TABLE 1203

ZERO SETTING SCALE

Barometric Dial Setting (MB)	Altitude Reading (Feet)	Tolerance (Feet)
952.50	1701	25
965.00	1344	25
980.00	920	25
1000.00	384	25
1013.25	0	25
1035.00	589	25
1045.00	856	25
1050.00	989	25

C. Case Leak

Observe for change in indication over a period of one minute in lieu of 30 seconds.

D. Scale Error Test at Room Temperature

(1) Set barometric scale to 1013.25MB.

(2) Use table 1204 in lieu of table 702.

TABLE 1204

FINAL SCALE ERROR TEST

Test Altitude (Feet)	Tolerance (Feet)	
	Room Temperature	-35°C (-31°F) +45°C (+113°F)
0	30	30
500	35	35
1000	35	35
1500	35	35
2000	40	40
2500	45	45
3000	45	45
4000	50	50
5000	55	55
6000	60	60
8000	70	70
10000	80	80
12000	90	90
14000	100	100
15000	105	105
16000	110	110
18000	120	120

TABLE 1204 (CONT)

Test Altitude (Feet)	Tolerance (Feet) Room Temperature	-35°C (-31°F) +45°C (+113°F)
20000	130	130
22000	140	140
25000	155	155
30000	180	180
35000	205	205
40000	230	230
45000	255	255
50000	280	280
55000	600	600
60000	800	800
70000	1200	1200
80000	1500	1500

E. Hysteresis and After Effect

Use table 1205 in lieu of table 703.

TABLE 1205
HYSTERESIS AND AFTER EFFECT

Altitude (Feet)	Time Before Reading	Permissible Variation (Feet)
80,000	Maintain pressure not longer than 15 minutes	-
25,000	Between 5 and 15 minutes	100
20,000	Between 5 and 15 minutes	100
0	Between 1 and 10 minutes	50

F. Position Error

Additional position error test attitude: Dial up position.

G. Friction Test

Use table 1202 in lieu of table 502.

Add: Without vibration decrease pressure from 0 to 80,000 feet altitude at a rate not exceeding 3000 feet per minute.

Observe pointer for irregular motion. Pointer shall not stop and jump more than the amounts specified in table 1206.

TABLE 1206

OPERATIONAL FRICTION TEST

Altitude (Feet)	Pointer Jump (Feet)
0 to 25000	120
25000 to 50000	250
50000 to 80000	850

H. Scale Error at -35°C (-31°F)

Use test altitudes and tolerances specified in table 1204.

Add: I. Scale Error at +45°C (+113°F)

Perform procedure specified in paragraph H. of this difference data sheet except temperature shall be +45°C (+113°F).

DIFFERENCE DATA SHEET

D22061 04 021

THE INSTRUCTIONS CONTAINED IN PRECEDING SECTIONS OF THIS MANUAL APPLY, EXCEPT FOR THE DIFFERENCES LISTED ON THIS SHEET.

0. DESCRIPTION AND OPERATION

B. Description

(2) Leading Particulars:

Operating Altitudes:	-1000 to 50,000 ft
Barometric Scale:	952 to 1050MB
Temperature Range:	-30°C (-22°F) +25°C (+77°F)

5. ASSEMBLY

F. Closing (See figure 1101)

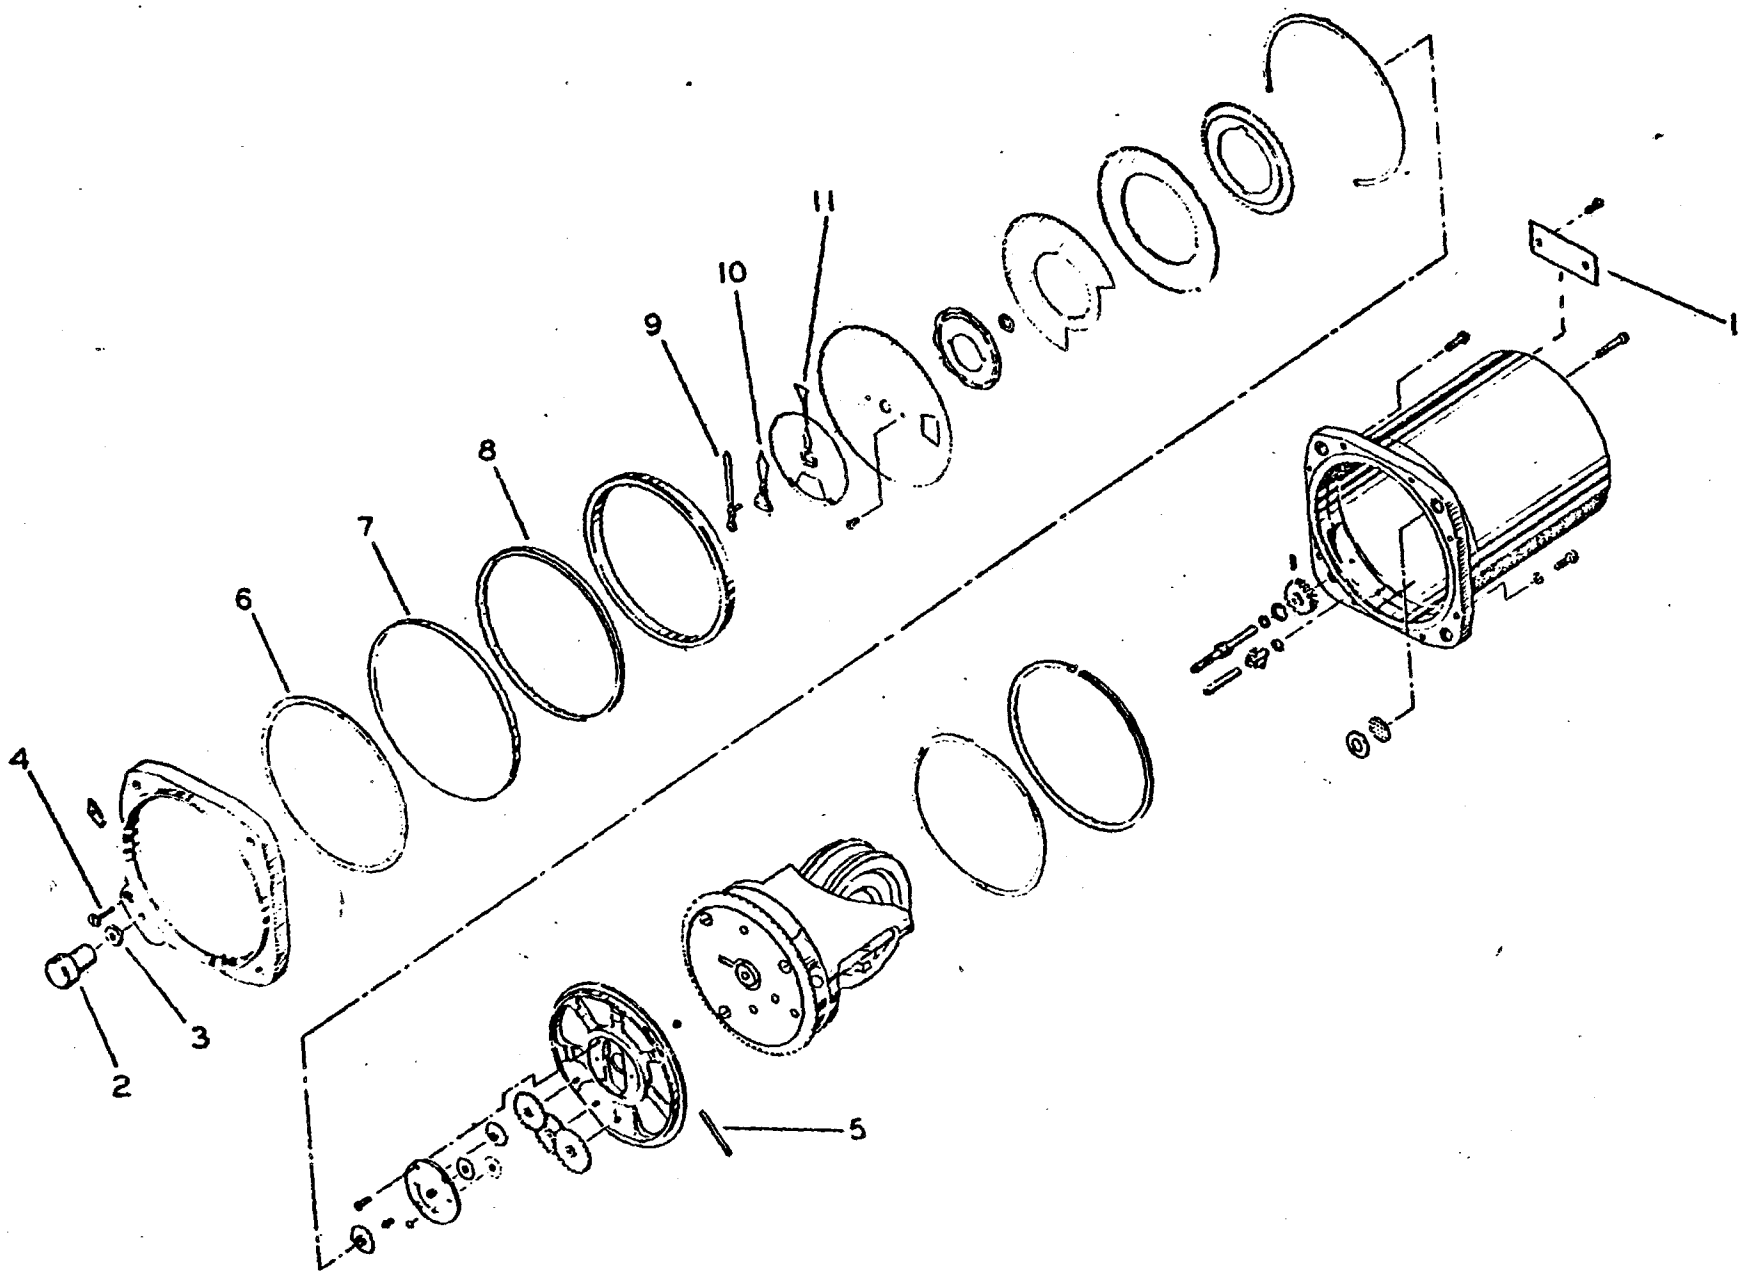
(7) Align 1050MB indication.

(8) Align 965MB indication.

(12) Position barometric dial assembly to indicate 1013.00MB.

(18) Position to 1013.00MB.

(19) Position to 1013.00MB.



7. TESTING

B. Zero Setting Scale - Use table 1207 in lieu of table 701.

TABLE 1207

ZERO SETTING SCALE

Barometric Dial Setting (MB)	Altitude Reading (Feet)	Tolerance (Feet)
965.00	-1344	±25
1013.00	- 7	25
1050.00	989	25

SECTION I
INTRODUCTION

1-1. GENERAL.

1-2. This publication covers the overhaul and test procedures for the Sensitive Altimeter manufactured by the Kollsman Instrument Corporation, Elmshurst, New York. (See figure 1-1.)

1-2. The following are the type number designations:

Kollsman Type Number	*AN Type*	*Navy Stock Number*
371P-4-01	—	R88A0352-000-000
671CP-8-016	5760-4A	—

LEADING PARTICULARS

TYPE: 371P-4-01

RANGE: 35,000 feet

BAROMETRIC SCALE: 28.1 to 31.0 inches of mercury

ILLUMINATION:

Dial—AN-L-1
Barometric dial—AN-L-1
Pointers—AN-L-1

TYPE: 671CP-8-016

RANGE: 50,000 feet

BAROMETRIC SCALE: 28.1 to 31.0 inches of mercury

ILLUMINATION:

Dial—AN-L-1 and Matte Green G 6/6
Barometric dial—AN-L-1
Pointers—AN-L-1

Note

Overhaul and test procedures for additional models are included in Section IV by the use of Difference Data Sheets. The procedures are the same as in Sections II and III except for the specific differences noted by the applicable Difference Data Sheets.

1-4. The sensitive altimeter is for use on aircraft to indicate the height of the aircraft above some reference point (generally mean sea level), assuming standard conditions of temperature and pressure. The sensitive altimeter measures the existing ambient pressure. Since atmospheric pressure varies with altitude, this pressure is indicated on the dial in feet of altitude.

1-5. PRINCIPLES OF OPERATION. *(See figure 1-2.)*

1-6. The atmosphere surrounding the earth exerts a pressure due to its weight. This pressure is greatest at sea level (the standard reference point) or points below sea level, but decreases as altitude is increased. Due to meteorological variations, the atmospheric pressure varies over the surface of the earth and over a period of time at a particular location.

1-7. The altimeter operates because of these changes in pressure. When installed in an aircraft, the airtight case is connected to the free air in such a way as to transmit the static pressure to the inside of the case. As pressure within the case decreases with increase in altitude, the forces acting on the diaphragm assembly decrease.

1-8. The diaphragm assembly (1) is compressed by atmospheric pressure since there is no air within the cells. As pressure is decreased, the diaphragm assembly expands and as pressure is increased, the diaphragm compresses. This motion is transmitted to the rocking shaft (2) through the link and calibration arm, then to the large hand through the sector, intermediate pinion wheel (3) and handstaff pinion (4). Movement of the second and third hands comes from the pinion (5) pressed onto the main handstaff through the gear train of the top plate assembly.

1-9. Since pressures are constantly changing, a means of correcting for these changes is incorporated into the instrument. By turning the setting knob (6) at the lower left corner of the indicator, the barometric scale (7) can be set to the existing barometric pressure as received from the weather station. As the knob is turned, the mechanism within the case, as well as the barometric scale and reference marks, also turn. Thus, when the new barometric pressure is set in inches of mercury pressure, the hands of the indicator move the equivalent in feet of altitude. The relationship is based on standard conditions of pressure and temperature. The reference marks indicate barometric pressure in feet of altitude and are used when existing barometric pressure is greater or less than the pressure indicated on the barometric scale.

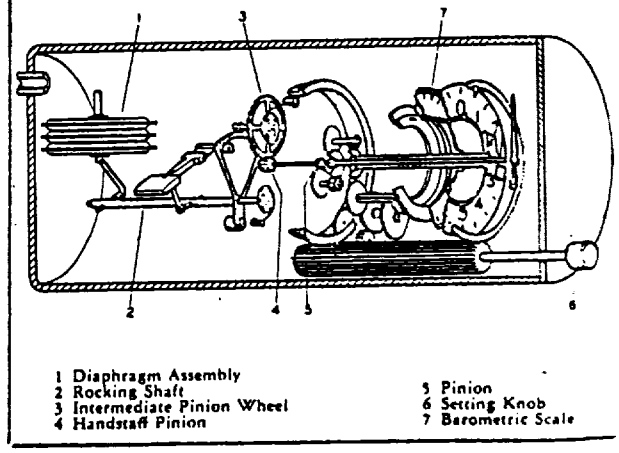

Figure 1-2. Schematic

SECTION II
OVERHAUL INSTRUCTIONS

2-1. SPECIAL OVERHAUL TOOLS REQUIRED.

Tool Number	*Nomenclature*	*Application*	*Figure No.*
TE583A	Calibration stand	To hold the mechanism during calibration	2-1
TE600B	Pressure chamber	Used as the chamber in which to operate the mechanism during calibration	2-2
TE628A	Wheel cleaning fixture	Used to hold the wheel for brushing	2-3
TE630A.1	Balance weight	To set the proper tension into the balance assembly	2-4
TE639	Vernier calibrating tool	Used to adjust the length of the calibration arm	2-5
TE5196	Diaphragm calibrating tool	Used to adjust diaphragm position when calibrating	2-6

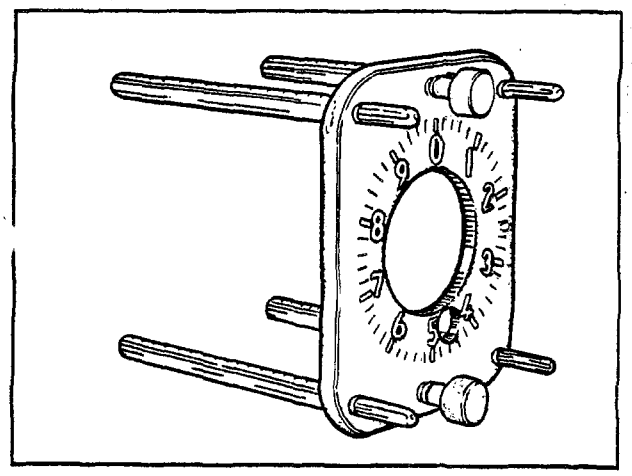

Figure 2-1. Calibration Stand (TE583A)

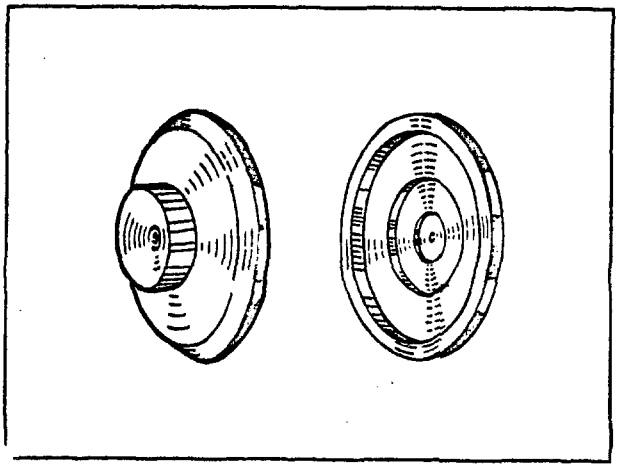

Figure 2-3. Wheel Cleaning Fixture (TE628A)

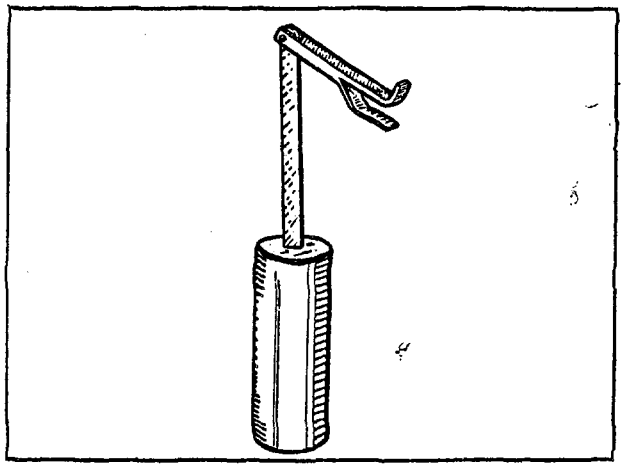

Figure 2-4. Balance Weight (TE630A.1)

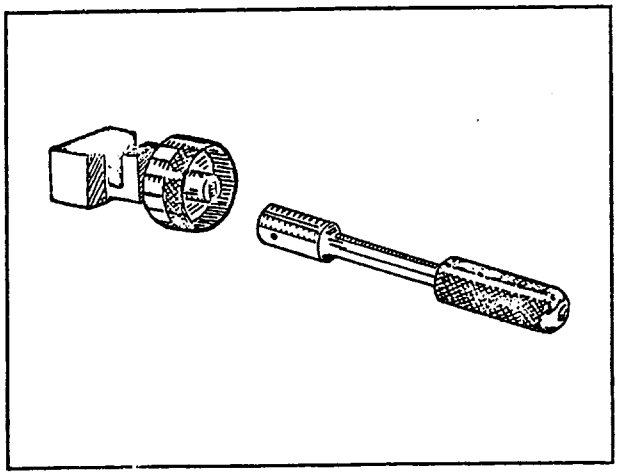

Figure 2-5. Vernier Calibrating Tool (TE639)

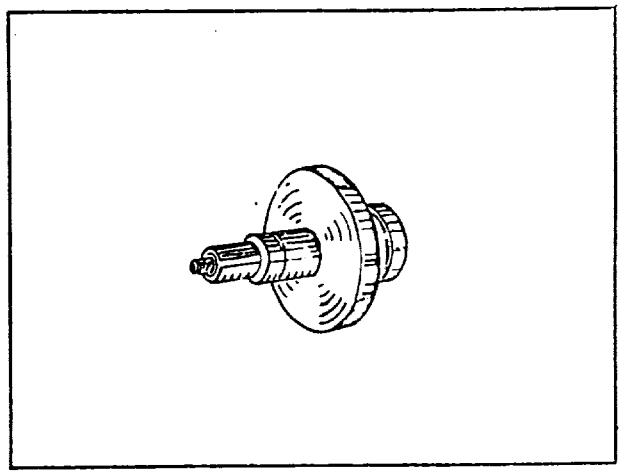

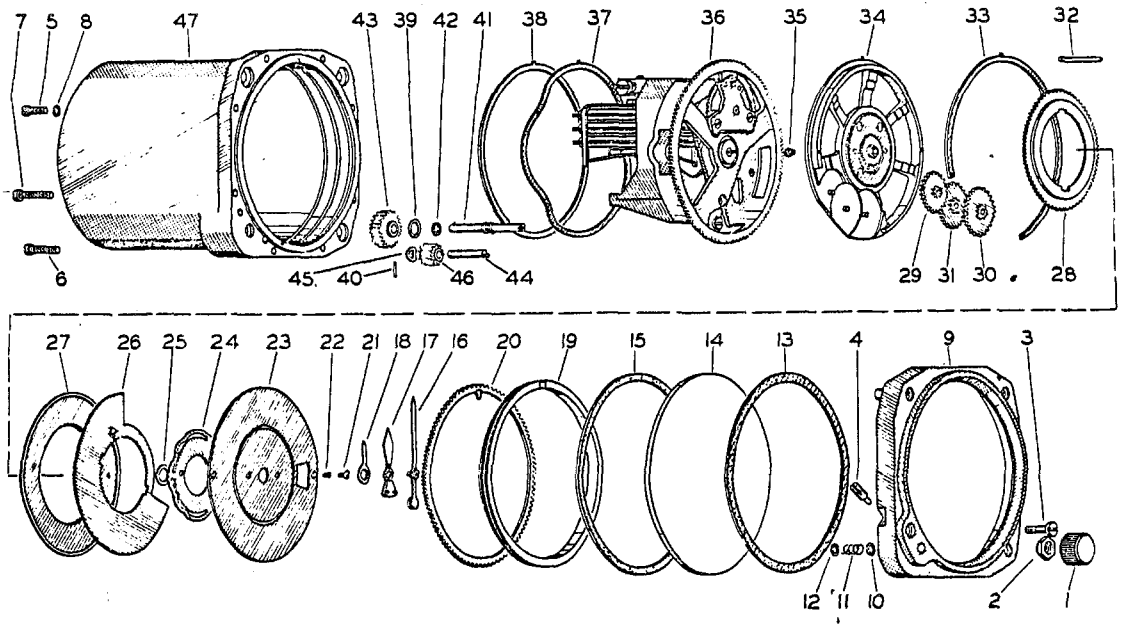

Figure 2-6. Diaphragm Calibrating Tool (TE5196)

2-2. DISASSEMBLY.

2-3. Malfunctioning of the instrument may generally be traced to certain troubles as listed in the following chart:

Trouble	*Probable Cause*	*Remedy*
FRICTION	Dirty pivots or jewels	Disassemble and clean.
	Cracked jewel due to excessive shock	Replace all cracked jewels. A cracked jewel will not only cause friction, but will damage a pivot if not replaced.
	Movable parts tarnished	Disassemble and clean.
	Second hand handstaff binding in bushing of upper bearing due to corrosion	Disassemble and clean.
	Insufficient end play	Reset end play.
	Links are binding, not aligned correctly	The links must work smoothly, without play on the bearing pins, and must be free of burrs.
	Poor bearing pins	The links must work smoothly, without play on the bearing pins, and must be free of burrs.
POINTERS INDICATING INACCURATELY	Shifting of parts due to shock	If no parts are broken, it may only be necessary to reset the barometric scale or recalibrate the instrument.
	Excessive pressures applied to static connection	
CASE LEAKS	Dried out leather washer at the adjustment knob stem	Replace leather washer.
	Dried out sealing gasket around the flange	Replace sealing gasket.
	Porous case	Replace with a new case.
POINTER OSCILLATES UNDER VIBRATION	Insufficient hairspring tension	Increase hairspring tension.
	Loose fitting bearing pins	Replace bearing pins.
	Insufficient tension on balance arm	Increase tension on balance arm.

2-4. REMOVAL OF THE MECHANISM FROM THE CASE. *(See figure 2-7.)*

2-5. TYPE 371P-4-01.

a. Remove the knob (1) and the locknut (2) from the adjustment knob stem.

b. Unscrew the locking stud screw (3) located to the left of the knob stem. Remove the locking stud (4).

c. Remove the flange mounting screws (5, 6 and 7) and lockwashers (8). Lift off the flange (9), front washer (10), spring (11) and rear washer (12). Remove the paper gasket (13), glass (14) and the sealing gasket (15).

d. Remove the large hand (16), the intermediate hand (17) and the third hand (18). Remove the gasket centering ring assembly (19). Lift out the outer setting ring (20).

e. Remove the two dial scerws (21) and lift off the inner dial. Remove the two dial locating pins (22) and lift off the outer dial (23). Remove the spacer (24) and the ring wheel spacer (25). Remove the shutter (26), barometric dial assembly (27) and the setting mark gear (28).

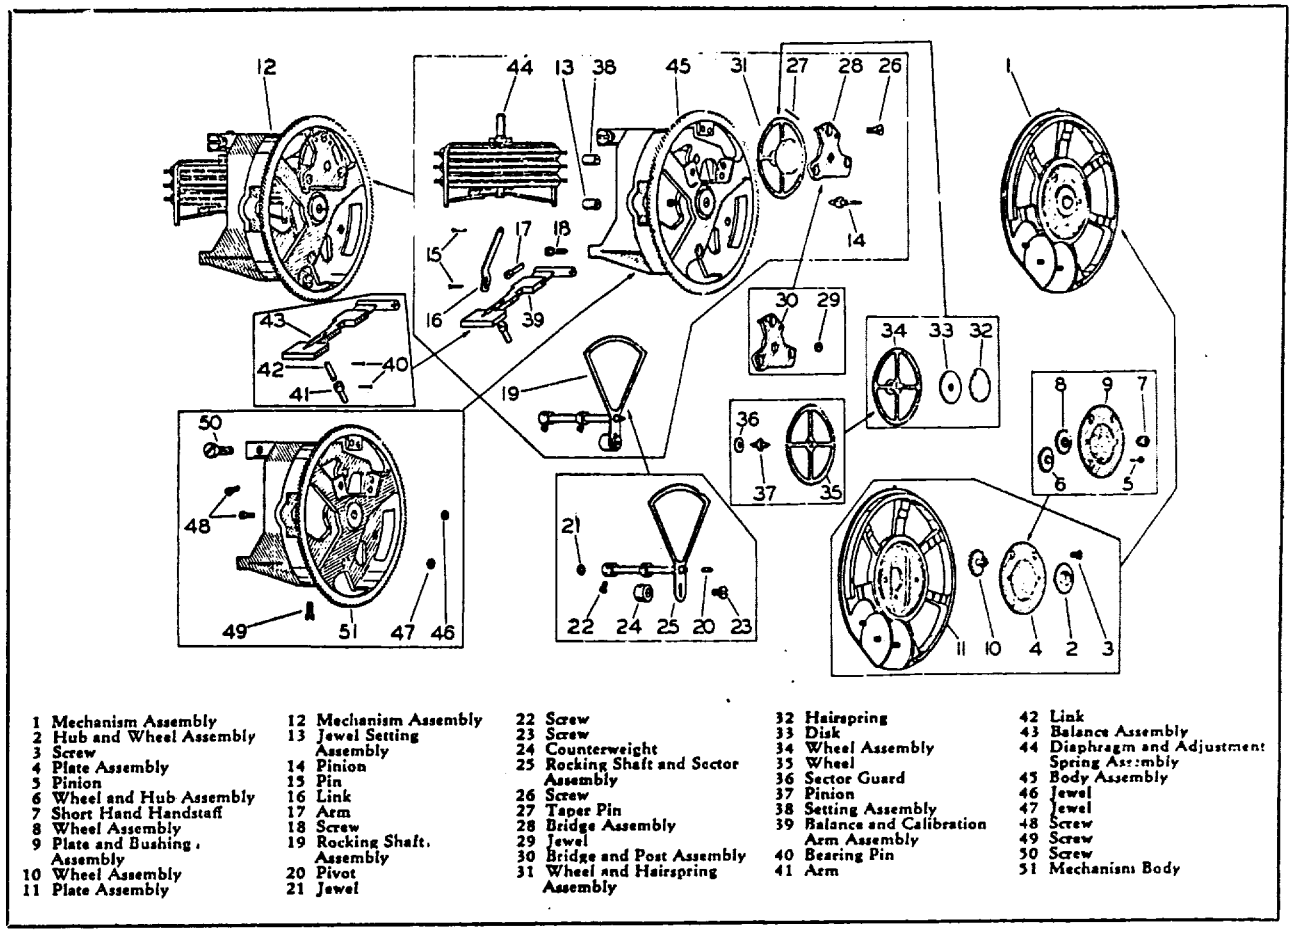
f. Remove the gear assemblies (29, 30 and 31).

g. Remove the top plate mounting spring (32) and the snap ring (33).

h. Before removing the top plate mechanism (34), remove the three bearing plate screws. Lift off the top bearing plate assembly and the wheel assembly.

i. With a pair of parallel jaw pliers, grasp a spoke of the top plate and remove it from the case (47). See paragraph 2-19 for the disassembly and reassembly procedures of the top plate assembly (34).

j. Grasp a spoke of the mechanism body (36) and remove it from the case (47). See paragraph 2-20 for the disassembly and reassembly procedures for the case.



2-6. DISASSEMBLY OF THE MECHANISM. *(See figure 2-8.)*

a. Place the mechanism assembly, diaphragm down, in a suitable assembly stand. Loosen the handstaff jewel assembly clamp screw (48).

b. With the back end of a pair of tweezers, press down on the handstaff (14), pressing the jewel setting assembly (13) from the mechanism body.

CAUTION

Pressure should be applied evenly as any side pressure may break the handstaff.

Figure 2-8. Mechanism Assembly

c. Lift the center pinion off the mechanism casting.

d. Remove the bearing pin (15) connecting the diaphragm link (16) and calibration arm (17).

e. Remove the bearing pin (40) connecting the balance link (42) and the arm (41).

Note

The two calibration arms (17) and (41) should be left in the rocking shaft (19). These arms are only moved for calibration and balancing.

f. Remove the rocking shaft pivot screw (18).

g. Lift the rocking shaft (19) straight up so the lower pivot clears the jewel, and remove it from the mechanism through the cutout provided in the front of the casting. See paragraph 2-18 for the repair of the rocking shaft assembly.

h. Remove the three bridge assembly mounting screws (26) and carefully pry the bridge loose from the mechanism body. Carefully turn the bridge assembly (28) over toward the center of the mechanism assembly. Holding the bridge assembly firmly at right angles to the mechanism, push the hairspring taper pin (27) free with pliers.

i. With tweezers inserted through the opening in the side of the casting, grip the pinion of the wheel and hairspring assembly (31) and lift it straight up so the lower pivot clears the jewel. Then move the assembly along the channel in the mechanism body and out of the mechanism. See paragraph 2-17 for the repair of the wheel and hairspring assembly.

j. Loosen the wheel jewel assembly clamp screw (48) and remove the jewel setting assembly (38).

Note

The balance assembly (39) and the diaphragm assembly (44) should not be removed from the mechanism body unless they are to be replaced.

k. Loosen the balance assembly clamp screw (49) and remove the balance assembly (39).

l. Loosen the diaphragm mounting screw (50) and remove the diaphragm and adjustment spring assembly (44) from the mechanism body (45).

2-7. FOR TYPE 671CP-8-016—The disassembly procedure for this type altimeter is the same as for type

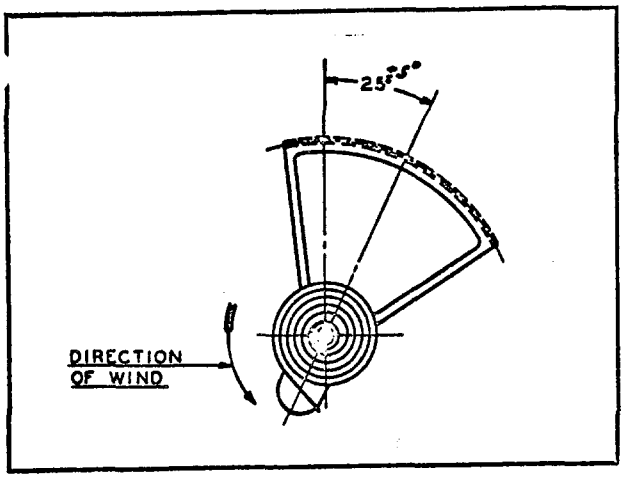

Figure 2-9. Direction of Hairspring on Rocking Shaft

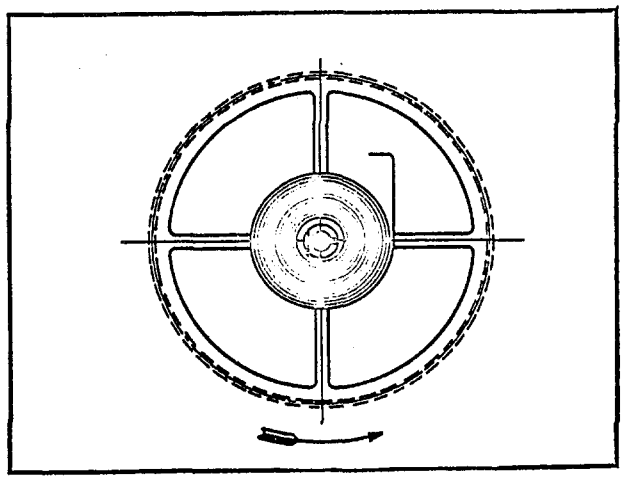

Figure 2-10. Position of Wheel Hairspring

371P-4-01 with one exception. The rocking shaft and sector assembly has a strong hairspring attached to it. Figure 2-9 shows the direction of wind and position of the end of the hairspring so that it will have ¾ to one turn tension when pinned at assembly.

2-8. *(Deleted.)*

2-8A. (Deleted.)

2-9. CLEANING.

2-10. GENERAL—All parts should be cleaned by washing in clean benzine or some other suitable cleaning solution and dried with dry air from a hose. Pivots are cleaned by pressing the pivot into the end grain of dry featherwood and twirling it between the fingers. Jewels and bearing holes are cleaned by twirling the sharpened end of a pegwood stick in the hole. Sector and pinion teeth are cleaned by brushing with a #2 watchmaker's brush dipped in benzine.

2-11. INSPECTION.

a. Inspect all gear teeth for wear or damage.

b. Inspect the jewels for chips or cracks.

c. All pinions and pivots must be free from corrosion and their polished surfaces must have a mirror-like finish.

d. The hairspring must be of proper length and in good condition.

e. The bearing holes in the links must not be worn.

f. Both compensating pins of the aneroid diaphragm must rotate from very light finger pressure.

2-12. TESTING.

2-13. WHEEL AND HAIRSPRING ASSEMBLY.

a. With a pin vise hold the wheel in a vertical plane and check the position of the hairspring. It should be parallel to the disk and the coils should lie in the same plane. (See figure 2-10.)

b. Check the concentricity of the wheel in a truing caliper. Any eccentricity will be apparent by comparison with a fixed guide. The concentricity may also be checked by spinning the wheel in a jeweler's lathe and checking its periphery against a guide.

CAUTION

If the hairspring is mounted on the wheel, do not spin the wheel at high speed as to do so will destroy the hairspring.

2-14. Check that the sector and hairspring are tight on their respective shafts.

2-15. REPAIR.

2-16. JEWELS—To remove a jewel from one of the assemblies, support the unit in a suitable manner and tap it out. Replace the jewel by tapping it into place from the opposite side. The removal and replacement of the rocking shaft assembly jewel is described in paragraph 2-18.

2-17. WHEEL AND HAIRSPRING ASSEMBLY.

a. Hold the wheel assembly in a pin vise. Place a *jeweler's screwdriver between the disk and the hairspring* collet and pry the hairspring from the staff. Before replacing the hairspring, the collet must be squeezed together to assure a tight fit.

b. To remove the wheel pinion, support it on a suitable staking frame and tap it out.

2-18. ROCKING SHAFT ASSEMBLY. *(See figure 2-8.)*—The calibration arms should not be removed from the rocking shaft unless they are damaged.

a. JEWEL—Place the rocking shaft (19), jewel end up, in the clamp similar to that shown in figure 2-11 and hold the clamp in a vise. With a scriber or other sharp pointed tool, break up the jewel (21) and remove

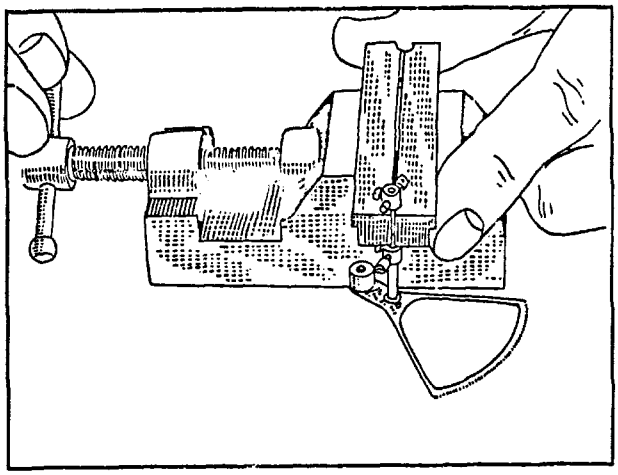

Figure 2-11. Rocking Shaft Held in Clamp

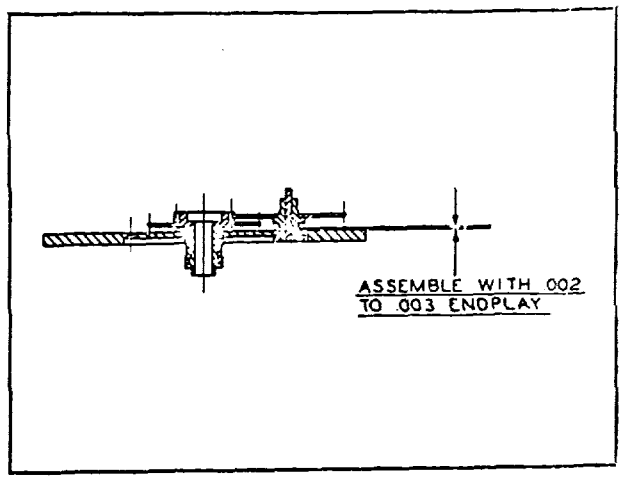

Figure 2-12. Bearing Plate

all fragments. With a No. 53 drill held in a pin vise, drill through the jewel setting. Obtain a 1-72 tap and grind the end flat. Holding it in a pin vise, screw it one or two turns into the jewel setting. Pull the setting out of the shaft. Place a new jewel setting assembly on the shaft so the flat face is up and tap it into place with a suitable punch.

b. PIVOT—Chuck the shoulder of the pivot (20) in a jeweler's lathe and carefully pull the assembly away from the pivot with a slight twisting motion. To replace the pivot, place the rocking shaft in the clamp (as shown above for replacement of jewel) and hold the clamp in a vise. Tap the new pivot into place using a suitable punch.

Note

If the pivot is loose, squeeze the end of the shaft in a collet of a jeweler's lathe to make the hole smaller before pressing in the pivot.

2-19. TOP PLATE ASSEMBLY. *(See figure 2-8.)*

a. HANDSTAFF—Place the bearing plate (4) on a staking frame with the handstaff in a suitable hole and the wheel up. With a suitable punch, tap the short hand handstaff (7) free of the wheel (8). Place the handstaff in a suitable hole in the staking frame so its shoulder rests on the table. Locate the bearing plate (9) on the handstaff, then place the wheel (8) on the staff and tap it in place with a suitable punch. Figure 2-12 shows the arrangement of the parts.

b. REMOVAL OF THE INTERMEDIATE PINION AND WHEEL—While holding the top bearing plate (4) press the staff of the intermediate pinion (5) with the back end of a tweezer until it is flush with the intermediate wheel and hub assembly (6). Place the pointed ends of the tweezers between the bearing plate and the wheel and pry off the wheel and hub assembly.

CAUTION

Use care when prying off the wheel assembly so as not to bend the staff of the pinion.

c. REPLACEMENT OF THE INTERMEDIATE PINION AND WHEEL—Insert the staff of the intermediate pinion (5) in the bearing hole from the front side of the plate. While holding the pinion in place with the finger, place the intermediate wheel and hub assembly (6), shoulder down, on the pinion staff. Place the assembly on the table of a staking frame so the hub of the intermediate wheel and hub assembly is in a suitable hole. Insert a 0.003 inch feeler gage between the intermediate wheel and the bearing plate. Press the pinion down and remove the feeler gage.

d. CHECKING THE ASSEMBLY FOR FRICTION—Reassemble the unit, being careful that the wheel assembly pivots are in the bearing holes when securing the top bearing plate (4) to the top plate (11). Use a short hand with the weighted end cut off and the paint removed. Press the hand onto the handstaff. Hold the assembly so the prepared hand is in a vertical plane, then turn the plate between the fingers. Any friction will be indicated by the tendency of the hand to rotate with the assembly. Any existing friction must be removed before replacing the unit in the case.

2-20. CASE ASSEMBLY. *(See figure 2-7.)*

a. REMOVAL OF THE ADJUSTMENT KNOB STEM AND LEATHER WASHER—Pry the snap ring (39) from the groove and push the pin (40) out of the stem (41). Remove the stem. Examine the leather washer (42). If conditions warrant, replace it.

b. REPLACEMENT OF THE ADJUSTMENT KNOB STEM AND LEATHER WASHER—Before the leather washer is replaced it must be soaked in a hot mixture of the following:

Beeswax	60 parts by weight
Tallow	20 parts by weight
Vaseline	20 parts by weight

c. After soaking in this mixture, withdraw the washer and remove the excess solution. Replace it in the recess of the case smooth side up. Replace the snap ring (39) on the hub of the pinion (43) but not in the

groove. Place the pinion in the recess of the case with the hub toward the front. Insert the stem (41) through the case into the hub of the pinion. Align the holes, insert the pin (40) and secure it with the snap ring (39).

d. REMOVAL OF THE IDLER GEAR—Do not remove the idler gear (46) unless it is absolutely necessary, as the idler shaft (44) must be sealed airtight. If it is necessary, place the case, front down, on a wooden block with the idler shaft over a suitable hole in the block. Tap the idler shaft out of the case with a pin punch.

e. RELACEMENT OF THE IDLER GEAR—Place the case, front up, on the bench. Place the spring washer (45) and the idler gear (46), hub down, in the recess of the case. The spring washer is toward the rear of the case. Insert the shaft (44) through the case tapping it into place with a suitable punch. Place a few drops of a suitable sealing compound on each end of the idler shaft.

2-21. LUBRICATION.

a. A powdered lubricant, if used on each end of the compensating pins of the aneroid diaphragm, will improve the performance and substantially reduce the hysteresis errors of the sensitive altimeter. The lubricant may be purchased from the Alpha Corporation, Greenwich, Conn., as Molykote, Type M.

b. Note in which detent the compensating pins are located. Carefully remove the pins. Fill the detents with the powdered lubricant. Replace the pins and with the fingers, using very little pressure, roll the compensating pins between the two bearing surfaces. Remove the pins and again fill the detent with the lubricant. Repeat this cycle until it is certain that a minute amount of the powdered lubricant is packed into the detent. When properly lubricated, the compensating pins will rotate smoothly from extremely light pressure. Remove the excess lubricant from the surfaces of the compensator and diaphragm centerpiece.

2-22. REASSEMBLY. *(See figure 2-8.)*

2-23. TYPE 371P-4-01.

a. Before assembling the mechanism, check the fit between the center hole of the top plate casting (11) and the center boss of the mechanism body (45).

b. Place the top plate on the mechanism body and check the action by slowly rotating the top plate. There should be no side play and the fit should permit a smooth action.

c. Insert the straight end of the link (16) in the slot of the diaphragm centerpiece and secure it with a new bearing pin (15). Bend and secure the bearing pin so it cannot turn in the bearing hole. Hold the diaphragm assembly (44) so the link hangs down and check the action of the parts by slowly rocking the diaphragm. There should be no play on the bearing pin, yet the parts should not bind.

d. Replace the diaphragm assembly (44) in the mechanism body (45) and secure it with the clamping screw (50). Replace the balance assembly (43) in the mechanism body and secure it with the clamping screw (49).

e. Replace the wheel jewel assembly (38) and secure it with the screw (48).

f. Insert the wheel and hairspring assembly (31), hairspring up, through the cutout in the mechanism body and place the pivot into the lower jewel (38). Hold the bridge assembly (28) over the mechanism and insert the hairspring into the post. Secure it with a new taper pin (27) and cut off the excess pin. The hairspring should be adjusted in such a way that the first leaf is parallel to the bridge plate. Secure the bridge assembly to the mechanism with three mounting screws (26).

CAUTION

Be certain that none of the hairspring convolutions are between the mechanism body and the bridge plate when securing the bridge plate to the mechanism.

g. Adjust the end play of the wheel and hairspring assembly (31) to 0.002 inch by moving the jewel setting assembly (38) in the mechanism body. The hairspring should be evenly spaced between the hairspring disk and the surface of the top plate and all the convolutions should lie in the same plane. Approximately three or four coils of the spring should extend past the disk opposite the hairspring post.

h. Check the freedom of movement of the wheel and hairspring assembly. Place the mechanism body, diaphragm up, on the assembly stand. With the hairspring relaxed, rotate the wheel 1/4 turn and allow it to swing free. It should return to its original position within 1/8 inch.

i. Insert the rocking shaft assembly (19) through the cutout of the mechanism body.

CAUTION

When inserting the rocking shaft, great care must be exercised not to damage the teeth of the sector or wheel assembly.

j. Adjust the rocking shaft assembly by repositioning the pivot screw (18) until an end play of 0.003 inch is obtained.

k. The sector should track approximately in the center of the wheel pinion of the wheel and hairspring assembly (31) and in one plane. Lift up or press down on the spokes of the sector until the correct alignment is obtained.

CAUTION

When checking the tracking of the sector, care must be exercised not to allow the wheel to run out of mesh while tension is applied to the hairspring, as this will cause the wheel to rotate rapidly and damage the hairspring.

l. With the mechanism on the assembly stand, diaphragm up, turn the rocking shaft in a clockwise direction until the sector is disengaged from the wheel pinion and allow the wheel to come to rest with no tension on the hairspring.

m. Hold the rocking shaft in this position by pressing against the counterweight and with a toothpick turn the wheel counterclockwise six revolutions (24 spokes) to apply tension to the hairspring. With this tension maintained on the hairspring, slowly re-engage the sector with the wheel pinion.

CAUTION

After tension has been applied to the hairspring and the wheel pinion engaged with the sector, the sector must be held at all times until the rocking shaft assembly is connected to the diaphragm assembly with the link. If this is not done the hairspring tension will disengage the pinion from the sector and cause damage to the hairspring.

n. With tweezers hold the diaphragm link in line with the slot in the calibration arm of the rocking shaft and slowly move the sector by its countrweight until the bearing hole in the link and the bearing hole in the calibration arm are aligned. Insert a new bearing pin in the aligned holes.

o. With a small pair of needle-nose pliers press the head of the pin until it "bites" into the calibration arm. Bend the pin at the arm and toward the rocking shaft. Test the freedom of the link. It should have no play on the bearing pin but yet should not bind in the calibration arm.

p. A special balance weight (TE630A.1) is necessary in order to adjust the balance arm tension properly. Figure 2-13 illustrates the application of this weight. It should be noted that reference "A" shows a clearance of 1/32 inch between the weight and the mechanism body when the weight is suspended on the balance arm. To correct any error in tension of the balance arm, turn the balance assembly post and secure the balance with the clamp screw (49).

Note

The spring of the balance assembly should follow a straight line from the post to the end of the arm. A slight curve is permissible. If the spring has more than a slight curve after it is set, it may be too weak and the assembly should be checked by placing the altimeter in a pressure chamber and subjecting it to minus 1500 feet, then to the maximum range of the instrument. The balance assembly must not contact the mechanism assembly or the diaphragm.

q. Check the alignment of the balance link assembly with the slot in the arm in the rocking shaft. The balance assembly must be adjusted so that the link is

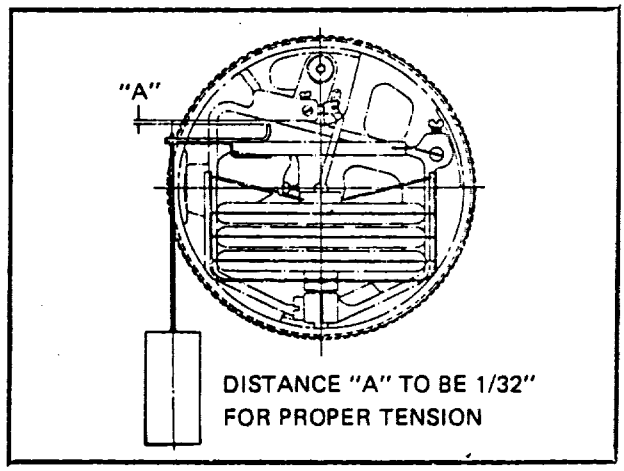

Figure 2-13. Application of Balance Weights

parallel with the slot, so as to move in it without binding. Insert the link in the slot and secure it with a new bearing pin.

r. Place the handstaff pinion (14) into the jewel in the mechanism body. Replace the handstaff jewel assembly (13) and adjust it until an end play of 0.003 inch is obtained. Secure it with the screw (48).

2-24. FOR TYPE 671CP-8-016—The reassembly procedure for type 671CP-8-016 is the same as for type 371P-4-01 with two exceptions.

a. Secure the rocking shaft hairspring so that it has from ¾ to one turn tension.

b. When applying tension to the wheel assembly hairspring as described in paragraphs 2-23 l and m, 6¾ revolutions (27 spokes) tension must be applied to the hairspring for this type of instrument.

2-25. (Deleted.)

2-25A. (Deleted.)

2-26. CALIBRATION.

2-27. CHECKING BEFORE CALIBRATION.

Note

The calibration procedure as outlined in the following paragraphs applies to all altimeters covered in this publication, regardless of their range.

2-28. CHECKING FOR BALANCE—The balance arm on the rocking shaft controls the position error of the instrument in the normal operating position and 180° from this position. The sector counterweight controls

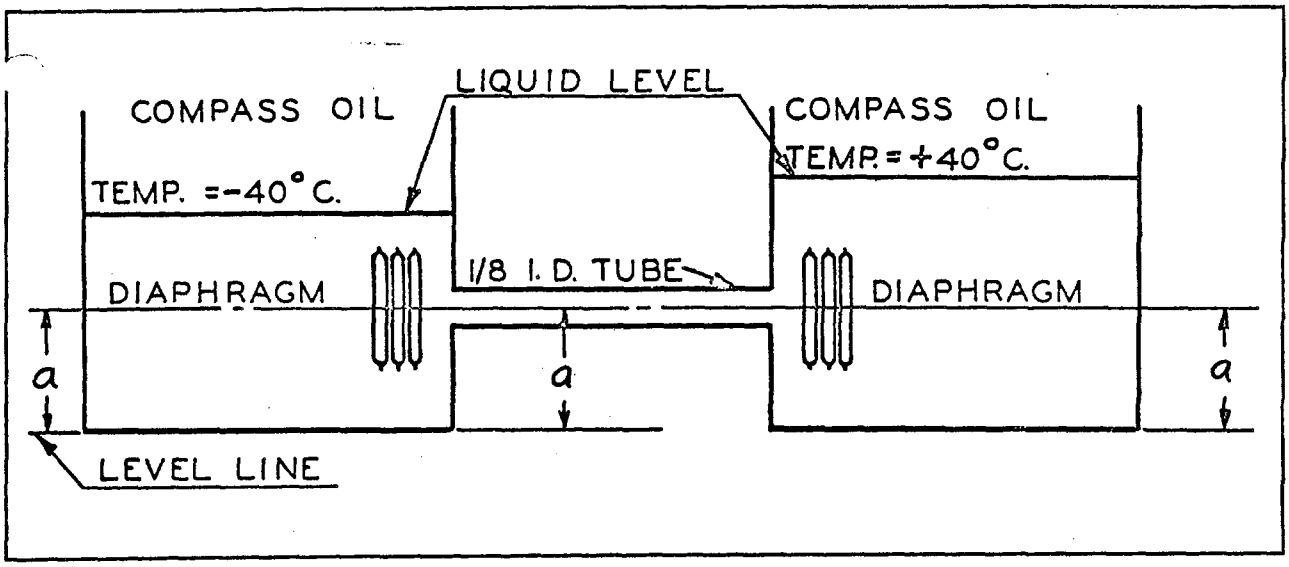

Figure 2-14. Schematic of Compensating Baths

the position error at 90° and 270° from the normal operating position.

a. Mount the mechanism in the calibration stand (TE583A) so the wheel assembly is at the zero position and place the stand, dial up, on the bench. Lightly press a balanced hand on the handstaff so it indicates zero. With the mechanism in the calibration stand and the hand pressed onto the handstaff at an indication of zero, hold the instrument dial vertical with the "0" on top. Tap the stand and note the reading. Turn the instrument 180 degrees (this places the "0" at the bottom) and, after tapping, note the indication of the hand. If the hand has moved clockwise (plus error) by more than 20 feet, correct the error by shortening the effective length of the calibration arm to which the balance is connected. If the error is minus, the effective length of the calibration arm must be increased.

b. Hold the mechanism dial vertical with the "0" on top. Tap the stand and note the reading. Turn the instrument 90 degrees counterclockwise. This places the zero at the left (9 o'clock). After tapping, note the indication of the hand. If the hand has moved clockwise (plus error) by more than 20 feet, correct the error by shifting the position of the sector counterweight toward the rocking shaft. If the error is minus by more than 20 feet, the counterweight should be moved away from the rocking shaft.

c. Alternate between the two adjustments until a maximum position error of ±5 feet is obtained.

2-29. TEMPERATURE COMPENSATION—Temperature compensation of an altimeter is necessary only if the bracket or adjustment nuts have been disturbed, or if the compensator pins have fallen out and their original location cannot be determined.

2-30. TEST EQUIPMENT — Temperature compensation is greatly facilitated if a chamber is used in which the air temperature can be regulated to give an overall change of 80°C (144°F). This allows testing and adjustment of altimeter temperature compensation with the greatest convenience. If such a chamber is not available, the altimeter mechanism can be subjected to the required variation of temperature by first placing it in a cold bath of kerosene or compass liquid, and then in a hot bath; or if only one vessel is available, the cold reading of the mechanism can be taken at room temperature, followed by heating the bath to a temperature +80°C (+144°F) above room temperature before taking the second reading. If liquid baths are used, there should be a third bath maintained at room temperature. The mechanism should be transferred to this bath before being immersed in the extreme temperature bath so as to permit it to change temperature more slowly and avoid cracking jewels.

Note

The procedure for temperature compensation in a chamber in which air temperature can be regulated is the same as that described below for the liquid bath method of temperature compensation.

a. The baths will give different hydro-static pressures at the same depths, according to the specific gravity of the liquid at each temperature. Thus if compass oil is used, the mechanism should be submerged 8 percent deeper in the warm bath than in the cold bath to equalize the hydro-static pressure. However, the need for different immersion depths may be avoided by connecting the two baths with a small tube. (See figure 2-14.) Tests are usually made at +40°C (+104°F) and —40°C (—40°F).

b. Select two vessels, each large enough to contain the mechanism, and connect them with a 1/8-inch copper tube (inside diameter) making certain that the tube

openings in each bath are opposite the center of the diaphragm. Also make sure that the baths are on the same level plane. Fill the vessels with enough liquid to cover the pointer of the mechanism.

c. Liquid in the hot bath can be heated safely by using one or more electric immersion heaters, or by a coil in the bath, through which hot water or steam is circulated.

CAUTION

Avoid fires. Do not heat the bath with an open flame or permit smoking or any spark or flame in the same room. The bath is heated to a temperature well above the flashing and burning points in the case of kerosene and certain volatile and inflammable constituents of the liquid are distilled off during heating. Work in a place with good ventilation and safe exits. Keep an extinguisher, for oil fires, within reach.

d. Liquid in the cold bath can be cooled in a refrigerator, or by a coil in the bath through which a refrigerant is circulated, or by placing in the bath one or more open metal vessels containing carbon dioxide, "dry ice." If the temperature cannot be lowered to —40°C (—40°F) and held there during the test period, raise the temperature of the hot bath until it is +80°C (+176°F) above that of the cold bath.

e. If it is not possible to have a difference of +80°C (+144°F) between the hot and cold baths, a smaller difference may be used, but the allowable change of reading shown in Table I will be proportionately reduced. If the temperature difference is +40°C (+104°F) the allowable change of reading is half the allowable change with an +80°C (+176°F) temperature change.

f. Fluctuations in atmospheric pressure during compensation testing must be taken into account. These changes in pressure may be noted in terms of feet of altitude from another standard altimeter. For instance, if the standard altimeter indicates 140 feet at the start of the compensation test and 170 feet when the test is completed, the mechanisn undergoing the compensation test also will have changed plus 30 feet during the same time. This error must be subtracted algebraically from the reading obtained from the test instrument in order to arrive at the true compensation. In the short period of the bath test, atmospheric pressure variations may or may not occur. Generally they are of such slight magnitude as to be negligible. During a 2-hour ice box test, however, appreciable changes in atmospheric pressure may take place.

2-31. Bring the baths to their proper temperatures [(usually +40°C (+104°F) and —40°C (—40°F)] and stir the liquid in each bath to insure uniform temperature throughout.

a. Place the altimeter mechanism in the calibration stand (TE583A).

b. With the hand at "0", immerse the mechanism in the cold bath for five minutes. Tap the frame lightly and record the reading. Any reading other than zero is an error.

Note

Agitate the liquid before taking a reading. When tapping the mechanism, the strokes should be made vertically. Horizontal tapping may move the mechanism sideways and so shift the sector position.

c. Remove the mechanism, reset to "0" and immerse it in the hot bath for five minutes. Tap the frame again and record the reading.

CAUTION

To avoid cracking jewels, allow the mechanism to warm up at room temperature. This is best done by immersing it in a bath at room temperature before placing it in the hot bath.

d. If the reading in the hot bath does not differ from the reading in the cold bath by more than the tolerances specified in Table I, the temperature compensation is satisfactory and no further adjustment is required.

TABLE I

Temperature Difference	*For 35,000 ft. Altimeters*	*For 50,000 ft. Altimeters*
Degrees Centigrade	*Tolerance Feet*	*Tolerance Feet*
80	+40	+50
60	30	40
40	20	30

Note

Table II shows the progression of error throughout the range of an instrument with the maximum allowable error at zero feet altitude; therefore, to maintain a minimum error at various altitudes, it is important to compensate the diaphragm as near to zero error as possible.

TABLE II

35,000 Foot Altimeters		*50,000 Foot Altimeters*	
Altitude in Feet	*Allowable Change of Reading in Feet*	*Altitude in Feet*	*Allowable Change of Reading in Feet*
0	± 40	0	± 50
6,000	± 70	6,000	±100
12,000	± 90	12,000	±175
18,000	±125	18,000	±275
25,000	±175	25,000	±375
35,000	±250	35,000	±525
		50,000	±750

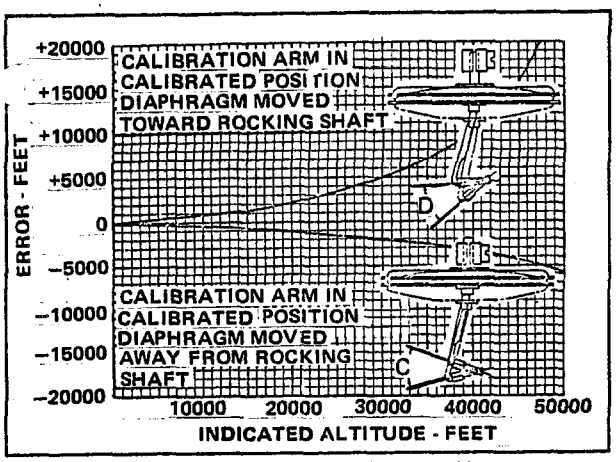

Figure 2-15. Effect of Diaphragm Movement on Calibration

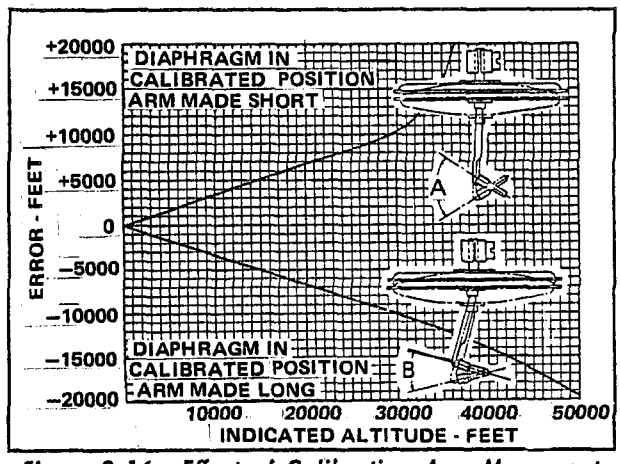

Figure 2-16. Effect of Calibration Arm Movement on Calibration

2-32. If the difference in hot and cold bath readings exceeds the tolerance shown in Table I, adjustment of the temperature compensator is necessary.

a. When the hot bath reading is greater than the cold bath reading by 50 feet or more, move both of the push rods (pins) between the diaphragm and the compensator bracket, into the next notch in the bracket, toward the diaphragm. Move the rods, one at a time by grasping the compensator bracket with tweezers and twisting lightly to spring the bracket away from the end of the rod while shifting the rod by grasping it with another tweezer. A movement of 1 notch gives a correction of from 50 to 65 feet in the reading.

b. When the original hot bath reading is less than 50 feet above the cold bath reading or when the remaining error after shifting the push rods is still clockwise, giving a reading that is too high, turn the diaphragm support nut, between the compensator bracket and the mechanism body, so it moves away from the diaphragm. Turn the second diaphragm support nut, between the compensator bracket and the diaphragm, in the same direction. A ¼ turn of the diaphragm support nut results in a correction of 10 feet.

c. When the hot bath reading is 50 feet or more below the cold bath reading, move each of the push rods to the next notch in the compensator bracket, away from the diaphragm.

d. If the original hot bath reading is less than 50 feet below the cold bath reading, or when the remaining error after shifting the push rods is still less than the cold bath reading, turn the diaphragm support nut, between the compensator bracket and the diaphragm, so it moves toward the diaphragm, then turn the second diaphragm support nut in the same direction.

e. When temperature compensation is completed, if the altimeter was placed in a liquid bath, disassemble the mechanism and clean all parts thoroughly to remove the film of oil, paying particular attention to the hairspring.

Note

Use of the adjustable centerpiece on current altimeters has greatly simplified compensation adjustments. The new centerpiece is made of beryllium copper which is a harder material than was formerly used on the old type centerpiece and, therefore, assures a more friction-free bearing surface for the compensator pins. The compensation procedure is basically the same with the exception that now close adjustments are made with the adjusting screw on the centerpiece instead of the two locknuts which were formerly used. A rough compensation may be obtained by positioning the compensating pins in the dimples of the compensator. Each dimple will correct an error of approximately 60 feet. By increasing the angle between the compensating pins and the centerpiece, a plus error can be corrected. Conversely, a lesser angle will correct a minus error. If the distance between dimples is too great and does not permit satisfactory compensation, it may be further adjusted by turning the screw on the centerpiece. To correct a plus error turn the screw out; to correct a minus error turn the screw in. Each revolution of the screw will correct an error of approximately 80 feet.

2-33. CALIBRATION PROCEDURE.

TABLE III

Standard Altitudes	*Equivalent Atmospheric Pressure*		*Scale Error Tolerance*	
	Mercury		*35,000 ft. Altimeters*	*50,000 ft. Altimeters*
feet	*mm*	*inches*	*feet*	*feet*
0	760.0	29.92	± 25	± 25
5,000	632.4	24.89	40	75
20,000	349.1	13.75	100	150
35,000	178.7	7.04	200	250
50,000	87.3	3.44	—	550

Note

The calibration points listed in Table III are the primary check points to be used during calibration.

2-34. Either a change of diaphragm position or a change in the length of the calibration arm "speeds up" or "slows down" the mechanism with a corresponding increase or decrease in the rate of hand rotation between zero and maximum altitude.

2-35. Shifting the diaphragm position changes the speed of rotation at high altitudes more than at low altitudes. Shifting the diaphragm toward the rocking shaft "speeds up" the mechanism while shifting it away from the rocking shaft "slows down" the mechanism. (See figure 2-15.)

2-36. Changing the length of the calibration arm causes a change in the speed of rotation throughout the range. Adjustment of the calibration arm "speeds up" or "slows down" the mechanism throughout the entire range. (See figure 2-16.)

2-37. By a combination of both adjustments, the speed of rotation can be selectively increased or decreased in the low, middle, or high altitude ranges.

2-38. CALIBRATION RATIOS (35,000 feet).

2-39. The following ratios may be applied when shifting the calibration arm or the diaphragm in relation to the correction obtained in the instrument indication. They are approximate but will help in the calibration procedure. The figures for the calibration arm are based on a final change in reading of the instrument caused by turning the drum of the vernier calibration tool (TE639) one segment. The figures for the diaphragm are based on a final change in reading of the instrument for an initial change in reading, caused by moving the diaphragm.

Method	*Ratio*	*Altitude*
Calibration arm	1 to 1	5,000 feet
Calibration arm	7 to 1	35,000 feet
Diaphragm	1 to 35	5,000 feet
Diaphragm	1 to 1	35,000 feet

2-40. If the calibration arm is adjusted with the vernier calibration tool so the drum moves the distance between two graduations, the change in indication at 5,000 feet will be approximately 20 feet and at 35,000 feet the change will be seven times as great or approximately 140 feet.

2-41. If the diaphragm is shifted so that the hand indicates a change of 350 feet, the change in indication at 35,000 feet will be 350 feet and at 5,000 feet the change will be 35 times less or approximately 10 fee.

2-42. Using the above ratios, corrections in scale readings may be approximately calculated when working with both the calibration arm and diaphragm corrections at the same time.

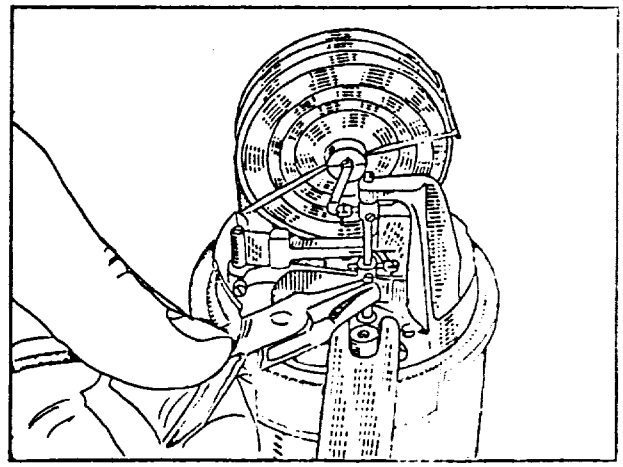

Figure 2-17. Shifting Sector of Rocking Shaft

EXAMPLE

Move arm +20 feet and diaphragm —350 feet

Correction Applied	*Change at 5,000 feet*	*Change at 35,000 feet*
Arm +20 feet	+20 feet	+140 feet
Diaphragm —350 feet	—10 feet	—350 feet
Total Correction	+10 feet	—210 feet

2-43. CALIBRATION RATIOS (50,000 feet range).

2-44. If the calibration is adjusted with the vernier calibration tool so the drum moves the distance between two graduations, the change in indication at different altitudes will be as follows:

approximate change of 20 feet at 5,000 foot indication
approximate change of 100 feet at 20,000 foot indication
approximate change of 150 feet at 35,000 foot indication
approximate change of 350 feet at 45,000 foot indication

2-45. If the diaphragm is shifted so that the hand indicates a change of 1,000 feet the change in indication at different altitudes will be as follows:

a change of 1,000 feet at 50,000-foot indication, created by shifting the diaphragm, causes an

approximate change of 500 feet at 45,000 foot indication
approximate change of 325 feet at 35,000 foot indication
approximate change of 125 feet at 20,000 foot indication
approximate change of 15 feet at 5,000 foot indication

Note

The following are not inflexible rules, but are to be used as a guide in judging irregular pointer movement. From "0" to 25,000 feet, without vibration, the hand must not jump more than an indication of 100 feet, and from 25,000 to 40,000 feet the hand must move smoothly although not necessarily regular when vibration is applied with a type A-11, size 2, 8-volt, Edwards bozzer operating on 60-cycle current.

Note

The following observations are hints as to where friction will be found. If a noticeable sticking or jumping occurs every revolution of the hand, examine the handstaff. In this event the handstaff may be too large. To overcome this, "mike up" several staffs and use the smallest one found. If a noticeable sticking or jumping occurs once in each 12,000 feet of indication, examine the wheel, of the wheel and hairspring assembly for corrosion, a burr between teeth, or a damaged tooth. If a noticeable sticking or jumping occurs once throughout the entire range, examine the sector for corrosion, a burr between teeth, or a damaged tooth.

2-46. Observe the point where the pinion meshes with the sector. The point of mesh should be approximately 1/8 inch from the end of the sector arc at sea level pressure. It is important to have this starting position in order to have the altimeter reach its maximum range of operation. To adjust the position of the sector hold the rocking shaft with the special pliers (figure 2-17) and with the sector wrench turn the sector as required.

2-47. ADJUSTMENTS.

a. Mount the mechanism in the calibration stand (TE583) so the diaphragm is on the same side as "0" and place it in the pressure chamber (TE600B) so "0" is at the top. By means of the knob on the calibration stand, set the hand of the test mechanism so that it will read zero when the master altimeter or barometer reads zero.

Note

If the hands of the master are below "0" close the chamber and reduce the pressure until the hands indicate "0." Note the position of the hand of the test instrument. If it is not on "0" open the chamber to atmosphere and turn the adjustment knob to reposition the hand. Repeat the procedure until the hands of both instruments indicate "0" simultaneously. If the hands of the master are above "0," the procedure is similar to that described above except that the instruments must be subjected to pressure.

b. Close the pressure chamber and slowly decrease the pressure until the master altimeter or barometer indicates a reading equivalent to 5,000 feet.

c. If the mechanism shows a plus or minus indication, remove it and adjust the effective length of the calibration arm to which the diaphragm link is connected. If the mechanism reading is too high, move the calibration arm out of the rocking shaft. If the mechanism reading is too low, move the calibration arm into the rocking shaft. For accurate adjustment of the calibration arm, use the calibration tool (TE639). Clamp the tool into the rocking shaft in a position as high as it will go so the drum rides against the end of the calibration arm. Then tighten the clamp screw.

Note

The clamp screw and screwdriver should be in exact alignment with the calibration arm before the screw is tightened. If they are not, the calibration tool will not be correctly aligned to give accurate adjustment.

d. To move the calibration arm into the rocking shaft loosen the adjusting clamp screw just enough to permit the arm to be moved and turn the vernier drum clockwise. The rim of the drum pushes the calibration arm into the rocking shaft. When the drum is turned the distance between two graduations, it moves the arm sufficiently to change the altimeter reading approximately 20 feet at 5,000 feet altitude. After adjusting the length of the calibration arm, tighten the adjusting clamp screw and remove the calibration tool from the rocking shaft. To move the calibration arm out of the rocking shaft, turn the drum of the calibration tool counterclockwise while gently pressing the end of the calibration arm with the finger to keep the arm in contact with the drum. When the altimeter mechanism reading agrees with that of the master altimeter or barometer at 0 and 5,000 feet, slowly reduce the pressure until the master indicates 20,000 feet and record the indication of the test altimeter. Reduce the pressure to the maximum range of the instrument and note the indication.

e. If the mechanism indicates a reading above or below that of the master altimeter, remove the mechanism and adjust the position of the diaphragm in the mechanism body. If the mechanism reading is too high, move the diaphragm out (away from the rocking shaft). The position of the diaphragm may be accurately adjusted with the tool (TE5196). Screw the end of the tool into the diaphragm centerpiece. Turn the large adjustment knob clockwise until the sleeve contacts the casting. Loosen the diaphragm clamping screw in the mechanism body. To move the diaphragm toward the rocking shaft, turn the adjustment knob counterclockwise. To move the diaphragm away from the rocking shaft, turn the adjustment knob clockwise. Tighten the diaphragm clamping screw and remove the tool.

CAUTION

The amount that the diaphragm may be moved toward the rocking shaft is limited by the balance arm. Do not move the diaphragm too far toward the rocking shaft or its expansion in the high ranges will be stopped by the balance arm.

f. Shifting the diaphragm to correct the indication at maximum altitude alters both the "0" position and the setting at 5,000 feet, therefore, the mechanism must be adjusted again so that it indicates 0 and 5,000 feet in accordance with the steps outlined above.

g. Further adjustment of the mechanism should be made as required until the readings come within the

tolerances specified in Table IV. For calibration purposes, the tolerances in Table IV are less than those specified in Section III, Test Procedures.

TABLE IV

Standard Altitudes	*Equivalent Atmospheric Pressure Hg*		*Scale Error Tolerance*	
			35,000 ft. Altimeters	*50,000 ft. Altimeters*
feet	*mm*	*inches*	*feet*	*feet*
0	760.0	29.92	± 25	± 25
500	746.4	29.39	25	25
1,000	732.9	28.86	40	40
1,500	719.7	28.33	40	40
2,000	706.6	27.82	40	40
2,500	693.8	27.31	40	40
3,000	681.1	26.81	40	40
4,000	656.3	25.84	40	75
5,000	632.4	24.89	40	75
20,000	349.1	13.75	100	150
35,000	178.7	7.04	200	250
40,000	140.7	5.54		350
45,000	110.8	4.36		450
50,000	87.3	3.44		550

h. Check the backward movement of the mechanism by slowly increasing the pressure until the altimeter indicates a minimum of —1,500 feet, maximum —2,500 feet. The sector must be shifted with the special pliers (figure 2-17) and wrench as described in paragraph 2-46, until the above condition exists.

2-48. REPLACING MECHANISM IN CASE. *(See figure 2-7.)*

a. Press the snap ring (38) into the lowest groove with the locating nib in the slot at the top of the case.

b. Place the spring ring (37) on a flat surface. It will be noted that there are three high points located 120 degrees apart. The spring should be placed in the case so that of the three high points, the one at the locating nib faces out toward the dial. It should also be noted that there are three pads or high spots on the underside of the top plate mechanism assembly (34). These pads should be matched with the high points on the spring ring. With the units assembled in the case in this manner, the stresses on the mechanism body will be evenly distributed and the potential source of barometric pressure errors will be eliminated.

c. Lower the mechanism assembly (36) into the case so the sector counterweight is next to the adjustment knob pinion.

Note

Do not replace the top plate mechanism assembly (34) with the top bearing plate or the wheel assembly assembled. First remove these parts.

d. Replace the mechanism top plate so the aligning pin is in the slot of the case. Press it down so the hole in the top plate fits over the boss of the mechanism

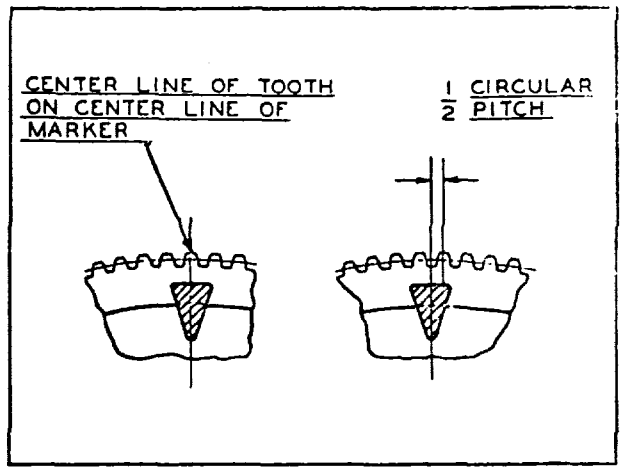

Figure 2-18. Outer Setting Marks

body. Secure the top plate with the snap ring (33). Replace the top plate mounting spring (32) directly opposite the knob stem.

e. With a test knob on the knob stem, check the action of the parts by rotating the mechanism assembly. It should be smooth and slightly stiff without any binding. Improper action of the mechanism assembly may be caused by too tight a mesh between the knob stem pinion (43) and the gear on the mechanism body.

f. Place a 0.005 in. thick slotted shim on the boss of the casting with the handstaff in the slot. With tweezers, press the center pinion, hub up, onto the handstaff until it rests against the shim.

CAUTION

Excessive force should not be used in pressing on the center pinion as the handstaff can easily be broken.

g. Replace the wheel assembly, pinion up, so the gear is in mesh with the center pinion. Lower the top bearing plate onto the top plate making certain that the wheel assembly is in mesh with the handstaff pinion and the wheel assembly pivot is in the pivot hole.

h. Lightly press the short hand onto the handstaff. While holding the top bearing plate in place with the finger, lightly flick the end of the hand. An oscillating, springlike, resistance to movement indicates correct assembly. Secure the top bearing plate to the top plate with three screws.

2-49. OPERATIONAL CHECK.

a. Press the long hand onto the handstaff and place the mechanism in a suitable pressure chamber (TE 600B).

b. Decrease the pressure at a rate of 3,000 feet per minute until an indication of 30,000 feet is reached, then allow the pressure to return to room pressure at the same rate. Note the action of the hand. It should move with a fair degree of smoothness. A slight hesitation is permissible but the hand should not "hang" on

an indication, then suddenly jump to the next point. During this check the instrument should be vibrated with a type A-11, size 2, 8-volt Edwards buzzer operated on 60-cycle current.

c. If any friction is apparent, it is in the top plate mechanism assembly. Determine the cause of malfunctioning by disassembling the top plate mechanism and examining for oxidation or dirt on the handstaff bushing assembly, bearing holes and pivots. Also examine the gear teeth for burrs or damge.

2-50. CLOSING. *(See figure 2-7.)*

a. Replace the center gear assembly (31) meshing it with the idler gear (46). Replace the gear assembly (30) further from the adjustment pinion. Replace the gear assembly (29) that meshes with the adjustment pinion (43).

b. Replace the setting mark gear (28). Replace the barometric dial assembly (27) aligning the reading 29.92 with the rivet hole at the right of the top plate. Replace the shutter (26) locating the lips of the shutter in the slots of the setting mark gear.

c. Replace the outer dial (23) aligning the rivet holes with the holes in the top plate and hold it temporarily in place by inserting a toothpick in each hole. With the dial held in this position, check that the inner setting mark indicates zero and the barometric dial indicates 29.92 with the reference mark on the dial. If the inner setting mark or the barometric dial is not in correct position, the dial (23) must be removed and the mark or barometric dial positioned correctly.

d. Remove one toothpick at a time and secure the outer dial to the top plate with two dial locating pins (22).

e. Replace the third hand hub and wheel assembly, meshing it with the intermediate pinion.

f. Place the wheel spacer ring (25) on the third hand hub and wheel assembly. Replace the spacer (24) and the inner dial (23) and secure it with two screws (21).

g. Replace the outer setting mark (20) so the teeth are in mesh with the idler gear and the reference mark is coincident with the zero indication of the dial. If the original setting mark is not replaced in the instrument, it may be necessary to use another mark having a different relationship between the reference mark and the circular pitch of the teeth. Figure 2-18 illustrates the differences of the two markers. The outer setting marker that gives zero error should be selected and used in the mechanism.

h. Replace the gasket centering ring assembly (19).

i. Replace the small hand (18) with a suitable hand replacing tool. Replace the intermediate hand (17) in the same manner as described for the small hand. Press the large hand (16) on the handstaff so it indicates the same altitude as the master when the barometric scale is set to indicate the existing barometric pressure.

j. With a suitable adjustment knob turn the mechanism so the large hand indicates "0". The intermediate and small hands should also indicate exactly "0". With the finger move the large hand 90 degrees clockwise. This should put the intermediate hand in such a position that the small hand is barely visible along the outside edge. Repeat the procedure by moving the large hand 90 degrees counterclockwise from "0" and note the position of the hands. It should be the same as above but on the opposite side. If the above conditions do not exist, the hand which is out of position may be shifted with a toothpick to the desired position. Turn the mechanism back to its original position.

k. Check to see that the hands do not interfere with each other and that the large hand will clear the glass.

l. Replace the rubber sealing gasket (15), glass (14) and paper gasket (13). Replace the rear washer (12), spring (11) and front washer (10) on the knob stem. Replace the mounting flange assembly (9) and secure it with proper lockwashers (8) and screws (7, 6 and 5).

m. Replace the locknut (2) and knob (1). Lightly tap the instrument glass to remove friction. Note the barometric pressure and compare it with that read from a station barometer. If it is necessary to adjust the barometric dial, pull the adjustment knob forward and while holding it in this position turn it to reset the barometric dial. When the desired barometric pressure is indicated, release the knob.

n. Insert the locking stud (4) into the case so it rides in the recess of the knob stem. Secure it with the locking stud screw (3).

2-51. CHECKING THE MECHANISM FOR LEAKS.

a. Connect a rubber tubing to the static connection and apply suction sufficient to produce a change of reading of the hands of approximately 18,000 feet. At this point, clamp off the tubing and note any change in reading. Over a period of 1 minute, the hand should not move more than 100 feet.

b. If a leak is apparent return the altimeter to atmospheric pressure. Then apply a pressure to move the long hand once around the dial (—1,000 feet). While maintaining this pressure, submerge the instrument in a container of water to determine the location of the leak. A leak around the flange is caused by a dried out or damaged sealing gasket (15). The flange must be removed and the gasket replaced. A leak around the knob stem indicates a dried out leather washer.

c. A leak around the static fitting connection on the rear of case due to damaged or stripped threads may be repaired by drilling out thread cavity and installing heli-coil or reducer bushing. Size will not exceed limits of standard static fitting (⅛ inch I.P.T.). All leak test tolerances must be maintained as outlined in Section III, paragraph 3-18.

SECTION III
TEST PROCEDURES

3-1. VISUAL EXAMINATION—Inspect each instrument for the following:

a. Appearance of the case including chips or cracks.

b. Burred or loose screws.

c. Appearance of the dial and hands.

d. Clearance of the hands.

e. Appearance of the glass for cleanliness and freedom from chips or cracks.

3-2. LUMINOUS PAINT—Each instrument should be checked in darkness. Those parts painted with luminous material should be clearly visible. The instrument should also be checked under ultra-violet light and the same conditions should hold. If the radio-active luminous paint does not meet the above tests, the parts should be repainted in accordance with the prescribed methods.

3-3. INDIVIDUAL TESTS—Unless otherwise specified the instrument shall be tested in normal operating position and shall be lightly vibrated or tapped before a test reading is taken.

3-4. COORDINATION—Set the zero setting pressure scale (barometric scale) to indicate several pressures in inches of mercury selected at random and read the corresponding zero setting altitudes in feet as indicated by the zero setting marks (not the hands). The altitude obtained shall not differ from the altitude corresponding to each pressure by more than the specified tolerance in Table V. Rotate the adjustment knob for one complete revolution of the mechanism to test the mesh for smooth action. There shall be no binding or rough movement of the gears.

3-5. REMEDIAL ACTION—Should the instrument fail to meet this specification, the zero setting marks must be reset as described in paragraph 2-50. If the adjustment knob turns too tightly or grinds, it is an indication of improper mesh between the pinion gear in the case and the mechanism body.

TABLE V

Altitude-Pressure-Table — Feet vs. Inches of Mercury

pressure inches	*0.00*	*0.01*	*0.02*	*0.03*	*0.04*	*0.05*	*0.06*	*0.07*	*0.08*	*0.09*

3-6. ZERO SETTING—Set the zero setting pressure scale (barometric scale) to indicate 29.92. The reference marks should indicate zero within ±5 feet. Connect the s : pressure connection of the indicator to a mercury barometer and sources of suction and pressure. Apply suction or pressure to bring the barometer to an indication of 29.92 inches of mercury. The hands should indicate zero within ±30 feet.

3-7. REMEDIAL ACTION—If the zero setting pressure scale or reference marks do not come within the prescribed limits, they must be reset.

3-8. SCALE ERROR (ROOM TEMPERATURE 25°C (77°F).

a. Set the zero setting system for standard sea level pressure (barometric dial 29.92). Place the instrument in an altitude chamber which is connected to a barometer and source of suction and pressure.

b. If the barometer indicates more than 29.92 inches of mercury, close the chamber and reduce the pressure until the barometer indicates "0" altitude. Note the position of the hands of the test instrument and if they are not on "0", open the chamber to atmosphere and turn the adjustment knob to reposition them. Repeat the procedure until the hands of the instrument indicates "0" simultaneously with the indication of 29.92 inches of mercury on the barometer.

c. Subject the altimeter successively to the pressures indicated with an asterisk (*) in Table VI at a rate of nge in pressure of approximately 3,000 feet per minute. The altimeter shall remain at the pressure corresponding to each test point for one minute before a test reading is taken except as noted for the hysteresis and after effect test. The scale error shall not exceed the tolerances specified in Table VI. The hysteresis and after effect test shall be performed with this test.

3-9. REMEDIAL ACTION—If the instrument fails to meet this test, it must be recalibrated as described in Section II.

3-10. HYSTERESIS AND AFTER EFFECT—This test must be performed with the scale error test described above. Place the instrument in an altitude chamber which

TABLE VI

Standard Altitudes	*Equivalent Atmospheric Pressure Hg*		*Scale Error Tolerance*

TABLE VII

Test Points	*Standard Altitude in feet*		*Equivalent Atmospheric Pressure (mm Hg)*		*Permissible Variation from Scale Error (ft)*		*Elapsed Time At Test Pressure Before Reading*
	35,000 ft Altimeter	*50,000 ft Altimeter*	*35,000 ft Altimeter*	*50,000 ft Altimeter*	*35,000 ft Altimeter*	*50,000 ft Altimeter*	
First hysteresis test point	16,000	20,000	411.8	349.1	Recorded scale error	Recorded scale error	5 minutes
Second hysteresis test point	18,000	25,000	379.4	281.9	Recorded scale error	Recorded scale error	5 minutes
Upper limits of range	35,000	50,000	178.7	87.3	—	—	1 minute
Third hysteresis test point	18,000	25,000	379.4	281.9	70 feet from "UP" reading	150 feet from "UP" reading	10 minutes
Fourth hysteresis test point	16,000	20,000	411.8	349.1	70 feet from "UP" reading	150 feet from "UP" reading	10 minutes
h hysteresis test point (after effect)	—	—	Existing pressure at ground level		50 feet from reading at start	60 feet from reading at start	5 minutes

is connected to a barometer and a source of suction. Subject the altimeter to a decrease in pressure at a rate corresponding to an increase in altitude of approximately 3,000 feet per minute until the pressure corresponding to the first test point given in Table VII is reached. The instrument shall remain at this pressure for the time specified. The pressure shall be further decreased at the above rate until the pressure corresponding to the second test point given in Table VII is reached. The instrument shall remain at this pressure for the time specified. It shall then be subjected to the pressure corresponding to the upper limits of the range of the instrument and held at this pressure for one minute. Increase the pressure at a rate corresponding to a decrease in altitude of approximately 3,000 feet per minute until the pressure corresponding to the next test point given in Table VII is reached. The instrument shall remain at this pressure for the time specified. Then further increase the pressure until the pressure corresponding to the next test point is reached and hold it at this pressure for the time specified. After the readings have been taken the pressure shall be increased until atmospheric pressure is reached. After completion of the hysteresis test, the hands shall have returned to their original indication, corrected for any change in atmospheric pressure, within the tolerance given in Table VII, as the last test point.

Note

The equipment must be leak-proof during this test.

3-11. REMEDIAL ACTION—If the instrument fails to meet this test the trouble may be corrected by decreasing the tension on the balance arm. Adjustments on the balance arm are very critical as a change of balance tension will affect the static balance as well as calibration; therefore, only very minor adjustments should be made. A misaligned link on the balance arm may also cause an apparent hysteresis error. If the error cannot be corrected by either of the methods described above, the diaphragm assembly must be replaced.

TABLE VIII

Altitude feet	*Tolerance feet*
1,000	± 70
2,000	70
3,000	70
5,000	80
10,000	90
15,000	100
20,000	125
25,000	150
30,000	175
35,000	200
40,000	250
50,000	400

3-12. FRICTION.

a. While holding the pressure constant at any point or points as listed in Table VIII, take two readings; the first before tapping the instrument and the second after tapping it. The change in reading of the hands shall not exceed the tolerances given in Table VIII.

b. While operating the instrument at a rate corresponding to an increase in altitude of approximately 3,000 feet per minute, a further check for friction is as follows:

c. From 0 to 25,000 feet, without vibration, the hand must not jump more than the indicated tolerances given in Table VIII.

d. From 25,000 to 40,000 feet, the movement of the hand must be smooth although not necessarily regular when vibration is applied with a type A-11, size 2, 8-volt Edwards buzzer, operating on 60-cycle current.

e. From 40,000 to 45,000 feet, some leniency is to be exercised and two 100-foot jumps of the hand are permissible when vibration is applied with the above buzzer.

f. Above 45,000 feet, reject the instrument only if the hand sticks, then spins.

g. This test may be combined with the test for scale error.

TABLE IX

Standard Altitudes	*Equivalent Atmospheric Pressure Hg*		*SCALE ERROR TOLERANCE*			
			ROOM TEMPERATURE		*LOW TEMPERATURE (−35°C) Variation from Room Temperature Reading.*	
			35,000 ft Altimeters	*50,000 ft. Altimeters*	*35,000 ft Altimeters*	*50,000 ft Altimeters*
feet	*mm*	*inches*	*feet*	*feet*	*feet*	*feet*
0	760.0	29.92	± 50	± 50	± 40	± 50
6,000	609.0	23.98	100	150	70	100
12,000	483.3	19.03	200	200	90	175
18,000	379.4	14.94	200	275	125	275
25,000	281.9	11.10	300	375	175	375
35,000	178.7	7.04	300	525	250	525
50,000	87.3	3.44	—	750	—	750

3-13. REMEDIAL ACTION—If the instrument fails to meet this test, it must be disassembled and cleaned as described in Section II.

3-14. LOW TEMPERATURE SCALE ERROR—For a period of not less than 6 hours prior to this test, the altimeter shall not have been subjected to any test involving operation at other than atmospheric pressures. The scale error (room temperature) test shall be repeated except that the temperature of the altimeter during the test shall be approximately —35°C (—31°F). The test points shall be those given in Table IX. The change in scale errors of this test from corresponding scale errors of the room temperature test shall not exceed the tolerances specified in Table IX. During this test the friction shall be checked.

3-15. REMEDIAL ACTION—If the instrument fails to meet this test, the diaphragm must be compensated as described in Section II and the instrument recalibrated.

3-16. OVERPRESSURE—The altimeter shall be subjected to an absolute pressure of 50 inches of mercury for a period of 1 hour. For a period of not less than 6 hours following this overpressure, the altimeter shall not be subjected to any operation other than atmospheric pressure. The scale errors shall not vary from the previously noted scale errors by more than the tolerances listed in Table X.

3-17. REMEDIAL ACTION—If the instrument fails this test, it must be disassembled and the cause of malfunctioning determined.

3-17. CASE LEAK—Connect the static pressure connection of the indicator to a source of suction. Apply a suction sufficient to produce a change of indication of the hands of approximately 18,000 feet. With the source closed off during a period of 10 seconds, the difference of indications shall not exceed 100 feet.

3-19. REMEDIAL ACTION—If a leak is indicated, check the instrument and correct for the leak as described in Section II.

3-20. POSITION ERROR TEST—At normal atmospheric pressure, readings shall be taken while the instrument is being tapped lightly in each of several different positions. The change in pointer indication with change in instrument position shall not exceed 20 feet.

3-21. REMEDIAL ACTION—If the instrument fails to meet this test, it must be adjusted for balance as described in Section II.

3-22. USE OF AFTO FORM NO. 139. All altimeters including those in applicable difference data sheets will have AFTO Form No. 139 prepared at every overhaul, recalibration, or technical order compliance. Errors will be noted on the form at all test points outlined in Table VI. This will include points not identified with an asterisk. The form has a general application, therefore points of test other than those noted in Table VI may be ignored. Forms will be attached to the case of each altimeter prior to packaging and shipment.

Note

Overhaul and Test Procedures for the models included in this section are the same as procedures for type 371P-4-01 and 671CP-8-016 Sensitive Altimeters except for the specific differences noted by the applicable Difference Data Sheet. Section II and III contain complete Overhaul and Test Procedure Information.

SENSITIVE ALTIMETER **TYPE 671CPX-4-037, AN TYPE 5760-43**

The instructions contained in preceding sections of this handbook apply except for the specific differences listed in this data sheet.

LEADING PARTICULARS

RANGE: 50,000 feet

BAROMETRIC SCALE: 28.1 to 31.0 inches of mercury

ILLUMINATION:

Dial — AN-L-1

Barometric Dial — AN-L-1

Pointers — AN-L-1

SPECIAL OVERHAUL TOOLS — Same as for type 671CP-8-016.

DISASSEMBLY — Same as for type 671CP-8-016.

CLEANING — Same as for type 671CP-8-016.

INSPECTION — Same as for type 671CP-8-016.

TESTING — Same as for type 671CP-8-016.

REPAIR — Same as for type 671CP-8-016.

LUBRICATION — Same as for type 671CP-8-016.

REASSEMBLY — Same as for type 671CP-8-016.

TEST PROCEDURES — Same as for type 671CP-8-016 with the following exception.

4-1. Zero Setting Scale — The altimeter shall be subjected to atmospheric pressure. The pressure scale shall be set, successively to the values listed in Table I. The altimeter shall be tapped or vibrated lightly and the pointer indication noted. After each reading has been recorded, the difference between the reading at the setting of 29.92 and the other setting shall be found. These differences shall be recorded and compared with the values in the "correct differences" column. The recorded value shall not differ from the correct differences by more than 25 feet at each setting.

TABLE I

Setting Pressure Scale	*Correct Differences*
28.5	1,340
29.92	0

4-2. Low Temperature Scale Error and Table II deleted.

LEADING PARTICULARS

RANGE: 50,000 feet

BAROMETRIC SCALE: 28.1 to 31.0 inches of mercury

ILLUMINATION:

Dial—AN-L-1 (one piece)
Barometric Dial—AN-L-1
Hands—AN-L-1

SETTING MARKERS: The inner and outer triangular setting markers are eliminated in this design.

SPECIAL OVERHAUL TOOLS

— Same as for type 671CP-8-016.

DISASSEMBLY

— Same as for type 671CP-8-016 except for the omission of the inner and outer setting markers. Because of this the key index numbers will differ.

CLEANING. — Same as for type 671CP-8-016.

INSPECTION — Same as for type 671CP-8-016.

TESTING — Same as for type 671CP-8-016.

REPAIR — Same as for type 671CP-8-016.

LUBRICATION — Same as for type 671CP-8-016.

REASSEMBLY — Same as for type 671CP-8-016, except for omission of inner and outer setting markers.

TEST PROCEDURES — Same as for type 671CP-8-016, with the following exceptions:

a. COORDINATION—Delete paragraph 3-4 and substitute the following:

ZERO SETTING SCALE—The altimeter shall be subjected to atmospheric pressure. The pressure scale shall be set, successively, at the values listed in Table I. The altimeter shall be tapped or vibrated lightly and the pointer indication noted. After the series of readings has been recorded, the difference between the reading at the setting of 29.92 and each other setting, shall be found. These differences shall be recorded and compared with the values in the "correct differences" column. The recorded values shall not differ from the correct differences by more than 25 feet at any setting.

TABLE I

ZERO SETTING MECHANISM

Setting Pressure Scale	*Correct Differences*
28.5	1,340
29.92	0
30.9	893

b. SCALE ERROR AT ROOM TEMPERATURE—Procedures are the same except that reading shall be taken at 500, 1,500 and 3,000 feet in addition to the other test points.

c. HYSTERESIS—Delete paragraph 3-10 and substitute the following:

HYSTERESIS—Not more than 15 minutes after the altimeter has been first subjected to the pressure corresponding to the upper limit of the scale in the Scale Error at Room Temperature test, the pressure shall be increased at a rate corresponding to a decrease in altitude of approximately 3,000 feet per minute until the pressure corresponding to the first test point given in Table II is reached. The altimeter shall remain at this pressure for at least 5 minutes but not more than 15 minutes, before the test reading is taken. After the reading has been taken the pressure shall be further increased at the specified rate until the pressure corresponding to the second test point given in Table II is reached. The altimeter shall remain at this pressure for at least 1 minute but not more than 10 minutes before the test reading is taken. After the reading has been taken, the pressure shall be further increased at the specified rate until atmospheric pressure is reached. The reading of the altimeter at either of the two test points shall not differ, from the reading of the altimeter for the corresponding altitude in the Scale Error test, by more than the tolerance given in Table II.

AFTER EFFECT—Not less than 1 minute and not more than 5 minutes after the completion of the Hysteresis test, the pointers shall have returned to their original reading, corrected for any change in atmospheric pressure, within the tolerance given in Table II as the third test point.

TABLE II

HYSTERESIS

Test Points	*Standard Altitude*	*Equivalent Atmospheric Pressure*	*Permissible Variation*
First point	25,000	11.10	150
Second point	20,000	13.75	150
Third point	—	Ground Level	60

d. OVERPRESSURE — Delete paragraph 3-16 and substitute the following:

OVERPRESSURE — The altimeter shall be subjected to an absolute pressure of 50 inches of mercury for a period of 1 hour. For a period of not less than 6 hours following this overpressure, the altimeter shall not be subjected to any operation other than atmospheric pressure. The scale errors shall not vary from the previously noted scale errors by more than the tolerances listed in Table III.

ZERO SETTING SCALE—The altimeter shall be subjected to atmospheric pressure. The pressure scale shall be set, successively, at the values listed in Table I. The altimeter shall be tapped or vibrated lightly and the pointer indication noted. After the series of readings has been recorded, the difference between the reading at the setting of 29.92 and each other setting, shall be found. These differences shall be recorded and compared with the values in the "correct differences" column. The recorded values shall not differ from the correct difference by more than 25 feet at any setting.

b. SCALE ERROR AT ROOM TEMPERATURE—Procedures are the same except that reading shall be taken at 500, 1,500 and 3,000 feet in addition to the other test points.

c. HYSTERESIS—Delete paragraph 3-10 and substitute the following:

TABLE I
ZERO SETTING MECHANISM

Setting Pressure Scale	Correct Differences
28.5	1,340
29.92	0
30.9	893

HYSTERESIS—Not more than 15 minutes after the altimeter has been first subjected to the pressure corresponding to the upper limit of the scale in the Scale Error at Room Temperature test, the pressure shall be increased at a rate corresponding to a decrease in altitude of approximately 3,000 feet per minute until the pressure corresponding to the first test point given in Table II is reached. The altimeter shall remain at this pressure for at least 5 minutes but not more than 15 minutes, before the test reading is taken. After the reading has been taken the pressure shall be further increased at the specified rate until the pressure corresponding to the second test point given in Table II is reached. The altimeter shall remain at this pressure for at least 1 minute but not more than 10 minutes before the test reading is taken. After the reading has been taken, the pressure shall be further increased at the specified rate until atmospheric pressure is reached. The reading of the altimeter at either of the two test points shall not differ, from the reading of the altimeter for the corresponding altitude in the Scale Error test, by more than the tolerance given in Table II.

AFTER EFFECT—Not less than 1 minute and not more than 5 minutes after the completion of the Hysteresis test, the pointers shall have returned to their original reading, corrected for any change in atmospheric pressure, within the tolerance given in Table II as the third test point.

TABLE II
HYSTERESIS

Test Points	Standard Altitude	Equivalent Atmospheric Pressure	Permissible Variation
First Point	25,000	11.10	150
Second Point	20,000	13.75	150
Third Point	0	Ground Level	60

SERVICE LETTER

TYPE 2105/L RMI

(INSTALLATION SCHEMATIC CORRECTION)

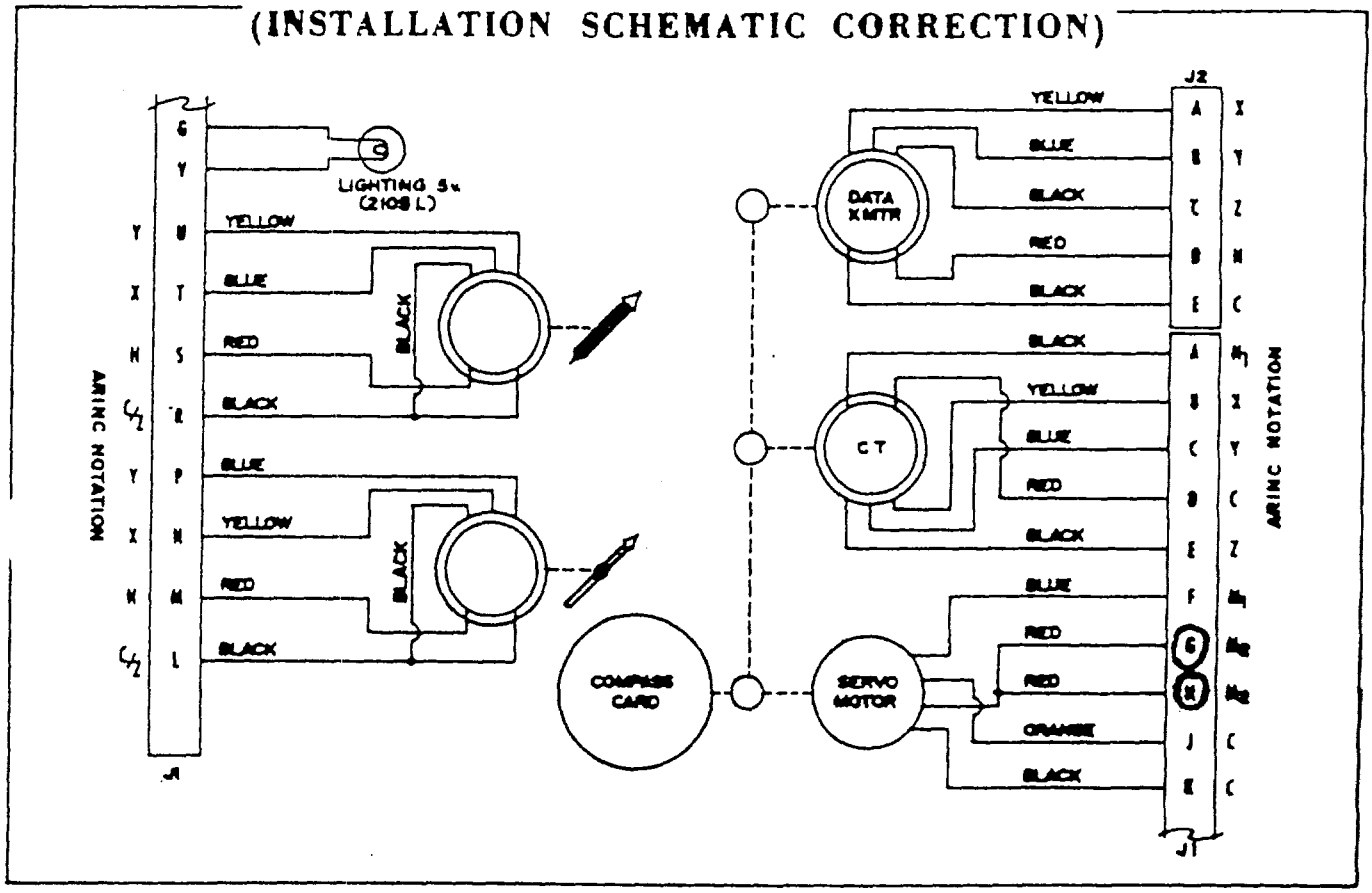

Figure 2–4 Type 2105 and 2105L RMI, Schematic Diagram

Reference: Figure 2-4, we call your attention to the pin connections on "G" and "H" - Please note that in the case of the 2105 unlighted the motor can be wired to either. However, in the case of the 2105L (lighted) the motor must be connected to pin "H" and the lighting to pin "G." Deviation from this procedure will result in a nonfunctioning card, and in case of 5 volt lighting, a burning out of the light bulbs.

Revised schematics will be issued for the 2105L. In the meantime, please note the above.

AERONETICS,

2100 SERIES RADIO MAGNETIC MAINTENANCE MANUAL

SECTION I

GENERAL DESCRIPTION

1.1 SCOPE OF MANUAL

The instruments described in this manual are the AERONETICS, DIVISION OF AAR CORP., 2100 Series Radio Magnetic Indicator (RMI) manufactured in Elk Grove Village, Illinois. This manual includes brief description and operation; overhaul disassembly, repair, reassembly, calibration, and testing procedures; and an Illustrated Parts List for the equipment types covered.

The overhaul procedures presented are intended as step-by-step procedures for overhaul and testing by qualified instrument technicians, working in properly equipped instrument shops.

NOTE: The Illustrated Parts List shall not be used as authority for disassembly without reference to the Overhaul procedures.

1.2 DESCRIPTION AND OPERATION (Refer to Figure 1-1)

The 2100 Series of Radio Magnetic Indicators (RMI) are dual pointer, rotating azimuth instruments displaying both the magnetic heading of the aircraft and the magnetic bearing to a selected radio facility.

The fixed outer dial mask of the indicator is marked with a triangular lubber line, and additional triangular markers at each 45° increment around the full 360° face of the instrument. Behind the mask a narrow single bar pointer, and a wide double bar pointer driven by synchro receivers provide magnetic radio bearing indications in accordance with a rotating inner dial. The inner rotating dial is numerically marked at 30° increments around the dial, and has intermediate graduations in either 5° or 2° increments. The dial repeats the bearing of the selected external compass system.

The 2107 Model has two knobs on the instrument face. These knobs actuate switches which select radio bearing signals from ADF or VOR receiving systems. These bearings will be indicated by either the single or double bar pointer.

1.3 SPECIFICATIONS

WEIGHT:	2105, 2108, 2109	2 lbs. 8 oz.
	2107	2 lbs.12 oz.
	Lighted MOdels add	3 oz.
ELECTRICAL:	26 Volt, 400 Cycle, single phase AC (voltage and frequency tolerances ±10%	
LIGHTING:	5 Volt DC or AC internal red or white.	
ENVIRONMENT:	Temperature range, operating -55°C to +70°C	
HUMIDITY:	95 percent at 70°C	
VIBRATION:	5 to 500 Hz at 5G Max. Acceleration	
ALTITUDE:	-1000 Ft. to 40,000 Ft.

SECTION 2

INSTALLATION

2.1 RECEIVING EQUIPMENT

Check packing slip for list of units. Unpack carefully checking for damage. Inspect units thoroughly. All claims must be filed with the transportation facility promptly. Retain packing material for proof of claim.

2.2 MOUNTING

The indicator should be mounted in a shock mounted instrument panel cut out as in the applicable figure reference according to type in Table 201.

TABLE 2-1

INSTALLATION AND SCHEMATIC DIAGRAMS

INDICATOR TYPE	INSTALLATION	SCHEMATIC
	FIGURE	FIGURE
2105-2105L	2-1	2-4

2108-2108L	2-3	2-6
2109-2109L	2-3	2-7

2.3 CONNECTIONS

Table 2-1 indicates the appropriate figure number for the schematic diagram of each type of indicator. This schematic represents the internal components and wiring, and indicates the AIRINC designations for necessary interconnections required to operate the indicator from any gyro stabilized compass system and ADF or OMNI range receiver.

A. The system used to operate the indicator should have some positive identification of power failure or malfunction.

B. Aircraft interconnection cabling to accomodate the indicator should utilize AWG 20 or 22 size wires terminating in the electrical connector indicated on the appropriate schematic drawing referenced in Table 2-1.

3. DISASSEMBLY		3-1
Considerations before Disassembly	3.1	3-1
Instrument Type Differences	3.2	3-1
Disassembly	3.3	3-2

SECTION 3

DISASSEMBLY

3.1 CONSIDERATIONS BEFORE DISASSEMBLY

Before beginning to disassemble the equipment, consider the objective. Complete disassembly to the last piece part is not always required or desirable. Therefore, the extent of disassembly is usually determined by the cause of trouble, except for life overhaul.

CAUTION: DISASSEMBLY SHOULD ONLY BE UNDERTAKEN BY EXPERIENCED INSTRUMENT REPAIRMEN AND IN A CLEAN, DUST FREE AREA.
IF SUCH FACILITIES ARE NOT AVAILABLE THE INSTRUMENT SHOULD BE RETURNED TO THE MANUFACTURER.

A. If a part is known to be defective, study the Detailed Parts List Illustrations and the equipment to determine the simplest approach. By-pass as many steps as possible.

B. Use proper tools and techniques to prevent damage to hardware, finishes, or components.

(1) Tag or otherwise identify all electrical leads and terminals before disconnecting components for removal.

(2) Identify the location and quantity of washers, gaskets, and shims.

(3) Witness mark all adjustable parts to simplify replacement, realignment, and adjustment.

(4) Store all parts in closed containers to protect them from dirt, humidity, mixing, loss or damag

CAUTION: DO NOT BEND, FORCE PARTS, OR DISASSEMBLE ITEMS NOT TAKEN APART IN THE PARTS LIST IN ORDER TO GAIN ACCESS.

3.2 INSTRUMENT TYPE DIFFERENCES

Since this manual covers more than one type of 2100 series instrument, the different procedures will be inserted at the applicable procedural steps. Such steps will be identified by an "*" preceeding the paragraph number or letter.

3.3 DISASSEMBLY

In general the following disassembly procedures are based on the relationship of parts established in the Illustrated Parts List. (Section 10.) Reference to parts is made by the generic noun or phrase, item number, and figure number taken from the parts list. Once a figure has been referenced, only item numbers will be used unless reference to a different figure is required. Immediately after such a reference the original figure will be referred to again and thereafter only item numbers will be used.

A. RADIO MAGNETIC INDICATOR (Ref. Figure 10-1)

Initial disassembly of the Radio Magnetic Indicator consists of removal of the case assembly, the mask, dial and pointers from the mechanical sub-assembly.

*(1) Type 2107 or 2107L Only. Before removing the case from Type 2107 indicators, perform the following steps:

(a) Remove knobs (1 and 2) by loosening two setscrews (3) in each.

(b) Remove rear cover plate (4) by taking out five screws (5).

(c) Remove two retaining rings (6) and withdraw shafts (7) with attached gears (8). Two washers (10) will drop free from each shaft.

(d) If replacement is required, gears (8) can be removed by loosening two setscrews (9) in each.

(2) Remove case assembly (11) by taking out three screws (12) and pulling it straight forward from the mechanism with a slight twisting motion. If repairs are required, the case assembly may be further disassembled as follows:

(a) Remove eight screws and lockwashers (14 and 15) and separate bezel (13), from rear bezel (16) releasing case (19), glass (21) and gaskets (22).

(b) If replacement is required bushings (17) and mounting nuts (18) may be removed from the rear bezel.

*(c) Types 2105L, 2107L, 2108L and 2109L Only. (Lighted Models)

Remove front and rear bezels (12) as in (a) above taking care not to bend terminals or sockets. Remove snap ring (23), rear lighting wedge (24) and gasket (25) from front bezel (13).

CAUTION: Front cover glass (26) and mask ring (27) should only be removed if damaged. This glass is bedded into the bezel with epoxy cement.

The two printed circuit boards (28) with lamps attached are connected with two wires. They may be removed together by taking our four screws (30). The six lamps (29) should not be removed unless inoperative.

(3) Remove presentation group from mechanical sub-assembly as follows:

(a) Remove mask (31) by taking out three screws (32).

(b) Remove pointers (33 and 34) with a suitable hand remover, bushing (35) will be freed.

(c) Remove dial (36) by taking out two screws (37).

NOTE: If more than one indicator is being overhauled, be sure to identify knobs (1 and 2) pointers (33 and 34) and dial (36) for proper reassembly with their respective case and mechanism.

(d) Remove indice mounting ring (38) from the mechanical sub-assembly by taking out three screws (39).

B. MECHANICAL SUB-ASSEMBLY. (Ref. Figure 10-2)

Disassemble the mechanical sub-assembly as follows:

(1) Remove the assemblage of the center bridge and gear assembly, top synchro mounting plate, front synchros, associated gears, and parts as follows:

*(a) Types 2105, 2105L, 2107 and 2107L Only. Remove idler gear assembly (1) by taking out idler gear screw (2) and slipping the idler gear assembly and lockwasher (3) outward. If ball bearing (4) is worn, it may be pressed out of gear (5) with suitable tool.

(b) Remove top synchro mounting plate sub-assembly (6) (with attached parts) and four spring clips (7) by taking out special screw (8) and three mounting posts (9)(using suitable pin wrench).

NOTE: If leads are laced, it may be necessary to cut lacing cords on synchro leads before lifting plate free..

(c) Lift top synchro mounting plate sub-assembly (6) and attached parts straight outward.

CAUTION: USE CARE TO AVOID BENDING OR BURRING OF POINTER SHAFT (10).

(d) Grip pointer shaft (10) with a pin vise and extract it from taper in damper assembly (56, 57, 59).

(2) Disassemble the assemblage of parts attached to the top synchro mounting plate as follows:

*(a) Types 2105, 2105L, 2107 and 2107L Only. Remove collar clamp (12) by loosening screw (13) and pulling clamp free. Remove two synchro clamps (17) by taking out two screws (15) and lockwashers (16). Withdraw control transformer synchro (14) while pulling anti-backlash gear assembly (11) outward from synchro shaft.

*(b) Types 2105, 2105L, 2107, 2107L 2108 and 2108L Only. Remove servo motor assembly (19) with pinion (18) installed by taking out two screws (20) and lockwashers (21), and pulling servo motor to the rear. Remove anti-backlash gear cluster (22) by taking out three screws, lockwashers, and

synchro clamps (27, 28 and 29), loosening screw (24) and taking off collar clamp (23) and pulling synchro assembly (25) carefully straight away from rear of plate, eccentric (26) will be freed.

*(c) Type 2109 and 2109L Only. Remove three screws, lockwashers and synchros clamps (27, 28 and 29). Support the top synchro mounting plate (6) and drop synchro assembly (25) down so gear and hub assembly (30) and damper weight (31) rest on plate. Tap on synchro shaft through gear hub to release tapered synchro shaft, damper weight (31) may be removed from gear and hub assembly (30) by taking off retaining ring (32). Synchro (25) and eccentric (26) will be freed.

(d) Remove synchro assembly (33) by taking out two screws, lockwashers, and synchro lamps (35, 36 and 37); supporting top synchro mounting plate (6); dropping synchro down so that damper weight (38) and gear and hub sub-assembly (40) rest on the plate; then, tap on synchro shaft through gear hub to lease tapered synchro shaft. Synchro eccentric (34) will be freed. The damper weight (38) may be removed from gear and hub (40) by taking off retaining ring (39).

(e) Remove the center bridge and gear assembly (41) from the top synchro mounting plate (6) by taking out three screws, lockwashers, and washers (42, 43 and 44). Lift assembly straight up, gears and pinions (45, 46, 47 and 48) and gear and shaft assembly (49) will be freed.

(3) Type 2107 and 2107L Only. Perform the following preliminary disassembly procedures on the rear portion of Type 2107 indicators:

(a) Remove retaining ring (65) and two washers (66) from cam shafts (64).

(b) Loosen two set screws behind two detent springs (70).

(c) Loosen two setscrews (68) in right and left cams (67). Pull two cam shafts (64) with right and left cam gears (71) attached, straight out from rear of receptacle mounting support (84). Cams will be free.

NOTE: Use care not to lose two balls (69) and springs (70) that will be freed by removal of cam gears, and washers (73) freed by the shafts.

(d) Right or left cam gear (71) may be removed from their cam shafts (64) by loosening two setscrews (72).

(e) Remove six switches (74) by taking off eight nuts (75), four lockwashers (76) and four washers (77) Remove four studs (78) and insulators (79). Two cam stop screws (80) and lockwashers (81) can also be removed from rear plate if necessary.

(4) DISASSEMBLY OF REAR PORTION OF ALL INDICATORS. Disassembly of the rear portion of indicator is as follows:

(a) Remove two screws (55), lockwashers (56) and synchro clamps (57).

(b) Drop synchro assembly (54) down so that damper assembly (50) rests on rear plate (61). Tap on synchro shaft through hub to release tapered synchro shaft.

(c) Remove rear plate (61) by taking out two upper top posts (58) and screw (62) and lockwasher (63).

(d) Two remaining lower top posts (58) may be removed by taking off two nuts or screws (59) and lockwashers (60).

(e) Remove three rear plate mounting posts (82) from receptacle mounting support (83 or 84) with an appropriate pin wrench. Setscrews (85) may be removed from support.

(f) Remove receptacle (86 or 87) from mounting support by taking out four screws (88) and lockwashers (89).

*(g) Type 2105 Only. Remove receptacle (90) by taking out four screws (91) and lockwashers (92).

*(h) Types 2105L, 2107L, 2108L and 2109L Only. Terminal strip (93) may be removed from synchro mounting plate by taking out two screws (94).

C. CENTER BRIDGE AND GEAR ASSEMBLY. (Ref. Figure 10-3).

To disassembly the center bridge and gear assembly proceed as follows:

1. Detach bridge plate (1) by removing three nuts (2) and washers (3), and pulling bridge straight away from bearing plate (6).

2. Separate gear and hub assembly (4) from hub and jewel sub-assembly (7) by removing collar (5) with an appropriate puller. Jewels (10, 11, 12 and 13) may now be removed from the synchro plate (9), bridge (1), bearing plate (6) and hub (8) respectively.

D. DISASSEMBLY BEYOND INSTRUCTIONS:

Disassembly of assemblies not detailed in the preceding instructions shall be considered beyond the scope of this manual. If synchros are to be disassembled, such procedures should be performed according to the manufacturer's recommendations, or in accordance with standard practices. Other sub-assemblies which contain parts joined by staking, riveting, brazing, welding, cementing, or by other permanent means are considered as irreparable since disassembly may be damaging or destructive.

4. CLEANING		
Equipment and Materials Required	4.1	4-1
Cleaning Gears and Bearings	4.2	4-1
Cleaning Structural Components and Hardware	4.3	4-1
Cleaning Electrical Components	4.4	4-1
Cleaning Case Glass or Lighting Wedges	4.5	4-2

SECTION 4

CLEANING

4.1 EQUIPMENT AND MATERIALS REQUIRED.

The following equipment and materials are recommended for cleaning the instruments. The materials have been selected for greatest effectivity with the lease danger to personnel and equipment.

CLEANING EQUIPMENT AND MATERIALS

Ultrasonic cleaning equipment (MIL-C-83754)
Waterless ultrasonic instrument cleaning solution
Ultrasonic rinsing solution
Low pressure dry compressed air source
Optical glass cleaner (not diatomous or silconized (MIL-C-43454A).
Camel hair brushes
Soft lint free cloths.

4.2 CLEANING GEARS AND BEARINGS.

Clean gears and bearings that have been removed from sub-assemblies, or are in open structures in a good ultrasonic cleaner. Rinse well and dry thoroughly. Non-stainless, ferrous bearings should be lubricated (see Lubrication in Assembly, Section 7) and wrapped. Place cleaned parts in clean, dry, covered containers.

4.3 CLEANING STRUCTURAL COMPONENTS AND HARDWARE.

Wipe surface dirt from housings, plates, supports, posts, shafts and similar items with clean lint-free cloths. Use a clean area of the cloth for each stroke. Do not use soiled cloths.

A. Immerse parts in cleaning solution. Soak until stain and dirt are loosened.

B. Dislodge stubborn dirt with a camel hair brush.

C. Flush parts with rinsing solution.

D. Dry parts with gentle stream of clean dry air.

E. Store cleaned parts in clean, dry, covered containers.

4.4 CLEANING ELECTRICAL COMPONENTS.

Clean synchros and servo motors by wiping away surface dirt with a clean dry cloth.

CAUTION: DO NOT IMMERSE SYNCHROS OR MOTORS. THIS MANUAL DOES NOT COVER THEIR OVERHAUL.

4.5 CLEANING CASE GLASS OR LIGHTING WEDGES.

Clean case glass inside and out with clean lint-free cloth moistened with a glass cleaner. Use a clean area of cloth for each wiping stroke. Dry glass surfaces and wrap in tissue paper for storage.

NOTE: IF LIGHTING COVER GLASS AND MASK WERE REMOVED, OLD EPOXY CEMENT MUST BE CAREFULLY CLEANED FROM BEZEL LIP BEFORE REPLACING MASK AND GLASS.

LIST OF TABLES

	TABLE	PAGE
Inspection Procedure	5.1	5-1

SECTION 5

INSPECTION

5.1 INSPECTION OF DISASSEMBLED PARTS.

TABLE 5-1 INSPECTION PROCEDURE

ITEM	CONDITION	REMEDY
Case, Bezel	Gouged, dented, distorted	Replace if severly damaged Repair minor damage
	Finish scratched or chipped Finish worn through	Touch-up Repaint
Lighting	No Light	Replace leads, terminals or lamps
	Uneven Light	Replace defective lamps
Structural Memers	Irridite finish damaged	Apply irridite
	Threads of tapped holes damaged	Re-tap or replace members if necessary
Case Glass	Scratched, chipped	Replace
	Paint missing from letters	Refill engraved letters
Hardware	Screw threads crossed or worn	Replace
	Screw heads damaged	Replace
	Flat washers burred or bent	Replace
	Setscrew sockets burred	Replace
	Lockwashers deformed or flattened	Replace
Shafts	Scored, bent, or worn	Replace
Bushings	Scored or worn	Replace

TABLE 5-1 INSPECTION PROCEDURE (Con'd)

ITEM	CONDITION		REMEDY
Ball Bearings	Run rough, worn		Replace
Gears	Spur	Teeth worn or burred	Replace
		Pivots worn	Replace
	Anti-back-lash	Fixed gear loose	Replace assembly
		Moveable gears bent	Replace assembly
		Springs missing	Replace springs or assembly
		Teeth worn	Replace assembly
Receptacle	Bent Pins		Straighten pins
	Corrosion		Replace
	Damaged shell or insert		Replace
Synchros	Inoperative or inaccurate		Return to manufacturer for overhaul
Jewels	Chipped, cracked or worn		Replace jewel
Connections	Insulation worn, chafed, charred or broken		Replace damaged leads
	Wire broken		Replace damaged leads
	Solder joints faulty		Rework
	Switches defective		Replace faulty switch
Dial, Pointers, Indice, Knobs	Finish scratched, chipped, discolored		Touch-up or replace as required

TABLE 5-1 INSPECTION PROCEDURE (Cont'd)

ITEM	CONDITION	REMEDY
Damper Assemblies	Damper weight must rotate freely	If tight, remove burrs or ream as required
	Retaining ring missing	Replace missing ring
Bridge and Plate	Worn bearing holes	Repair or replace
	Jewels Loose	Repair or replace
Gaskets	Discard gaskets	Replace gaskets

SECTION	PARAGRAPH	PAGE
6. REPAIR AND REPLACEMENT		
Repair of Parts	6.1	6-1
Replacement of Parts	6.2	6-1

November 21/69

SECTION 6

REPAIR AND REPLACEMENT

6.1 REPAIR OF SUB-ASSEMBLIES OR PARTS

Damaged or badly worn parts must be replaced during overhaul to assure reliability through the next service life of the equipment. The following instructions detail repairs which can be made without jeopardizing dependability or performance.

A. EXTERIOR FINISH

If painted surface of case requires refinishing, proceed as follows:

(1) Strip old paint.

(2) Check irridite finish for nicks and scratches; refinish where required.

(3) Paint case, bezel, receptacle mounting support, and rear plate cover with flat black paint per Federal Standard 595, color number 37038.

(4) Touch-up indice points, or other white markings with matte white, Federal Standard 595, color 37875.

B. SYNCHROS AND MOTORS.

Synchros and motors shall be overhauled before being installed during equipment reassembly. Overhaul of motors and synchros shall be accomplished according to procedures specified by the synchro or motor manufacturer, or the item shall be overhauled by the manufacturer's facility.

6.2 REPLACEMENT OF PARTS.

If replacement of parts is necessary, they must be identical to the original. The Illustrated Parts List (Section 10) gives sizes and types of hardware and also the information necessary for ordering identical replacement parts.

CAUTION: Any substitution of parts not identical to the original may result in unsatisfactory operation or damage to the instrument.

SECTION	PARAGRAPH	PAGE
7. ASSEMBLY		
Assembly Procedures	7.1	7-1
Lubrication	7.2	7-1
Assembly Precautions	7.3	7-1

SECTION 7

ASSEMBLY

7.1 ASSEMBLY PROCEDURES.

Assembly procedures are based on the consideration that the equipment has been completely disassembled to the least procurable sub-assembly or individual part as listed in the Illustrated Parts List. Since disassembly to this degree may not be warranted in certain cases, the assembler will be expected to modify the procedures to fit the requirements of the individual piece of equipment. In general, reassembly is the reverse of the disassembly order presented in the parts list. Where a reassembly procedure applies only to particular type(s), an * (asterisk) will precede the paragraph number. Immediately after an * paragraph number the applicable type(s) will be identified. Such steps will be placed ahead of procedures which otherwise apply to all types, and as close as possible to the point of application.

7.2 LUBRICATION.

During reassembly lubricate the equipment as follows:

A. BALL BEARINGS.

Lightly pack ball bearings with high-low temperature instrument grease, Military Specification MIL-G-3278.

B. BEARINGS, BUSHINGS.

Apply a droplet of high-low temperature aircraft instrument lubricating oil Military Specification MIL-L-6058 to bearings and bushings.

C. GEARS.

Brush a thin coating of multi-purpose grease, plate 630AA (Fiske Brothers Refining Co., Newa... N. J.) on all gear teeth, except that no oil should be applied to bearings or teeth of gears (49, 30 or 40, Figures 10-2), or (4, Figure 10-3). Lubricate anti-backlash gear interfaces with high-low temperature aircraft instrument lubricating oil Military Specification MIL-L-6058 inserted with a syringe.

7.3 ASSEMBLY PRECAUTIONS.

During reassembly the following precautions shall be taken:

A. Reassembly shall only be undertaken by qualified personnel and in clean, dust free facilities.

B. No undue force shall be applied in reassembly that might result in damage or mis-alignment of parts.

C. All screws not having lockwashers shall be secured with cement (liquid stake red).

D. All leads shall be secured with lacing tape.

7.4 REASSEMBLY.

A. MECHANICAL SUB-ASSEMBLY, GENERAL (Ref. Figure 10-2).

Reassemble the indicator mechanical sub-assembly as follows:

(1) Place required sleeving over lead groups as noted during disassembly.

(2) Thread leads through receptacle mounting support (83 or 84) and solder proper leads to pins of receptacle(s) (86, 87 and/or 90). Secure receptacle to support with appropriate four screws and lockwashers (88 and 89) or (91 and 92).

(3) Install front pointer synchro assembly (54) on rear plate (61) and secure with two screws, lockwashers, and synchro clamps (55, 56 and 57).

(4) Install two upper top posts (58) in lower holes in rear plate (61) and secure with screws or nuts and lockwashers (59 and 60).

(5) Screw three rear plate mounting posts (82) into receptacle mounting support (83 or 84).

(6) Position assembled rear plate, synchro, and posts on three posts (82) and secure with two lower top posts (58) and screw and lockwasher (62 and 63).

*B. TYPES 2107 and 2107L ONLY, ADF/VOR SWITCHING. (Ref. Figure 10-2.)

Assemble rear portion of these indicators as follows:

(1) Install two switch studs (78) in rear plate (61) and secure with nuts and washers (75 and 77).

(2) Place insulators and switches (79 and 74 on studs and secure with plain washers, lockwashers and nuts (77, 76 and 75).

(3) Mount right and left cam gears (71) on cam shafts (64) and secure with two setscrews (70) in each gear. Place one washer (73) over each shaft and position against face of gears.

(4) Turn setscrews (85) into receptacle mounting support (84) to a depth of about 1/8 inch.

(5) Apply a light coating of Lubriplate 630AA (Fiske Brothers Refining Co., Newark, N. J.) to two detent springs (70).

(6) Insert detent springs (70) into holes in receptacle mounting support (84). Place detent balls (69) on top of springs.

(7) Install shafts (64) through proper holes in support (84) and through appropriate cam (67) placing one washer (66) on each shaft as it is pushed through.

(8) When ends of shafts pass through rear plate (61), place second washer (66) on each and secure with retaining rings (65).

(9) Rotate each cam gear to its ADF detent position (turn left cam gear clockwise, and right cam gear counter-clockwise-as viewed in Figure 2-2). Adjust setscrews (85) to apply adequate spring tension on detent balls to effect positive indexing of gears in ADF detents.

(10) Set cams (67) against stops(80) and tighten + setscrews (68) in each.

C. CENTER BRIDGE AND GEAR ASSEMBLY. (Ref. Figure 10-3).

Reassemble the center bridge and gear assembly as follows:

(1) If jewel (12) has been removed, or required replacement, install in bearing plate (6).

(2) If jewel assembly (11) has been removed, or requires replacement, install in bridge (1).

(3) Insert hub and jewel assembly (7) through jewel (12). Place gear and hub assembly (4) over shaft of hub and jewel assembly (7) and secure with collar (5).

(4) Guide bridge (1) jewel assembly (11) over shaft of hub and jewel assembly (7) and secure bridge to bearing plate (6) with three nuts and lock-washers(2 and 3).

(5) Install jewel (10) in top synchro mounting plate (15).

D. TOP SYNCHRO MOUNTING PLATE ASSEMBLY. (Ref. Figure 10-2.)

Continue assembly of the indicator as follows:

(1) Position damper hub (52) on shaft of front pointer synchro assembly (54). To prevent damage to synchro bearings, support rear end of synchro shaft on a dowel rod in a vise, or by similar means and tap hub onto shaft to set securely. Install damper weight (51) on hub and secure with retaining ring (53). Damper weight must turn with complete freedom.

NOTE: Flange of hub (52) should clear rear plate (61) by not less than 0.025 inch. If hub touches plate or clearance is below minimum install a new hub. New hubs may require reaming from flange side with a 3° reamer to obtain proper seating on shaft.

(2) Apply a thin film of Alcoa Thread Lubricant (Aluminum Company of American, New Kensington, Pa.) on both sides of synchro eccentrics (26 and 34) and place in proper holes in top synchro mounting plate (32) with shoulder of eccentrics entering holes in plate. Position proper synchro assembly (33 and 25) in eccentrics and secure each lightly with two screws, lockwashers and synchro clamps (35, 36, 37; and 27, 28 and 29).

(3) Insert pointer shaft (10) in taper hole in shaft of front pointer synchro assembly (54). Tap shaft with proper tool to seat. True-up shaft if necessary.

NOTE: With synchro installed and shaft in place, end of shaft shall be 0.968 $^{+0.000}_{-0.01}$ inches outward from outer face of synchro mounting plate (61). If dimension is greater (shaft too long) ream the synchro (54) shaft with a 3° reamer until correct dimension is obtained.

(4) Carefully guide top synchro mounting plate assembly (6) into assembly so pointer shaft (10) enters jewel (10 Figure 10-3). When properly oriented and in contact with four top posts (58, Figure 10-2) secure plate with three indice mounting ring posts (9), special mask mounting screw (8) and four spring clips (7) one clip under each post and screw.

(5) Carefully install gear and shaft assembly (49) over pointer shaft (10), into jewel in top plate (10, Figure 10-3).

(6) Install gear and hub sub-assembly (40, Figure 10-2) on shaft of synchro assembly (33) and in engagement with gear and shaft assembly (49) tap hub to seat on shaft.

NOTE: Flange of gear hub (40) should clear top plate (6) by not less than 0.025 inch. If hub touches plate a new unit must be installed. New assemblies may require reaming from flange side with a 3° reamer.

(7) Assemble damper weight (38) on gear and hub sub-assembly (40) and check for complete freedom of rotation. Secure with retaining ring (39).

*E. TYPES 2105, 2105L, 2107 and 2107L ONLY. (Ref. Figure 10-2.)

Install ball bearing (4) in gear (5) forming idler gear assembly (1). Position assembly on top synchro mounting plate (6) with lockwasher (3) and secure with idler gear screw (2). Check for free rotation.

(1) Mount control transformer synchro assembly (14) on rear of top synchro mounting plate assembly (6) with two screws, lockwashers and synchro clamps (15, 16 and 17).

(2) Install anti-backlash gear assembly (11) on shaft of control transformer synchro assembly (14),load gear one or two teeth and slide into engagement with idler gear (5). Slide collar clamp (12) onto hub of gear assembly (11). Be sure full width of both anti-backlash gears (11) is in mesh with idler gear (5) secure clamp (12) by tightening screw (13).

(3) Install anti-backlash cluster gear assembly (22) on shaft of synchro assembly (25) loading lower gear one or two teeth as it is slid into engagement with idler gear (5). Secure gear assembly (22) at best depth of engagement by tightening screw (24) in collar clamp (23).

(4) Install gear and pinion (48) and gear and pinion (47) in top synchro mounting plate (6).

(5) Load large anti-backlash cluster gears (22) one or two teeth, engage pinion of gear and pinion with loaded gears and install in plate (6).

(6) Install gear and pinion (45) in top plate (6) in engagement with pinion of (47) and gear of (46).

(7) Assemble center bridge and gear assemblage prepared in step C above over pointer shaft (10) and shaft of gear and shaft assembly (49) and studs of top plate (6) guiding gear and pinion pivots into their proper bearing holes and maintaining center bridge plate in alignment with thru bridge mounting posts.

(8) Install three screws, lockwashers, and washers (42), 43 and 44) and carefully tighten while checking position of all components. Check gear train for free rotation.

(9) Adjust mesh between gears (40 and 49) to approximately 75 percent of tooth depth by rotating synchro eccentric (34). Secure by tightening two screws (35).

(10) Adjust mesh between top gear of anti-backlash cluster gear assembly (22) and gear of gear and hub assembly (4, Figure 10-3) by rotating synchro eccentric (26, Figure 10-2 to obtain approximately 75 percent of tooth depth. Secure by tightening two screws (27).

*F. TYPES 2108 and 2108L ONLY. (Ref. Figure 10-2.)

Install gear and pinion (48), gear and pinion (47), gear and pinion (46) and gear and pinion (45) in top synchro mounting plate (32). Continue assembly as follows:

(1) Place anti-backlash cluster gear assembly (22) on shaft of synchro assembly (25).

(2) Load anti-backlash gears one or two teeth and slide down to mesh with pinion of gear and pinion (46).

(3) Carefully lower center bridge and gear assemblage prepared in step C above over pointer shaft (10) and shaft of gear and shaft assembly (49) and studs of top plate (6), guiding gear and pinion pivots into their proper bearing holes, and maintaining center bridge plate in alignment with three bridge mounting posts.

(4) Install three screws, lockwashers and washers (42, 43 and 44) and carefully tighten while checking position of all components. Check gear train for free rotation.

(5) Adjust mesh between gears (40) and (49) to approximately 75 percent of tooth depth by rotating synchro eccentric (34, Figure 10-2). Secure by tightening two screws (35).

(6) Adjust mesh between anti-backlash cluster gear assembly (22) and gear of gear and hub assembly (4, Figure 10-3) by rotating synchro eccentric (26, Figure 10-2 to obtain approximately 75 percent of tooth depth. Secure by tightening two screws (27).

*G. TYPES 2109 and 2109L ONLY. (Ref. Figure 10-2.)

Install center bridge and gear assemblage prepared in step C above over pointer shaft (10) and shaft of gear and shaft assembly (49) and studs of top plate (6), guiding gear and pinion pivots into their proper bearing holes and maintaining center bridge plate in alignment with three bridge mounting posts. Continue as follows:

(1) Install three screws, lockwashers and washers (42, 43 and 44) and carefully tighten while checking position of all components. Check for free rotation.

(2) Install damper weight (31) on gear and hub assembly (30) and secure with retaining ring (32). Check for free rotation.

(3) Place weight and gear assembled in step (2) above on shaft of synchro assembly (25) damper weight first sliding gear (30) into mesh with gear and hub assembly (4, Figure 10-3). Tap hub of gear (30, Figure 10-2)to seat on tapered shaft of synchro.

NOTE: Damper weight must clear top synchro mounting plate (6) by at least 0.025 inch and entire width of gear (4, Figure 10-3) must be in mesh with gear (30, Figure 10-2). If gear does not go on shaft far enough for proper engagement, or if hub and gear (30) is new, it may be Necessary to ream from the hub side with a 3° reamer to obtain proper seated position.

(4) Adjust mesh between gear (40 , Figure 10-2) and gear (49) to obtain mesh of approximately 75 percent of tooth depth by rotating synchro eccentric (34). Secure by tightening two screws (35).

(5) Adjust mesh between gear (30) and gear (4, Figure 10-3) to obtain mesh of approximately 75 percent of tooth depth by rotating synchro eccentric (26, Figure 10-2). Secure by tightening two screws (27).

H. MASK DIAL AND POINTERS ASSEMBLY. (Ref. Figure 10-1.)

Assemble the following items to the front of the mechanical sub-assembly:

(1) Attach indice mounting ring (38) to mounting posts (9), Figure 10-2) with flat head screws (39, Figure 10-1).

(2) Place dial (36) on dial hub (8, Figure 10-3), and secure with two screws (37, Figure 10-1). Check all around indice mounting ring (38) through complete rotation of dial (36) for adequate clearance and parallelism between dial and ring.

(3) Install bushing and No. 2 pointer (35 and 34), tap to seat and check for 0.030 ±0.005 clearance at center and each end of pointer in every 30° position. If clearance is too great ream pointer bushing (35) with 3° reamer for required clearance. If clearance is too small replace bushing and check as above.

(4) Install No. 1 front pointer (33) on pointer shaft (10, Figure 10-2) tap to seat and check for 0.015 ±0.005 inch clearance and parallelism between pointer No. 1 (33) and pointer No. 2 (34) point to point and point-to-tail at 30° intervals around the dial. If clearance is too great, ream hub with 3° reamer to obtain required clearance. If clearance is too small, install a new No. 1 pointer and check as above.

(5) Install dial indice ring mask (31, Figure 10-1) over dial and secure to indice mounting ring (38) with three screws (32). Check dial for free movement throughout 360° rotation.

*I TYPES 2105, 2105L, 2107, 2107L, 2108 and 2108L ONLY. (Ref. Figure 10-2.)

Support rear end of shaft running through servo motor (19). Place pinion (18) on shaft and tap to seat. Check for 0.095 ±0.005 inch dimension from face of servo motor adapter plate to outer face of pinion (18). If clearance is too great ream pinion with 3° reamer until required dimension is obtained. If clearance is too small replace pinion, repeating above procedure. Install servo motor (19) on top synchro mounting plate (6), making certain pinion engages properly with gear and pinion (48). Secure motor with two screws and lockwashers (20 and 21).

J. INSPECT INDICATOR ASSEMBLY.

Inspect indicator assembly at this point for free rotation of train gears and dial. Check for any loose or missing hardware. Check electrical leads for neat routing, freedom from stress, secure connections, and containment within the mechanism envelope. Indicator is now ready for calibration and testing procedures.

K. CASE REASSEMBLY. (Ref. Figure 10-1.)

After the indicator has been calibrated and tested as directed in the section on calibration and testing. Complete reassembly as follows:

(1) If case assembly (11) has been disassembled, cleaned and repaired, reassemble by placing proper glass (21) in front bezel (13).

(2) Place proper inner gasket (22) on glass..

(3) Position bezel and glass properly on case (19).

NOTE: Screened lettering on glass for Type 2107 indicators must be relative to the knob shaft holes in the bezel.

(4) Slip rear bezel (16) down over case (19) and position on ears.

(5) Secure rear bezel to front bezel with light screws and lockwashers (14 and 15).

*L. TYPES 2105L, 2107L 2108L and 2109L ONLY. (Ref. Figure 10-2.)

(1) Mount terminal strip (93) to synchro mounting plate (6) using screws (94).

(2) If cover glass wedge (26), (Figure 10-1) and mask (27) were removed or replaced, they must be cemented in position in bezel (13). Carefully, apply 1/64th of an inch bead of epoxy cement on inside lip of bezel.

(3) Insert cover glass wedge and mask in bezel (carefully aligning lamp notches of glass and bezel). CAUTION: Do not allow cement to smear glass. Bake out bezel 2 hours @ 300°F.

(4) Position gasket (25) and lighting wedge glass (24) in front bezel. Secure with snap ring (23).

(5) Install printed circuit boards (28) aligning lamps (29) in correct notches and secure with four screws (30).

*M TYPES 2107 and 2107L ONLY. (Ref. Figure 10-1.)

(1) Install two gears (8) on knob shafts (7) and secure each with two setscrews (9).

(2) Set left cam gear (71, Figure 10-2) counter-clockwise to VOR detent and right cam gear clockwise to VOR detent. Place two washers (10, Figure 10-1) on knob shafts (7) and install shafts and gears (7 and 8) through holes in receptacle mounting plate (84), Figure 10-2). Secure with retaining rings (6, Figure 10-1).

(3) Install rear plate cover (4) on sub-assembly (41) and secure with five screws (5).

(4) Guide case assembly (11, Figure 10-1) over mechanical sub-assembly (41) so knob shafts (7) enter holes in front bezel (13).

(5) Slide case assembly (11) back slowly into place while watching the No. 1 pointer (33). The pointer must not touch glass (21 or 24) when cover is fully engaged with receptacle mounting plate (84, Figure 10-2). If shaft is too long, refer to paragraph D-3 for adjustment.

(6) Secure case assembly (11) with three screws (12).

(7) Place right knob (2) and left knob (1) on respective shafts (7) and secure each in vertical position with two setscrews (3).

N. <u>TYPES 2105, 2105L, 2108, 2108L, 2109 and 2109L ONLY.</u>

(1) Install case assembly (11, Figure 10-1) over mechanical sub-assembly (40, 42 or 43).

(2) Secure case assembly with three screws (12).

8. CALIBRATION AND TESTING		
General	8.1	8-1
Calibration and Testing	8.2	8-1

SECTION 8

CALIBRATION AND TESTING

8.1 GENERAL

An AAR-1002 Test Set is used to perform the calibration and test procedures included in this section. (Refer to Figure 9-1 and 9-2.)

8.2 CALIBRATION AND TESTING.

A. Preliminary Procedures

(1) Set power switches on test set to OFF.

(2) Connect test set power cables to single phase 115 volt 60 Hz, and single phase 115 volt 400 Hz power sources.

(3) Connect appropriate test cable - from appropriate RMI connector J1 or J3 on test panel to indicator under test.

(4) If a type 2105 or 2105L indicator is being tested connect appropriate test cable between DATA XMTR connector J2 on test set and data transmitter connector J1 on indicator.

B. POWER APPLICATION.

(1) Set 60 Hz and 400 Hz power switches on (up).

(2) Associated pilot lights should light.

(3) If pilot lights do not light, check associated fuse, power connection and power source.

C. STARTING PROCEDURE.

(1) Set POINTER SWITCHING switch S1 to VOR.

(2) Set MOTOR MODE switch S3 to OFF.

(3) Set ROTOR EXCITATION VOLTAGE switches S4 and S5 to their 26V position. This will energize the No. 1 and No. 2 pointers.

(4) Set COMPASS AND REPEATER FUNCTION switch S6 to SERVO'D CARD position. This will energize the indicator dial compass card. After servo amplifier has warmed-up card will start turning.

(5) After compass card (dial) stops rotating and takes up a heading. Dial of indicator may be calibrated to its appropriate zero or 180° setting by the applicable procedures D and E below.

D. INITIAL ZERO SETTING OF INDICATOR DIAL.

(1) On test set place COMPASS AND REPEATER dial at 0 (zero).

(2) On indicators of type 2105, 2105L, 2107 or 2107L loosen two screws (15, Figure 10-2). On indicators of type 2108, 2108L, 2109 and 2109L loosen two screws (27, Figure 10-2).

(3) Rotate applicable synchro (25 or 14) until dial 0 (zero) is aligned with lubber line point of dial indice ring mask (31, Figure 10-1).

(4) Rotation of test set COMPASS AND REPEATER will result in corresponding rotation of indicator dial to check indicator error.

E. CLOSE TOLERANCE DIAL ZERO SETTING.

(1) Interconnect VTVM and HI, GND jacks on test set.

(2) Set VTVM switch to ON.

(3) Set COMPASS AND REPEATER FUNCTION switch SC to CAL CARD POSITION - This sets up test set repeater master synchro and indicator control transformer or dial synchro into a meter null configeration.

(4) Set test set COMPASS AND REPEATER DIAL to 0°.

(5) DATA XMRT INDICATOR should read 0° (or 180° for 2109 type indicator) and VTVM should read null.

(6) If reading is not exact, carefully adjust applicable synchro (25 or 14, Figure 10-2) until 0° $\pm$0.5° and null readings are obtained.

(7) Tighten two applicable screws (27 or 15, Figure 10-2). Recheck for 0° and null.

F. DIAL FRICTION TEST.

(1) Set COMPASS AND REPEATER FUNCTION switch S6 to the NORMAL-MOTOR position.

(2) Set the VARIABLE 0-50 VOLTS variac for 18 volts.

(3) Increase VARIABLE 0-5 VOLTS from zero volts until indicator dial card begins to rotate. Rotation shall start before 2-volt level is reached.

(4) Reset VARIABLE 0-5 VOLTS to zero volts.

(5) Reset COMPASS AND REPEATER FUNCTION switch to REV-MOTOR position.

(6) Increase VARIABLE 0-5 VOLTS variac until indicator dial begins to rotate. Rotation shall start before 2 volt level is reached.

G. DIAL STANDARD RATE ROTATION CHECK.

(1) Set COMPASS AND REPEATER FUNCTION switch S6 to SERVO'D CARD position.

(2) Set MOTOR MODE switch S3 alternately to CCW-CARD and CW-CARD positions-this puts the test set motorized master synchro into the circuit, turning the DAT XMTR INDICATOR dial at 12° per second (2 RPM) as selected in a clockwise or counter-clockwise direction. The indicator dial shall rotate in the selected direction within 5 percent of the test set dial rate.

(3) Dial shall turn in direction selected by switching with no apparent hesitation or hang-up.

*H. TYPES 2105, 2105L, 2107 and 2107L ONLY. SETTING DATA XMTR SYNCHRO TO ZERO.

(1) Set MOTOR MODE switch to OFF.

(2) Set COMPASS AND REPEATER dial to 0 (zero).

(3) Loosen two screws (27, Figure 10-2).

(4) Carefully turn data transmitter synchro (25, Figure 10-2) in synchro eccentric (26, Figure 10-2) while lightly tapping DATA XMTR INDICATOR in test set until it reads 0 (zero).

CAUTION: SYNCHRO ECCENTRIC MUST NOT BE TURNED DURING SYNCHRO ROTATION OR GEAR MESH SETTING WILL BE ALTERED.

(5) Secure two screws (27, Figure 10-2).

*I. TYPES 2105, 2105L, 2107 and 2107L ONLY. DATA TRANSMITTER ACCURACY CHECK

(1) Set COMPASS AND REPEATER FUNCTION switch S6 to CAL DATA XMTR position.

(2) VTVM at ON; VTVM and HI, GND jacks interconnected.

NOTE: The COMPASS AND REPEATER dial will be 90° off from DATA XMTR INDICATOR reading.

(3) Check for maximum error of ±1.0° at successive 30° settings.

(4) If necessary reset data transmitter synchro as directed in applicable steps of procedure "H" above.

J. CALIBRATION AND TEST OF NO. 2 POINTER.

(1) Set the NUMBER 2 POINTER dial on test set to exactly 0° with MOTOR MODE switch S5 at OFF.

(2) If No. 2 (rear) pointer of indicator does not indicate 0°, loosen two screws (35, Figure 10-2).

(3) Rotate synchro (33, Figure 10-2) until zero indication is obtained.

(4) Tighten two screws (35, Figure 10-2).

(5) Position NUMBER 2 POINTER dial at successive 30° positions and check indicator No. 2 pointer for error.

(6) SET MOTOR MODE switch S6 alternately in 2CCW and 2CW positions.

(7) No. 2 pointer of indicator should rotate at a standard rate of 2 RPM ±50 percent of selected counterclockwise or clockwise direction with no hesitation or hang-up.

K. NO. 2 POINTER FIT TEST.

To check whether or not No. 2 pointer is seated securely on shaft proceed as follows:

(1) Set test set NUMBER 2 POINTER dial to 0.

(2) Set associated ROTOR EXCITATION VOLTAGE switch S5 to OFF.

(3) Set NUMBER 2 POINTER dial to 170°.

(4) Set ROTOR EXCITATION VOLTAGE switch S5 to 26V position.

(5) No. 2 pointer should snap to 170°, check for exact calibration.

L. NO. 2 POINTER DAMPING CHECK.

(1) Set NUMBER 2 POINTER dial on test set to 0° and check that No. 2 pointer on indicator comes to 0°.

(2) Set ROTOR EXCITATION VOLTAGE switch S5 to OFF position.

(3) Set NUMBER 2 POINTER dial on test set to 90°.

(4) Set VARIABLE 0-50 volt variac control to full clockwise position.

(5) Set ROTOR EXCITATION VOLTAGE switch S5 to VARIABLE position.

(6) No. 2 pointer shall snap to 90° and stop oscillating within 6 seconds.

M. No. 1 POINTER FIT AND DAMPING CHECKS.

Repeat procedural steps of K and L above for the No. 1 pointer of indicator, substituting NUMBER 1 POINTER dial and ROTOR EXCITATION VOLTAGE switch S4 as applicable.

N. FINAL OPERATIONAL AND CLEARANCE CHECKS.

(1) Set NUMBER 1 POINTER, NUMBER 2 POINTER and associated ROTOR EXCITATION VOLTAGE switches S4 and S5 to 26V positions.

(2) Set COMPASS AND REPEATER FUNCTION switch S6 to SERVO'D CARD position-this will energize all functions of the indicator under test.

(3) The test set NUMBER 1 POINTER, COMPASS AND REPEATER, and NUMBER 2 POINTER dials may not be positioned at random to make a final check clearance of dial and pointers for proper clearance in all positions.

O. SHUT DOWN.

Set NUMBER 1 POINTER, COMPASS AND REPEATER AND NUMBER 2 POINTER dials to 0; set all switches and controls to OFF or full counterclockwise, Disconnect cables from indicator under test.

*P. TYPES 2105L, 2107L, 2108L and 2109L ONLY. LIGHTING CHECK.

Check for evenness of light. Uneven light or dark areas would indicate a lamp malfunction. A glare area indicates coating chipped from lamp.

SECTION 9

SPECIAL TOOLS, FIXTURES AND TEST EQUIPMENT

9.1 SPECIAL TOOLS AND FIXTURES.

This manual is intended for use by skilled instrument repairment only. All procedures should be feasible with the normal complement of tools and fixtures found in an instrument shop. Where special tools or fixtures, or unusual procedures would be required, the affected sub-assembly is not indicated as disassembled in either the procedures or parts lists. Such sub-assemblies are to be procured and replaced the same as detail parts. If such sub-assemblies need to be disassembled, serviced, or overhauled; those procedures are to be performed by the applicable manufacturer or according to his instructions.

9.2 TEST EQUIPMENT REQUIRED.

Calibration and test procedures in this manual are performed with the AAR 1002 RMI Test Set. If such a test set is not available, one may be fabricated using the panel layout shown in Figure 9-1, and in accordance with electrical schematic Figure 9-2.

9.3 DESCRIPTION OF AAR-1002 TEST SET. (Ref. Figure 9-1 and 9-2)

The AAR-1002 RMI Test Set is designed for testing and calibrating radio magnetic indicators and contains the necessary power supplies master synchro transmitters, and master indicator.

A. A Ballentine 300 VTVM is incorporated in the top of the test for null detection, and a large dial DATA TRANSMITTER INDICATION used to read the position of the bootstrap synchro transmitter in the indicator under test.

B. Three large dials in the center of the test set panel divided in 360° and fitted with a 0.1 degree vernier are connected to a master synchro transmitter. a large knob in the center of each dial is used for coarse positioning and a small knob on the right of each dial provides a fine adjustments. These dials are right to left:

(1) NUMBER 1 POINTER

(2) COMPASS AND REPEATER

(3) NUMBER 2 POINTER

C. On the left lower side the ROTOR EXCITATION VOLTAGE section contains the following:

(1) Switch S4 providing 26V, OFF and VARIABLE settings.

(2) A 0 to 50 AC VOLTS meter, M1.

(3) A VARIABLE 0-30 VOLTS VARIAC, T3.

(4) Power switches 59 and 58, fuses, and neon indicator pilot lights for 115-volt 60 Hz and 115-volt 400 Hz power inputs.

D. In the lower center the COMPASS AND REPEATER FUNCTION rotary switch S6 provides the following calibration and test positions for card (dial) and bootstrap.

(1) CAL DATA XMTR

(2) CAL CARD

(3) SERVO'D CARD

(4) NORMAL - MOTOR

(5) REV - MOTOR

E. Near the center bottom of the panel POINTER SWITCHING switch, S1 provides VOR or ADF selection.

F. At lower center right a MOTOR MODE switch, S3 controls the master BOOTSTRAP INDICATOR for checking friction error in the indicator under test, providing positions:

(1) OFF

(2) 1 CCW

(3) 1 CW

(4) 2 CCW

(5) 2 CW

(6) CCW-CARD

(7) CW - CARD

G. The lower right section of the test set panel the ROTOR EXCITATION VOLTAGE section contains the following:

(1) Switch S5 providing 26V, OFF, and VARIABLE settings.

(2) A 0-5 AC VOLTS meter M2.

(3) A VARIABLE 0-5 VOLTS variac, T2.

H. In the extreme lower right of the panel two VTVM jacks are mounted for external connection to the H1 and GND jacks in the top (VTVM) panel.

I. At the bottom five electrical connectors provide for cable interconnections with the indicator under test.

SECTION 10

ILLUSTRATED PARTS

10.1 INTRODUCTION.

A. PURPOSE. The Illustrated Parts List is provided as an aid for provisioning, requisitioning, storing, and issuing replaceable parts of the 2100 Series of RADIO MAGNETIC INDICATORS. The Illustrated Parts List augments the overhaul portion of this manual by illustrating and listing assemblies sub-assemblies, and parts in general disassembly order. The Illustrated Parts List shall not be considered authority for disassembly without reference to overhaul procedures.

B. HOW TO USE THIS PARTS LIST. The Illustrated Parts List is divided into a Detailed Parts List and a Numerical Index supported by exploded views of the equipment. To use this list proceed by the applicable following procedure:

1. If the part number is known, find the part number in the Numerical Index Listings, and use the associated figure and item number to locate the part in the Detailed Parts List or in the referenced figure.

2. If the part number is not known, refer to the figure illustrating the portion of the equipment in which the item is located. Use the associated figure and index number to locate the part in the Detailed Parts List.

C. DETAILED PARTS LIST.

The Detailed Parts List presentation is made up of five columns containing the following details:

(1) FIGURE AND ITEM NO. COLUMN. This column identifies the figure containing the illustration of the item and lists the index number which appears at the outer end of the leader line which terminates at the particular item listed.

(2) PART NUMBER COLUMN. The part number column lists the AERONETICS part number assigned to the particular item. In some instances a group of parts are shown assembled for convenience although no such assembly drawing exists. These groups will be identified as a NO NUMBER group.

(3) NOMENCLATURE COLUMN. The nomenclature column contains the name of item appearing on the manufacturer's part drawing, presented identifying noun or phrase first, followed by the additional modifying information which will assist in describing the item. The major assembly appears flush left on the first line; thereafter, the items removed from that assembly, or any lesser assembly or sub-assembly are indented one unit at a time to show part relationship. Additional information, such as Vendor or Design Manufacturer's part numbers follows the description enclosed in parentheses.

(4) ITEMS PER ASSEMBLY COLUMN. This column records the quantity of the item that is used in each of the assemblies, or sub-assemblies in which it appears. Where more than one item is indicated, the quantity of any attaching parts listed immediately thereafter will be multiplied by that quantity. Where an option between two or more parts is offered and only one item is used, each quantity number will be followed by an asterisk; thus 1*. When the same item is shown in two locations, the quantity will be shown at the first listing, whereas the notation "REF" will appear in the alternate locations.

(5) TYPE USED ON COLUMN. This column identifies the type number of the equipment in which the particular item is used by the last numeral in the type number of the each of the applicable types. Thus: Type 2105 is coded 5; Types 2105 and 2108 are coded 5, 8. Where the part is used on all types no code is used. Lighted model (L) parts will be noted only where parts specifically pertain to lighting. In all other instances where parts are used in both the basic and the lighted instrument, only the basic code (5,7,8, 9) will be used.

D. NUMERICAL INDEX. The numerical Index is made up of three columns containing the following information:

(1) PART NUMBER COLUMN. The part number column lists the part numbers of all items in numerical order: 0 through 9, from left to right.

(2) FIGURE AND ITEM NO. COLUMN. This column lists the figure and item number location of each item in the figure illustrating the part, and in the Detailed Parts List.

(3) ITEMS REQUIRED COLUMN. This column contains the quantity of items used at each location. To find the total quantities of each item, it will be necessary to check the Detailed Parts List for the type of instrument involved.

OVERHAUL MANUAL
ALTIMETER INDICATOR, 120 (series), 135 (series)

INTRODUCTION

1. This manual presents overhaul instructions with an illustrated parts list for the Altimeter Indicator, part numbers (Refer to table 1), manufactured by the Mac Leod Instrument Corporation (11824) located in Fort Lauderdale, Florida.

2. It is not recommended that indicator covered in this manual be disassembled routinely during overhaul or repair of system in which it is installed. Disassembly for repair should be undertaken only when testing of instrument indicates a malfunction, and then only to the extent necessary to correct the apparent trouble.

DESCRIPTION AND OPERATION

1. Description (Refer to figure 2.)

   A. The altimeter indicator measures atmospheric pressure encountered in altitude variations. Altimeter provides a visual indication of its carrier's altitude in terms of feet above sea-level.

   B. The case of indicator is airtight when assembled except for a static pressure port at rear of case. It is secured to instrument panel with three screws inserted in openings provided in case flange.

   C. Instrument contains three pointers which indicate altitude in unit measurements, respectively. Pointers are as follows: hundred-foot pointer (18), thousand-foot pointer (19) and ten thousand-foot pointer (20).

   D. Altimeter dial (22) is graduated in minor increments of twenty-foot intervals with major increments of one hundred-foot intervals when measured by the hundred-foot pointer (18). Dial numerals, one through ten (zero), indicate multiples of unit measurements of pointer being observed.

   E. The barometric dial assembly (24), visible through cut-out in altimeter dial, indicates the barometric pressure standard. (Refer to table 1.)

   F. Altimeter and barometric dial markings are matte white or fluorescent color on a dull black background. The indicating end of pointers are matte white or fluorescent color with a dull black pivotal section. (Refer to table 11.)

   G. A striped white or fluorescent colored area on altimeter dial face is provided as a warning display. Only indicators containing a ten-thousand foot pointer disc will have warning display capabilities. (Refer to tables 1 and 11)

Table 1. Leading Particulars

Altimeter Indicator Part Number	Range (feet)	Barometric Dial Range	
		Inches of Hg	Millibars
12002-0105	-1000 to +20,000	28.1 to 31.0	
12002-0106	-1000 to +20,000		946 to 1050
12003	-1000 to +20,000	28.1 to 31.0	
12003M	-1000 to +20,000		946 to 1050
12008-9	-1000 to +20,000	28.1 to 31.0	
12008-13	-1000 to +20,000		946 to 1050
12009-1000	-1000 to +20,000	28.1 to 31.0	
12009-2000	-1000 to +20,000	28.1 to 31.0	
13502-0201	-1000 to +35,000	28.1 to 31.0	
13502-0202	-1000 to +35,000		946 to 1050
13503	-1000 to +35,000	28.1 to 31.0	
13503M	-1000 to +35,000		946 to 1050
13508-1	-1000 to +35,000	28.1 to 31.0	
13508-5	-1000 to +35,000		946 to 1050
13522-1000	-1000 to +35,000	28.1 to 31.0	
13522-1100	-1000 to +35,000		946 to 1050
Maximum overall length: 5.242 inches Maximum width: 3.260 inches Weight: one pound two ounces			

2. Operation (Refer to figure 2.)

A. Meteorological variations cause atmospheric pressure to constantly change. Position of indicator pointers, with respect to zero, must be adjusted to compensate for this change. Design of indicator provides an adjustment knob (5) for setting ambient barometric pressure while pointers simultaneously adjust to this setting.

B. Ascertain ambient barometric pressure from a mercurial barometer. Rotate adjustment knob until the barometric dial assembly (24) indicates ambient reading in cut-out of altimeter dial (22). The hundred-foot pointer (18) will simultaneously adjust to this setting.

3. Theory of Operation

Atmospheric pressure exerted upon surfaces of aneroid at zero altitude is greater than the pressure within aneroid. This unequal distribution of pressure causes aneroid to contract. An increase in altitude decreases atmospheric pressure, thereby exerting less pressure upon surfaces of aneroid allowing it to expand. This motion is transferred through mechanism to the transmission assembly, thereby actuating radial movement of instrument pointers.

DISASSEMBLY

1. General

   A. Figures 2 and 3 are exploded view illustrations of the indicator. Index numbers are listed in disassembly order of appearance. Parts which are illustrated in assembled form are considered inseparable and nonreparable and should be replaced as an assembly if necessary.

   B. Before disassembly, test the indicator in accordance with TESTING to determine the extent of overhaul required.

   C. When disassembling, keep parts together and protected from dust and dirt.

   D. Do not hold glass parts so that finger marks on surfaces result. Handle glass on edges only.

2. Bezel Assembly (Refer to figure 2.)

   A. Remove vent plug (3) from static pressure port at rear of case (46).

   B. Wrap friction tape around adjustment knob (5). Place wrench on knob locknut (6), and with pliers gripping knob, loosen locknut. Remove knob and locknut from adjustment stem (42).

   C. Back-off locking stud screw (13) mounted in bezel (14). Position locking stud screw to left side of elongated hole, thereby disengaging locking stud (12) from adjustment stem (42).

   D. Remove six screws (9), lockwashers (10), and two screws (11). Separate bezel assembly (8) from front of case (46).

   E. Separate gasket (15), glass (16) and bezel gasket (17) from bezel (14).

3. Pointers and Dials

   A. Carefully remove hundred-foot pointer (18), thousand-foot pointer (19), and ten thousand-foot pointer (20) from face of indicator.

   B. Separate spacer ring (21) from case (46).

   C. Remove two dial screws (23). Separate altimeter dial (22) and barometric dial assembly (24) from transmission housing cover assembly (30).

4. Transmission and Mechanism Assembly

   A. Separate barometric setting gear assembly (25) from transmission housing assembly (35).

   B. Rotate eccentric locking pin (26), as required, until tension is relieved on snap ring (27). Remove snap ring from inner groove of case.

C. Separate spur gear unit (28) from transmission housing cover assembly (30).

D. Rotate adjustment stem (42) until clearance hole in transmission housing assembly (35) is aligned with No. 6–40 threaded hole in gear plate assembly (25, figure 3). Insert screw (used for disassembly purposes only) No. 6–40 UNF–2A x 2 inches long in threaded hole and carefully remove both transmission assembly (29) and mechanism assembly (36) from inner case (46). Remove screw No. 6–40 UNF–2A x 2 inches long from mechanism.

E. Remove three shoulder screws (31) from transmission housing assembly (35). Separate transmission housing cover assembly (30) from transmission housing assembly (35). Care should be taken when cover is separated from housing, thereby preventing damage to journals of shafts within housing.

F. Separate gear assembly (32) from transmission housing assembly (35).

NOTE: Wheel and hub assembly (33) and stem pinion (34) should be disassembled only when defect is noted.

G. If defect is noted, press stem pinion (34) from wheel and hub assembly (33).

H. Remove spring ring (37) and snap ring (38) from inner groove of case (46).

5. Adjustment Stem

Remove pin retainer ring (40) from hub of zero setting gear (45). Press gear lock pin (41) from zero setting gear and adjustment stem (42). Pull adjustment stem from case (46). Remove zero setting gear and compression spring (44) from inner case cavity. Separate packing (43) from shoulder of adjustment stem.

6. Mechanism Assembly (Refer to figure 3.)

A. Handstaff Pinion

Separate center pinion (2) from large jewel bushing (3). Loosen screw (4) and remove jewel bushing and handstaff pinion (5) from gear plate assembly (25).

B. Rocking Shaft Assembly

(1) Press clock taper pin (6) from frame subassembly (30). Remove bearing pin (7) and separate link arm and link subassembly (14) from aneroid assembly (23).

(2) Loosen nut (10, figure 1). Back-off pivot screw (11, figure 1) until rocking shaft assembly (8) is disengaged. Remove sector gear end of rocking shaft assembly from eccentric jewel in gear plate assembly (25).

(3) Loosen screws (10) and (12). Separate rocking shaft counterweight (9) and rocking shaft pin (11) from rocking shaft subassembly (22).

(4) Remove elastic stop nut (13). Loosen screw (15) and separate link arm and link subassembly (14) from rocking shaft subassembly.

(5) Remove bearing pin (16) thereby disengaging mechanism link (17) from link arm (18).

(6) Remove screw (20) from sector gear of rocking shaft and remove sector gear counterweight (19).

NOTE: Further disassembly of rocking shaft subassembly is not recommended.

C. Intermediate Gear Assembly

(1) Remove four screws (26) and separate gear plate assembly (25) from frame subassembly (30).

(2) Press clock taper pin (27) from frame subassembly (30). Separate intermediate gear assembly (28) from gear plate assembly (25).

(3) Loosen screw (9, figure 1) and remove large jewel bushing (29) from center of frame subassembly.

CLEANING

1. General

Place all parts in a small wire mesh basket and wash in a watch type cleaning solution. Then rinse thoroughly in benzine (Federal Specification VV-B-231) and dry.

CAUTION: DO NOT IMMERSE JEWEL ASSEMBLIES IN BENZINE. SOME FLUID MAY BECOME TRAPPED INSIDE.

2. Gears and Pinions

A. Carefully brush all gear teeth with a No. 3 watchmaker's brush occasionally rubbing across a piece of prepared chalk. Hold the parts being brushed in a piece of watchmaker's paper keeping the brush clean and preventing it and the parts being brushed from coming in contact with the bare skin. This paper will soil very rapidly. Use a clean portion for each part.

B. Clean pinion of handstaff by pressing it into end grain of dry featherwood (pith wood).

3. Pivots

Clean pivots by pressing them into end grain of a piece of featherwood.

4. Jewels

Replace dirty jewel assemblies with new jewel assemblies.

INSPECTION AND CHECK

1. General

A. Check all jewels for cracks and flaws. Examine the pivots and check for polish, size and straightness.

B. Examine sector gear for broken or nicked teeth. Examine the handstaff pinion for pivot finish, trueness and condition of teeth.

C. Examine aneroid for bent edges and dents or nicks.

D. Check link for burrs and general wear.

E. Replace all gaskets and packings.

F. Check for sharp bends or kinks in hairspring.

G. In the event any parts do not meet preceding requirements, they should be replaced.

H. After inspection, place parts in a dust and moisture free container until reassembly.

REPAIR AND REPLACEMENT

Repair procedure should be confined to realignment and polishing. Parts needing further work should be replaced. (Refer to table 2. Inspection Chart.)

Table 2. Inspection Chart

Figure and Index Number	Nomenclature	Procedure
Figure 3, 8	Rocking Shaft Assembly	Inspect as applicable for distorted or broken link arm, bent or kinked hairspring, broken or worn teeth on sector gear, chipped or broken jewels, and damaged pivot. If damaged this assembly should be replaced as a unit.
Figure 3, 23	Aneroid Assembly	Check for dents, puncture or seal defects. Replace entire assembly if damaged.
Figure 3, 5	Handstaff Pinion	Inspect for worn or damaged teeth and bent or broken handstaff. If damaged replace with new handstaff pinion.
Figure 3, 28	Intermediate Gear Assembly	Inspect for worn or damaged teeth. Check hairspring for bent or kinked convolutions. Replace entire assembly if damaged.
Figure 2, 25 28 32 33 34	Barometric Setting Gear Assembly Spur Gear Unit Gear Assembly Wheel and Hub Assembly Stem Pinion	Inspect gears for worn or damaged teeth. Replace item if damaged.

ASSEMBLY

1. Lubrication

   Indicator requires no lubrication.

2. General

   Refer to applicable figure and assemble indicator in reverse order of disassembly as outlined by index numbers on illustration.

3. Mechanism Assembly (Refer to figure 3.)

   A. Intermediate Gear Assembly

      (1) Insert large jewel bushing (29) in center bore of frame subassembly (30). Observe that bushing is flush with surface of inner frame. Secure in position with screw (9, figure 1).

(2) Place journal of intermediate gear assembly (28), opposite hairspring end, in jewel bushing assembly (8, figure 1).

(3) Insert free end of gear assembly hairspring in applicable hole in altimeter frame (12, figure 1). Secure in position with clock taper pin (27).

(4) Align and insert free journal of intermediate gear assembly in eccentric jewel unit of gear plate assembly (25). Secure gear plate assembly to frame subassembly (30) with four screws (26).

CAUTION: PRIOR TO TICHTENING SCREWS (26) OBSERVE THAT INTERMEDIATE GEAR ASSEMBLY HAS SUFFICIENT ENDSHAKE, THEREBY PREVENTING POSSIBLE DAMAGE TO JEWEL OR DISTORTION OF JOURNALS.

(5) Adjust endshake in accordance with table 4.

B. Aneroid Assembly

Attach threaded centerpiece of aneroid assembly (23) to aneroid support (4, figure 1) with two hex nuts (24). Slot of centerpiece, opposite threaded centerpiece, should be parallel to base of frame.

C. Rocking Shaft Assembly

(1) Secure sector gear counterweight (19) to sector gear of rocking shaft with screw (20).

(2) Align bearing holes of link arm (18) and mechanism link (17) and insert bearing pin (16). Press flat end of pin flush to surface of link arm; then bend opposite end approximately 45 degrees to plane of link arm.

(3) Insert threaded section of link arm (18) in upper clearance hole of rocking shaft subassembly (22) and secure with screw (15). Attach elastic stop nut (13) to threaded section of link arm.

(4) Secure rocking shaft counterweight (9) to end of rocking shaft pin (11) with screw (10). Insert free end of rocking shaft pin in lower clearance hole of shaft and secure with screw (12).

(5) Insert journal, on sector gear end of rocking shaft assembly, in eccentric jewel mounted in gear plate assembly (25). Align opposite end of rocking shaft with pivot screw into end jewel of rocking shaft.

D. Handstaff Pinion

(1) Insert mechanism link (17) in slot of aneroid assembly (23). Align bearing holes of both items and insert bearing pin (7). Press flat end of pin flush to surface of aneroid centerpiece; then bend opposite end approximately 45 degrees to plane of centerpiece.

(2) Insert free end of rocking shaft hairspring (21) in hole provided in altimeter frame (12, figure 1) and secure with clock taper pin (6).

(3) Pass short journal of handstaff pinion (5) through center of gear plate assembly (25) and insert journal in large jewel bushing (29).

(4) Place large jewel bushing (3) on other end of handstaff pinion. Insert bushing in center bore of gear plate and secure with screw (4). Observe that intermediate gear assembly (28) is properly engaged with handstaff pinion.

(5) Adjust endshake of handstaff pinion by loosening screw (9, figure 1) and varying axial position of large jewel bushing (29). Adjust gear mesh with intermediate gear assembly (28) by radially adjusting intermediate gear eccentric jewel assembly mounted in gear plate. (Refer to table 4.)

(6) Adjust rocking shaft endshake using pivot screw (11, figure 1). Adjust sector gear and intermediate gear mating by radially adjusting rocking shaft eccentric jewel assembly mounted in gear plate assembly (25).

(7) Set endshake and gear mesh in accordance with table 4. When endshake of rocking shaft assembly is within specified tolerance secure pivot screw with nut (10, figure 1).

(8) Press center pinion (2) on section of handstaff pinion extending from gear plate assembly.

4. Transmission Assembly (Refer to figure 2.)

A. Place stem pinion (34) in bushing hole of transmission housing cover assembly (30) with 0.002 inch thick shim stock between gear of pinion and housing. Press wheel and hub assembly (33) on pinion shaft extending from opposite side of housing. Observe that stem pinion is properly meshed with mating cetner gear of cover assembly. Remove shim stock and check stem pinion endshake in accordance with table 4.

B. Insert journal, on pinion end of gear assembly (32), in bushing hole of transmission housing cover assembly (30).

C. Align bearing holes of transmission housing assembly (35) with journals of mounted gears in cover assembly. When journals of gear assembly (32) and stem pinion (34) are properly inserted in bearing holes of housing attach three shoulder screws (31). Observe that screws are evenly tightened, thereby preventing distortion to journals.

NOTE: Check rotary movement of gears for evidence of binding. Movement of gears shall be smooth and non-erratic.

D. Place spur gear unit (28) on shoulder of center bushing of cover assembly. Observe that spur gear is properly meshed with stem pinion (34).

E. Place transmission assembly in a clean container until calibration of mechanism assembly has been satisfactorily completed.

5. Calibration (Refer to figure 3.)

A. General

(1) Place a hundred-foot pointer (18, figure 2), used for testing purposes, on journal of handstaff pinion (5).

(2) Using a soft material, carefully bend outer radius of sector gear of rocking shaft assembly (8) until disengaged from mating intermediate gear assembly (28). Rotate test pointer approximately thirty six counterclockwise revolutions, thereby loading hairspring of intermediate gear. When hairspring is loaded, as specified, engage sector gear with intermediate gear.

NOTE: Sector gear of rocking shaft assembly shall have a sufficient travel to permit test pointer to indicate - 1000 feet on altimeter dial (22, figure 2).

(3) Radial movement of rocking shaft assembly shall produce an even rotation of pointer. If erratic or uneven pointer movement is observed, check mechanism for improper gear mesh and insufficient endshake in accordance with table 4.

NOTE: Correction to faulty gear train movement, if required, shall be made before proceeding further with calibration.

(4) All calibration readings shall be recorded while mechanism is being subjected to vibration using Edwards Vibrators, No. 1983, or equivalent.

(5) Remove test pointer.

B. Ranging (Refer to figure 3.)

(1) Mount mechanism on a standard altimeter calibration fixture.

(2) Attach altimeter dial (22, figure 2), used for testing purposes, to front face of fixture with two dial screws (23, figure 2).

(3) Press hundred-foot pointer (18, figure 2), used for testing purposes onto journal of handstaff pinion (5).

(4) Place mechanism in an altitude chamber. A master altimeter should be either in chamber or in some way connected to chamber.

(5) Observe ambient reading of master altimeter; then rotate mechanism assembly within calibration fixture until pointer indicates corresponding ambient reading on dial.

(6) Seal altitude chamber.

(7) Apply pressure in accordance with table 3. Readings at each test point, for both mechanism and master altimeter, shall be recorded.

(8) If mechanism readings, as compared to master altimeter, indicate a minus error in low range and a plus error in high range, loosen two nuts (24) and increase the distance between the aneroid assembly (23) and rocking shaft assembly (8). Tighten nuts securing aneroid and range mechanism, as outlined in paragraphs (4) through (7) above, to check adjustment made with aneroid assembly.

(9) If mechanism readings, as compared to master altimeter, indicate a plus error in low range and a minus error in the high range, loosen two nuts (24) and decrease the distance between aneroid assembly (23) and rocking shaft assembly (8). Tighten nuts securing aneroid assembly and range mechanism, as outlined in paragraphs (4) through (7) above, to check adjustment made with aneroid assembly.

NOTE: Whenever the effective length of mechanism link (17) has been altered, due to adjustment of aneroid assembly, freedom of link movement shall be checked.

(10) If mechanism readings indicate a consistant plus error throughout entire range loosen screw (15) and rotate elastic stop nut (13) approximately one revolution counterclockwise. Push stop nut toward rocking shaft subassembly (22) until contact is made. Tighten screws (15) and range mechanism, as outlined in paragraphs (4) through (7) above, to check adjustment made to effective length of link arm and link subassembly (14).

(11) If mechanism readings indicate a consistant minus error throughout entire range loosen screw (15) and rotate elastic stop nut (13) approximately one revolution clockwise. Tighten screw (15) and range mechanism, as outlined in paragraphs (4) through (7) above, to check adjustment made to effective length of link arm and link subassembly (14).

(12) When all tests points are satisfactorily within tolerances specified in table 3, apply glyptal to all screws and nuts.

Table 3. Ranging Chart

Altitude (feet)	Equivalent Atmospheric Inches of Hg	Pressure Millibars	Tolerance (± feet) Room Temperature
-1,000	31.0185	1050.41	20
0	29.9213	1013.25	20
500	29.3846	995.08	20
1,000	28.8557	977.17	20
1,500	28.3345	959.52	25

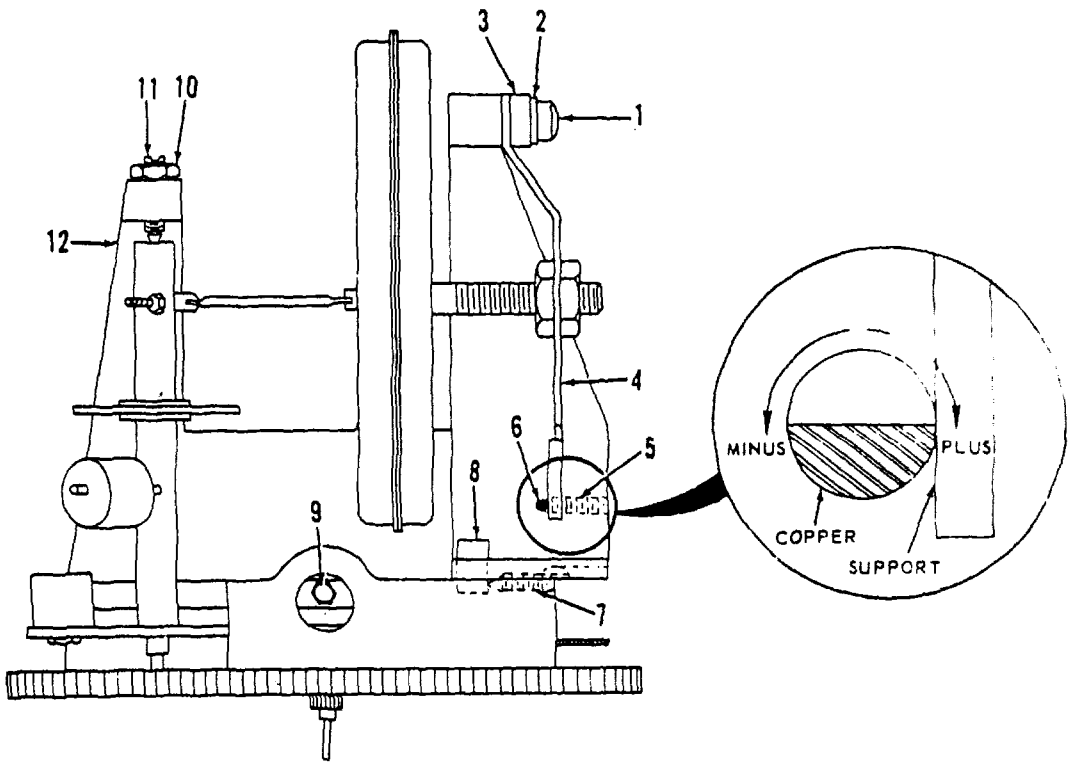
35,000*	7.0406	238.42	205

*135 (series) only

C. Temperature Compensation



(1) Observe reading of master altimeter corrected for ambient barometric pressure

(2) Rotate mechanism within calibration fixture until pointer indicates corresponding ambient reading on dial.

(3) Record reading at room temperature, then place mechanism in a cold chamber -35°C (-31°F) for a period of one hour. Record second reading.

(4) The change in reading at room temperature and reading at cold temperature shall not exceed ± 40 feet.

NOTE: Readings shall be corrected to compensate for barometric pressure change during one hour period in cold chamber. Changes in pressure may be noted in terms of feet altitude. If the master altimeter indicates 500 feet at the start of compensation test and 530 feet at completion of test, the

11. Pivot screw
12. Altimeter frame

Frame Subassembly (Temperature Compensation)
Figure 1

mechanism undergoing test will have changed plus 30 feet. Subtract this error algebraically from reading obtained to arrive at corrected compensation reading.

(5) If the difference between room temperature reading and cold temperature reading exceeds ±40 feet, adjustment of temperature compensator (6, figure 1) will be necessary. Proceed as follows:

(6) Loosen screw (5, figure 1). Insert a jeweler's screwdriver in slotted end of compensator. Correct error by rotating compensator. (Refer to figure 1.)

NOTE: A fifteen degree rotation of temperature compensator will correct an error of approximately seventy five feet, respectively.

(7) Tighten screw securing compensator and repeat test as outlined in paragraph (1) through (4) above.

(8) When mechanism is satisfactorily within tolerances specified, apply glyptal to screw (5, figure 1.)

D. Position Error (Refer to figure 3.)

(1) This procedure shall be conducted with mechanism subjected to vibration.

(2) Position calibration fixture with mechanism assembly in a normal operating position with zero indication of dial at 12 o'clock. Rotate mechanism within fixture until pointer indicates zero.

(3) Lightly tap mechanism and record reading. Rotate calibration fixture clockwise until pointer is at 6 o'clock position. Tap mechanism and record reading. The difference between readings shall not exceed ±20 feet.

(4) If a plus error is indicated, loosen screw (12) and position rocking shaft counterweight (9) away from rocking shaft subassembly (22); then tighten screw. If a minus error is indicated, position counterweight toward rocking shaft; then tighten screw. Balance mechanism to specified tolerance.

(5) Rotate calibration fixture until pointer is at 9 o'clock position; then lightly tap mechanism and record reading. Rotate calibration fixture clockwise until pointer is at 3 o'clock position. Tap mechanism and record reading. The difference between readings shall not exceed ±20 feet.

(6) If a plus error is indicated, loosen screw (20) and position sector gear counterweight (19) toward rocking shaft subassembly (22). If

a minus error is indicated, position counterweight away from rocking shaft. Tighten screw (20) when mechanism is balanced within specified tolerance.

NOTE: Remove excessive pointer oscillation, if necessary, by increasing tension of rocking shaft hairspring (21).

(7) Position the calibration fixture with mechanism dial facing up. With pointer at zero lightly tap mechanism to remove friction. If pointer indicates an error, loosen nut (10, figure 1) and adjust pivot screw (11, figure 1) to correct for excessive endshake of rocking shaft assembly (8). Tighten nut when mechanism is balanced within specified tolerance.

(8) Repeat procedures as outlined in paragraph D. to insure that mechanism is balanced to within specified tolerance.

6. Final Check

A. Ranging

Repeat ranging procedures as outlined in paragraph 5.B. making adjustments where applicable.

B. Temperature Compensation

Repeat compensation procedures as outlined in paragraph 5.C. making adjustments where applicable.

C. Endshake and Gear Mesh

(1) Movement of pointer shall be smooth and non-erratic. Check endshake and gear mesh in accordance with table 4.

(2) Remove test pointer and dial; then separate mechanism assembly from calibration fixture.

(3) Apply glyptal to all screws and nuts not secured to mechanism with a mechanical fastener.

7. Case Assembly (Refer to figure 2.)

A. Adjustment Stem

(1) Place a new packing (43) on shoulder of unthreaded end of adjustment stem (42). Insert unthreaded end of stem through hole in open end of case (46).

(2) As stem begins to protrude through inner surface of case cavity, place compression spring (44) and zero setting gear (45) on stem. Push stem in bearing hole of cavity.

(3) Position pin retainer ring (40) around hub of gear. Align holes of adjustment stem and zero setting gear; then press in gear lock pin (41).

(4) Adjust pin retainer ring (40) to secure lock pin (41) in position.

B. Transmission and Mechanism Assembly

(1) Insert snap ring (38) in innermost groove of case (46). Position spring ring (37) over snap ring.

(2) Carefully position transmission assembly (29) over gear plate assembly (25, figure 3) and align center pinion (2, figure 3) in center opening of transmission assembly. Insert center pinion in opening and mesh pinion with gear assembly (33). Transmission assembly should now be seated on gear plate assembly with handstaff pinion (5, figure 3) centrally located within transmission housing cover assembly.

(3) To facilitate installation of transmission and mechanism assemblies into case (46) align clearance hole in transmission housing assembly (35) with No. 6-40 threaded hole in gear plate assembly (25, figure 3); then insert screw (used for installing purposes only) No. 6-40 UNF-2Ax2 inches long in threaded hole of transmission housing assembly.

(4) Align locating pin on outer edge of transmission housing assembly (35) with locating slot of inner case. Carefully lower transmission assembly (29) and mechanism assembly (36) into case (46).

(5) Insert snap ring (27) in upper groove of inner case (46).

(6) Insert eccentric locking pin (26), as required, in transmission housing assembly (35) and radially adjust pin for proper tension.

(7) Remove installation screw.

(8) Place barometric setting gear assembly (25) on housing stud. Observe that zero setting gear (45) and barometric setting gear assembly are properly meshed.

(9) Rotate adjustment stem (42) clockwise and counterclockwise. Rotary movement of gears shall be smooth and non-erratic.

C. Pointers and Dials

(1) Position barometric dial assembly (24) on transmission housing cover assembly (30); then place altimeter dial (22) over barometric dial with numeral six oriented in close proximity to zero setting gear (45). Secure altimeter dial to cover assembly with two dial screws (23).

(2) Assemble pointer to mechanism each indicating zero on altimeter dial. Proceed as follows:

(3) Press ten thousand-foot pointer (20) and thousand-foot pointer (19) on center bushing of transmission assembly (29). Press the hundred-foot pointer (18) on handstaff pinion (5, figure 3) centrally located within center bushing.

(4) Position spacer ring (21) on rim of case (46).

D. Bezel Assembly

(1) Place bezel gasket (17) on case rim.

(2) Clean both surfaces of glass (16) and position on bezel gasket. Place gasket (15) on outer surface of glass.

(3) Insert threaded section of adjustment stem (42) in applicable hole in bezel (14). Attach bezel to case with six screws (9), lockwashers (10) and two scres (11).

(4) Turn knob locknut (6) and adjustment knob (5) onto threaded section of adjustment stem (42). When heighth of knob is adjusted in accordance with table 4, secure in position by turning locknut in a counterclockwise direction while holding knob in a stationary position.

(5) Observe reading of master altimeter for ambient altitude; then rotate adjustment knob (5) until pointers indicate corresponding altitude on dial.

(6) Observe reading of a mercurial barometer; then pull adjustment knob outward and rotate until barometric dial assembly (24) indicates corresponding reading in altimeter dial cut-out. Release knob.

(7) Position locking stud screw (13) towards adjustment stem and tighten, thereby securing locking stud (12).

FITS AND CLEARANCE

This section lists fits and clearances which should be observed and maintained for the proper operation of indicator. (Refer to table 4.)

Table 4. Fits and Clearances

Description		Fits or Clearances (inches)		
		Fig.-Item	Normal	Tolerance
Endshake	Intermediate gear assembly	3 - 28	0.003	0.002 - 0.004
	Rocking shaft assembly	3 - 28	0.002	0.001 - 0.003
	Handstaff pinion	3 - 5	0.003	0.002 - 0.004
	Stem pinion	2 - 34	0.003	0.002 - 0.004
Gear mesh	Sector gear of rocking shaft subassembly with intermediate gear assembly	3 - 22	0.0002	0.0001-0.0003
	Intermediate gear assembly with handstaff pinion	3 - 28	0.0002	0.0001-0.0003
Play	Mechanism link with bearing pin (7 and 16, figure 3	3 - 17	0.005	0.004 - 0.006 (loose)
Clearance	End of adjustment knob to bezel (14, figure 2)	2 - 5	0.900	0.890 - 0.910

TESTING

1. Test Conditions

   A. Unless otherwise specified, the indicator shall be tested in its normal operating position with the dial vertical.

   B. All tests shall be conducted in an environment as follows:

Ambient Temperature	$23^{\circ} \pm 5^{\circ}C$
Atmospheric Pressure	28 to 32 inches of Hg
Relative Humidity	No greater than 55%

   C. All test readings shall be recorded while instrument is being subjected to vibration using Edwards Vibrators, No. 1983, or equivalent.

2. Test Equipment

   Test equipment required is listed in SPECIAL TOOLS, FIXTURES, AND EQUIPMENT section.

3. Test Procedures

   Visually inspect the indicator to verify that workmanship conforms to aerospace equipment. This inspection shall include a check of overall appearances of

finish and tightness of fastenings, cleanliness and proper alignment of mechanical parts. The indicator window shall have no defects that could impair or distort reading of dials.

4. Scale Error at Room Temperature

A. Indicator shall not have been operated at other than approximately 29.92 inches of Hg and at an ambient temperature of approximately 25°C for a period of not less than twelve hours prior to this test.

B. Place indicator in an altitude chamber. A master altimeter should be either in chamber or in some way connected to chamber.

C. Rotate adjustment knob (5, figure 2) until 29.92 inches of Hg is indicated on barometric dial assembly (24, figure 2). The barometric dial shall remain at this setting while indicator is successively subjected to the pressures specified in table 5. Reduction in pressure shall be made at a rate not in excess of 20, 000 fpm to within approximately 2, 000 feet of test point. Indicator shall remain at pressure corresponding to each test point for at least one minute but not more than ten minutes before reading is recorded. Error at each test point shall not exceed tolerance specified in table 5.

Table 5. Scale Error Chart

Altitude (feet)	Inches of Hg	Millibars	Tolerance (± feet)	
			Room Temperature	-35°C (-31°F)
-1, 000	31.0185	1050.41	20	--
0	29.9213	1013.25	20	40
500	29.3846	995.08	20	--
1, 000	28.8557	917.17	20	--
1, 500	28.3345	959.52	25	--
2, 000	27.8210	942.13	30	--
3, 000	26.8167	908.12	30	--
4, 000	25.8418	875.10	35	--
6, 000	23.9782	811.99	40	60
8, 000	22.2249	752.62	60	--
10, 000	20.5769	696.81	80	--
12, 000	19.0293	644.41	90	90
14, 000	17.5773	595.24	100	--
16, 000	16.2164	549.15	110	--
18, 000	14.9421	506.00	120	120
20, 000	13.7501	465.63	130	--

Table 5. Scale Error Chart (continued)

Altitude (feet)	Inches of Hg	Millibars	Tolerance (±feet)	
			Room Temperature	-35°C (-31°F)
22,000*	12.6363	427.91	140	--
25,000*	11.1035	376.01	155	155
30,000*	8.8854	300.89	180	--
35,000*	7.0406	238.42	205	205
*135 (series) only				

5. Hysteresis

A. This test shall be performed not more than fifteen minutes after indicator has been subjected to the pressure corresponding to the upper limit test point. While indicator is still at this pressure proceed as follows:

B. Increase pressure at a rate simulating a descent in altitude of approximately (but not exceeding) 20,000 fpm until within 3,000 feet of first test point. (Refer to table 6.) Approach this test point at a rate of approximately 3,000 fpm. Within ten seconds after pressure has been stabilized at this test point, indicator reading shall be within 100 feet of scale error as specified in table 5.

Table 6. Hysteresis Chart

Test Point	Altitude (feet)	Equivalent Atmospheric Pressure		Tolerance (±feet)
		Inches of Hg	Millibars	
First	25,000*	11.1035	376.01	75
	14,000	17.5773	595.24	75
Second	20,000*	13.7501	465.63	75
	10,000	20.5769	696.81	75
*135 (series) only				

C. Indicator shall remain at this pressure for at least five minutes but not more than fifteen minutes before test reading is taken.

D. Pressure shall be increased, at the above rate, until the pressure corresponding to the second test point is reached. Indicator shall remain at this pressure for at least one minute but not more than ten minutes before test reading is taken.

E. Pressure shall be increased, at the above rate, until ambient atmospheric pressure is reached. The indicator reading at each test point shall not exceed tolerance specified in table 6.

6. After Effect

A. This test procedure shall be performed not more than five minutes after the completion of hysteresis test.

B. With the return of pointers to original ambient readings the error shall not exceed ± 30 feet after correction for any change to ambient atmospheric pressure has been made.

7. Friction

The indicator shall be subjected to a steady rate of a decrease in pressure equivalent to about 750 fpm in accordance with table 7. At each test point two readings are to be recorded; the first before tapping instrument and the second after tapping instrument. Friction error shall not exceed tolerance listed in table 7.

Table 7. Friction Error Chart

Altitude (feet)	Tolerance (± feet)
1, 000	70
2, 000	70
3, 000	70
5, 000	70
10, 000	80
15, 000	90
20, 000	100
25, 000*	120
30, 000*	140
35, 000*	160
*135 (series) only	

8. Case Leakage

Connect the static pressure port of indicator to a source of pressure. Apply pressure, equivalent to 18, 000 feet, to case. Ath this point clamp off connection from pressure source. Record any change in reading during a one minute inerval. Case leakage shall not exceed 100 feet.

9. Position Error

A. Test shall be performed with indicator mounted on a position error fixture.

B. Readings shall be recorded with indicator in a vertical position with dial up and another in a normal operating position.

C. Additional readings shall be taken with the hundred-foot pointer (18, figure 2) at 12, 3, 6, and 9 o'clock positions. These readings shall be recorded.

D. The difference between pointer indications with indicator in a normal operating position and in around the clock positions, as described above, shall not exceed ±20 feet.

10. Barometric Scale Error

A. Test shall be conducted with indicator subjected to a constant ambient pressure.

B. Rotate adjustment knob (5, figure 2) until the barometric dial assembly (24, figure 2) indicates each of the various settings in accordance with table 8. While barometric dial is being adjusted to test setting, the hundred-foot pointer will simultaneously adjust to setting. Record pointer readings at each setting.

C. When pointer reading at each setting has been recorded, determine the difference in altitude between each reading and zero. The differences shall not exceed tolerances listed in table 8.

Table 8. Barometric Scale Error Chart

Equivalent Pressure		Altitude Difference From Zero (feet)	Tolerance (±feet)
Inches of Hg	Millibars		
28.10	950	-1727	25
28.50	964	-1340	25
29.00	982	- 863	25
29.50	998	- 392	25
29.92	1013	0	
30.50	1033	+ 531	25
30.90	1047	+ 893	25
30.99	1049	+ 974	25

11. Scale Error at Low Temperature

A. The indicator shall be exposed to a temperature of -35°C (-31°F) for a period of three hours minimum.

B. While at this temperature the indicator shall be subjected to similar test as outlined in paragraph 4., except the change in reading as compared to reading at room temperature at each test point, shall not exceed applicable tolerances specified in Table 5.

TROUBLESHOOTING

1. General

This section presents general troubleshooting information to assist in locating and correcting any malfunctions of the indicator. A troubleshooting chart, table 9, is provided for reference.

2. Troubleshooting Procedure

A. Troubleshooting should begin after testing and careful observation of indicator performance. Pointer readings should be recorded for reference. Based on indicator performance, attempt to isolate the malfunction to altimeter mechanism or case assembly.

B. When the malfunction has been isolate, check for mechanical malfunctions. This can be done quickly by inspection. Typical malfunctions would be loose gears on shafts, binding gears, defective jewels, foreign matter in jewels, loose pointers on dial, broken or damaged gear teeth, etc.

Table 9. Troubleshooting Chart

Trouble	Probable Cause	Remedy
Mechanism fails to respond properly.	Dirt or other foreign matter on gear teeth.	Remove and clean gears with benzine cleaning solution.
	Incorrectly adjusted gear train mesh.	Refer to fits and clearances, table 4.
Altimeter will not maintain a constant reading.	Aneroid leakage.	Replace aneroid assembly (23, figure 3).
Hundred-foot pointer (18, figure 2) fails to read - 1000 feet.	Insufficient sector gear travel.	Correct condition by referring to Assembly, paragraph 5.A.(2) and (3).
Hundred-foot pointer (18, figure 2) oscillates on indication.	Excessive endshake of rocking shaft assembly (8, figure 3).	Adjust endshake in accordance with Assembly, paragraph 3.D.(6).
Instrument indicates a minus error in low range and a plus error in high range.	Aneroid assembly (23, figure 3) oriented too close to rocking shaft assembly (18, figure 3).	Correct error in accordance with Calibration, paragraph 5.B.(8).

Table 9. Troubleshooting Chart (continued)

Trouble	Probable Cause	Remedy
Instrument indicates a plus error in low range and a minus error in high range.	Aneroid assembly (23, figure 3) oriented to far from rocking shaft assembly (8, figure 3).	Correct error in accordance with Cablibration, paragraph 5.B. (9).
Instrument indicates a consistant plus or minus error throughout entire range.	Improper setting of link arm and link subassembly (14, figure 3).	Correct error in accordance with Calibration, paragraph 5.B. (10) for consistant plus error, paragraph 5.B. (11) for consistant minus error.

PACKAGING AND STORAGE

1. Packaging and Storage Instructions

Requirements for packaging and storage conform to U. S. government specification (MIL-P-116D). A summary of the most often used methods of packing for storage is included.

A. Packaging for Storage

(1) Packaging for immediate use (for mechanical and physical protection only).

The instrument shall be enclosed in wrappings, boxes, bags, cartons or other containers, as applicable, to the extent necessary to provide protection from hazards of contamination and physical damage encountered in general handling, shelf storage and issue. When bags, wraps, or other flexible barriers are used, cushioning shall be applied as required to protect the enclosing media. If packaged in a rigid container this container shall be supported by rigid or resilient dunnage as necessary to prevent free movement. Materials in contact with the surface of the instrument shall be as dry as practicable and in accordance with commercial practice.

(2) Packaging for Short Term Storage (up to six months)

The instrument shall be wrapped or padded so that all projections or sharp edges that might damage a barrier bag are covered sufficiently to avoid damage to the bag. The usual method for accomplishing this is to pack the instrument in dunnage in a corrugated

paper carton. The corners of the carton should be crushed so that they will not damage the barrier bag. The dunnage should be either Kim-Pak, rubberized hair or fiber. The barrier bag shall be constructed of one or more plies in any manner which will insure water vapor proofness and flexibility. The material must have low water transmission characteristics for use in packaging. Lapping or butting of the component materials of the finished product is not permitted except in the direction perpendicular to the rolling direction. The lapped areas shall be plainly externally flagged to prevent use of that portion of the roll when a lap or butt weld is made on the finished product, the foil component (if present) or cloth backing (if present). The barrier bag is usually made of canvas covered foil and can be heat sealed airtight.

(3) Packaging for Long Term Storage (up to nine years)

For a long term storage the item should be packed as in paragraph (2), however, a desiccant and humidity indicator shall also be included within the bag. This package shall be opened and checked at three year intervals and if the humidity indicator has changed color the desiccant and the humidity indicator should be replaced, the instrument checked for damage from moisture and then resealed in the bag. If the humidity indicator has not changed color, the bag should simply be resealed. A bag is usually good for about three resealings or nine years.

B. Storage

(1) When the instrument is removed from the carrier the vent plug (3, figure 2) should be inserted immediately to prevent foreign matter from entering the connection openings. If this plug is not available, the static port should be sealed in some manner.

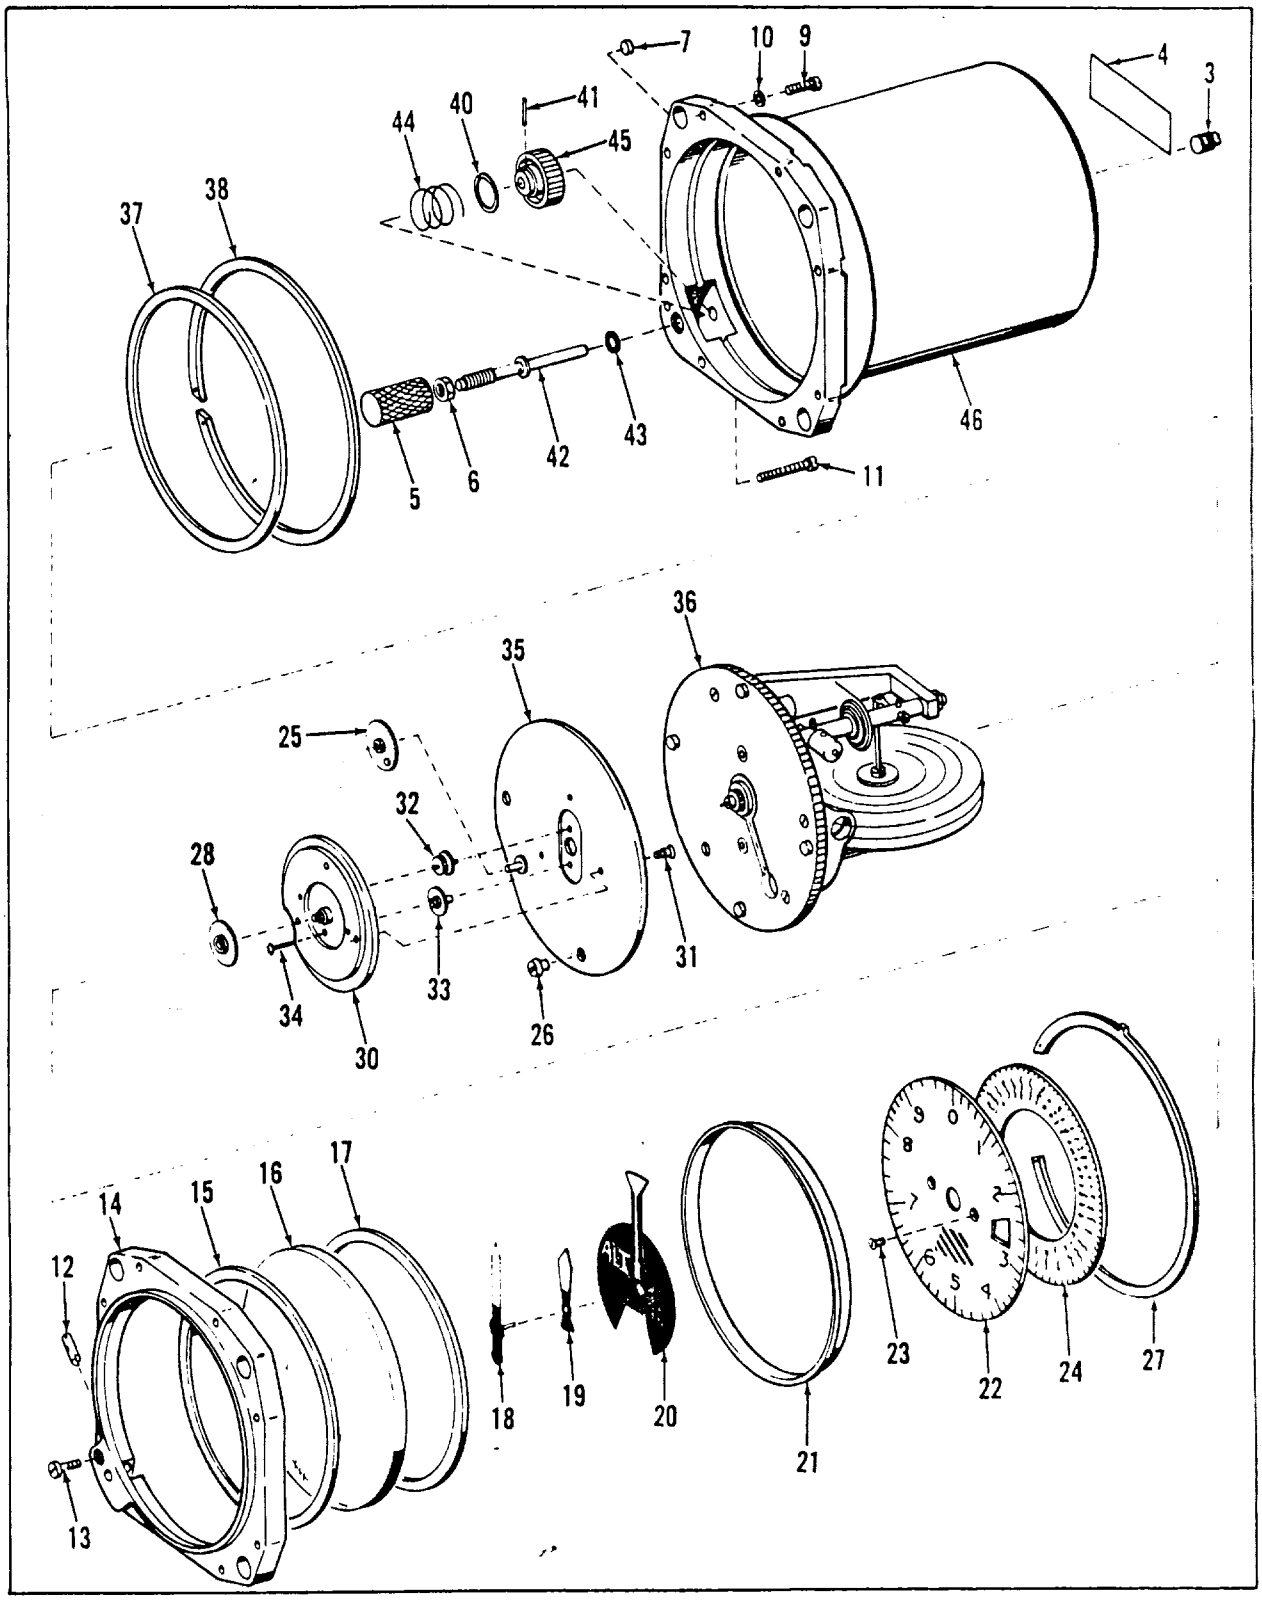
(2) When packaging for storage instructions are closely followed, no special storage conditions are required except a dry area where the instrument will be protected from being crushed.

SPECIAL TOOLS, FIXTURES, AND EQUIPMENT

1. Test Equipment

Edwards' Vibrator, No. 1983, manufactured by the Edwards Company, Incorporated, located in Norwalk, Connecticut.

2. Materials Used in Repair and Calibration of Indicator



Benzine (Federal Specification VV-B-231)
Purple Glyptal, ZV-903, General Electric
Compressed air, clean, filtered, 20 psi maximum
Standard Calibration fixture

ILLUSTRATED PARTS LIST

Replaceable parts for the altimeter indicator are listed in disassembly order of appearance keyed to illustrations. (Refer to figures 2 and 3.) Parts numbers listed originate with Mac Leod Instrument Corporation (11824). The nomenclature of a vendor-supplied item includes a five digit manufacturers supply code as listed in Cataloging Handbook H4-1. (Refer to table 10.)

INTRODUCTION

1. General

A. This manual is written to the ATA specification 100 and in AECMA simplified English. SI units of measurement are used with imperial units in parentheses.

B. The manual describes physical and technical issues concerning the compass and gives the necessary information to perform overhaul of the compass units listed on the title page.

C. This manual concentrates on compasses manufactured to a 'MOD.02' build level. MOD.02 compasses were introduced in 1988 and no MOD.01 compasses have been built since that date. All compasses overhauled by SIRS Navigation Ltd., are modified to MOD.02. It is strongly recommended that all MOD.01 compasses are modified to type MOD.02 when submitted for Repair/Overhaul. Where differences occur in this manual between the two MOD Levels, the initial information is for type MOD.02 and the variations are explained for MOD.01

D. The manual does not describe maintenance on the component when it is installed on the aircraft. The compass is a sealed unit and should be repaired by the manufacturer or an approved repair agent.

E. Only approved persons with the necessary skills must be used for the maintenance procedures described in this manual

F. This manual contains:
- Technical data for the component.
- Maintenance and repair procedures for the component.
- An Illustrated parts list (IPL) . Parts are identified in all sections of the manual by an IPL Figure and an item number.

G. The 'Disassembly', 'Testing', 'Fault Isolation' and 'Assembly Procedures' detailed within this manual have been verified by actual performance.

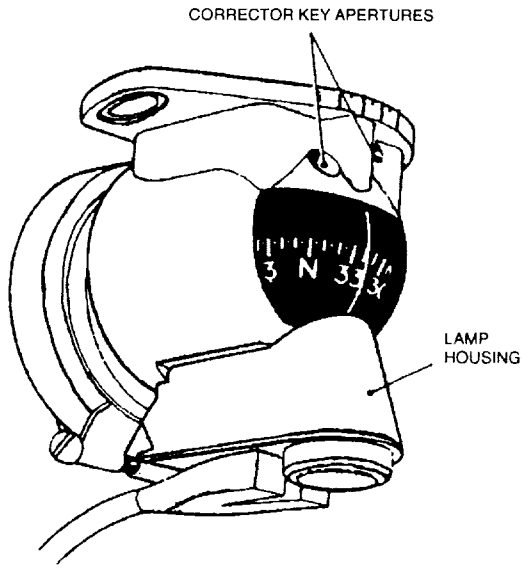
H. SIRS Navigation Ltd. Purchased, in 1994, all rights to the compass products from 'Smiths Industries'. All issues relating to the compass or this overhaul manual should be directed to SIRS Navigation Ltd.

2. How to use this manual

A. Make sure the manual contains the information applicable to your component. Look on the title page for the part number.

B. If you need to identify a part or find a part number refer to the IPL which has an introduction to detail the procedure

The instructions in this manual must be used for all the component maintenance. Read all the applicable WARNINGS and CAUTIONS before you work on the component.



DESCRIPTION AND OPERATION

A. General

The standby compasses (fig.1) are self-contained magnetic units which provide a constant indication of aircraft heading. Usually mounted in the pilots field of vision, they are designed to be fitted at or above eye level.

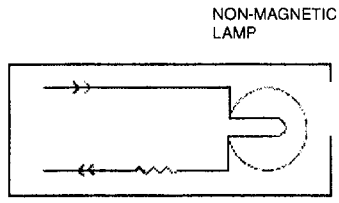
Aircraft heading is read direct from a compass card against a vertical lubber line engraved on the inside of the compass bowl. The compass card is illuminated by a non-magnetic lamp through a coloured filter.

Magnetic correctors are fitted to enable errors, due to coefficients 'B' and 'C', to be corrected.

General View
fig. 1

The complete compass may be rotated on its fixing screws to correct errors due to coefficient 'A'.

B. Description.



The compass card is of conic section with markings at intervals on the outside face. It is attached to a dome carrying a cobalt magnet and pivot. The pivot locates in a sapphire cup mounted in a stem assembly, which is secured to the compass bowl by a bracket.

The compass bowl forms the main body of the compass and is a transparent plastic moulding painted on the outside surface except for a clear portion at the front through which the compass card is viewed. A small translucent portion at the base allows the compass card to be illuminated.

The compass bowl is filled with silicone fluid to dampen the movement of the compass card. Bellows, clamped to the rear of the compass bowl, allow for expansion and contraction of the fluid due to changes in temperature and pressure.

A filling plug, disc and washer are located at the front of the compass bowl beneath the 'Horizontal Corrector Assembly' which includes a mounting plate with a scale in 5 deg increments engraved on the front edge to measure the coefficient 'A' correction. The horizontal correctors, for coefficients 'B' and 'C', consist of small bar magnets in the gear shafts of the corrector mechanism. Indicator lines on the end of the gear shafts identify the position of the magnets. Any rotation of the gear shafts can be seen on top of the mounting plate as an angular difference between the indicator lines and the associated index lines. The correctors are at the magnetic null, or neutral position, when the indicator lines and index lines are aligned. The correctors are adjusted by means of a key inserted into apertures in the front of the bowl. 'B' and 'C' engravings on the front edge of the mounting plate identify the apertures.

The lamp housing is a plastic moulding secured to the base of the bowl *(Compasses built to pre-MOD 02 standards have the Lamp Housing attached by four screws. MOD 02 compass are held in place by a clip action).* The D.C. supply is fed to the lamp via a lead and socket assembly which clips on to two connection pins on the underside of the lamp housing. The non-magnetic lamp fits into a lamp spring and is secured in position by a retaining cap. The lamp circuit is shown in fig. 2.

Lamp circuit
fig. 2

C. Operation

The compass 'Electrical Lead Assembly' (CE2-A26), should be connected to the aircraft electrical power supply before installation of the compass.

The compass should be installed into its correct position and secured using two suitable screws with a head diameter no greater than 6.9mm (0.27").

CAUTION: THE SECURING SCREWS SHOULD BE 'NON-MAGNETIC' AND MUST NOT BE OVERTIGHTENED.

IMPORTANT: REFERENCE SHOULD BE MADE TO THE INSTALLATION DRAWING FOR DETAILED INFORMATION CONCERNING THE COMPASS.

The compass requires no power to operate, other than that provided for illumination, and it will start to indicate a heading as soon as it is installed into its correct position.

The compass will need to be adjusted to compensate for magnetic deviations caused by the aircraft or local components or instruments. A correction procedure for this compass is described in detail in section 11001 of this manual.

D. Leading Particulars

Name:	Standby Compass		
Code:	Refer to title page		
Size:	57.2mm (2.25in) x 58.0mm (2.29in) x 52.4mm (2.07in)		
Weight:	0.113kg (4 oz) including lead and socket		
Electrical supply:	28V d.c. (except models: KCA0107W & WL1001KCA1 = 5V d.c.)		
Ambient Operating Temperature:	-40°C to 85°C (except models to MOD.01 = -40°C to 70°C)		
Value of resistor in lamp circuit:	KCA0104FY, KCA0104W, KCA0105W, KCA0106W and KCA0109W	330	Ω
	KCA0112W	820	Ω
	KCA0110W and KCA0114W	47	Ω
	KCA0113W and KCA0113FY	390	Ω
	WL1001KCA1, KCA0107W, KCA0101C, KCA0101W, KCA0102C and KCA0102W	None	

Testing & Fault Isolation

A. General

This section is arranged to identify and rectify those faults, which are likely to occur when the compass is in service.

NOTE: Whenever any adjustment, repair or component replacement has been carried out, the unit must be subjected to the complete series of tests* described within this section. *(* Other than the replacement of Lamp – 360)*

The magnetic tests detailed within this section that can be applied to the compass in service are to be used as a guide and for reference purposes only. Accurate magnetic tests can only be carried out within an approved magnetic test facility.

The faults most likely to occur in service are:

(i) Directional Error
(ii) Failure of illumination.
(iii) Slow Movement of the Compass Card
(iv) Fluid Loss/Air Bubble
(v) Magnetic Correction Problems

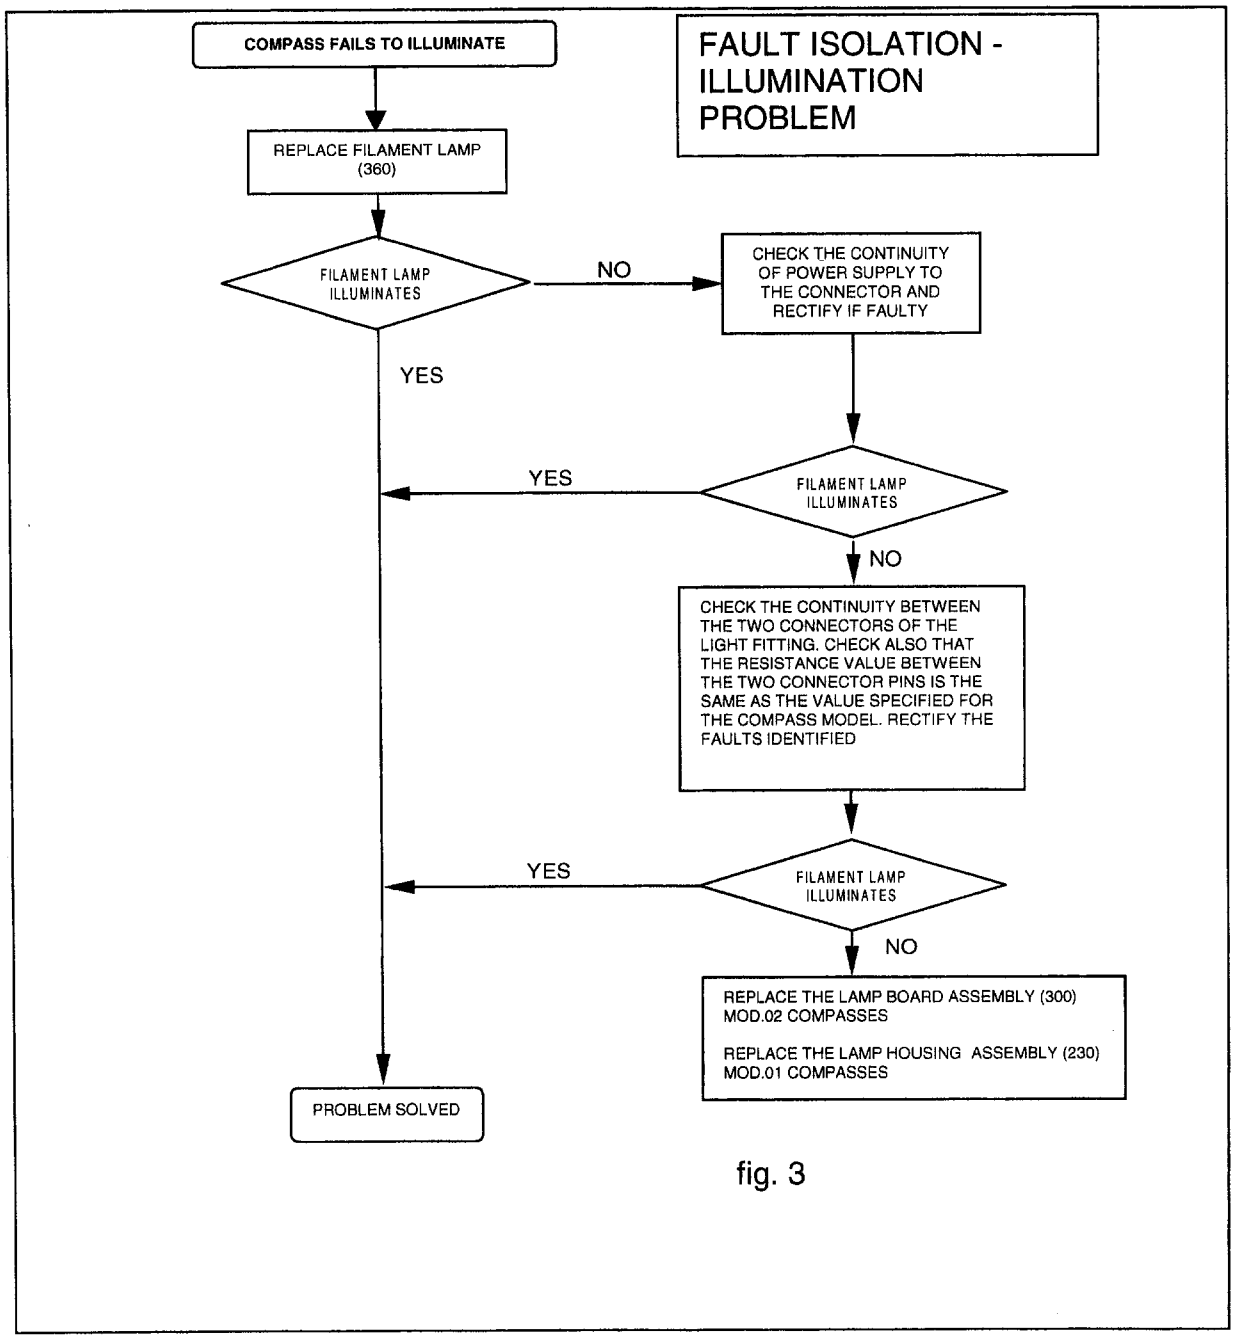
(i) Directional Error.

The compass may appear to have an incorrect heading. This may be due to one or a combination of the following problems.

a) Excessive Friction within the Compass preventing the card from rotating freely. (See 'para iii' to verify if this is the problem)
b) Magnetic error with the main compass magnet, mounted within the compass card
c) Magnetic error within the Corrector Assembly (160) (See 'para v' to verify if this is the problem)

(ii) Failure of illumination.

If the compass unit fails to illuminate, carry out the following procedure identified within figure 3.



COMPASS FAILS TO ILLUMINATE
FAULT ISOLATION - ILLUMINATION PROBLEM
REPLACE FILAMENT LAMP (360)
FILAMENT LAMP ILLUMINATES
NO
CHECK THE CONTINUITY OF POWER SUPPLY TO THE CONNECTOR AND RECTIFY IF FAULTY
YES
YES
FILAMENT LAMP ILLUMINATES
NO
CHECK THE CONTINUITY BETWEEN THE TWO CONNECTORS OF THE LIGHT FITTING. CHECK ALSO THAT THE RESISTANCE VALUE BETWEEN THE TWO CONNECTOR PINS IS THE SAME AS THE VALUE SPECIFIED FOR THE COMPASS MODEL. RECTIFY THE FAULTS IDENTIFIED
YES
FILAMENT LAMP ILLUMINATES
NO
REPLACE THE LAMP BOARD ASSEMBLY (300) MOD.02 COMPASSES
REPLACE THE LAMP HOUSING ASSEMBLY (230) MOD.01 COMPASSES
PROBLEM SOLVED

fig. 3

iii Slow Movement of the Compass Card

This problem will be noticed as slow movement of the card assembly during minor alterations of the aircraft heading. The card may appear to be frozen in one position for small changes of aircraft heading.

To identify if the compass is faulty, the following procedure should be followed.

a) Remove the compass from the aircraft
b) Place the compass, in its normal operating attitude, on a non-magnetic stand or table in an area away from any magnetic disturbance.
c) Align the compass to a north facing position.
d) With the use of a small magnet, deflect the compass card by 5°, allow the card to settle and then remove the small magnet. The card should return to within 1° of the original heading.
e) Repeat this test for each main cardinal points
f) If the compass fails this test, the unit should be repaired or replaced.
g) If the compass passes this test, it is unlikely that there is a problem with the instrument and there may be a problem with a component located close to the compass that is magnetically affecting the compass.

(iv) Fluid Loss/Air Bubble

This problem will be noticed as the appearance of an air bubble within the bowl of the compass unit. It is unlikely that there will be evidence of fluid the outside of the compass, due to its evaporation.

The appearance of a small bubble does not render the compass inaccurate, but the compass unit should be repaired or replaced at the earliest opportunity.

The appearance of a large air bubble may render the compass inaccurate. The compass should always be repaired or replaced.

v) **Magnetic Correction Problems**

This problem will be noticed by a difficulty in correcting the compass unit once it has been installed within an aircraft and during the 'aircraft swing' procedure.

To identify if the compass may have 'magnetic correction problems', the procedure detailed below should be followed...

These tests are specified for guidance purposes only and do not relate exactly to the product test specification. The tests are not being carried out in an approved magnetic test facility and it is therefore considered that the results obtained will not be exact. The results will however indicate if there are any problems associated with the compass.

a) Remove the compass from the aircraft

b) Re-set the magnetic correctors to their neutral position*

** reference to the Installation Instructions, section 13000, is recommended before carrying out these tests*

c) Place the compass, in its normal operating attitude, on a non-magnetic stand or table in an area away from any magnetic disturbance.

d) Align the compass to a North facing position.

e) With the use of the Corrector Key (220), place the Key in Corrector hole 'C', engage the key with the shaft and rotate. The compass card should deflect as the Corrector Key (220) is rotated. The card will reach a maximum deflection on one side of North and it will then return through North and reach a maximum deflection on the other side of North, before returning to its original position. Note the deflection of the compass card while rotating the key. The card should deflect from North by 25 to 35°and the magnitude of deflection, either side of North should be approximately equal.

f) If the card deflection is within the tolerance band stated above, then the correction operation for North is within specification

g) Repeat this operation for the South heading. The maximum deflections recorded for the North and South positions should be close and within 5 degrees of each other.

h) Repeat this operation for the East and West positions but insert the key into the 'B' corrector Hole. The deflections recorded for East and West should be the same as specified for North.

i) If the compass fails this test, the correction facility is faulty and the unit should be repaired or replaced by the manufacturer or at an approved repair facility.

j) If the compass passes this test, it is unlikely that there is a magnetic correction problem.

Performance Testing

1. GENERAL

The following tests are those, which must be carried out after overhaul or whenever any component has been renewed or repaired (unless stated otherwise). They are also the only tests necessary to establish the serviceability of a standby compass.

Tests should be carried out in an area that has been approved for magnetic testing.

Unless otherwise stated, the tests must be done within these conditions:
Room temperature (15 to 25°C)

NOTE: The following magnetic conditions are those existing in Southern England. The performance at other locations may require amendment and should be determined.

Magnetic conditions-horizontal field intensity of 0.18 oersted attracting a North seeking pole toward the magnetic North and a vertical field intensity of 0.44 oersted attracting a North seeking pole downward.

Mounting plate horizontal and uppermost.

2. EQUIPMENT REQUIRED

Items 1 to 6,12 and 15 to 17 of section 9001 'SPECIAL TOOLS, FIXTURES AND EQUIPMENT'.

3. PROCEDURE

WARNING: DO NOT SUBJECT THE COMPASS TO A TEMPERATURE IN EXCESS OF +85°C *(OR +70°C. MOD.01 COMPASSES)*

A. Silicone Fluid

(1) Place the compass in the vacuum chamber standing the unit on its bellows. Place the vacuum chamber in the oven and maintain the temperature at 30°C for 4 hours, then reduce the pressure to 4 in. Hg absolute, for an hour, after which time return the pressure to normal.

(2) Remove the compass and examine the fluid; there must be no bubbles, sediment, cloudiness or discoloration. Also there must be no fluid leakage.

B. **Electrical**

(1) Remove the lamp retaining cap and lamp from the lamp housing.

(2) Using the insulation tester, check that the insulation resistance between the two connecting pins is not less than 20 megohms at 500 V D.C.

(3) Return the lamp and lamp-retaining cap to the lamp housing

(4) Connect the insulation tester between the two connecting sockets of the lead and socket assembly (310) and check that the insulation resistance is not less than 20 megohms at 500 V D.C.

NOTE: The following test should be carried out in a darkened room.

(5) Connect the lead and socket assembly to the connecting pins on the lamp housing and connect the 28 V or 5 V D.C. supply (dependant on unit type) to the lead.

(6) Switch on the supply and observe that the compass card markings and the lubber line are illuminated and clearly visible.

(7) Switch off and disconnect the supply.

C. **Temperature**

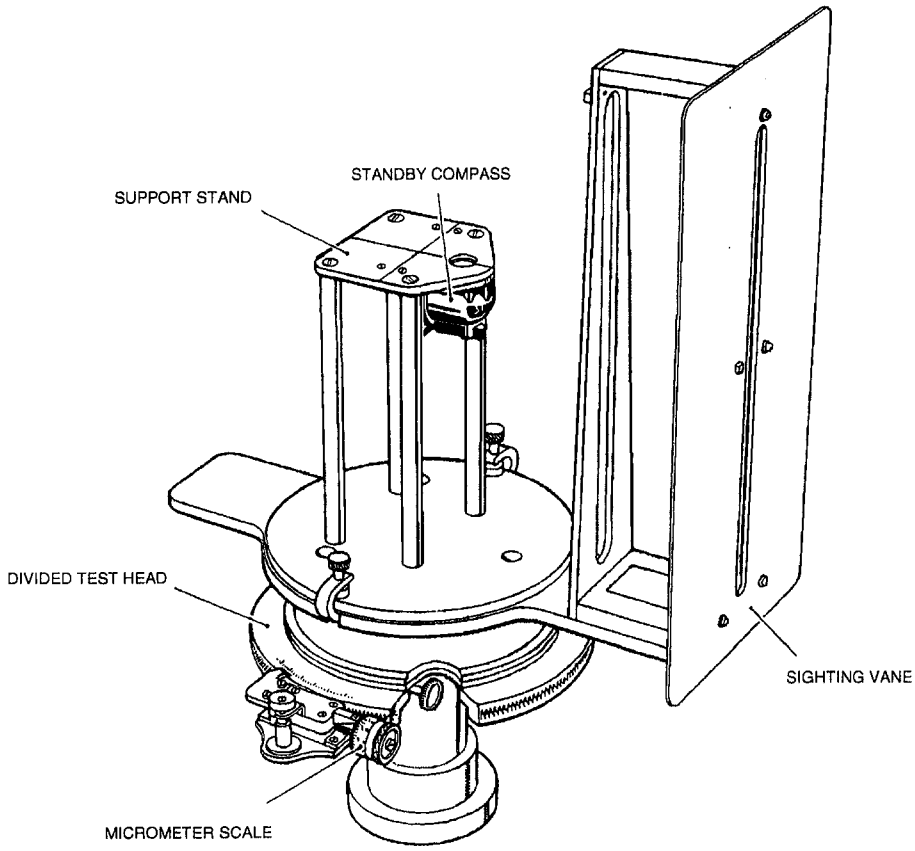
(1) Subject the compass to a temperature of between -38 and -42°C for three hours in the refrigerator.

(2) Remove the compass and allow it to return to room temperature; this will take approximately two hours.

(3) Ensure that there is no sign of cracks, fluid leakage, discoloration or bubbles within the compass.

(4) Place the compass in an oven and increase the temperature from room temperature to +85°C ± 2°C *(MOD 01 COMPASSES +70°C ± 2°C)*, at a steady rate for a period of four hours. Maintain this temperature for one hour.

(5) Repeat the procedures as detailed in paragraphs (2) and (3).



D. **Directional Errors** (Refer to fig.1001)

(1) Ensure that the 'B' and 'C' correctors are set to the neutral position i.e. the indicator lines are aligned exactly with the index lines.

NOTE: A misalignment of 0.25mm (0.010"), i.e. the width of an index line, will produce a deviation error in the compass of approximately 2.5 deg.

(2) Set the divided test head and its micrometer scale to zero.

(3) Place the standard magnetic needle on the sighting vane and, using the coarse and fine controls beneath the turn-table, align the sighting vane with the magnetic meridian.

Directional Error Test Jig
Fig. 1001

(4) Mount the compass in the support stand and place the support stand on the sighting vane. Viewing through the sighting vane, adjust the support stand until the lubber line is aligned with the magnetic meridian.
(5) Again viewing through the sighting vane, turn the test head to align the compass card cardinal headings with the lubber line and at each cardinal heading note the error from the divided test head scale.
(6) Ensure that:

(a) The individual errors obtained do not exceed 2°
(b) The algebraic sum of the errors N + S and E + W respectively do not exceed 5°.
(c) The algebraic difference of the errors N - S and E - W respectively do not exceed 5°.

E. **Time of Swing**

(1) Using the deflector magnets, deflect the compass card through 30°, maintaining the deflection for at least 10 seconds to allow the liquid to settle.

(2) Remove the deflector magnets to allow the compass card to return to its original reading. The time for the card to rotate back by 25° (to the 5° mark) should be between 1.4 to 1.8s.

F. **Friction Error**

(1) Using the deflector magnets, deflect the card through 5° deg and maintain the deflection for 10 seconds.

(2) Remove the deflector magnets and allow the compass card to settle. Record the settling position.

(3) Repeat (1) and (2) but deflect the compass card in the opposite direction. The angular difference between the two settling positions must not exceed 2.5°.

G. **Horizontal ('B' and 'C') Correctors**

(1) Ensure that all correctors are exactly at neutral.

(2) Align the lubber line with N on the compass card.

(3) Rotate the 'C' corrector through 90°, i.e. the indicator lines must be at 90° to the index lines.

(4) Record the deflection of the compass card.

(5) Repeat (3) and (4) but rotate the 'C' corrector in the opposite direction. Check that the compass card deflects not less than 25° from each side of the lubber line and that the difference between the two deflections does not exceed 4°. (Return the correctors to the neutral position)

(6) Align the lubber line with E on the compass card.

(7) Repeat the procedure detailed (1) to (5) inclusive but in this case rotate the 'B' corrector.

(8) Remove the support stand, with the compass attached, from the divided test head.

H. **Angle of Tilt**

(1) Mount the tilt stand, with the support stand and the compass attached, on the divided test head or any other level surface capable of being rotated through 360° in azimuth.

(2) Tilt the compass forward to an angle of 20° from the vertical. *(MOD 01 COMPASSES 18 deg.).*

(3) Slowly rotate the compass through 360° and observe that the compass card is free to rotate on its pivot.

J. **Parallax**

(1) Note the exact compass heading when viewed from directly in front.

(2) Without disturbing the compass, check that when released from 22.5°, left and right of the lubber line, the readings do not vary by more than 2.5° from that noted in (1).

DISASSEMBLY

1. GENERAL

The work should be carried out in a clean, dust free atmosphere, and absolute cleanliness of workbench, components and tools must be maintained throughout. Protect components as they are removed and observe the normal precautions regarding the correct use of tools and cleaning fluids.

During each overhaul a new bellows gasket (60), filling washer (200) and filling plug disc (210) must be fitted.

2. EQUIPMENT REQUIRED

Non Magnetic Screwdrivers, Clean Glass Container (up to 100ml).

3. PROCEDURE

A. Horizontal Corrector Assembly (160)

(1) Hold the compass in an upright position.

(2) Withdraw the four screws (170) securing the horizontal corrector assembly and mounting plate to the compass bowl (180) and remove the assembly.

B. Bellows Assembly (10)

(1) Unscrew the filling plug (190). Extract and discard the filling plug disc (210) and filling plug washer (200)

(2) Expel the fluid into a small, clean, glass container by gentle manipulation of the bellows. Seal the glass container and store in a cool, dry, dark place.

(3) Melt the solder locking the nut (40) and release the screw (30) securing the bellows retaining clip (20) to the compass bowl (180). Gently spring open the ends of the retaining clip and remove it from the compass bowl, together with the retaining clip packing piece (50). Remove the bellows (10) and the bellows gasket (60). Remove the compensating ring (70) (All codes except KCA0109W).

NOTE: If the bellows or bellows gasket adhere to the compass bowl, gently prise off, taking care not to damage the bellows or bowl seating.

(4) Discard the bellows gasket (60).

C. **Stem Assembly (80) and Compass Card (130)**

CAUTION: THE STEM ASSEMBLY AND THE COMPASS CARD ASSEMBLY ARE BOTH VERY DELICATE. TAKE CARE NOT TO DAMAGE THEM.

(1) Remove the two screws (90) securing the bracket of the stem assembly (80) to the compass bowl (180). Give support to the stem bracket during this procedure, as the assembly will tilt when the screws are released. This may damage the card assembly. Remove the stem assembly and compass card (130) from the compass bowl.

(2) Carefully lift the compass card from the stem assembly and store safely.

D. **Lamp Housing Assembly** (290)

(1) Unscrew the cap (370) and withdraw the bulb (360) from the locating spring.

(2) Unclip the lamp housing assembly (290) From the compass bowl and remove the assembly. *(MOD 01 COMPASSES, Remove the four screws (240 & 250)*

E. **Lead and Socket Assembly** (380)

NOTE: This item does not sub-divide into any individual components. The item may not always be returned with the compass for repair as it may be attached to the aircraft.

CLEANING

Items required to assist with the cleaning procedures are detailed within fig 4001 below.....

Nomenclature	Vendor
Silicone fluid (Viscosity 3 cs ± 10%).	SIRS Navigation Ltd, 186a Milton Road, Swanscombe, Kent. DA10 0NN
Electrical Cleaner (Ambersil FE10) NATO Code: 6850-99-6636478 Grease (DTD 5598 or Castrol LM)	Commercially available

Cleaning Agents
fig. 4001

1. PROCEDURE

WARNING: CERTAIN CLEANING FLUIDS ARE FLAMMABLE AND TOXIC.

A. Stem Assembly (80)

(1) Wash in Electrical Cleaner and dry in a jet of clean, dry air.

(2) Polish the sapphire cup using peg wood.

B. Horizontal Corrector Assembly (160)

(1) Spray Gear Components with Electrical cleaner.
(Avoid Electrical Cleaner contact with the label)

(2) Dry in a jet of clean, dry air.

(3) Lightly lubricate the corrector gear spindles with grease.

C. **Lamp Housing** (290)

(1) Clean the lamp housing components and circuit board (MOD.02) with a lint-free cloth moistened with Electrical Cleaner.

(2) Dry with a jet of clean, dry air.

D. **Compass Bowl** (180)

CAUTION: DO NOT USE ANY SOLVENT BASED CLEANING FLUIDS TO CLEAN THE COMPASS BOWL, THE SOLVENT WILL DAMAGE THE PLASTIC MATERIALS USED FOR THE COMPASS CONSTRUCTION.

(1) Wipe the bowl clean with a dry, clean, lint-free cloth. If excessively dirty, use a solution of mild detergent and warm water. The bowl should then be rinsed and dried with a clean, dry air jet.

E. **Compass Card Assy** (130)

This item will be covered with a film of silicone fluid. It is not advisable to carry out a specific cleaning operation as this may damage the card. It should be stored in a container of clean 'Silicon fluid' until required for use.

F. **Components**

The remaining components should be carefully cleaned in a solution of mild detergent and warm water. The components should be rinsed then dried with a clean, dry air jet.

INSPECTION / CHECKS

1. GENERAL PROCEDURE

The following procedures also apply to new components. Additional inspection necessary is given in paragraph 3.

A. All Components

Examine, as applicable, for:

(1) Cleanliness.
(2) Distortion.
(3) Cracks (visual unless otherwise stated).
(4) Corrosion, including deterioration of protective finish.
(5) Scores.
(6) Dents.
(7) Evidence of wear (visual unless otherwise stated).
(8) Serviceability of items not disassembled.

B. Electrical Components

Examine for:

(1) Deterioration of wiring and insulation.
(2) Security of all connections, soldered or otherwise.
(3) Evidence of overheating.

2. EQUIPMENT REQUIRED

Items 18 and 21 of 'SPECIAL TOOLS, FIXTURES AND EQUIPMENT'. (section 9001)

3. DETAILED PROCEDURE

A. **Compass Bowl** (IPL item 180)

(1) Examine carefully for cracks, distortion, stripped threads or any other damage.

(2) Check the bowl for optical clarity at the point where the light from the lamp shows through.

(3) If unserviceable, replace the bowl.

B. **Stem Assembly** (80)

(1) Using a binocular microscope carefully examine the Sapphire bearing cup on the Stem Assembly (80). The cup must be free from cracks, flaws or any other damage. The junction between the sapphire and the cup holder at the bottom of the conical section should be free from burrs or contamination.

(2) Using the microscope, examine the sloping inner surface of the cupholder for cracks, scores and other damage.

(3) Replace the Stem Assembly (80) if the item is deemed unserviceable.

C. **Compass Card Assembly** (130)

(1) Examine the card carefully for distortion and check the security of the cobalt magnet.

(2) Using the microscope, examine the pivot for wear. The tip of a pivot in good condition will have a spherical radius of 0.13mm (0.005"). The tip of the pivot should not show any sign of wear.

(3) Replace the compass card if it is damaged or distorted. If the pivot is worn, replace as described in the section REPAIR - (section 6001).

D. **Lamp Housing Assembly** (290)

(1) Observe that the spring is captive and undistorted.

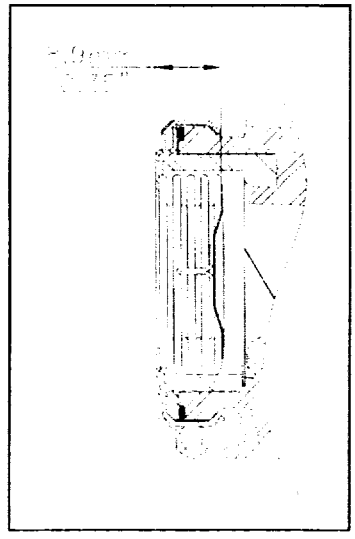
(2) Check that the coloured filter is captive within its holder and that it is not damaged or cracked.

(3) Using an ohmmeter, check that the value of the resistor relative to the compass type is correct. See fig. 5001

330 ± 33 ohms:	KCA0104W, KCA0105W, KCA0109W, KCA0104FY, KCA0106W	Fig. 5001
820 ± 82 ohms:	KCA0112W	
390 ± 8 ohms	KCA0113W, KCA0113FY	
47 ± 4.7 ohms	KCA0110W, KCA0114W	
Compass WL1001KCA1 does not have a resistor.		

(4) If the spring, filter or resistor is unserviceable, replace the Lampboard assembly as described in section 'REPAIR' Pages 6001 onward *(MOD.01 replace the complete Lamphousing Assembly - 230)*

E. Horizontal Corrector Assembly (160)



(1) Using the corrector key, rotate the corrector mechanisms two or three turns; they must turn smoothly but with sufficient inherent friction to prevent them being disturbed by shock or vibration.

(2) An unserviceable corrector mechanism must be renewed.

F. Bellows Assembly (10)

(1) The depth of the Bellows should be 8.9mm (0.35") as shown in fig. 5002. If the dimension is different, rectify as specified in the 'Repair' section.

(2) Check the condition of the paintwork of the bellows, particularly for signs of blistering or flaking.

Depth of bellows
Fig. 5002

G. **Paintwork**

(1) Inspect all paint for signs of peeling or blistering.

(2) Renew paintwork where necessary as described in 'REPAIR'.

H. **Silicone Fluid**

(1) If there are signs of cloudiness, sediment or discoloration, discard the fluid.

(2) If the fluid is clean and clear, place it in a suitable container and reduce it to a temperature of -40°C in a refrigerator. Discard the fluid if it appears cloudy at this temperature.

REPAIR

1. GENERAL

Faulty parts should be replaced by approved spares, only after inspection for serviceability. These spare components are available from SIRS Navigation Ltd.

After any component has been renewed or repaired, carry out the full procedure as detailed in the section TESTING unless stated otherwise.

Electrical connections should be made with approved solder using the smallest amount necessary to achieve an efficient joint.

Material	Supplier	Required For
Paint, air drying - matt black Code L481	SIRS Navigation Ltd	Compass Bowl. All Models except type KCA0106W
Paint, air drying - grey, Code L481G	SIRS Navigation Ltd	Compass Bowl. Model type KCA0106W
Paint, White Enamel	Commercially available	Lubber Line on Compass Bowl
White Spirit	Commercially available	Lubber Line on Compass Bowl

Materials, Figure 6001

1. PROCEDURE

A. Card Assembly (130)

There is no repair procedure specified for this item. It is recommended that a new Card Assembly is fitted if a problem exists. The new card assembly will be supplied magnetised to the correct level and balanced.

B. Lamp Housing Assembly (290)

If components within the lamp housing assembly (290) are faulty, a new Lampboard Assembly (300) will be required *(MOD.02 only*)*. The existing assembly can be removed by pushing up the connection pins and threaded boss through the plastic moulding. The replacement item is fitted in the reverse way. It may be useful to gently open the moulding at the entry face to allow easier entry of the Lamp board assembly.

** For Pre MOD.02 compasses, the complete LampHousing Assembly should be replaced*

C. Bellows (10)

If the depth of the bellows is less than 8.9mm (0.35"), extend the dimension by running a suitably tapered piece of peg wood round the outer convolutions. If the dimension is greater, gently compress the assembly until the correct dimension is achieved.

D. Paintwork

CAUTION: ON NO ACCOUNT SHOULD CLEANSING FLUIDS OR PAINT THINNERS BE ALLOWED TO CONTACT THE BOWL.

DO NOT SUBJECT THE BOWL TO TEMPERATURES IN EXCESS OF 85°C.

(1) **Compass Bowl** (180)

Retouch where necessary with the specified paint and dry in the electric oven at +85°C for a period of 1 hour or Air Dry for 12 hours.
(Pre MOD.02 Compasses +70° C for 1.5 hours)

(2) **Lubber line**

(a) If necessary, remove original paint by careful use of White Spirit

(b) Using a pointed piece of peg wood or suitable alternative apply the appropriate paint to fill the lubber line groove, remove any excess paint with a cloth impregnated with white spirit.

(c) Dry in the electric oven at +85°C for a period of 1 hour or Air Dry for 12 hours
(Pre MOD.02 Compasses +70° C for 1.5 hours)

ASSEMBLY

1. GENERAL PROCEDURE

The work should be carried out in a clean, dust free atmosphere and in an area free from magnetic interference. Absolute cleanliness of workbench, components and tools must be maintained throughout.

Precautions must be taken when using electrical equipment in the vicinity of the divided test head KTQ-0121. Also, the movement of items constructed of ferrous materials should be avoided.

During each overhaul a new bellows gasket, filling washer and filling plug disc must be fitted.

2. EQUIPMENT REQUIRED

Items 1 to 10, 13, and 15 to 20 of section 9001 'SPECIAL TOOL, FIXTURES AND EQUIPMENT'.

Materials

Material	Supplier	Required For
Silicone fluid (viscosity 3 centistokes 10%)	SIRS Navigation Ltd	Compass Bowl Fluid
Balancing paste 9415	SIRS Navigation Ltd	Compass Card
Balancing paste thinners, 8590X1	SIRS Navigation Ltd	Balancing Paste
Filter paper, 234/0337-10	SIRS Navigation Ltd	Silicone Fluid
Electrical Cleaner (Ambersil FE10) NATO Code: 6850-99-6636478	Commercially available	Soldered Joints
60/40 cored solder		Soldered Joints
Vibratite VC3	SIRS Navigation Ltd	Thread Locking where specified

Fig.7001

3. PROCEDURE

A. Magnetising the Compass Card (130)

The compass card will already be magnetised by the manufacturer to the correct value.

If a repair agent specifically wishes to re-magnetise the card, specific instructions can be supplied by SIRS Navigation Ltd including information concerning the latest equipment available.

B. Balancing the Compass Card

NOTE: The compass card is balanced during manufacture so that the N-S axis dips 1 ± 1 deg at its North-seeking end, i.e. S on the card. This condition applies to latitude 51 deg North where the vertical force of the Earth's magnetic field is 0.44 oersted. The E-W axis of the card should be horizontal ± 1 deg.

(1) Using the bubble protractor and the magnetic needle, adjust the balancing bowl 3254 LMT to the angle required for the latitude concerned i.e. the angle to which the card should balance.

(2) Fill the bowl with alcohol. Invert the compass card in the alcohol to prevent air being trapped in the dome. With the compass card still submerged, turn it upright and locate the Using the bar and adjustable pointer, check the level of compass card.

(3) Using the bar and adjustable pointer, check the level of compass card. If the compass card is not level with the rim of the balancing bowl note the 'high' spot and carry out the procedure detailed in 3.B. (4 to 6).

If the balance is satisfactory, carry out the procedure detailed in 3.B. (4) and (7) then continue with procedure 3.C.

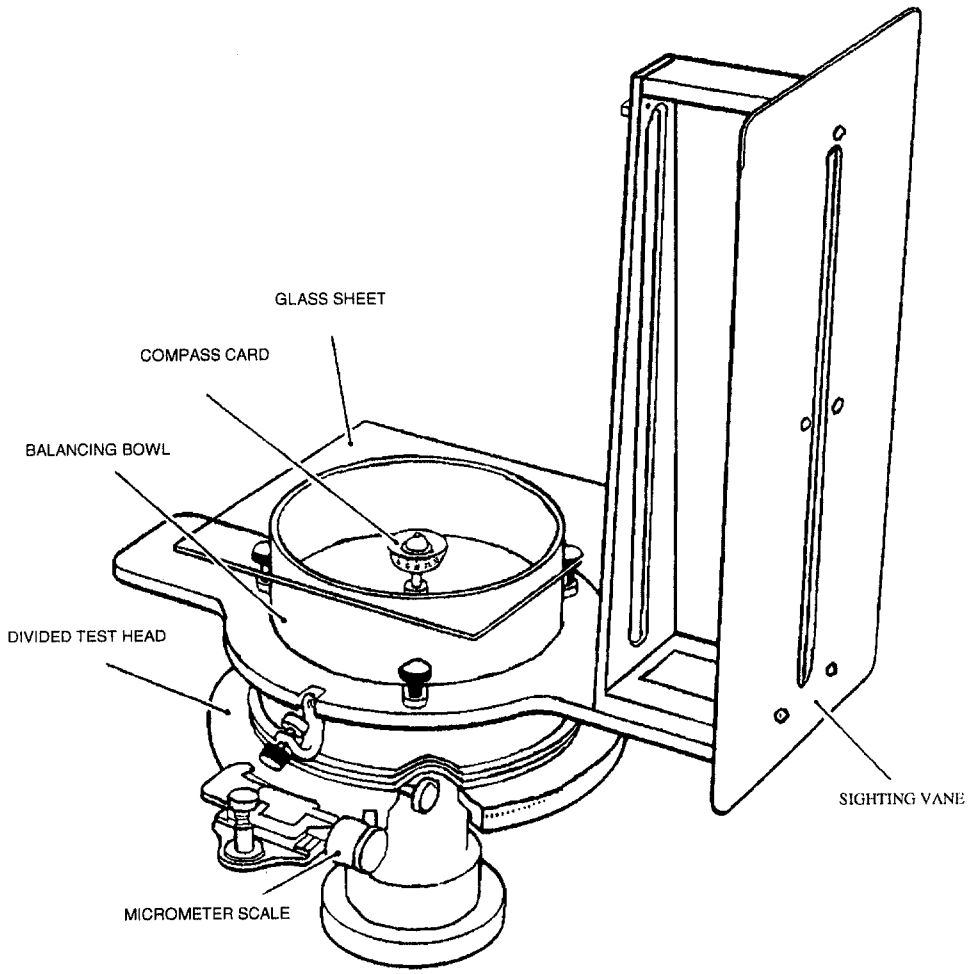
(4) Remove the compass card from the balancing bowl and dry thoroughly in a jet of clean, dry air.

(5) Apply a small quantity of the approved balancing paste to the inner face of the compass card at the 'high' position. Surface dry with a jet of clean, dry air.

(6) Repeat the procedure described in 3.B. (3 to 5) until the card is correctly balanced.

(7) Accurately weigh the compass card; the dry weight must not exceed 2.8g.

C. Checking the Heading Errors (Refer to fig. 7002)



(1) Place the balancing bowl on the sighting vane attached to the divided test head.

(2) Exactly centralise the stem sapphire over the centre line engraved on the lower limb of the sighting vane and clamp the bowl firmly in position.

CAUTION: THE BOWL MUST NOT BE DISTURBED DURING THE FOLLOWING PROCEDURE.

(3) Set the micrometer scale on the test head to zero. Using the standard magnetic needle 3252 LMT placed diametrically across the bowl, align the sighting vane with the magnetic meridian, adjusting the coarse and fine controls beneath the test head turn-table.

(4) Place the compass card in the balancing bowl and cover the bowl with a sheet of glass.

Checking heading errors
Fig. 7002

(5) Rotate the test head very slowly to align each of the four cardinal points, in turn, with the sighting vane. Note the test head reading at each heading; the error must not exceed ± 1°. If the headings are not within these limits the card assembly should be replaced.

D. Stem Assembly (80) and Compass Card (130)

(1) Position the bracket of the stem assembly in the compass bowl (180) and secure with two non-magnetic screws (90).

(2) Place the sapphire checking plate 3256 LMT on top of the compass bowl with the aperture nearest the front of the compass. Secure the sapphire checking plate with the two knurled screws.

(3) Illuminate the inside of the compass bowl and view through the aperture in the sapphire checking plate, observing that the bearing cup in the stem sapphire is aligned with the aperture. If it is not, carefully bend the vertical stem of the Stem Bracket Assembly with a pair of small pliers until it is so.

(4) Unscrew the two knurled screws securing the sapphire checking plate to the compass bowl and remove the plate. Unscrew the two screws (90) securing the bracket of the stem assembly to the compass bowl and remove the stem assembly.

(5) Place the compass card in position on the stem and insert the assembly into the compass bowl. Secure with two non-magnetic screws (90).

(6) Ensure the compass card can rotate freely within the compass bowl.

(7) Note the exact compass heading when viewed from directly in front.

(8) Without disturbing the compass check that when viewed from 22 1/2°, left and right of the lubber line, the readings do not vary by more than 2.5° from that noted in (7).

If the value exceeds the specification limits described, re-examine the central location of the Stem Assembly.

E. Bellows Assembly

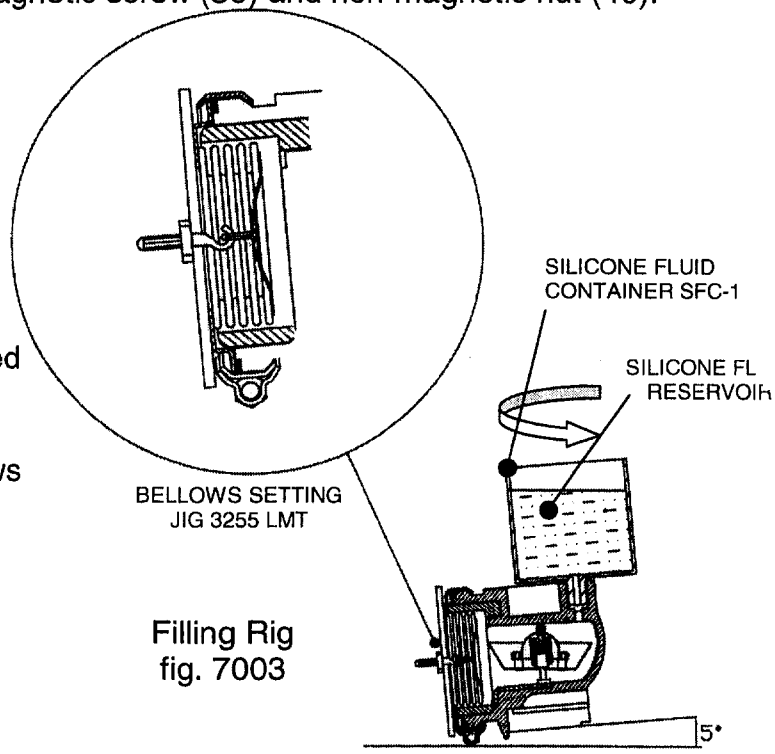
NOTE: The bellows gasket (60) should be soaked in silicone fluid for a period of 1 hour prior to assembly.

CAUTION: Do not damage the bellows gasket with sharp edges of the assembly components.

(1) Place the compensating ring (70) (*all codes except KCA 0109W*) and a new bellows gasket (60) in their recesses in the rear of the compass bowl (180). See figure 5002.

(2) With the lug in the centre of the bellows facing outwards, position the bellows on the rear of the compass bowl.

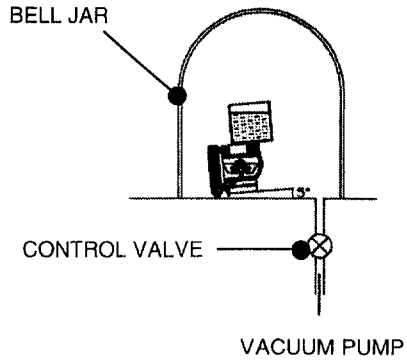
(3) Place the bellows retaining clip (20) in position, with the ends lowermost.



(4) Insert the retaining clip packing piece (50) under the ends of the clip and secure the clip with the non-magnetic screw (30) and non-magnetic nut (40).

NOTE: When assembled, the gap between the ends of the Bellows retaining clip must be not less than 0.8 mm (1/32")

F. Filling (Refer to fig.7003)



NOTE: The process should be carried out at a temperature of 20°C ± 2°C

(1) Fit the hooked rod of the bellows setting jig 3255 LMT to the lug on the bellows diaphragm.

Filling Rig
fig. 7003

The equipment detailed is an example of a 'Filling Rig' that may be used. Alternative similar facilities may also be permissible. SIRS can provide technical support with this issue.

(2) Place the distance-piece, given in the table fig. 7004, between the jig and the bellows diaphragm. The distance represents the dimension shown in fig.5002

Fluid temperature (°C)	Length of distance-piece
20	8.9mm (0.350")

fig.7004

(3) Screw the knurled nut on to the hooked rod until the distance piece is lightly gripped between the diaphragm and the jig bar.

NOTE: The following procedure is specified as a guide to explain one method to fill the compass bowl and de-gass all soluble air. Other methods are suitable providing the vacuum levels and durations are maintained. Specialist advice is available from SIRS Navigation Ltd.

(4) Assemble the 'Silicone Fluid Container' to the compass bowl by screwing the container into the filler plug hole.

(5) Place the assembly into a vacuum chamber and fill the container with 35ml of clean silicone fluid. The bowl should be inclined at an angle of 5° to the horizontal, to help allow the air bubbles to escape.

(6) Reduce the pressure of the Vacuum chamber to 2 in Hg for a period of approximately 30 seconds. This will remove the majority of the air within the compass.

(7) Allow the pressure to return to the atmospheric level and add some more fluid to the container to ensure that the filler plug hole is always covered.

(8) Reduce the pressure of the Vacuum chamber to 2 in Hg for a period of approximately 1.5 hours to remove the remainder of the soluble air.

(9) **NOTE:** The following procedure must be carried out in the shortest possible time.

Immediately after opening the vacuum chamber unscrew the 'silicone fluid container', ensuring that the filler plug hole remains full of fluid. Fit the filling washer (200), filling plug disc (210) and filling plug (190) using the torque screwdriver tighten the filler plug with a torque of 2880 gf/cm (40 ozf).

CAUTION: ONLY A PLASTIC FILLER PLUG MUST BE USED. ANY OTHER MATERIAL MAY CAUSE DAMAGE TO THE BOWL.

Remove the setting jig and return the compass to the vacuum chamber, standing the instrument on its bellows.

(10) Subject the compass to a vacuum of 4 in Hg absolute for 20 minutes. Observe that no bubbles appear in the fluid. If any bubbles do appear, remove the filling plug, plug disc and plug washer and repeat the procedure described at the beginning of this section.

(11) If the fluid is satisfactory, lock the threads of the nut (40) and screw (30) securing the bellows retaining clip (20) using the approved multicore solder.

G. **Horizontal Corrector Assembly** (160)

NOTE: APPLY VIBRATITE VC3 TO THREADS OF THE FOUR SCREWS (170) AND SPREAD COMPLETELY AROUND THE THREADS. ALLOW TO DRY COMPLETELY BEFORE ASSEMBLY (APPROXIMATELY ONE HOUR). WHEN DRY, THE THREADS OF THE SCREWS SHOULD BE AT LEAST HALF FILLED.

(1) Position the horizontal corrector assembly on top of the compass bowl and secure with four non-magnetic screws (170).

(3) Using the corrector key, set the 'B' and 'C' correctors at neutral.

H. **Lamp Housing Assembly** (230)

(1) Position the lamp housing (230) on the base of compass bowl and clip-on. *(MOD 01 Compasses, fasten in place with 4 screws 240 & 250)*

(2) Insert the bulb (350) into the retaining spring and fit the cap (370).

J. **Lead and Socket Assembly** (380)

(1) Fit a new lead and socket assembly (380).

K. **Testing**

(1) Carry out the full procedure on the compass as described in TESTING pages 1001 onwards.

SPECIAL TOOLS, FIXTURES AND EQUIPMENT

1. GENERAL

Items with an LMT part number are for local manufacture. Full manufacturing information for these items may be obtained from SIRS Navigation Ltd. When requesting information, please quote the part number. Precautions must be taken when using electrical equipment in the vicinity of the divided test head. Also the movement of items constructed of ferrous materials should be avoided during the testing of a compass. Throughout overhaul and repair, observe absolute cleanliness of workbench, tools and equipment. The procedure in TESTING should be carried out at a temperature between 15 and 25°C.

2. ELECTRICAL SUPPLIES

5 or 28 V D.C

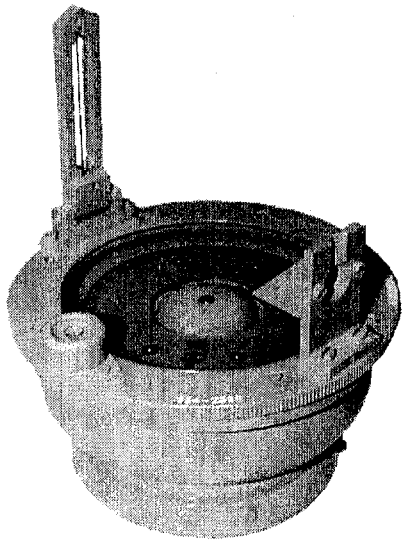
Tools, Fixtures and Equipment – Next page

3). TOOLS, FIXTURES AND EQUIPMENT

Item	Description	Part No. or Ref.	Vendor
1	Divided test head	KTQ-0121	SIRS Navigation Ltd, 186a Milton Road, Swanscombe, Kent, DA10 0NN
2	Sighting vane adapter	KTQ-0122	
3	Tilt stand adapter D	KTQ-0124	
4	Support stand adapter E	KTQ-0125	
5	Corrector key	CE2-40	
6	Standard Magnetic Needle	3252 LMT	
7	Balancing bowl	3254 LMT	
8	Bellows setting jig	3255 LMT	
9	Sapphire checking plate	3256 LMT	
10	Filling Rig	3257 LMT	
11	Ohmeter		Commercially Available
12	Insulation tester (500 V d.c. 20MΩ)		
13	Vacuum chamber. Capable of maintaining 2 in Hg absolute. Minimum internal dimensions 305mm cube.		
14	Peg wood stick		SIRS Navigation Ltd

COMPONENT MAINTENANCE MANUAL
KCA*** & WL1001KCA1 Series**

Item	Description	Part No. or Ref.	Vendor
15	Electric oven. Capable of maintaining an even +85°C. Minimum internal dimensions 300mm cube.		Commercially Available
16	Refrigerator. Capable of maintaining an even -40°C. Minimum internal dimensions 305mm cube. Bubble protractor		
17	Deflector magnets. Two small bar magnets with the same dimensions.		
18	Vernier gauge		
19	Torque screwdriver. Capable of applying 445 gf/cm (40 ozf in).		
20	Variac, (variable transformer)		
21	Binocular microscope (X 30 magnification)		



COMPONENT MAINTENANCE MANUAL
KCA***** & WL1001KCA1 Series

SPECIAL TOOLS REQUIRED FOR COMPASS ADJUSTMENT

Once the compass is installed, the instrument should be adjusted to compensate for the magnetic interference from the aircraft or local components. The procedure to adjust the compass is described within section ' Special Procedures', section 11001 onwards.

To carry out the compass adjustment the following tools are recommended:

PART NUMBER	DESCRIPTION	SUPPLIER	PAGE BLOCK WHERE USED	REQUIRED/ RECOMENDED	COMMENTS
CE2-40	CORRECTOR KEY	SIRS NAVIGATION LTD	11001	REQUIRED	SUPPLIED WITH NEW COMPASS, BUT ALSO AVAILABLE AS A SPARE ITEM
954-2399	STANDARD COMPASS FOR 'COMPASS SWING'	SIRS NAVIGATION LTD	11001	RECOMENDED	SEE FIG 9001 *A SPECIAL NON-MAGNETIC TRIPOD SHOULD ALSO BE USED WITH THIS COMPASS.*

STANDBY COMPASS
ILLUSTRATED PARTS LIST

WARNING: ONLY SPARES AND COMPONENTS SPECIFIED BY SIRS NAVIGATION SHOULD BE USED.

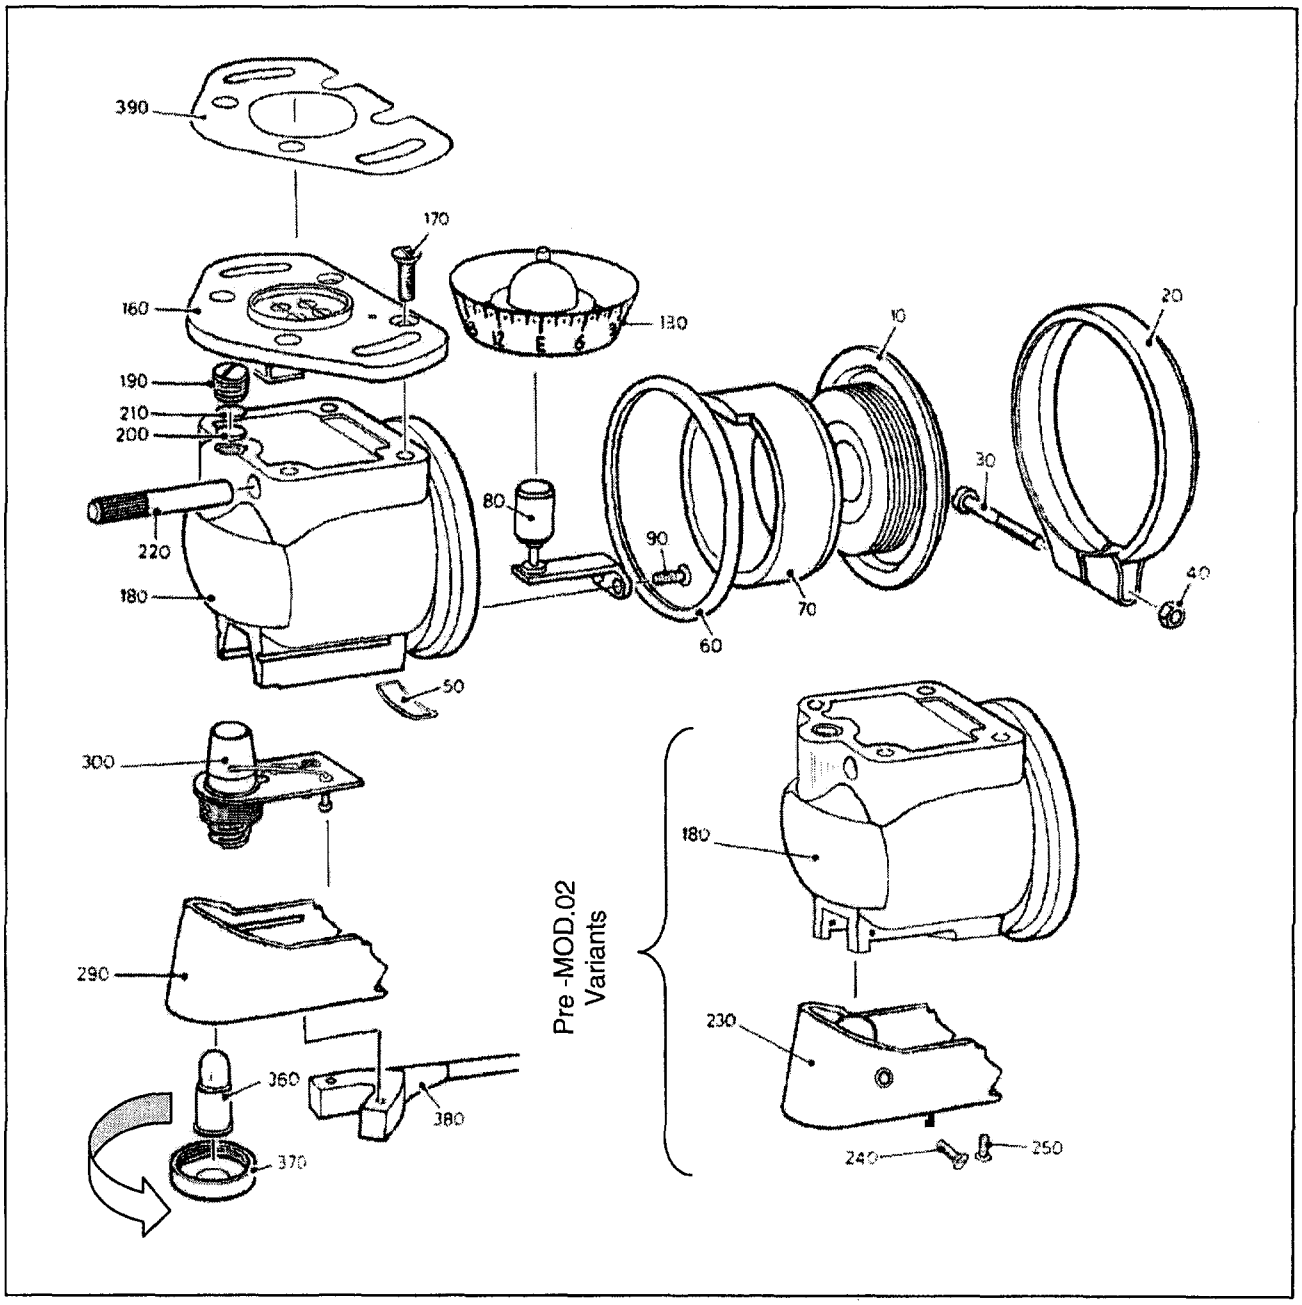
NOTE:

ORDERING

Certain spare parts listed in the IPL are manufactured by other contractors and have the manufacturer's number or British Standards reference quoted in addition to the part number under which SIRS Navigation supply.

When ordering from SIRS Navigation please quote the SIRS part number, the other manufacturers number or British Standards reference and the code number of the LRU, on all orders of enquiries.

When ordering from other manufacturers please quote the manufacturers and / or British Standards reference only.



GENERAL

The illustrated parts list provides information and identification of replaceable parts and assemblies of units covered by this manual. The information consists of a vendor's code list, a detailed parts list and a numerical index. The abbreviation used for British Associated screw threads is – BA.

NOTE: It is strongly recommended that MOD.01 compasses are upgraded to build level MOD.02 during a Repair or Overhaul operation. The additional components required for this conversion are shown in fig. 10001 below.

SPECIAL PROCEDURES

COMPASS MAGNETIC CORRECTION

A. General

The compass is provided with a compensating system, which will enable you to eliminate, some of the magnetic disturbances created by the mechanical and electrical characteristics of the aircraft.

Compass magnetic correction can be achieved by using the special corrector key (220) and inserting it into either of the two holes located on the front face of the compass. The engagement of the key and rotation will provide approximately 30 to 35 degrees of compensation. An indication of the correction setting is seen from the top of the compass.

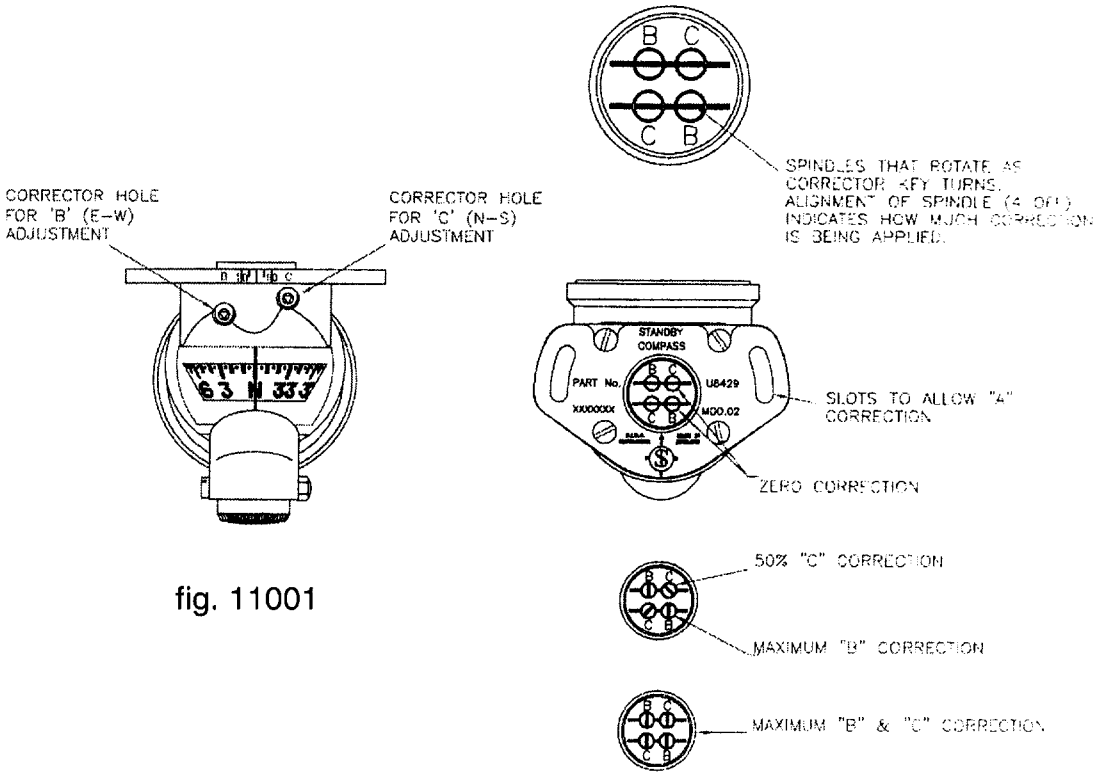

fig. 11001

ADJUSTING THE COMPASS

Before your compass can be adjusted the aircraft must be capable of being accurately aligned to the main cardinal headings.

The use an another calibrated compass outside the aircraft or the use of a 'compass rose' on the ground, to determine the cardinal points is advised. (See 'special tools' section, pages 9001 onwards)

NOTE: These following notes should be used for guidance only; in-house procedures may be different from these described and should be used as the prime reference for the correction activity.

CORRECTION EAST/WEST ('B' Coefficient)

1) Align the aircraft to face East, insert the Corrector Key provided, into the Left hand hole at the front of the compass, designated 'B' and rotate the key in either direction until the East heading of the card is aligned with the Index line.

2) Align the aircraft to face West and check that the West heading of the card is aligned with the Index line; any error may be corrected by readjusting the correctors to remove HALF the error shown.

3) The process of adjustment between East and West should be repeated and the error halved each time to reduce the final deviation value to a level that complies with the aircraft specification.

CORRECTION NORTH/SOUTH ('C' Coefficient)

1) Align the aircraft to face North, insert the Corrector Key provided, into the Right hand hole at the front of the compass, designated 'C' and rotate the key in either direction until the North heading of the card is aligned with the Index line.

2) Align the aircraft to face South and check that the South heading of the card is aligned with the Index line, any error may be corrected by re-adjusting the correctors to remove HALF the error shown.

3) The process of adjustment between North and South should be repeated and the error halved each time to reduce the final deviation value to a level that complies with the aircraft specification.

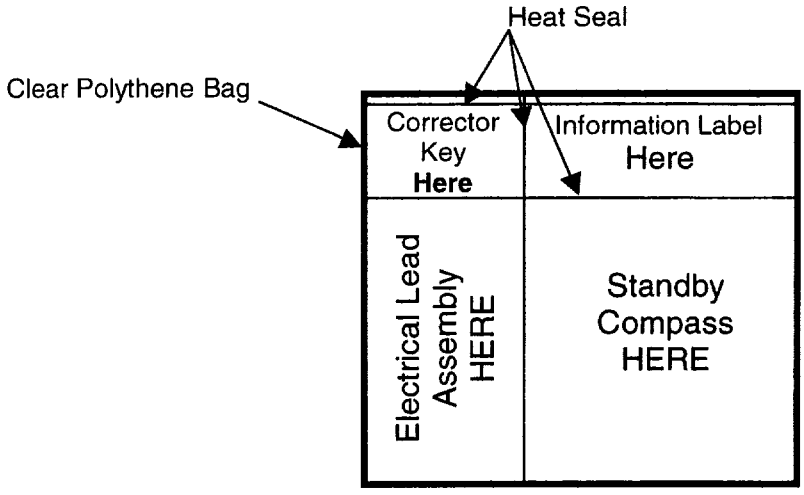
NOTE: **Adjustment of the east-west setting does not affect the North South values and visa-versa.**

If the compass cannot be corrected to comply with the correct specification, there could be a problem with either:

1) The compass correction facility is not functioning correctly or

2) The aircraft has a magnetic influence that is higher than that which can be corrected by the Standby Compass.

COMPONENT MAINTENANCE MANUAL
KCA*** & WL1001KCA1 Series**



STORAGE INSTRUCTIONS

NOTE: These instructions are applicable to temperate and tropical climates. The packaging is adequate for storage and transit purposes.

1. PACKAGING PROCEDURE

A. Record the compass details, shown on the unit-mounting flange.

B. Place the Compass unit in a clear polythene bag together with the corrector Key (220) and Electrical Lead assembly (380).

C. Partially heat-seal the bag, expel as much air as possible and complete the seal.

D. Place the polythene bag in an ATA 300 category 2 foam-lined container. If necessary add packing to ensure that the components fit securely into the shock-resistant material.

F. Close the container lid and secure with waterproof adhesive tape.

G. Secure to the container a label giving the following information:

(1) Name, code and serial number of the unit.
(2) Modification state.
(3) Date of last overhaul.
(4) Batch Number.
(5) Shelf Life.

Protect the label with transparent adhesive tape or film.

2. STORAGE CONDITIONS AND STORAGE LIFE

For this information refer to publication SAV/OH/SPR, available from SIRS Navigation Ltd.

STORAGE LIMITING PERIOD

The compass can be stored up to 5 years before being re-certified.

A. Remove unit from packing.

B. Examine unit visually for signs of corrosion or damage.

C. Carry out serviceability tests described in TESTING.

D. Pack in accordance with para. 1.

Following the re-certification, the compass can be stored for a further 5 years.

After 10 years of storage the compass should be overhauled to replace the Silicone fluid and Bellows Gasket.

STANDBY COMPASSES

TRANSFER OF SUPPORT RESPONSIBILITIES

Effectivity: All aircraft equipped with Standby Compasses supplied by Smiths Industries Aerospace

Equipment Affected:

KCA0101C	KCA0104W	KCA0107W	KCA0113FY
KCA0101W	KCA0104FY	KCA0109W	KCA0113W
KCA0102C	KCA0105W	KCA0110W	KCA0114W
KCA0102W	KCA0106W	KCA0112W	WL1001KCA1

Reference: Smiths Industries Overhaul Manual 34-25-21

Introduction:

In November 1993 Smiths Industries Aerospace and Defence Systems Ltd. (SI) agreed the sale of the Standby Compass business to SIRS Navigation Ltd. (SIRS) and at that time also advised the manufacturers of aircraft to which the compasses were then being fitted of this arrangement. Subsequently SI have continued to offer support services, however, these will cease on the 31st July 2000. SIRS meanwhile have developed a comprehensive support capability and will, as the designer and manufacturer under the UK Civil Airworthiness Authority's approval, be the prime source of all support after 31st July 2000.

The only exception to the above will be the AOG service, which SI will continue to provide on behalf of SIRS until further notice.

Recommendation:

Orders for new compasses, component parts, repairs, testing and all other support functions (including technical matters) should be directed to SIRS at the address detailed on page 2. Orders currently placed upon SI, or any received prior to 1st August 2000, will be satisfied by SI, where practicable. Any orders that SI have not satisfied by 1st August 2000 and any received after that date will be passed to SIRS for action and the customers so advised.

Service Information Letter

HEATHROW AIRPORT – LONDON U.K. • MELBOURNE AUSTRALIA • CLEARWATER FLORIDA U.S.A.

A Component Maintenance Manual produced by SIRS will replace the existing SI Overhaul Manual (34-25-21). Arrangements are being made for the technical document distribution department or technical library of each of SI's customers to obtain the required number of CMM's from SIRS. Individual manual holders need not and should not contact SIRS directly.

The SI ATA 200 listing for all Standby Compasses will no longer be updated and should be discarded. It has been agreed however, that SIRS will retain all of the SI component Part Numbers at least until after the transfer period.

All references to Standby Compasses in the SI "Overhaul and Storage Period Recommendations" (OH/SPR) should be ignored after the 31st July 2000.

For any aspect of support after 31st July 2000 (except AOG) please contact:-

SIRS Navigation Ltd.
186a Milton Road
Swanscombe
Kent DA10 OLX
England

REVISION NO. 1 DATED NOV 20/86

HIGHLIGHTS

Revised pages are outlined below together with highlights of this revision. Remove affected pages and enter Revision No. 1, dated Nov 20/86 to the Record of Revisions page. This revision basically adds a new configuration, Part No. 900-700-039-29 to the manual.

Page No.	Description of Change	Effectivity
Title Page	Added new part no. 900-700-039-29.	
Record of Revisions	Added Rev. No. 1.	
List of Effective Pages 1 and 2	Updated to reflect changed pages.	
1	Added new part number, -29, to text.	
4, 101	Added item 12B and -29 to text.	
501	Added items 12B, -29 and NOTE to text.	
505	Added -29 to text.	
506	Added NOTE relating to -29 to text. In steps (5) and (6) identified outlets (12) and (14).	

Page No.	Description of Change	Effectivity
507	Added -29 to Table 501. Identified items 12, 14 in Table. In step (5) identified outlets (12A) and (14A).	
508	In Table 502 identified items (12A) and (14A). Added NOTE. Identified outlets (12A) and (14A).	
509	Identified outlets (12A) and (14A).	
510	Added item (12B).	
702	Added -29 to text. Added NOTE. Identified outlets (12), (12A), (14), (14A).	
801,802	Added item (12B).	
901	Added -29 to text.	
1101	Added vendor code 02217.	
1103	Added items -1C, -12B and usage code D to parts list. Corrected item 14 part number.

DESCRIPTION AND OPERATION

1. Description

A. This publication is issued as the basic overhaul manual for the Portable Oxygen Cylinder Assemblies, Model 4113, Part Number 900-700-039-04, -06, -12, and -29, manufactured by Sabre Industries, Inc., Burbank California.

B. The Oxygen Cylinder Assemblies are designed to provide supplemental oxygen to the passengers and cabin attendants of a commercial airliner as required by Federal Regulations.

C. The Oxygen Cylinder Assemblies (Figure 1) consist of a high pressure oxygen storage cylinder (4.25 cubic feet for the 900-700-039-04, -29 Assemblies and 11.0 cubic feet for the 900-700-039-06, -12 Assemblies), and On-Off Pressure Reducer, a safety outlet of the replaceable frangible disc type, a fill and check valve, a supply pressure gage and quick disconnect constant flow outlet fittings. The Oxygen Cylinder Assemblies also have a carrying strap. The Oxygen Cylinder Assemblies are shown in Figure 1 in a functional diagram with the various sections identified by function.

NOTE: This Oxygen Cylinder Assembly 900-700-039-29 has one constant flow and one demand flow quick disconnect outlet fitting.

D. The ON and OFF positions of the Pressure Reducer and the various ports in the body of the Pressure Reducer are marked to indicate the proper usage.

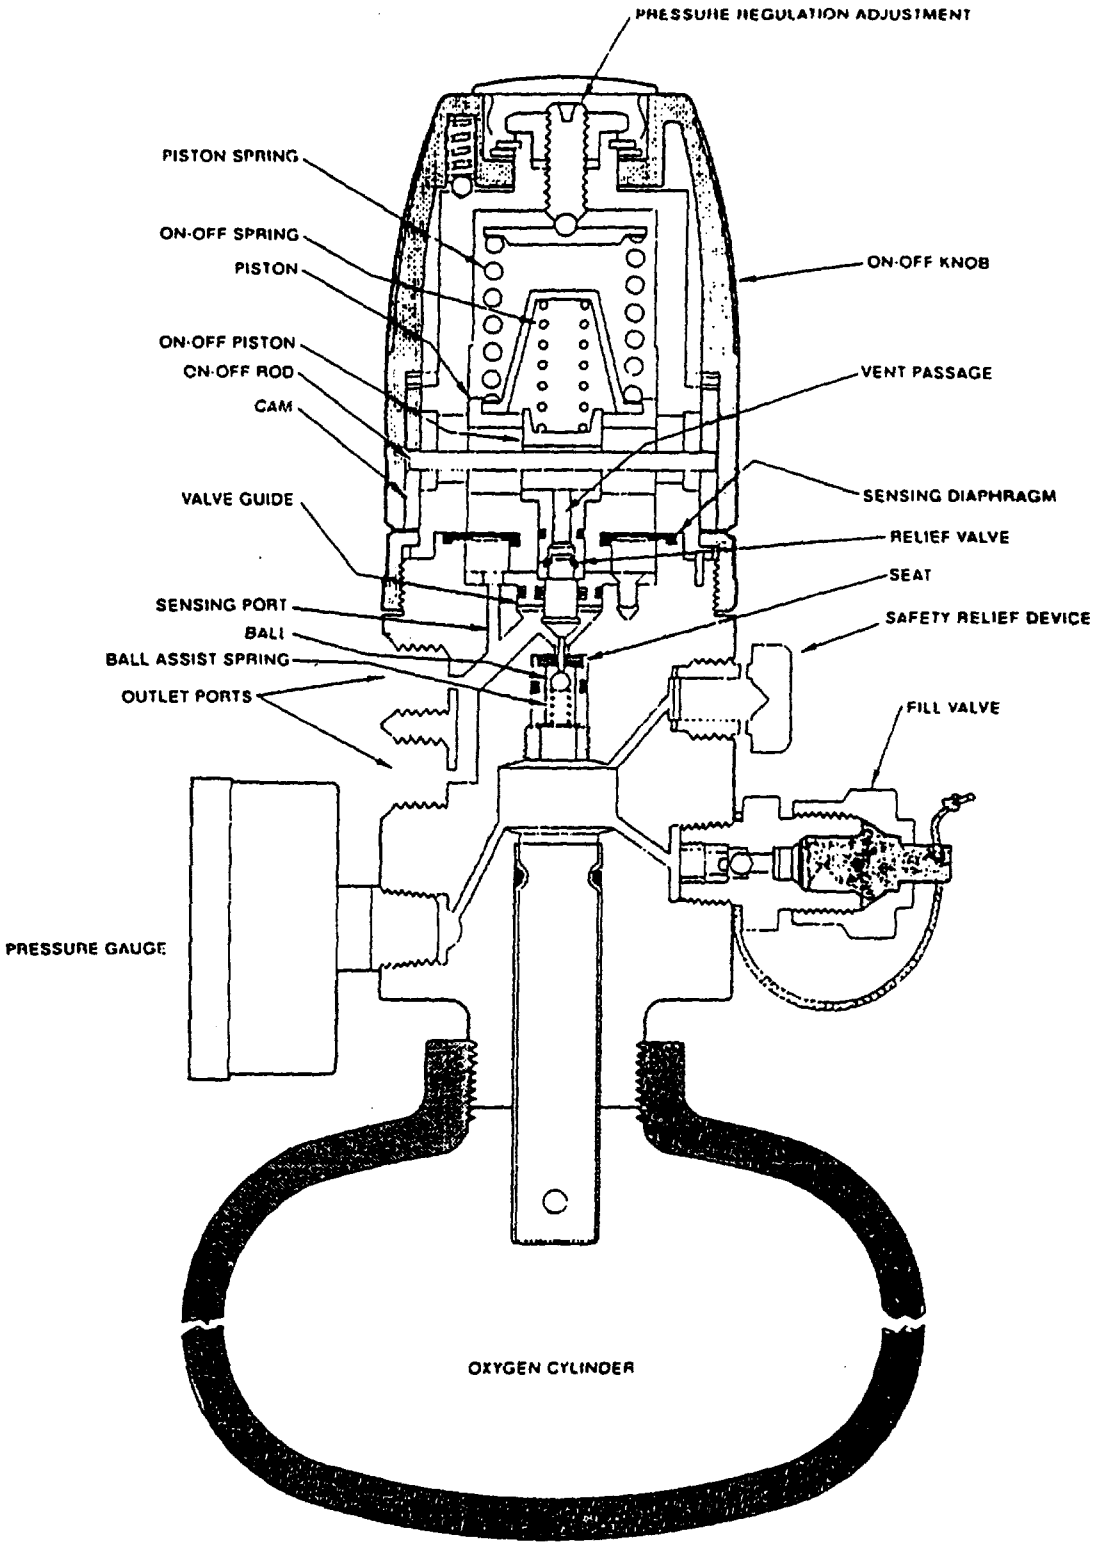
2. Operation

A. The Oxygen Cylinder Assemblies can be filled with high pressure oxygen through the fill check valve on the Pressure Reducer body by removing the cap on the valve and attaching a supply source. The check valve allows flow into the cylinder only and an additional seal in the valve cap assures that no leakage occurs from the fill and check valve. If the cylinder should become dangerously over-pressurized, the frangible disc in the safety device will rupture and vent. See TABLE 1 for the maximum fill pressures and the pressure ranges in which the safety device will rupture.

B. To obtain a flow of oxygen from the Oxygen Cylinder Assemblies, turn the On-Off knob on the Pressure Reducer counterclockwise to the "ON" position (Figure 1 shows the Pressure Reducer in the "ON" position). The main valve (seat, ball, and ball assist spring) is opened by the force of the On-Off spring pushing down on the On-Off piston which makes contact with the relief valve to push the ball off its seat. Oxygen will flow past the ball

into the outlet ports. The sensing chamber simultaneously becomes pressurized through the sensing port. When the pressure force in the sensing chamber balances the force of the piston spring, the piston and On-Off piston will rise, thereby allowing the relief valve to rise and the ball to approach the seat. The flow in the outlet ports will be at regulated pressures and will depend on the force applied by the piston spring. The unit will maintain an outlet pressure between 40 and 60 pounds per square inch gage and will deliver a flow between 0 and 20 liters per minute at any inlet pressure within the range of 200 to 1850 pounds per square inch gage. The ball will modulate to allow oxygen flow in proportion to the demand and will shut off when the demand is zero. A relief valve is incorporated in the Pressure Reducer to exhaust to atmosphere any excess pressure that may occur in the regulated outlet system. When the outlet ports are subjected to excess pressure, the piston and On-Off piston will rise against the piston spring force until the ball seats and seals the inlet; moves free of the O-ring on the relief valve. Oxygen will flow through the sensing port, past the relief valve, through the vent passage, and out through the clearances in the parts of the upper housing and On-Off knob.

C. The outlet flow is stopped by turning the On-Off knob clockwise to OFF. When the On-Off knob is rotated clockwise, the On-Off rod slides upward on the cam which is indexed to the On-Off knob, to pick up and move the On-Off piston upward. This action allows the force of the ball assist spring to move the relief valve and ball upward. The relief valve is now completely free of the ball and the ball is seated on the seat when the On-Off knob is in the "OFF" position. The sealing force is provided by the inlet pressure and the ball assist spring.



3. Leading Particulars

Refer to TABLE 1 for reference to the characteristics and capabilities of the unit.

4. Maintenance Recommendations

A. Make a preflight visual check of the pressure gage on the Oxygen Cylinder Assembly to insure a sufficient oxygen supply.

B. The overhaul period is indefinite. The unit need not be overhauled as long as the tests specified in Oxygen Cylinder Assembly Test (see TESTING) can be successfully performed and there is no visible damage to the unit.

Functional Diagram of Oxygen Cylinder Assembly.
Figure 1.

TABLE 1

LEADING PARTICULARS	
Operating Medium	Gaseous Oxygen
Operating Temperature Range	-40 to +160 degrees Fahrenheit
Inlet Operating Pressure	200 to 1850 pounds per square inch gage
Regulated Outlet Pressure	50 pounds per square inch gage nominal
Outlet Flow	
Outlet #1 (Ref. 12, IPL Fig. 1)	2.7 liters minimum NTPD at sea level
Outlet #1 (Ref. 12A, IPL Fig. 1)	8.4 liters minimum NTPD at sea level
Outlet #1 (Ref. 12B, IPL Fig. 1)	Demand flow (non-orificed)
Outlet #2 (Ref. 14, IPL Fig. 1)	5.0 liters minimum NTPD at sea level
Outlet #2 (Ref. 14A, IPL Fig. 1)	2.7 liters minimum NTPD at sea level
Outlet System Relief Valve	50 liters per minute at 150 pounds per square inch gage
Safety Device Rupture Pressure	2700 to 3000 pounds per square inch gage
Fill Valve Connection	Per SAE Aerospace Standard AS 1046
Maximum Fill Pressure	1980 pounds per square inch gage maximum
DOT Rating of Cylinder: (900-700-039-04, -29) (900-700-039-06, -12)	 3AA1800 3AA1800
Weight: (900-700-039-04, -29)	 4.3 pounds maximum (uncharged) 4.8 pounds maximum (charged)
(900-700-039-06, -12)	6.5 pounds maximum (uncharged) 7.5 pounds maximum (charged)

DISASSEMBLY

NOTE: Prior to complete disassembly, if malfunction is suspected, inspect visually and/or perform necessary functional tests and overhaul procedures to determine cause, and remedy.

1. Disassembly of Part Number 900-700-039-04, -06, -12 and -29 (see IPL Figure 1)

A. Remove clamp (2) from cylinder (4) or (4A).

B. Using a suitable holding fixture, clamp cylinder (4) or (4A) securely in a vise.

C. Position a mating disconnect into outlets (12), (12A), (12B), (14) or (14A), and slowly turn Pressure Reducer (3) to ON. Verify that cylinder (4) or (4A) is empty of oxygen.

CAUTION: OXYGEN SHALL BE VENTED SLOWLY AND SHALL BE REMOTE FROM ANY POSSIBLE SOURCE OF IGNITION.

D. Remove Pressure Reducer (3) from cylinder (4) or (4A). See separate instructions below for detailed disassembly of the Pressure Reducer.

E. Remove strap (5) and install a cover (not illustrated) on cylinder opening to prevent contamination.

F. Remove the check valve assembly (6) from the Pressure Reducer (3) and remove the loop end of braid (8) from the check valve assembly (6). Slip the loop end of braid (8) through sleeve (9) and remove sleeve (9) from braid (8).

G. Remove cap (10) from the check valve assembly (6), untie the knot on one end of braid (8), and slip braid (8) through the hole in plug (11). Remove plug (11).

H. Remove outlets (12, 12A, 12B, 14 and 14A), gage (13) from Pressure Reducer (3). Do not remove vent port (15), washer (16), and rupture disc (17) from the Pressure Reducer unless disc (17) has ruptured.

I. Do not remove identification plate (18) or instruction plate (19) unless replacement is necessary.

2. Disassembly of Part Number 904-002-527-02 (See IPL Figure 2) (For next higher assembly, see IPL Figure 1.)

A. Remove plug (3), nut (4), setscrew (5), ball (6), retaining ring (8), washer (9), and washer (10). Discard washer (10).

B. Remove knob (7), ball (11), spring (12), washer (13), washer spring (14), On-Off rod (15), and cam (16). Discard washer (13).

C. Remove end cap (17). Remove and discard O-ring (18).

D. Piston spring (22) exerts force to separate housing (20), and inlet body (43), which are held together by ring retainer (19). Use an arbor press to hold housing (20) to inlet body (43) while removing ring retainer (19). Then release pressure on arbor press, and allow piston spring (22) to expand.

E. Remove housing (20), washer (46), retainer plate (21), piston spring (22), washer (48), spring retainer (23), On-Off spring (24), piston (25), O-ring (26), piston (27) and diaphragm (28). Discard O-ring (26) and diaphragm (28).

F. Remove screws (30), and valve guide (29) with O-ring (31), retainer (32), relief valve (33), and O-rings (47 and 49) still attached. Discard screws (30).

G. Remove O-ring (31), retainer (32), and relief valve (33) from valve guide (29). Discard O-ring (31), retainer (32), and O-rings (47 and 49).

H. Using wrench 197T41, remove setscrew (35), filter (36), and seat assembly (42A). Discard filter (36) and seat assembly (42A).

I. Do not remove pin (44) unless replacement is necessary. If replacement is necessary, discard pin (44).

J. Do not remove decal (45) from plug (3) unless replacement is necessary.

CLEANING

NOTE: The Pressure Reducers are oxygen breathing equipment, and must be cleaned and assembled in an area where normal conditions of cleanliness are maintained at all times. All tools, fixtures, and test equipment in this area must be free from hydrocarbon contamination and moisture.

WARNING: ALL PARTS, INCLUDING NEW PARTS, MUST BE CLEANED BEFORE ASSEMBLY. SPECIAL ATTENTION MUST BE GIVEN TO HYDROCARBON RESIDUES BECAUSE OF THEIR DANGEROUS PROPERTY OF BREAKING INTO SPONTANEOUS COMBUSTION UPON CONTACT WITH GASEOUS OXYGEN.

THE PRESSURIZED GAS OR AIR SUPPLY USED TO DRY THE PARTS MUST BE FREE FROM HYDROCARBON CONTAMINATION AND MOISTURE.

1. Wash all metallic parts in trichloroethane or perchlorethylene (MIL-T-81533A), and dry with noncontaminated, dry, pressurized gas or air.

   WARNING: USE SOLVENTS IN A WELL VENTILATED AREA, AVOID PROLONGED INHALATION OF FUMES. KEEP AWAY FROM OPEN FLAME. AVOID CONTACT WITH RUBBER COMPOUND PARTS.

2. Force solvent through all holes. With the parts held on clean paper, spray the solvent through apertures and passages. Using a 20-power magnifier, check the residue for foreign matter. Repeat this procedure until no contamination is evident. Dry parts with noncontaminated, dry, pressurized gas or air.

3. Wash all nonmetallic parts in a solution of detergent in distilled water. Rinse in distilled water, and dry with noncontaminated, dry, pressurized gas or air.

TABLE 201

CLEANING MATERIALS AND COMPOUNDS
Distilled water.
Commercial liquid detergent.
Dry, pressurized gas not contaminated with hydrocarbons.
Trichloroethane or perchlorethylene per MIL-T-81533A.

INSPECTION/CHECK

1. Visually inspect the oxygen cylinder for corrosion, nicks, cuts, dents, and damaged threads. The extent of allowable dmaage is specified in the Code of Federal Regulations, Title 49, Paragraph 174.34.

2. Inspect the Pressure Reducer body and components for damaged threads, broken or distorted springs, cut or flattened O-rings, damaged sealing surfaces, nicks, cuts and scratches. Give special attention to seat assembly (Ref. 42A, IPL Figure 2), piston (27) and ON-OFF piston (25). See CLEANING and REPAIR where applicable to correct these defects.

REPAIR

1. Except for minute scratches that can be polished out with crocus cloth (Federal Specification P-C-458), repair of detail parts is not practicable.

2. Replace all damaged parts.

3. The repair of the Oxygen Cylinder (Ref. 4 or 4A, IPL Figure 1) is specified in the Code of Federal Regulations, Title 49, Paragraph 174.34.

NOTE: Welding or metal spinning the Oxygen Cylinder is prohibited.

ASSEMBLY

WARNING: THE CLEANLINESSS REQUIREMENTS OF CLEANING MUST BE OBSERVED DURING THE ENTIRE ASSEMBLY OF THIS UNIT IN ORDER TO PREVENT DANGEROUS HYDROCARBON CONTAMINATION.

1. Assembly of Part Number 904-002-527-02

A. If pin (Ref. 44, IPL Figure 2) was removed, place inlet body (43) in a padded vise and assemble pin (44) into hole on face of body using Punch 147T270. The height of the pin from face of inlet body must be between 0.050 and 0.060 inches.

B. Install seat assembly (42A) into inlet body (43) with plastic end of (42A) pointing down into body (43).

C. Install filter (36) into inlet body (43) flat against seat assembly (42A).

D. Using wrench 197T41, install setscrew (35) into body (43) and torque to 50 pound-inches.

E. Deleted.

F. Deleted.

G. Deleted.

H. Deleted.

I. Using Scotch Brand Pipe Thread Sealant Tape on threads, install gage (13). Apply a thin coat of Krytox 240 AZ on the surface of vent port (15) that contacts rupture disc (17). Install washer (16), rupture disc (17), and vent port (15) into inlet body (Ref. 43, IPL Figure 2) and torque vent port (15) to 150-175 pound-inches.

NOTE: Thread vent port (Ref. 15, IPL Figure 1) into body (Ref. 43, IPL Figure 2) until hand tight. Torque vent port to 150-175 pound-inches.

J. (For Part Number 900-700-039-04, -06, -29). Prior to installing outlet (14, 12 and 12B) onto the Pressure Reducer (3), perform the following. Then install outlets 14, 12 and 12B using Scotch Brand Pipe Thread Sealant Tape.

NOTE: On cylinder assembly 900-700-039-29, outlet (12B) is a demand flow outlet; therefore, no testing is required for this outlet.

NOTE: An adapter, Fluid Power, Inc. (FSC99227), Part No. 2305, must be connected to outlets (12, 14) when measuring flow values.

(1) Connect a regulated oxygen pressure source, capable of delivering 50 ± 1 pounds per square inch gage, to the Pressure Reducer side of outlet (14) and a flowmeter to the other side of outlet (14).

(2) Apply a pressure of 50 ± 1 pounds per square inch gage to outlet (14) and measure a flow of 5.0 to 5.5 liters per minute. If the correct flow cannot be obtained, replace outlet (14).

(3) Repeat steps (1) and (2) using outlet (12). The flow shall be 2.7 to 3.0 liters per minute. If the correct flow cannot be obtained replace outlet (12).

K. (For Part Number 900-700-039-12). Prior to installing outlet (14A and 12A) onto the Pressure Reducer (3), perform the following. Then install outlets (14A) and (12A) using Scotch Brand Pipe Thread Sealant Tape.

NOTE: An adapter, Fluid Power, Inc. (FSC 99227), Part No. 2305, must be connected to outlets (12A, 14A) when measuring flow values.

(1) Connect a regulated oxygen pressure source, capable of delivering 50 ± 1 pounds per square inch gage, to the Pressure Reducer side of outlet (14A) and a flowmeter to the other side of outlet (14A).

(2) Apply a pressure of 50 ± pounds per square inch gage to outlet (14A) and measure a flow of 2.7 to 3.0 liters per minute. If the correct flow cannot be obtained, replace outlet (14A).

(3) Repeat steps (1) and (2) using outlet (12A). The flow shall be 8.4 to 9.3 liters per minute. If the correct flow cannot be obtained, replace outlet (12A).

L. Install plug (11) into cap (10). Insert braid (8) through hole in plug (11) and tie a knot on the plug end of braid (8). Make a loop on the other end of braid (8), insert the loop of braid (8) through sleeve (9), and tie a knot on the sleeve end of braid (8).

M. Clip off excessive braid from the knots on both ends of braid (8) and carefully apply heat to melt loose ends of braid (8) together. Attach the loop end of braid (8) onto the check valve assembly (6).

N. Perform the Check Valve Assembly Test as follows:

(1) Connect the check valve assembly (6) to the oxygen supply.

(2) Apply 1850 ± 50 pounds per square inch gage, then apply 100 ± 10 pounds per square inch gage. Leakage through the check valve assembly (6) must not exceed 100 standard cubic centimeters per minute at either pressure.

O. After the successful completion of the above test, replace cap (10) and torque cap (10) to 90-100 pound-inches.

P. Remove the check valve assembly (6) from the test setup.

Q. Apply Scotch Brand Pipe Thread Sealant Tape to the threads on the check valve assembly (6) and screw body into inlet body (Ref. 43, IPL Figure 2) FILL port.

R. Perform the Pressure Reducer Main Valve Seat Test as follows:

(1) Mount the unit into a test setup similar to that shown in Figure 701.

(2) Insert Test Fixture 79T65, using the appropriate nut that fits on the 1/2 inch NPT inlet port. Tighten knurled nut hand tight.

(3) Connect the inlet test fitting to the primary pressure source.

(4) Apply 1850 pounds per square inch gage, and allow a 3-minute period for the main seat ball (Ref. 40, IPL Figure 2) to seat. Using Leak Detector Solution (MIL-L-25567), check for main seat leakage.

CAUTION: DO NOT PUSH THE MAIN SEAT BALL (40) OFF SEAT MANUALLY AT 1850 POUNDS PER SQUARE INCH GAGE.

(5) If no leakage is evident, reduce inlet pressure to 100 pounds per square inch gage, and recheck for leakage.

(6) If no leakage is evident, reduce inlet pressure to zero. Install O-ring (47) in the inside diameter groove in valve guide (29).

S. Install O-ring (49) in the outside diameter groove of valve guide (29). Install relief valve (33) through valve guide (29).

T. Install retainer (32) and O-ring (31) on the end of relief valve (33). Lubricate the relief valve with Krytox 240 AZ. Insert the subassembly (items 29, 31, 32 and 33) into the inlet body (43) so that the smaller diameter of relief valve (33) (when depressed) pushes ball (40) off seat. Secure with screws (30).

U. Install O-ring (26) on piston (25) and lubricate with Krytox 240 AZ.

V. Insert piston (25) into the ID of piston (27) and align the holes in the two pistons.

W. Apply Krytox 240 AZ to the smooth side of diaphragm (28). Install diaphragm (28) onto piston (27) making sure that the smooth side of diaphragm (28) is placed against piston (27).

X. Install setscrew (5) in housing (20).

CAUTION: THE END OF SETSCREW (5) MUST BE FLUSH WITH THE INSIDE SURFACE OF HOUSING (20).

Y. Lubricate the inside diameter of housing (20) (up to the slots) with Krytox 240 AZ.

Z. Apply Halocarbon 25-5S grease to ball (6) and place ball in cup of setscrew (5).

AA. Install retainer plate (21) in housing (20). Insure that the countersink in retainer plate (21) locates on ball (6).

BB. Install washer (46) on plate (21) and insert piston spring (22) into the inner diameter of housing (20). Insure that piston spring (22) locates on retainer plate (21).

CC. Install washer (48) over spring retainer (23). Install spring retainer (23) in the inner diameter of spring (22).

DD. Install spring (24) into spring retainer (23).

EE. Position the diaphragm-piston assembly (items 25, 26, 27 and 28) into the bore of housing (20). Align the holes in the pistons with the slots in housing (20).

CAUTION: STEPS FF, GG, AND HH ARE VERY CRITICAL. USE EXTREME CARE TO AVOID MALFUNCTION OF THE PRESSURE REDUCER.

FF. Place retainer ring (19) on a slotted plate in an arbor press.

GG. Place the housing assembly from step (EE) under the arbor press with open end up.

HH. Place the subassembly from step (T) over piston (27), and under the ram of the arbor press. Insure that hole in body (20) is in position to mate with spirol pin (44) in inlet body (43). Depress the ram until the flange of retainer (23) can be seen through the slots in housing (20). Using tweezers, position flange of retainer (23) into the guide diameter of piston (27).

II. Push downward on inlet body (43) until it registers into the bore of housing (20), and the spirol pin (44) enters the mating hole in flange of housing (20).

JJ. While holding the ram of the arbor press down so that the upper and lower assemblies of the Pressure Reducer mate, bring retaining ring (19) upward and engage the threads of inlet body (43). Tighten retaining ring (19) by hand. Release the ram of the arbor press.

KK. Check the assembly to make certain the holes in piston (27) align with the slots in housing (20).

LL. Using a strap wrench, tighten retaining ring (19).

MM. Apply Halocarbon 25-5S grease to the bottom flange of cam (16) and to the bottom of the cam slots (2 places).

NN. Assemble cam (16) over housing (20), and insert rod (15) through slots in cam (16), housing (20) and piston (27).

OO. Install washer (13) over hub of housing (20).

PP. Install spring washer (14) concave side up over housing (20).

QQ. Apply Halocarbon 25-5S grease to ball (11), and place it into the detent countersink in the top of housing (20) so that ball (11) is positioned in the detent that is opposite of spring (12) when knob (7) is in the OFF position.

RR. Apply Halocarbon 25-5S grease to detent spring (12), and insert spring into counterbore in knob (7).

SS. Install knob (7) over housing (20) in the OFF position so that spring (12) will mate with ball (11).

TT. Install washer (10) and flat washer (9) into the counterbore of knob (7). Secure knob to housing (20) with retaining ring (8).

UU. Install lock nut (4) on setscrew (5) hand-tight only.

VV. Install button plug (3) and decal (45).

2. Assembly of Part Number 900-700-039-04, -06 and -29

A. If identification plate or instruction plate (Ref. 18 or 19, IPL Figure 1) were removed, replace.

B. Calibrate the Pressure Reducer Assembly (For Part Number 909-700-039-04, -06, -29) as follows:

NOTE: An adapter, Fluid Power, Inc. (FSC99227), Part No. 2305, must be connected to outlets (12, 14) when measuring flow values.

NOTE: On Cylinder Assembly 900-700-039-29, outlet (12B) must be capped for this calibration. Insure that outlet (12B) does not leak.

(1) With the appropriate nut of Test Fixture 79T65 on the inlet port of the Pressure Reducer Assembly (3), mount the unit in a test setup similar to that shown in Figure 701.

(2) Connect both outlet ports (Ref. 12, 14, IPL Figure 1) of the Pressure Reducer Assembly (3) to the flowmeter fittings.

(3) With On-Off knob (Ref. 7, IPL Figure 2) in the OFF position, apply 200 pounds per square inch gage to the inlet port. There must be no audible leakage.

(4) Turn On-Off knob (7) to ON. The unit will open and begin to regulate (see outlet gage and flowmeter).

(5) With valve #4 open, valve #1 closed, subject the Pressure Reducer to the inlet pressure listed in TABLE 501, remove button plug (Ref. 3, IPL Figure 2), and adjust regulated pressure as necessary using setscrew (5). Turn setscrew (5) clockwise to increase and counterclockwise to decrease pressure. Repeat until the flow is within the limits of TABLE 501 for outlet (12) and the outlet pressure on gage connected to outlet (14) is within 50 $\pm$5 pounds per square inch. Make certain that there is no leakage at the disconnect fittings since this would affect the pressure reading. If the flow and pressure requirements cannot be obtained simultaneously, the outlet disconnects should be removed from the pressure reducer and rechecked per flow test in ASSEMBLY. Since the adjustment of setscrew (5) affects the flows of Steps (5) and (6), it is necessary to repeat Steps (5) and (6) until both flow requirements are met without further adjustment.

(6) With valve #1 open, valve #4 closed, subject Pressure to the inlet pressure listed in TABLE 501, remove button plug (Ref. 3, IPL Figure 2), and adjust regulated pressure as necessary using setscrew (5). Turn setscrew (5) clockwise to increase and counterclockwise to decrease pressure. Repeat until the flow is within the limits of TABLE 501 for outlet (14). Since the adjustment of setscrew (5) affects the flows of Steps (5) and (6), it shall be necessary to repeat Steps (5) and (6) until both flow requirements are met without further adjustment.

TABLE 501

PRESSURE AND FLOW (900-700-039-04, -06, -29)		
Inlet Pressure (pounds per square Inch gage	Flow (O_2) (liters per minute)	
	Min.	Max.
1800 ± 100	(Ref. 12, IPL Fig. 1) (Ref. 14, IPL Fig. 1)	

C. Calibrate Pressure Reducer Assembly (For Part Number 900-700-039-12) as follows:

(1) With the appropriate nut of Test Fixture 79T65 on the inlet port of the Pressure Reducer Assembly (3) mount the unit in a test setup similar to that shown in Figure 701.

(2) Connect both outlet ports (Ref. 12A, 14A, IPL Figure 1) of the Pressure Reducer Assembly (3) to the flowmeter fittings.

(3) With On-Off knob (Ref. 7, IPL Figure 2) in the OFF position, apply 200 pounds per square inch gage to the inlet port. There must be no audible leakage.

(4) Turn On-Off knob (7) to ON. The unit will open and begin to regulate (see outlet gage and flowmeter).

NOTE: An adapter, Fluid Power, Inc. (FSC 99227) Part No. 2305, must be connected to outlets (12A, 14A) when measuring flow values.

(5) With valve #4 open, valve #1 closed, subject the Pressure Reducer to the inlet pressure listed in TABLE 502, remove button plug (Ref. 3, IPL Figure 2), and adjust regulated pressure as necessary using setscrew (5). Turn setscrew (5) clockwise to increase and counterclockwise to decrease pressure. Repeat until the flow is within the limits of TABLE 502 for outlet (12A) and the outlet pressure on gage connected to outlet (14A) is within 50 ±5 pounds per square inch. Make certain that there is no leakage at the disconnect fittings since this would affect the pressure reading. If the flow and pressure requirements cannot be obtained simultaneously, the outlet disconnects should be removed from the pressure reducer and rechecked per the flow test in ASSEMBLY. Since the adjustment of setscrew (5) affects the flows of Steps (5) and (6), it is necessary to repeat Steps (5) and (6) until both flow requirements are met without further adjustment.

(6) With valve #1 open, valve #4 closed, subject Pressure Reducer to the inlet pressure listed in TABLE 502, remove button plug (Ref. 3, IPL Figure 2), and adjust regulated pressure as necessary using setscrew (5). Turn setscrew (5) clockwise to increase and counterclockwise to decrease pressure. Repeat until the flow is within the limits of TABLE 502 for outlet (14A). Since the adjustment of setscrew (5) affects the flows of Steps (5) and (6), it shall be necessary to repeat Steps (5) and (6) until both flow requirements are met without further adjustment.

TABLE 502

PRESSURE AND FLOW (900-700-039-12)			
Inlet Pressure (pounds per square inch gage)	Flow (O_2) (liters per minute)		
	Min.		Max.
1800 ±100	8.4 2.7	(Ref. 12A, IPL Fig. 1) (Ref. 14A, IPL Fig. 1)	9.3 3.0

D. Perform the Pressure Reducer Assembly Test as follows:

NOTE: An adapter, Fluid Power, Inc. (FSC 99227), Part No. 2305, must be connected to outlets (12, 14) when measuring flow values.

NOTE: On Cylinder Assembly 900-700-039-29, outlet (12B) must be capped for this calibration. Insure that outlet (12B) does not leak.

(1) Flow Regulation Test (for Part Number 900-700-039-04, -06, -29)

(a) Mount the Assembly in a test setup similar to that shown in Figure 701.

(b) Connect the Assembly constant flow disconnects (Ref. 12, 14, IPL Figure 1) through flowmeter #6.

(c) With On-Off knob (Ref. 7, IPL Figure 2) in the ON position, valve #4 open, valve #1 closed, the Assembly must be subjected to and comply with the requirements of TABLE 501 for outlet (12). Close valve #4, open valve #1, and repeat the test for outlet (14).

(2) Flow Regulation Test (For Part No. 900-700-039-12)

NOTE: An adapter, Fluid Power, Inc. (FSC 99227), Part No. 2305, must be connected to outlet (12A, 14A) when measuring flow values.

(a) Mount the Assembly in a test setup similar to that shown in Figure 701.

(b) Connect the Assembly constant flow disconnects (Ref. 12A, 14A, IPL Figure 1) through flowmeter #6.

(c) With On-Off knob (Ref. 7, IPL Figure 2) in the ON position, valve #4 open, valve #1 closed, the Assembly must be subjected to and comply with the requirements of TABLE 502 for outlet (12A). Close valve #4, open valve #1, and repeat the test for outlet (14A).

(3) On-Off Test

(a) Mount the Assembly in a test setup similar to that shown in Figure 701.

(b) With valves #1 and #4 closed and with an inlet pressure of 1800 ±100 pounds per square inch gage applied, turn On-Off knob (Ref. 7, IPL Figure 2) to OFF.

(c) Outlet pressure shall decay to zero.

(d) Repeat this test with an inlet pressure of 200 ±25 pounds per square inch gage.

(4) Internal Leakage Test

(a) Mount the Assembly in a test setup similar to that shown in Figure 701.

(b) Turn On-Off knob (Ref. 7, IPL Figure 2) to OFF.

(c) Seal the Assembly in the sealed chamber with valve #1 and #4 closed and valve #3 open. With an inlet pressure of 1800 ±100 pounds per square inch gage applied, there must be no leakage as indicated by flowmeter #3.

(d) Repeat this test with an inlet pressure of 100 ±10 pounds per square inch gage.

(e) With an inlet pressure of 1800 ±100 pounds per square inch gage applied, there shall be no leakage as indicated by flowmeter #3.

(5) External Leakage Test

(a) Mount the Assembly in a test setup similar to that shown in Figure 701.

(b) Turn On-Off knob (Ref. 7, IPL Figure 2) to ON.

(c) Seal the Assembly in the leakage test chamber with valve #3 open and with outlets (Ref. 12, 12A, 12B, 14, 14A, IPL Figure 1) disconnected.

(d) With an inlet pressure of 1800 ±100 pounds per square inch gage applied, there shall be no leakage as indicated by flowmeter #3.

(e) Repeat this test with an inlet pressure of 100 ±10 pounds per square inch gage.

(6) Gage Accuracy Test

(a) Mount the Assembly in a test setup similar to that shown in Figure 701.

(b) Turn On-Off knob (Ref. 7, IPL Figure 2) to OFF and apply an inlet pressure of 2000, 1500, 1000, and 500 pounds per square inch gage.

(c) The gage on the Assembly shall indicate the correct pressures within ±60 pounds per square inch gage.

E. Using a suitable holding fixture, clamp cylinder (Ref. 4 or 4A, IPL Figure 1) securely in a vise. Remove protective cover (not illustrated) from cylinder (4) or (4A).

F. Install O-ring (Ref. 18, IPL Figure 2) and cap (17).

G. Place the carrying strap (Ref. 5, IPL Figure 1) loop over the neck of the cylinder (4 or 4A). Apply Scotch Brand Pipe Thread Sealant Tape to the threads of the Pressure Reducer (3). Apply a film of Krytox 240 AZ over the Sealant Tape to prevent galling. Install the Pressure Reducer (3) into the neck of cylinder (4) or (4A). Torque the Pressure Reducer (3) to 400 to 450 in-lbs.

H. Install clamp (2). Clamp screw is to be oriented 90 degrees in either direction away from the face of the gage (13).

I. Remove the Oxygen Cylinder Assembly from the vise.

J. Perform the Oxygen Cylinder Assembly Test (see TESTING).

K. Store or ship the Oxygen Cylinder Assembly (see STORAGE INSTRUCTIONS).

TABLE 503

ASSEMBLY MATERIALS AND COMPOUNDS*	
Halocarbon Grease, Series 25-5S	Halocarbon Products Corporation Hackensack, New Jersey
Scotch Brand Pipe Thread Sealant	Minnesota Mining and Mfg. St. Paul, Minnesota
Leak Detector Solution	MIL-L-25567, Type I
Krytox 240 AZ Fluorinated Grease	Petroleum Chemicals Division E. I. duPont de Nemours & Co. Wilmington, DE 19898

*Equivalent Materials/Components may be used.

FITS AND CLEARANCES

1. The height of the pin (Ref. 44, IPL Figure 2) from face of inlet body must be between 0.050 and 0.060 inches.

2. Torque the Pressure Reducer (Ref. 3, IPL Figure 1) to 400-450 lb-in.

TESTING

WARNING: THE CLEANLINESS REQUIREMENTS OF CLEANING MUST BE OBSERVED DURING ALL TESTING OF THE PRESSURE REDUCER IN ORDER TO PREVENT HAZARDOUS HYDROCARBON CONTAMINATION.

1. Test Equipment and Conditions

A. Equipment

The equipment necessary to test the Pressure Reducer consists of a Test Stand, as shown in Figure 701.

Test equipment tolerances are as follows:

(1) Pressure Gages ± 2 percent

(2) Flowmeters ± 1 percent

B. Conditions

All tests are to be performed at an atmospheric pressure of between 28 and 32 inches of mercury, at temperatures of between plus 60 degrees and plus 90 degrees Fahrenheit, and a relative humidity of not more than 95 percent.

2. Oxygen Cylinder Assembly Test

A. Leakage Test

(1) With On-Off knob (Ref. 7, IPL Figure 2) in the OFF position, remove cap (Ref. 10, IPL Figure 1), and connect the oxygen supply to the Oxygen Cylinder Assembly fill check valve using fill adapter, Sabre Industries Part No. 525-900-085 or equivalent.

CAUTION: THE SABRE INDUSTRIES FILL VALVE AND FILL VALVE ADAPTER COMPLY WITH THE LATEST REQUIREMENTS OF SAE AEROSPACE STANDARD AS 1046. SOME OF THE EARLIER FILL VALVE ADAPTERS OF OTHER MANUFACTURERS MAY NOT COMPLY WHICH COULD RESULT IN AN IMPROPER FIT. IF THIS OCCURS, OBTAIN A SABRE INDUSTRIES FILL VALVE ADAPTER, PART NO. 525-900-085.

(2) Fill the Oxygen Cylinder Assembly to 1850 ± 50 pounds per square inch gage.

(3) Check the Oxygen Cylinder Assembly for leakage using Leak Detector Solution conforming to MIL-L-22567, Type 1.

(4) No leakage is allowed from the Oxygen Cylinder Assembly or its components.

(5) Disconnect oxygen supply and replace cap (Ref. 10, IPL Figure 1). Torque cap (10) to 90-100 lb-in and check for no leakage.

NOTE: It is not necessary to perform para. B, C, or D, below during routine filling of the Oxygen Cylinder Assembly (Ref. 1, 1A, 1B, IPL Figure 1).

B. Flow Test (For Part Number 900-700-039-04, 06, -29)

NOTE: An adapter, Fluid Power, Inc. (FSC 99227), Part No. 2305, must be connected to outlets (12, 14) when measuring flow values.

NOTE: On Cylinder Assembly 900-700-039-29, outlet (12B) must be capped for this calibration. Insure that outlet (12B) does not leak.

(1) Connect the Oxygen Cylinder Assembly to a test setup similar to that shown in Figure 701, less the Leak Chamber and regulated pressure source.

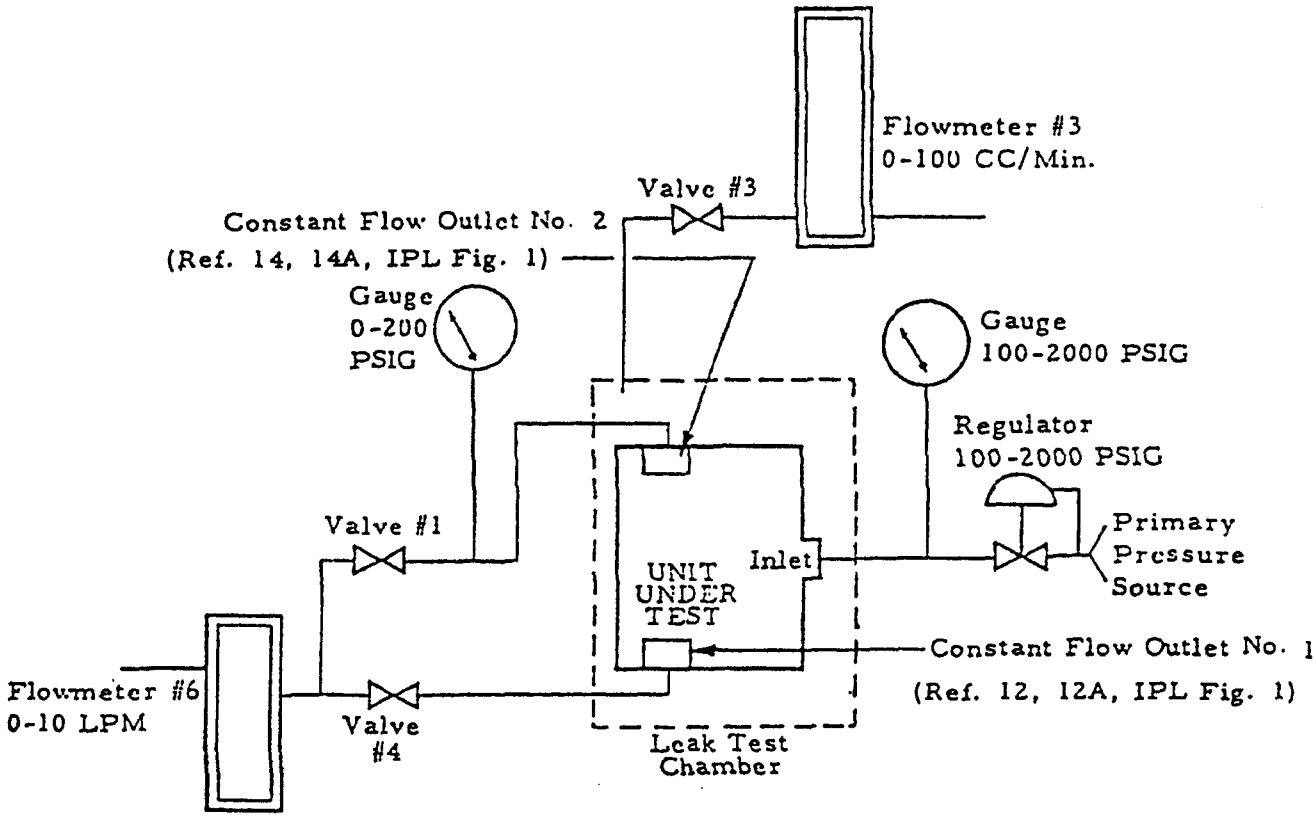
(2) Connect the constant flow outlets (Ref. 12, 14, IPL Figure 1) through flowmeter #6.

(3) With On-Off knob (Ref. 7, IPL Figure 2) in the ON position, valve #4 open, valve #1 closed, the Oxygen Cylinder Assembly must be subjected to and comply with the requirements of TABLE 501 for outlet (12). Close valve #4, open valve #1, and repeat the test for outlet (14).

C. Flow Test (For Part Number 900-700-039-12)

NOTE: An adapter, Fluid Power, Inc. (FSC 99227), Part No. 2305, must be connected to outlets (12A, 14A) when measuring flow values.

(1) Connect the Oxygen Cylinder Assembly to a test setup similar to that shown in Figure 701, less the Leak Test Chamber and regulated pressure source.



(2) Connect the constant flow outlets (Ref. 12A, 14A, IPL Figure 1) through flowmeter #6.

(3) With On-Off knob (Ref. 7, IPL Figure 2) in the ON position, valve #4 open, valve #1 closed, the Oxygen Cylinder Assembly must be subjected to and comply with the requirements of TABLE 502 for outlet (12A). Close valve #4, open valve #1, and repeat the test for outlet (14A).

D. Cylinder Pressure

(1) Record the pressure and leave the Oxygen Cylinder Assembly pressurized for a minimum of 14 days.

(2) The pressure in the cylinder shall not decay more than 50 pounds per square inch gage by the end of 14 days.

Schematic for Test Stand.
Figure 701.

TROUBLESHOOTING

Refer to TABLE 801 for assistance in determining and correcting the cause of pressure reducer regulator malfunction.

TABLE 801 (Sheet 1 of 2)

TROUBLESHOOTING CHART		
PROBLEM	PROBABLE CAUSE	REMEDY
1. Inward or outward leakage.	A. Leakage of main valve seat due to:	
	Damaged seat assembly (42A).	Replace seat assembly (42A).
	B. Leakage of pressure due to:	
	Gage (Ref. 13, IPL Figure 1), Check Valve Assy (Ref. 6, IPL Figure 1), Outlet Quick Disconnect (Ref. 12, 12A, 12B, 14, 14A, IPL Figure 1), and Vent Port (Ref. 16, IPL Figure 1) not sealed.	Tighten or reseal threads.
	Spring (Ref. 22, IPL Figure 2) damaged or distorted.	Replace spring (22).
	Pressure Reducer not assembled correctly.	Reassemble. Pay particular attention to positioning of parts and application of sealants and lubricants.
2. Outlet pressure does not decay to zero when the reducer is turned to the OFF position with inlet pressure applied.	Faulty relief valve (Ref. 33, IPL Figure 2).	Replace relief valve (33).

TABLE 801 (Sheet 2 of 2)

TROUBLESHOOTING CHART		
PROBLEM	PROBABLE CAUSE	REMEDY
3. Flows do not meet requirements of TABLE 501 or 502.	A. Pressure reducer is out of adjustment.	Readjust setscrew (Ref. 5, IPL Fig. 2).
	B. Faulty self-sealing quick disconnects (Ref. 12, 12A, 12B, 14, or 14A, IPL Figure 1).	Replace self-sealing quick disconnects (12, 12A, 12B, 14 or 14A).

STORAGE INSTRUCTIONS

1. The pressure in the cylinder must be 1850 ± 50 pounds per square inch gage with the On-Off knob in the OFF position. Tag the cylinder as follows:

   WARNING: DO NOT ALLOW CONTAMINANTS OF ANY KIND TO BE USED ON OR ABOUT THE OXYGEN CYLINDER ASSEMBLY.

2. Place male or female plastic protectors over all exposed openings on the Oxygen Cylinder Assembly and place the Oxygen Cylinder Assembly into a plastic bag. Pack in a padded carton for storage or shipment. Seal the carton and tag with the Oxygen Cylinder Assembly part number, serial number, and test data.

3. The Oxygen Cylinder Assembly may be stored indefinitely at ambient temperatures within the range of -65 to 165 degrees Fahrenheit. Any Oxygen Cylinder Assembly stored for 36 months or longer should be subjected to, and comply with, the requirements of the Oxygen Cylinder Assembly Test (see TESTING) before being placed in service.

4. In addition to the above recommendations, the Oxygen Cylinder Assembly is subject to the test requirements and regulations required by the U.S. Department of Transportation for cylinders with a rating of 3AA1800 for the 900-700-039-04, -29 Oxygen Cylinder Assemblies and 3AA1800 for the 900-700-039-06, -12 Oxygen Cylinder Assemblies. These requirements are contained in Title 49, Code of Federal Regulations.

   NOTE: The 3AA Cylinders shall be retested every 5 to 10 years. Refer to Title 49, Code of Federal Regulations for the specific service life and retest period. The preceding information is reflected in the current (January 1, 1969) Title 49, Code of Federal Regulations and is subject to change.

SPECIAL TOOLS, FIXTURES AND EQUIPMENT

WARNING: THE CLEANLINESS REQUIREMENTS OF CLEANING MUST BE OBSERVED TO PREVENT HAZARDOUS HYDROCARBON CONTAMINATION OF THE EQUIPMENT LISTED IN TABLE 1001.

TABLE 1001

SPECIAL TOOLS, FIXTURES AND EQUIPMENT	
TOOL NUMBER	NOMENCLATURE

LIGHT OVERHAUL

1. Inspection and Test

Any Oxygen Cylinder Assembly that can pass a visual inspection for obvious external damage, and comply with the Oxygen Cylinder Assembly Test in TESTING, is suitable for use.

2. Troubleshooting

Defects can be located by using the Troubleshooting Chart, TABLE 801, in conjunction with TESTING.

3. Repair

TABLES 1301 and 1302 indicate the various sections of the Oxygen Cylinder Assembly (Ref. 1-1, -1A, or -1B, IPL Figure 1) and the Pressure Reducer (Ref. 2-1, IPL Figure 2) that can be independently repaired and the necessary calibration and testing required to insure that the particular assembly involved has been returned to usable condition.

SERVICE PROCEDURE

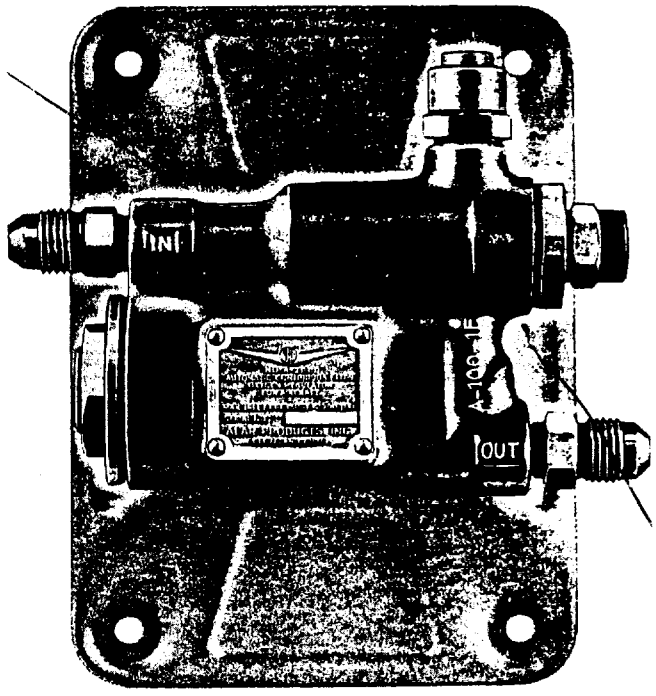
OXYGEN - PORTABLE
- CYLINDER ASSEMBLY, CONSTANT FLOW -
PART NUMBER 900-700-039-021

1. Effectivity

This service procedures affects all PN 900-700-039-021 constant flow portable oxygen cylinder assemblies manufactures by Adams Rite Sabre International (formerly Sabre Industries) of Glendale, California.

2. Reason

An overhaul manual specifically written for this end item does not exist.



3. Instructions

To service this product, refer to IPL Figure 1, on page 1103 of Adams Rite Sabre International "Overhaul Manual With Illustrated Parts List," 35-31-08, and incorporate the following changes:

Fig. Item	Part Number	Nomenclature	Usage Code	Units Per Assy
-1D	900-700-039-21	CYLINDER ASSY, Oxygen, portable	E	RF
4	904-002-475-04	. CYLINDER	A, D, E	1
-12C	525-900-093-BN	. OUTLET, (No. 2)	E	1
-14B	525-601-002	. PLUG, Pipe 1/8 NPT hex socket (Outlet No. 1)	E	1

MODEL IDENTIFICATION

Code	Model	Code	Model	Code	Model	Code	Model
A	3014	E	B100	I	A2000WA	M	A2000YA
B	3014A	F	A2000	J	A2000W1	N	A2000Y1
C	3016	G	A2000A	K	A2000W1A	O	A2000Y1A
D	3016A	H	A2000W	L	A2000Y		

NOTE: Models B100, A2000, A2000Y, and A2000Y1 are covered by instructions in basic handbook.

Actuating bellows (8) is mechanically connected to the second stage valve (9A) by means of a socket head screw on the valve stem.

During disassembly, after removing (1) thru (7), (25) may remain with (2) or (5), loosen bellows (8) but do not remove. Simultaneously back out bellows (8) while turning in valve stem by means of long series socket screw key for No. 10 set screw (3/32 hex). The reverse proceedure must be followed during reassembly. Place bellows in position to install, start threaded valve stem into bellows, "back" into place approximately 7 turns (relative to the bellows (8)) while turning bellows into place.

Threaded connection between valve and bellows provides an adjustment for minimum or "ground level" pressures. Turning the valve stem in (clockwise) will lower minimum presssures, out (counterclockwise) will raise them. Pressures will change about five (5) psi for one (1) turn with assemblies using the 5505A10 Bellows Assy, and about 10 psi for one (1) turn with the 5525A4 Bellows Assy.

Altitude in feet Above Sea Level	Delivery Pressure PSI Absolute	Flow at Alt. L/Min STP Conditions
0	19.5 ±2.5	1.1 ±0.2

20,000	33.5 ±2.5	3.0 ±0.2
30,000	40.0 ±2.5	3.6 ±0.2

Table III. Delivery Table for Models A-2000-W, A-2000-WA, A-2000W1, A-2000-W1A, 3014, 3014A, 3016, 3016A

The A-2000W, 3014 and 3016 series of regulators are designed to provide oxygen flows in accordance with CAR amendment 4b-3 to altitudes of 30,000 ft. Performance should be in accordance with Table III.

First Stage pressure is adjusted to maintain 45 to 75 psi.

Recommend Test Set-Up of fig. 4, rather than fig. 3, in basic handbook. It is more versatile and can be used for all models; fig. 3 is suitable for A-2000, A-2000Y, A-2000Y1, and B100 only.

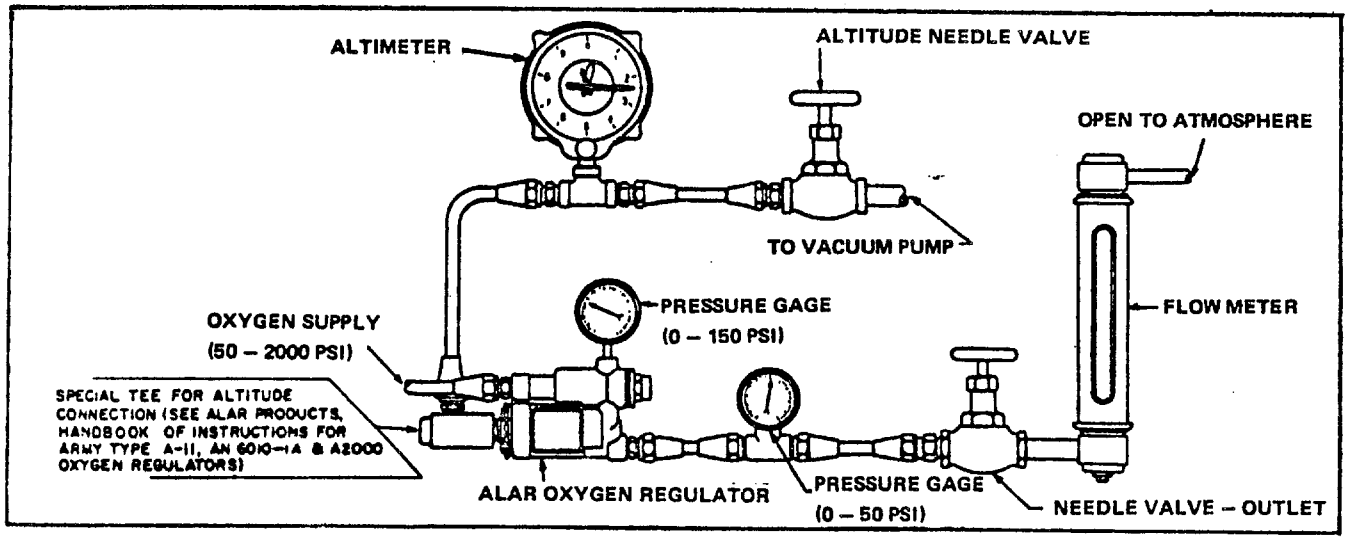

Figure 4. Regulator Test Set-Up.

MODEL 5505A ONLY

For 5505A, inlet pressure range is 50 to 75 psi, output pressures to be in accordance with Table IV.

Altitude in feet Above Sea Level	Delivery Pressure PSI Absolute	Flow at Alt. L/Min STP Conditions
0	19.5 ±2.5	1.1 ±0.2

ALAR OXYGEN REGULATORS

Types A-2000, A-100, AN-6010-1, and USAAF A-11

INTRODUCTION

The ALAR regulator is an automatic, altitude compensating, continuous flow, multiple person, high pressure oxygen regulator. The purpose of this regulator is to reduce the pressure of oxygen in supply cylinders to a lower and more suitable working pressure and to automatically regulate this working pressure so that the proper amount of oxygen will be supplied to passengers and crew members of aircraft through fixed orifices in accordance with predetermined altitude and physiological requirements. These requirements were established by the Aero-Medical Unit of the Air Materiel Command, United States Army Air Forces, Wright Field, Dayton, Ohio, and are set forth in Army-Navy Specification AN-R-15a.

It must be emphasized that an ALAR Oxygen Regulator is a pressure regulator ONLY, and consequently does not directly regulate oxygen flow, the actual flow of oxygen being metered to each potential user by means of fixed orifices connected to the distribution system at each respective station. The regulator has ultimate control over the flow in that it maintains the required predetermined pressure behind each orifice, regardless of the number of metering orifices opened to oxygen flow.

The various models of the ALAR regulator are summarized briefly in Table I:

TABLE I

Type	Inlet Pressure Range	Altitude Operating Range	Maximum Flow Range L/Min. at 70F, 760mm
USAAF A-11	50 - 500 p.s.i.	8,000 - 30,000 ft.	0 - 36
Army-Navy AN-6010-1	50 - 500 p.s.i.	8,000 - 30,000 ft.	0 - 36
Alar A-100 Serial Nos. 0-999 inc.	50 - 500 p.s.i.	8,000 - 30,000 ft.	0 - 48
Serial Nos. from 1,000 on	50 - 500 p.s.i.	sea level - 30,000 ft.	0 - 48
Alar A-2000	35 - 2200 p.s.i.	sea level - 30,000 ft.	0 - 48

It will be noted that the A-2000 and A-100 regulators provide flow down to sea level, maintaining the flow obtained at 10,000 ft. in this range, while the A-11 and AN-6010-1 do not supply oxygen below about 8,000 ft. In addition, the A-2000 and A-100 will maintain greater flows without loss of distribution pressure, and the A-2000 will operate at inlet pressures up to 2200 p.s.i.

The ALAR regulator will, of course, supply increasing amounts of oxygen at altitudes above 30,000 ft., this altitude being the maximum at which the regulator is normally checked.

The ALAR regulators are completely automatic with no means of manual control necessary nor provided. NO MAINTENANCE IS REQUIRED, AND ANY ADJUSTMENTS MADE WITHOUT THOROUGH TESTS WITH CALIBRATED TEST EQUIPMENT WILL LEAD TO IMPROPER PERFORMANCE. Extreme conditions of high temperature, shock, age, or contaminated oxygen require tests and possible repair and calibration.

GENERAL CONSTRUCTION AND OPERATION

Basic components of the ALAR regulators and their function are as follows: (Reference is made to the cross section drawing and indicated part numbers shown on Figure 1.)

1. Forged aluminum regulator body (A-100-1F) housing all components of the regulator and having three mounting lugs to which the optional mounting plate (A-100-10) may be attached. The body has been forged solid and the interior cavities formed by machining in order that maximum density may be obtained to prevent leakage. Inlet and outlet bosses are tapped 1/8NPT so that standard fittings may be used for connecting the regulator to supply and distribution systems. Type AN-816 aluminum fittings (A-100-13) for 5/16 in. O.D. tubing are customarily supplied except for the inlet fitting of the A-2000 regulators. The same type fitting, but for 3/16 in O.D. tubing, is supplied on the inlet of the A-2000.

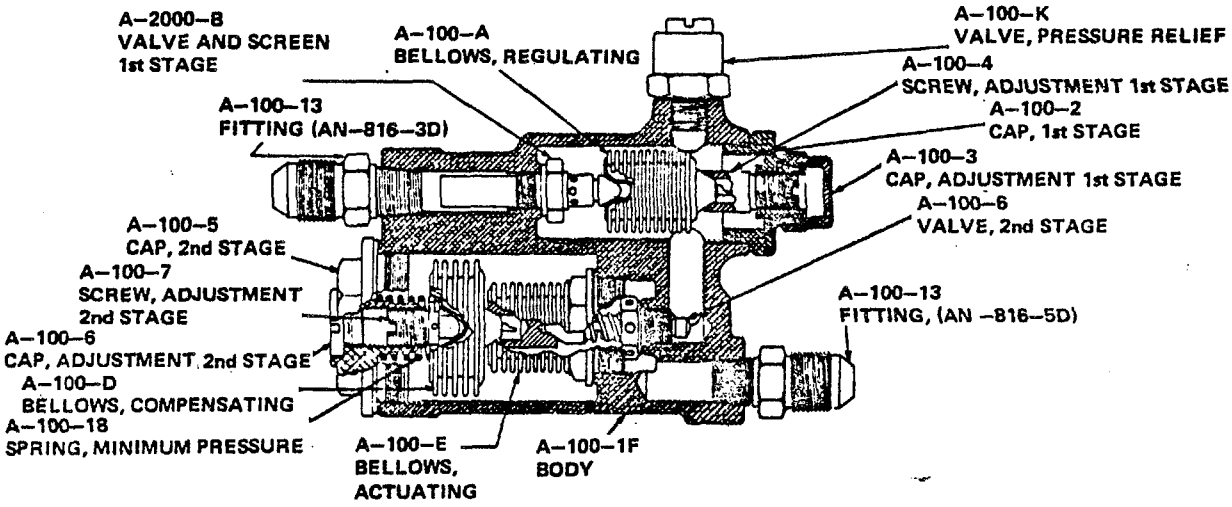

Figure 1

2. First stage or inlet pressure reduction system which reduces the widely varying inlet pressure to a first stage pressure varying not more than 30 p.s.i. In the A-2000 this system consists of a high pressure or first stage valve (A-2000-B) incorporating a very fine mesh screen to prevent entry of foreign particles, a pressure sensitive means of regulating bellows (A-100-A), a first stage adjustment screw (A-100-4), a first stage cap (A-100-2), and first stage adjustment cap (A-100-3). This regulating bellows is completely evacuated and sealed so that temperature changes will not affect regulation and any pressure change in the space surrounding this bellows will cause it to lengthen or collapse, thus opening and closing the valve, thereby producing the desired pressure regulation. The A-100, A-11 and AN-6010-1 regulators are the same except for the smaller first stage valve (A-100-B) protected by a separate screen (A-100-C).

3. Pressure relief valve (A-100-K) connected to the first stage chamber and serving as protection against valve leakage which might cause regulator failure. These valves have been set to open at a pressure between 110 and 150 p.s.i. Older model pressure relief valves (A-100-F) have been supplanted by this newer, improved model.

4. Actuating or delivery pressure regulating system which maintains the pressure level in the distribution system connected to the regulator outlet. Parts of this system are a second stage valve (A-100-G) and a pressure sensitive means or actuating bellows (A-100-E). Distribution system pressures acting on the inside of this bellows will cause it to expand or contract which will close or open the the valve until the force developed by the distribution pressure counterbalances the spring and variable atmospheric forces on the outside of the bellows.

5. Altitude compensating system having an atmospheric sensitive element which loads and unloads the delivery pressure regulating system in accordance with the altitude. This system consists of an evacuated compensating bellows (A-100-D), a second stage adjustment screw (A-100-7) and a second stage cap (A-100-5) with adjustment screw cap (A-100-6). In addition to being compressed by atmospheric pressure, this altitude compensating bellows is compressed between the actuating bellows and the adjustment screw so that any changes in atmospheric pressure will change the force on the actuating bellows thereby changing the pressure level in the distribution system.

6. Minimum pressure regulating system which takes up control of the delivery pressure system when the altitude drops below 10,000 feet and maintains the 10,000 foot oxygen delivery pressure on down to sea level. This system consists of a minimum pressure spring (A-100-18) compressed between the compensating bellows (A-100-D) and the second stage cap (A-100-5) and is incorporated in the A-2000 and ALAR A-100 regulators only.

NOTE: The AN-6010-1 regulators supplied to the United States Army Air Forces bore the Part No. " B-100," and many of the components of the regulator were numbered " B-100-" with a final letter or number to identify the component. The " B-100-" components are interchangeable with the " A-100-" components, differing only in minor construction features, and are now designated as " A-100-" components.

The ALAR regulators have been designed to provide long life and to have permanent adjustment for a minimum of inspection and maintenance. Non-metallic parts are kept to an absolute minimum and all exposed parts are made of non-corrosive materials. Permanent adjustment is obtained in the following manner: by using metal to metal sealing surfaces throughout, by having all reacting forces operate in line, by friction-locked adjustment screws, and by fixed spring location.

The delivery pressures to which the ALAR regulators are adjusted are shown in Table II. The pressures are those which will give physiologically adequate oxygen flow at all altitudes for an inactive person when the flow is metered through an 0.016 inch diameter metering orifice. Any deviation from the 0.016 inch diameter orifice will give a variation in Table II flows directly proportional to the change in orifice area. Thus, if some person such as a crew member required double the oxygen at all altitudes due to higher level of activity, he would, by connecting to the distribution system through a metering orifice of twice the area (0.023 in. dia.), receive the proper oxygen flow. The pressure tolerances indicated in Table II are specified to cover variations due to combinations of inlet pressure, temperature, flow demand, and vibration.

TABLE II

Altitude in Ft. above Sea Level	Delivery Pressure p.s.i. Absolute	Flow at Altitude in L/min. (Corrected to 760mm & 70 F) Thru 0.016" Dia. Orifice
0	19.5 ± 2.0	1.1 ± 0.2
10,000	18.5 ± 2.0	1.6 ± 0.2
20,000	23.1 ± 2.5	2.0 ± 0.2
30,000	26.5 ± 2.5	2.4 ± 0.2

INSTALLATION

The ALAR A-2000 is installed between the oxygen supply and the oxygen distribution systems. The supply can be at any pressure between 35 and 2200 p.s.i. and the oxygen flow taken from the distribution line can be anything from 0 to 48 liters per minute per regulator. The A-100 regulator will supply the same oxygen flow, but the inlet pressure must not exceed 500 p.s.i. The A-11 and AN-6010-1 also operate at a maximum inlet pressure of 500 p.s.i. but the oxygen flow should not exceed 36 liters per minute per regulator. The manner in which this flow is taken, whether it be through small or large metering orifices, has no effect on the regulator. Additional regulators may be installed in parallel to meet oxygen flow requirements in excess of the capacity of one regulator.

The oxygen line connecting supply cylinders to regulator inlet should be of sufficient strength to withstand the supply pressure, and the distribution line should be of sufficient size to handle the flow. Standard 5/16 in. O.D. metallic tubing will handle the full capacity of one ALAR regulator for lengths up to thirty feet without serious pressure drop.

Mounting dimensions are shown in Figure 2, and apply to all ALAR regulators.

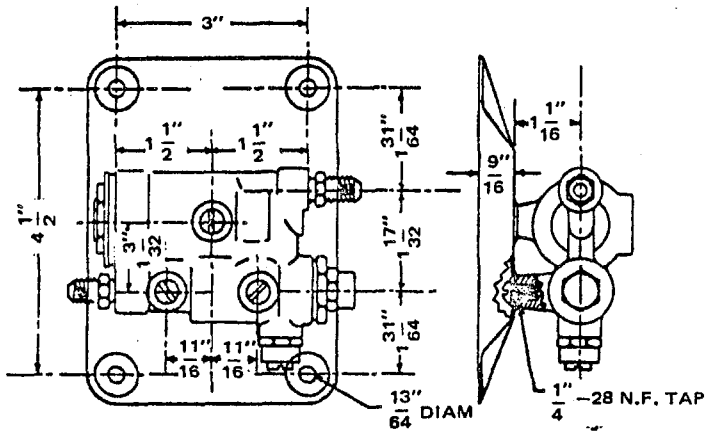

Figure 2

CAUTIONS

Care must be taken to see that the pressure supplied to the regulator does not exceed that for which the regulator is intended.

Under no circumstances should the outlet of an ALAR regulator be connected to an oxygen source which will create a pressure on the outlet side of the regulator greater than 40 p.s.i.

It is very important that all moisture and foreign particles be removed from the oxygen lines before a regulator is installed.

SPECIAL PRECAUTION:

EXTREME CARE MUST BE EXERCISED TO PREVENT ANY OIL OR GREASE FROM COMING IN CONTACT WITH OXYGEN EQUIPMENT, SINCE SPONTANEOUS COMBUSTION MIGHT OCCUR. SPECIAL COMPOUNDS ARE AVAILABLE FOR USE WITH HIGH PRESSURE OXYGEN.

INSPECTION AND TESTS

Although ALAR Oxygen Regulators are designed to operate several years without

inspection or maintenance, unusual conditions of use may warrant an inspection test. Actual failure of a regulator part or loss of calibration will require removal from the airplane and complete examination on a calibration stand. However, there are several inspection tests which can be performed while the regulator is installed in the aircraft.

The delivery pressure can be measured by substituting an accurate pressure gage for an oxygen mask and plugging into one of the outlets---preferably one nearest the regulator to eliminate false readings due to line drop. At least three other outlets for each regulator installed in the distribution system should be open and flowing in order to eliminate the slight elevation of pressure which occurs at zero flow in pressure regulators of this type due to forces necessary to effect 100% shut-off at the valve seat. Pressures thus obtained may then be compared with those of Table II to give an indication of performance at the altitude at which the reading is made. Also, the effect on full flow capacity pressure will be indicated by opening all outlets handled by the regulators being tested. Naturally this gives only one pressure measurement to indicate over-all performance, unless the pressures are taken in flight and over a sufficient range in altitudes to give more than one comparative reading. Extreme care must be taken to always correct for barometric pressure and convert to the absolute scale as indicated in Table II. The pressure gage should be accurate to within 1/4 p.s.i., otherwise a mercury manometer should be employed. Since the regulator is of simple direct acting design, a correct pressure reading for one altitude is a good indication of correct calibration for all altitudes.

The only other type of test that can be conducted on the regulator while installed, is a leakage test which can be made with soap solution or observed by pressure drop in the system isolated from the supply cylinders. From the above leakage and delivery pressure tests, the following regulator failures will be indicated:

1. Delivery pressures which are slightly out of limits given in Table II indicate loss of adjustment by the altitude compensating or minimum pressure regulating systems.

2. Excessively high delivery pressures at low flow (one or two outlets open) indicates dirt on the second stage valve seat (A-100-G). Some pressure elevation at zero flow is to be expected.

3. Excessively high pressure at full flow (20 passenger outlets or equivalent open) indicates loss of vacuum in the compensating bellows (A-100-D).

4. Exact location of leakage will be indicated by soap bubble test except at the second stage adjustment cap where internal leakage at the actuating bellows (A-100-E) is indicated. Also, leakage at the relief valve openings may indicate failure other than at the relief valve seat.

5. A small but steady leak at the relief valve indicates loss of adjustment of first stage, dirt on the first stage valve seat, or dirt on the relief valve seat.

6. A large flow from the relief valve indicates a break in the regulating bellows (A-100-A).

Any of the above outlined failures except leakage at fittings, which can be stopped by tightening, require that the regulator be dismantled from the plane before repair or recalibration can be made.

REPAIR AND CALIBRATION

IT IS RECOMMENDED THAT, IF REPAIR AND CALIBRATION ARE NECESSARY, THE REGULATOR BE RETURNED TO THE MANUFACTURER. However, if conditions require calibration be done by the user, the following paragraphs describe a simple method of recalibration.

Tools required for assembly and disassembly are a set of extra deep socket wrenches, small screw driver, and adjustable wrench. Any damaged assemblies must be replaced with a new assembly. On re-assembly, care must be taken to keep the regulator free from loose particles, oil, or dirt; and all aluminum to aluminum threads must be treated with an anti-sieze compound suitable for use with oxygen.

A simplified calibration set-up is shown in Figure 3, and the basic equipment required consists of the following:

1. A 35 to 2200 p.s.i. source of oxygen that may be accurately controlled at pressures up to 500 p.s.i.

2. A 0 to 150 p.s.i. pressure gage for connecting into the relief valve opening for measuring first stage pressures.

3. A 0 to 30 p.s.i. calibrated gage or equivalent mercury manometer to be installed in the outlet line for measuring regulator delivery pressures.

4. An altimeter, mercury manometer or vacuum gage to measure altitude conditions for calibration. It will be necessary to place the altimeter in a bell jar unless it has a well-constructed airtight case.

5. A globe valve to shut off altimeter and connection to second stage cap while leakage tests are being conducted.

6. A large capacity manual control needle valve having oilfree packing.

7. A source of vacuum capable of maintaining a vacuum of at least 22 inches of mercury with a flow of four cubic feet per minute.

8. Five special adapters will have to be made: (1) to connect the first stage pressure gage to the relief valve opening (5/16-32 NEF thread), (2), (3) and (4) are outlet fittings to house metering orifices equivalent to low and high flow distribution line conditions, and (5) a special Tee to connect the second stage adjustment cap opening (5/16-32 NEF thread) with a line leading to the downstream side of the metering orifice, one branch of the Tee being left open to prevent back pressures on the actuating and compensating bellows. The opening may be closed with a finger when altitude tests are conducted.

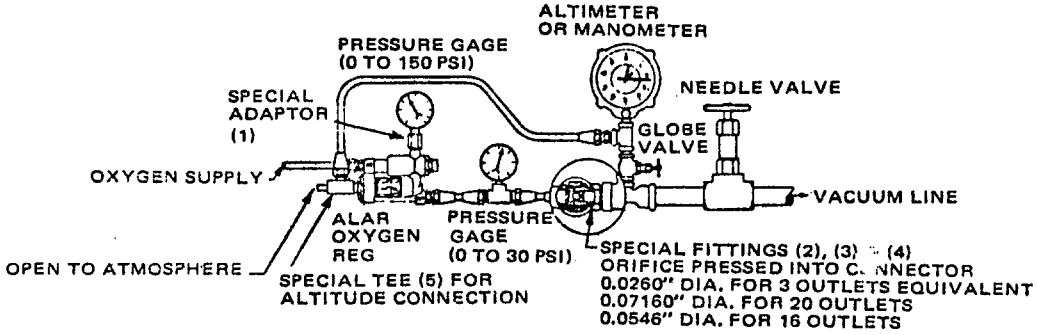

Figure 3

The calibration procedure is as follows:

1. Install the 3 outlet orifice in the line, adjust the oxygen inlet pressure to 90-110 p.s.i. and open the vacuum line sufficiently to remove the back pressure from the altitude gage and connection to the second stage cap. Then observe the first stage pressure on the gage installed in the relief valve opening. This pressure should be between 58 and 62 p.s.i. for A-2000 regulators and should be 65 to 70 p.s.i. for the A-100. If this pressure is not within the proper limits, shut off the inlet pressure, remove the first stage adjustment cap and turn the screw to a point where the pressure is within these limits when the inlet pressure is reapplied.

Adjustment of A-11 and AN-6010-1 regulators is the same as for the A-100 except that A-11 regulators may have first stage pressures as high as 80 p.s.i.

2. Manipulate the vacuum line valve to a point where an altitude reading of 20,000 feet is obtained, and observe the delivery pressure as indicated by the gage in the outlet line. If the delivery pressure does not agree with Table II, remove the vacuum line (atmospheric) connection from the second stage adjustment screw opening, and turn the adjusting screw to a point where the desired pressure is obtained upon re-application of the 20,000 ft. vacuum.

3. Check the delivery pressure against Table II for the other altitudes given for the full range of inlet pressures, and for flow orifices of diameters equivalent to 3 and 20 outlets (3 and 15 outlets for A-11 and AN-6010-1).

4. First stage pressures of A-2000 regulators should not drop below 27 p.s.i., and not below 40 p.s.i. for A-100 regulators, under any conditions of inlet pressure or flow.

5. The valve mechanism is tested for leakage by imposing the maximum inlet pressure and shutting off the vacuum control valve. If there is a continuous rise in pressure indicated on either gage, a valve leak is indicated. Leakage around caps and fittings may be checked by shutting off the supply and observing if the pressure readings drop. For these leakage tests, close the globe valve shutting off the altimeter and connection to second stage cap. Care must be taken so that no leakage occurs through the valves and fittings connected to the regulator.

It is advisable that a final leakage test with the relief valve in place be conducted with separate equipment involving fewer valves and fittings and utilizing a very accurate inlet pressure gage capable of indicating pressure changes of one pound per square inch. An inlet pressure of 500 p.s.i. is suitable for all regulators.

The inlet pressure gage should be connected to the regulator on a line with a valve so arranged that the system may be charged to the desired pressure and then disconnected from the oxygen supply. Any leakage will be indicated by a drop in inlet pressure. Some variation in the inlet pressure will be caused by temperature changes such as that occurring when an oxygen line is suddenly charged to a high pressure. A few minutes delay in making initial observations will allow equilibrium conditions to be established and minimize the effect of temperature changes.

Leakage to the outlet may be determined at the same time by connecting a 0 to 30 p.s.i. pressure gage to the outlet of the regulator. Internal volume of this gage and connecting tubing should not exceed two cubic inches.

With a gage and connecting tubing have an internal volume of five cubic inches, inlet pressure decrease due to leakage must not exceed 3.5 p.s.i. in 15 minutes.

Leakage to the outlet shall be such that the pressure indicated on the outlet gage shall not exceed 15 p.s.i. when leakage tests are conducted at a barometric pressure of approximately 760 millimeters of mercury. Inasmuch as the A-2000 and A-100 regulators provide a minimum pressure to allow flow at sea level and some pressure elevation occurs when no oxygen is flowing through the regulator, the initial pressure indicated by the outlet pressure gage will range from 8 to 12 p.s.i.

All pressures referred to in the above calibration procedure are gage pressures at sea level. Since the ALAR regulators are designed to maintain definite Absolute pressures, and tests made at altitudes appreciable above sea level will increase gage pressures by an amount equivalent to the atmospheric pressure decrease.

The ALAR oxygen regulator design has had sufficient laboratory and service tests to verify that the above calibration test with replacement of damaged assemblies will fit the regulator for continued service. Should difficulty be experienced in conducting the above tests, contact the manufacturer for further information.

5500 & 5600 SERIES
COMPONENT MAINTENANCE MANUAL WITH IPL

INTRODUCTION

This manual establishes the proper maintenance procedures which shall be followed by user maintenance, overhaul and service personnel when performing any type of service on the 5500 Series and 5600 Series Portable Oxygen Units described herein.

It is the primary intent of this manual:

a. To specify proper safety regulations to be followed during performance of service on oxygen equipment used in aviation applications.

b. To establish proper sequence of operations to be performed on the defined equipment.

c. To provide the user with the data necessary to properly maintain, check, test and repair the equipment.

The following WARNINGS are presented to inform the user of this manual of the requirements which shall be adhered to when performing service procedures on this equipment. Additional WARNINGS will be found in the procedural steps in the manual.

WARNING: ANY SERVICE OR OVERHAUL PERFORMED ON THIS APPARATUS SHALL BE DONE ONLY BY THOSE FACILITIES EXPERIENCED IN, OR BY PERSONNEL KNOWLEDGEABLE IN AVIATION OXYGEN EQUIPMENT. IF NONE ARE KNOWN, CONTACT SCOTT AVIATION OR ITS DISTRIBUTORS FOR NAMES OF AUTHORIZED SERVICE CENTERS.

WARNING: ALL PROCEDURES DESCRIBED IN THIS MANUAL SHALL BE PERFORMED IN AN AREA FREE OF OIL, GREASE, FLAMMABLE SOLVENTS OR OTHER COMBUSTIBLE MATERIALS. SUCH MATERIALS, AS WELL AS DUST, LINT, AND FINE METAL FILINGS ARE ALL POTENTIAL COMBUSTIBLES WHICH MIGHT, WHEN EXPOSED TO OXYGEN UNDER PRESSURE IGNITE AND RESULT IN AN EXPLOSION AND/OR FIRE.

WARNING: DO NOT ALLOW OIL, GREASE, FLAMMABLE SOLVENTS, OR OTHER COMBUSTIBLE MATERIALS TO COME IN CONTACT WITH PARTS THAT WILL BE EXPOSED TO PRESSURIZED OXYGEN. SUCH MATERIALS, AS WELL AS DUST, LINT, AND FINE METAL FILINGS ARE ALL POTENTIAL COMBUSTIBLES WHICH MIGHT, WHEN EXPOSED TO OXYGEN UNDER PRESSURE, IGNITE AND RESULT IN AN EXPLOSION.

PORTABLE OXYGEN BREATHING EQUIPMENT

DESCRIPTION AND OPERATION

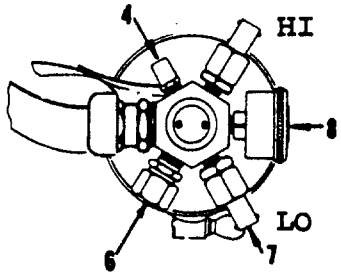
1. General

   A. This manual provides overhaul instructions with illustrated parts list for the 5500 series and 5600 series Portable Oxygen Breathing Units.

   B. The instructions in this manual apply to all assemblies unless specific reference is made to a particular part number.

2. Description

   A. Each of the various assemblies (see figure 1) consists of an oxygen cylinder (1), pressure regulator (2), "ON-OFF" valve (3), relief valve (4), safety plug (5), charging valve (6), constant flow mask outlet assembly (7), and gauge (8). In addition the 5600 series contains a demand type or pressure demand type oxygen regulator (9). The part number of a particular assembly is determined by the part numbers of the various components that make up the assembly.



3. Leading Particulars. See figures 2 and 3 for leading particulars.

4. Purpose of Equipment

   A. This equipment provides a portable oxygen breathing source. The 5500 series contains outlet assemblies used to adapt a rebreather type mask. The rebreather type mask provides the user with supplementary oxygen for high altitude breathing and/or therapeutic use. The 5600 series provides oxygen for the above uses and, in addition, provides a walk-around oxygen supply for a demand type mask suitable for smoke and fume protection.

5. Typical Installation

   A. All assemblies are completely portable and have a carrying strap. They should be stored in a convenient and accessible location.

6. Overall Operation

   A. Oxygen is supplied from the high pressure cylinder to the pressure regulator. The safety plug, pressure gauge and "ON-OFF" valve are exposed to cylinder pressure. The "ON-OFF" valve controls the flow of oxygen from the cylinder to the regulating mechanism in the regulator body. It also controls the flow of oxygen from the charging valve to the cylinder.

      When the valve is in the "OFF" position, oxygen cannot flow through the regulator. The safety plug contains a fusible alloy and burst disc. In the event of excessive heat, the fusible alloy melts, and with subsequent pressure rise, the safety disc ruptures and allows cylinder oxygen to be vented to atmosphere. The pressure gauge indicates the pressure of the oxygen in the cylinder.

   B. When the "ON-OFF" valve is open, oxygen flows into the upper portion of the regulator body, which contains the pressure reducing mechanism. It reduces the cylinder oxygen pressure to a lower pressure which is suitable to supply a rebreather type mask, through the outlet assemblies, or a demand regulator.

   C. The regulator contains a charging valve assembly which enables the cylinder to be filled (recharged) with high pressure oxygen. A relief valve is located in the low pressure portion of the regulator to protect the regulating mechanism against over pressurization.

7. Detailed Operation.

   A. "ON-OFF" Valve. The "ON-OFF" valve (3, figure 4) is a rotary type valve installed in the high pressure portion of the pressure regulator. Rotation of the valve knob in a clockwise direction causes the valve head assembly to seat against a port in the regulator body, thus preventing flow to the upper portion of the regulator. Rotation of the knob in a counterclockwise direction opens the port and allows oxygen to enter the pressure regulating mechanism.

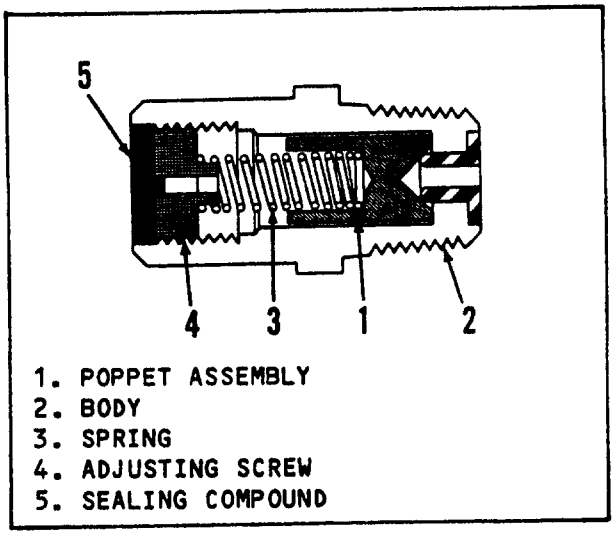
Regulator Cross Section
Figure 4

B. Safety Plug. The safety plug (4, figure 4) is installed in the high pressure portion of the regulator. The center of the plug is filled with a low melting point metal alloy. In the event of fire, the alloy melts and with subsequent pressure rise, the safety disc ruptures and allows the oxygen to vent to atmosphere, thus preventing a hazardous pressure build up in the cylinder.

C. Pressure Gauge. The pressure gauge (8, figure 1) is installed in the high pressure portion of the regulator. It indicates the pressure of the oxygen in the high pressure cylinder, thus giving an indication of the amount of available oxygen.

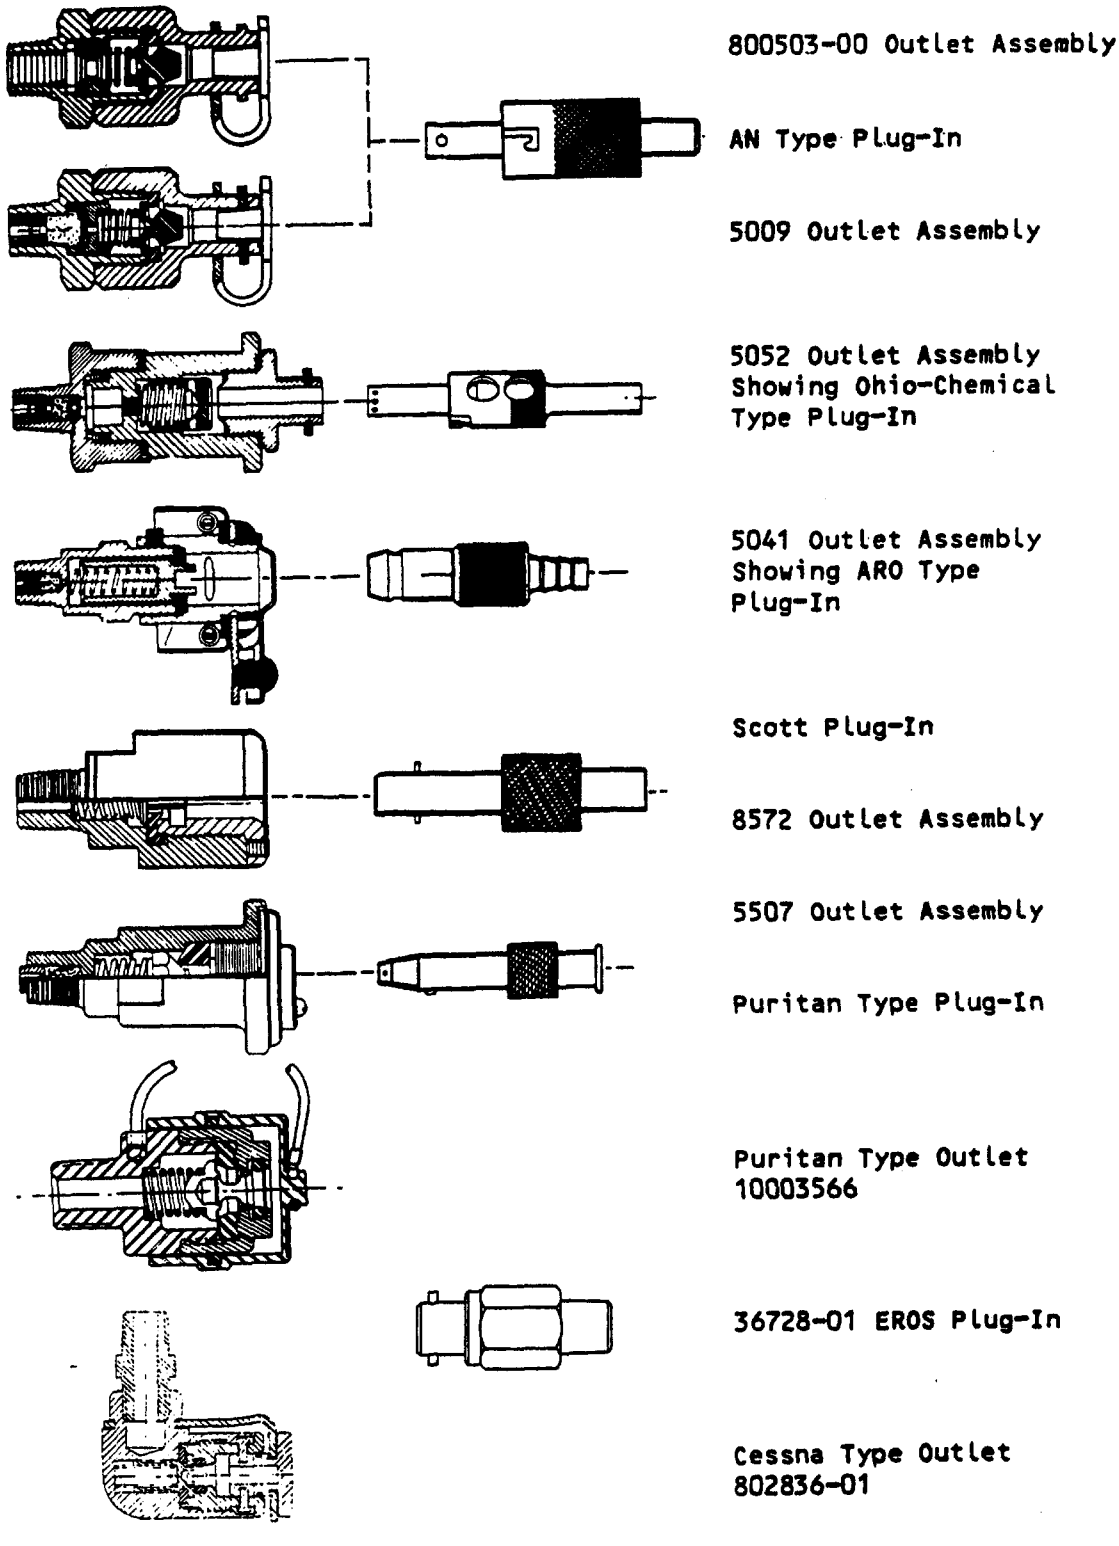


D. Pressure regulator. Pressure regulator (see figure 4) reduces high pressure oxygen to a lower pressure. When the "ON-OFF" valve is open, oxygen flows to the pressure reducing mechanism. It performs in the following manner. High pressure oxygen and spring (9) act upward on thrust pin (10). These forces act to seat the pin against valve seat (11) to prevent flow out of the regulator. The other end of the pin rests against thrust plate (12) and diaphragm (13). One side of the diaphragm is acted upon by spring (14) and the other side is acted upon by outlet pressure. The spring acts downward and tends to move thrust pin (10) away from seat (11). Outlet oxygen pressure acts upward on the diaphragm to counter the spring pressure. Oxygen will flow through the regulator as long as the force of spring (14) exceeds the outlet pressure and forces tending to move thrust pin (10) against its seat. However, an increase in outlet pressure counter-balances spring (14), and thrust pin (10) is forced toward its seat by inlet oxygen pressure and spring (9) until a condition of equilibrium is established and regulator pressure is maintained. Spring (14) is preset to maintain an outlet pressure of approximately 55 psi (0.38 MPa).

E. Charging valve assembly. Charging valve assembly (see figure 5) is used to fill the oxygen cylinder with high pressure oxygen. Since it is located in the upper portion of the regulator, the "ON-OFF" valve must be open to allow oxygen to flow into the cylinder. High pressure oxygen applied at charging valve inlet (1) forces valve (2) away from its seat, and oxygen flows through porting into the high pressure cylinder. The valve seats against its housing to prevent flow out of the cylinder. A cap installed on the charging valve prevents seepage past valve (2).

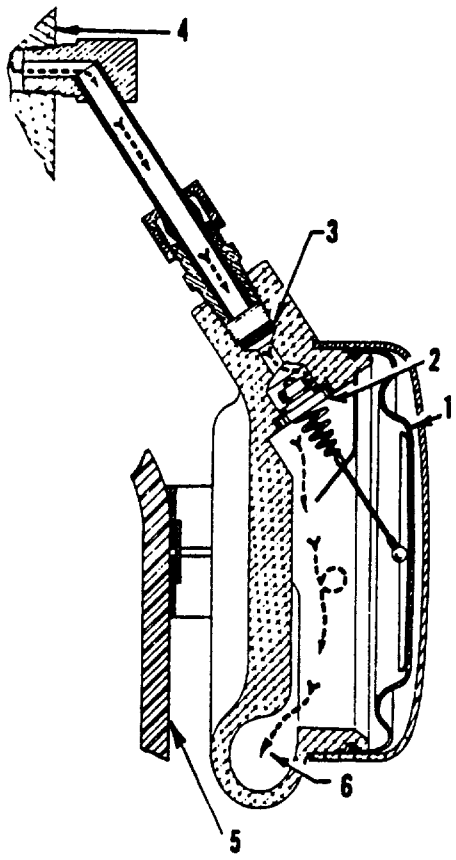
Charging Valve Assembly
Figure 5

F. Relief Valve. Relief valve (see figure 6) is installed in the low pressure portion of the regulator. The relief valve serves as a safety device to prevent excessive outlet pressure build-up. In the event of excessive outlet pressure poppet assembly (1) is forced away from it seat in body (2), and oxygen is vented through the openings in the body. When pressure drops to an acceptable value, spring (3) forces the poppet against its seat, thus stopping the flow of oxygen.



Relief Valve
Figure 6

G. Outlet Assemblies. Different outlet assemblies are available. The type used on a particular installation is dependent on the type of mask insert to be used. Each outlet is similar in that it contains an internal check valve and an oxygen hose plug-in adapter. Part number 8572, 10003566, 36728-01 and 800503-00 are unrestricted flow outlets. All other outlets contain glass cord for metering flow. When a plug-in is inserted in an outlet, it opens the check valve and allows flow into a mask.



H. Two outlet assemblies are provided on most 5500 series assemblies although one and three outlets may also be found. The 5600 series may contain one or two outlet assemblies. Different outlet assemblies are illustrated in figure 7.

I. Demand Regulator (See figure 8.) The 5600 series contains a demand type regulator. The inlet of the regulator is connected to one of the pressure reducer outlet openings. The demand regulator allows oxygen to flow, on demand, to a demand type mask. Inhalation in the demand mask withdraws oxygen from the body of the demand regulator. This causes a pressure drop in the regulator case which allows atmospheric pressure, acting on the outside of diaphragm (1), to force the diaphragm inward against the stem of valve (2). This action opens the valve and causes oxygen to enter the regulator body, thus raising the pressure in the regulator body. The increased pressure moves the diaphragm away from the valve stem, thus stopping the flow of oxygen. The regulator functions in this manner to supply oxygen on demand.

J. Pressure Demand Regulator. (See figure 8.) This unit is similar to the demand regulator described in step 9 except that the cover has a slide lever to select demand or pressure-demand modes. In the pressure-demand mode the diaphragm is slightly loaded with a spring. This causes the regulator to build up a positive pressure before shut-off. Masks used with this regulator must have compensated exhalation valves.

TESTING AND FAULT ISOLATION

1. Testing

WARNING: IN ALL PROCEDURES LISTED BELOW, OXYGEN IS SPECIFIED AS THE TEST GAS. WATER PUMPED NITROGEN OR OIL-FREE AIR MAY BE SUBSTITUTED, BUT RESULTS MUST BE CONVERTED PRIOR TO BEING COMPARED WITH THE RESULTS SPECIFIED FOR OXYGEN. DO NOT, UNDER ANY CIRCUMSTANCES, USE OIL PUMPED GAS AS THIS WILL CAUSE CONTAMINATION OF THE REGULATOR AND TEST EQUIPMENT. OIL, EVEN IN MINUTE QUANTITY, COMING IN CONTACT WITH OXYGEN MAY CAUSE AN EXPLOSION OR FIRE.

NOTE: Table 101 lists the consumable materials necessary for testing. Equalvent materials may be used.

MATERIAL	DESCRIPTION	MANUFACTURER*	REFER TO TESTING PARAGRAPH
Leak Test Solution	Snoop (MIL-L-25567)	V18034	1.C.(2) 1.F.(12) 1.C.(5) 1.G.(2) 1.C.(6)
Oxygen	MIL-O-27210, Type I	V07098	All

*Refer to Illustrated Parts List, paragraph 1.E for Vendor's Code

List of Consumable Materials for Testing
Table 101

NOTE: The equipment required to perform testing procedures are listed on each of the figures in this section. With the exception of equipment listed with Scott part numbers, all test equipment is considered to be "standard" in oxygen repair shops. Equivalent equipment may be used.

A. All tests shall be conducted with a cylinder pressure of 1800 +50, -0 psi (12.41 + 0.34, -0 MPa). Fully charge the cylinder to 1800 +50, -0 psi (12.41 + 0.34, -0 MPa) in accordance with the following instructions.

(1) Check the pressure shown on the pressure gauge. If it indicates less than 1800 +50, -0 psi (12.41 + 0.34, -0 MPa), the cylinder shall be charged.

(2) Use an oxygen charging system as shown in figure 101.

(3) Open the "ON-OFF" valve fully, and remove the cap from the charging valve.

(4) Connect the supply cylinder set up (see figure 101) to the charging valve.

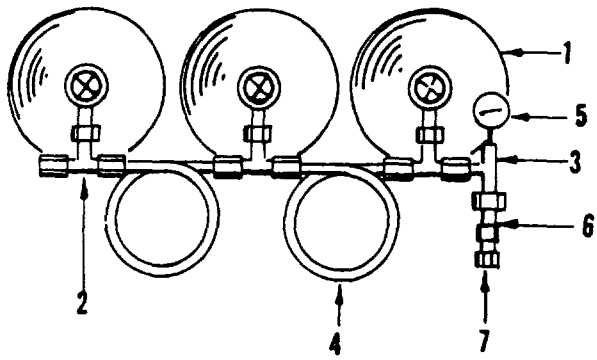
(5) Slowly open the supply cylinder valve, charging at a rate not to exceed 300 psi (2.07 MPa) per minute. Compare the indications of the gauge on the unit and the gauge of the supply cylinders. When the pressure in the breathing oxygen cylinder equals the supply cylinder pressure, close the supply cylinder valve. Allow the cylinder to cool, and recheck the pressure shown on the pressure gauge. The cylinder shall contain 1800 +50, -0 psi (12.41 + 0.34, -0 MPa) at not over 70°F (21.1°C).

B. Relief Valve

(1) Connect the relief valve to a suitable oxygen pressure source.

(2) Apply 90 psi (0.62 MPa) to the relief valve. Valve must hold 90 psi (0.62 MPa).

(3) Increase pressure to 135 psi (0.93 MPa). Relief valve must flow fully.



(4) Reduce pressure to 90 psi (0.62 MPa). Valve must reseat.

C. Outlet Assemblies

(1) Connect the appropriate outlet assembly to a suitable oxygen pressure source.

(2) Apply 55 ± 2 psi (0.38 ± 0.01 MPa)to the outlet assembly and apply leak test solution to all body joints and the outlet port. Bubbles indicate leaks which must be corrected.

(3) Insert the appropriate mask plug-in into the outlet. The plug-in must be securely held and allow oxygen to flow.

1. SUPPLY CYLINDERS
2. TEE, P/N 6258
3. TEE, P/N 6145
4. PIGTAIL, P/N 5082
5. OXYGEN GAUGE 0-2000 PSI (0 - 13.79 MPa)
6. REFILL COUPLING, P/N 5020
7. CONNECT CHARGING VALVE OF PORTABLE BREATHING UNIT TO REFILL COUPLING

Setup for Recharging Portable Breathing Unit
Figure 101

(4) Shut off the oxygen supply to the outlet assembly. Connect a suitable flowmeter to the mask plug-in. Apply an inlet pressure of 55 ± 2 psi (0.38 ± 0.01 MPa). The flow for a particular outlet is determined by the coding of the 5500 or 5600 part numbers (see figure 2 and 3) of which the outlet is a part. This code is also stamped on the hexagonal base of each outlet. When flow settings differ on outlets of one 5500 or 5600 unit, "LO" flow and "HI" flow are indicated on the appropriate outlet assemblies. At ground level, outlet flows must agree with the values listed in figure 102 for the particular flow and altitude markings. If flows to not agree, adjust the outlet assembly in accordance with the following instructions.

(5) Check for external leakage at the joint of the outlet and the mask plug-in using leak test solution. No leakage is allowed.

(6) Remove the plug-in and check for leakage at the outlet port using leak test solution. No leakage is allowed.

NOTE: Outlet assemblies, part numbers 10003566, 8572, 36728-01 and 800503-00 are unrestricted flow outlets and do not contain glass cord packing.

(a) Remove the oxygen supply from the outlet assembly.

(b) Flow adjustment is accomplished by compressing the glass cord. This is done by threading the adjusting screw into the outlet. This action serves to decrease flow. Adjust and test outlets until desired flow is obtained.

ALTITUDE FLOW LITERS/MINUTE (STPD) (760 mm Hg, 0°C)	ALTITUDE - FEET X 1000					
	5	10	15	20	25	30
	REQUIRED GROUND LEVEL FLOW SETTING IN LITERS/MINUTES (NTPD) (760 mm Hg, 21°C) PERMISSIBLE TOLERANCE ±5%					
0.5	0.74	0.86	0.91	0.96	1.00	1.08
0.7	0.96	1.10	1.15	1.20	1.24	1.32
2.0	2.51	2.65	2.72	2.80	2.84	2.89

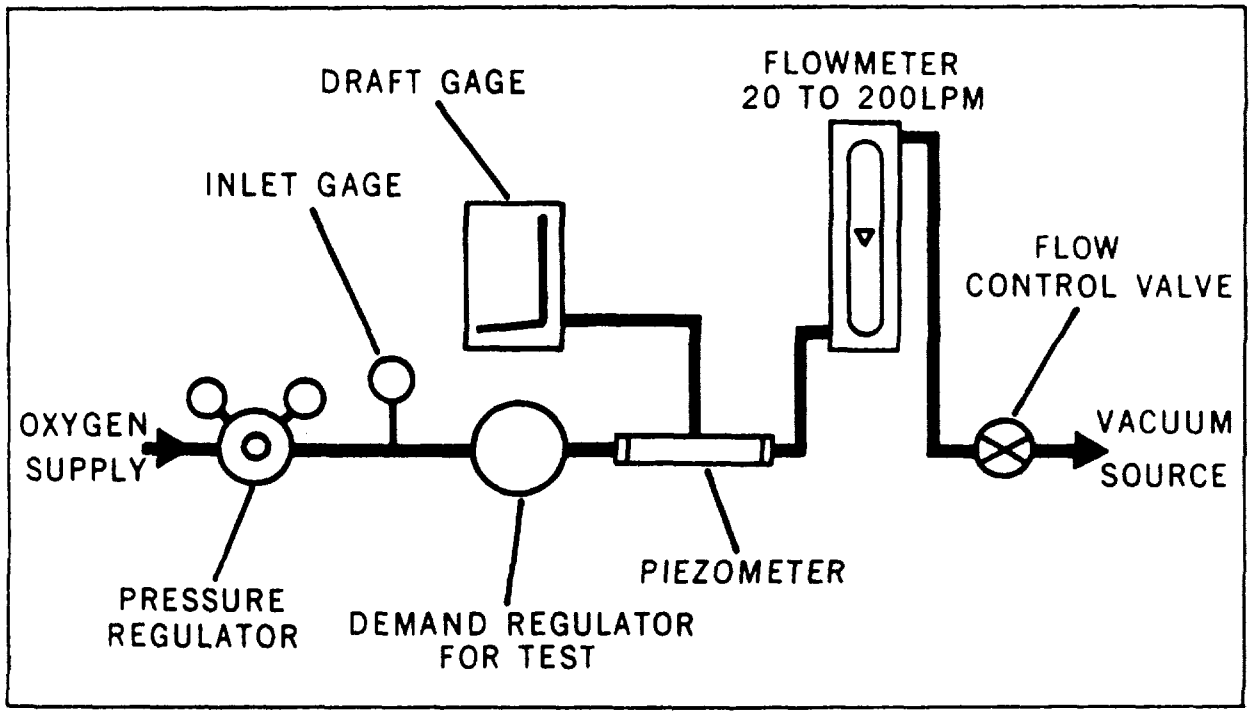
8.0	9.58	9.71	9.92	10.02	10.12	10.25

NOTE: Interpolate given values to obtain flow settings for altitudes between given altitudes.

Outlet Assembly Setting
Figure 102

NOTE: Since glass cord will not expand once compressed, removal of adjusting screw will not alter flow. Adjustment should be done with care. The only method for increasing flow is to remove the compressed glass cord and repack the outlet assembly.



D. 6379-2 Series Demand Regulator Test. (See figure 103.)

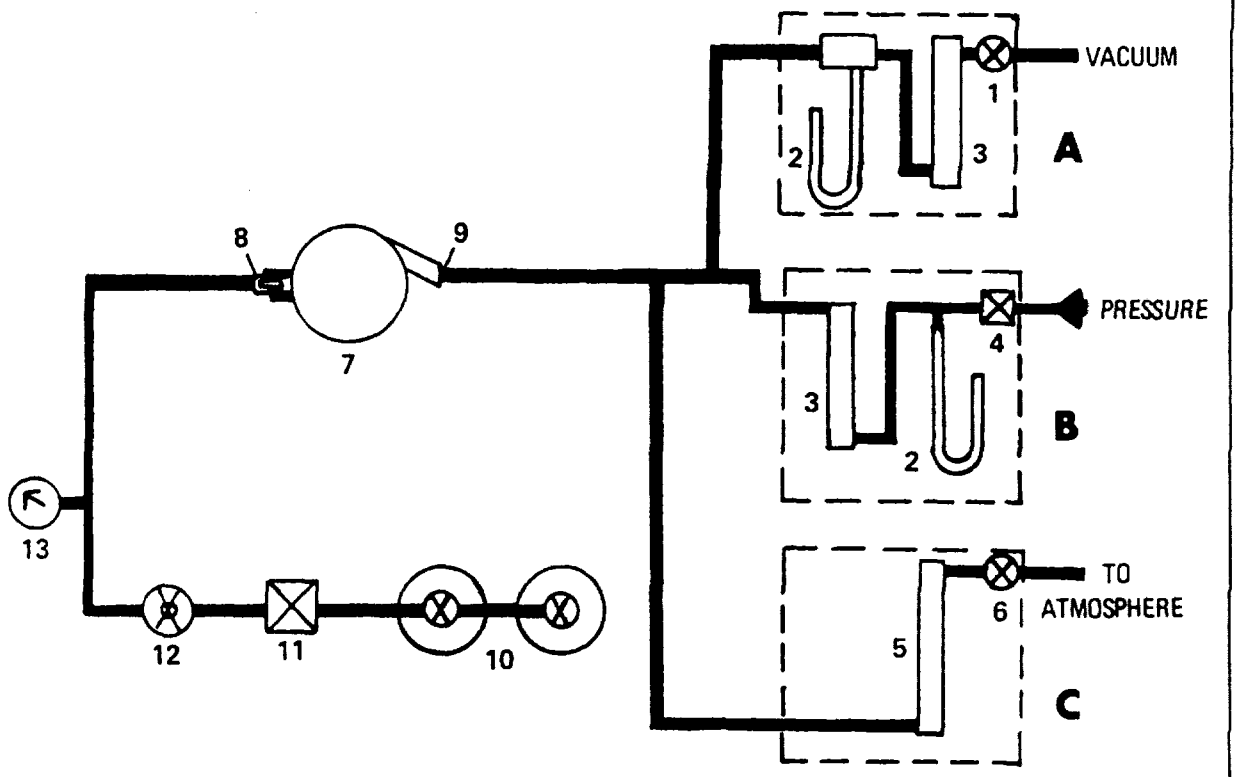
(1) Connect an assembled regulator to the test setup shown in figure 103.

(2) With inlet pressure of 35 psi (0.24 MPa), adjust flow control valve for a minimum flow of 20 liters per minute. Resistance, indicated on draft gauge, shall not be greater than 0.7 inches (17.78 mm) of water.

(3) With inlet pressure of 85 psi (0.59 MPa), adjust flow control valve for a minimum flow of 125 liters per minute. Resistance, indicated on draft gauge, shall not be greater than 2.0 inches (50.8 mm) of water.

NOTE: The regulated inlet pressure must be maintained during test.

Test Setup for Demand Regulator P/N 6379
Figure 103



E. 800649 Pressure/Demand Regulator Tests

(1) Proof Pressure Test
(a) With the selector switch in the "DEMAND" position, apply 125 psi (0.86 MPa) to the inlet port and hold for two minutes. Relieve the pressure. There shall be no evidence of damage, deterioration, or permanent set. Acceptable performance of the unit in the following tests will indicate conformance to this requirement.

(2) Overpressure Test (See figure 104, Parts A and B)
(a) Seal the regulator assembly inlet port, keeping the selector switch in the "DEMAND" position.
(b) Apply a negative (vacuum) pressure of 29 inches (736.6 mm) H_2O to the outlet port for two minutes per Part A, then relieve the pressure.
(c) Apply a positive pressure of 24 inches (609.6 mm) H_2O to the outlet port for two minutes per Part B, then relieve the pressure.
(d) Carefully remove the regulator cover and inspect for integrity of the diaphragm tie cord and for damage (bending) of the diaphragm plate.
(e) Replace the regulator cover and proceed with the following tests.

(3) Inward Leakage (See figure 104, Part A)
(a) Seal the regulator assembly inlet port, keeping the selector switch in the "DEMAND" position.
(b) Apply a negative (vacuum) pressure of 1 inch (25.4 mm) H_2O as indicated on manometer (2) to the outlet port.
(c) Leakage, as measured on flowmeter (3), shall not exceed 100 cc/min.

(4) Outward Leakage (See figure 104, Part B)
(a) Seal the regulator assembly inlet port, keeping the selector switch in the "DEMAND" position.
(b) Apply a positive pressure of 12 inches (304.8 mm) H_2O as indicated on manometer (2) to the outlet port.
(c) Leakage, as indicated on flowmeter (3), shall not exceed 100 cc/min.

1. NEEDLE VALVE
2. MANOMETER (0-30 in.) (0-762 mm) H_2O
3. FLOWMETER (0-150 cc/min.) (0-100 LPM)
4. PRESSURE REGULATOR
5. FLOWMETER (0-15 cc/min.)
6. CONTROL VALVE
7. 800649 REGULATOR UNDER TEST
8. REGULATOR INLET
9. REGULATOR OUTLET
10. OXYGEN SOURCE
11. PRESSURE REDUCER
12. SLOW OPENING VALVE
13. GAUGE (0-200 psi) (0-1.38 MPa)

A. Setup for Overpressure Test (Para. 1.E. (2)) and Inward Leakage Test (Para. 1.E. (3)).

B. Setup for Outward Leakage TEst (Para. 1.E. (4)).

C. Setup for Outlet (Valve Seat) Leakage (Para. 1.E. (5)).

Flow, Leakage and Pressure Tests Setups
Figure 104

(d) Remove the seal from the regulator assembly inlet.

(5) Outlet (Valve Seat) Leakage (See figure 104, Part C)
(a) With he selector switch in the "DEMAND" position, regulator inlet (8) connected to oxygen source (10) and regulator outlet (9) connected as shown in Part C, open valve (12) until 35 psi (0.24 MPa) is indicated on gauge (13).
(b) Open control valve (6); leakage, as indicated on flowmeter (5), shall not exceed 10 cc/min.
(c) Increase pressure until 75 psi (0.52 MPa) is indicated on gauge (13).
(d) Leakage, as indicated on flowmeter (5), shall not exceed 10 cc/min.

(6) Flow Tests (See figure 104.)
(a) With the selector switch in the "DEMAND" position, regulator inlet (8) connected to oxygen source (10) and regulator outlet (9) connected as shown in Part A, open valve (12) until 35 psi (0.24 MPa) is indicated on gauge (13).
(b) Slowly open needle valve (1) until 20 LPM is indicated on flowmeter (3). Manometer (2) shall indicate a maximum of -.75 inches (-19.06 mm) H_2O.
(c) Continue to open needle valve (1) until 70 LPM is indicated on flowmeter (3). Manometer (2) shall indicate a maximum of -1.55 inches (-39.37 mm) H_2O.
(d) Open needle valve (1) until 100 LPM is indicated on flowmeter (3). Manometer (2) shall indicate a maximum of -2.00 inches (-50.8 mm) H_2O. Shut off oxygen supply at valve (12).
(e) Place selector switch in the "PRESSURE DEMAND" position with the regulator still connected as in step (a) above.
(f) Slowly open needle valve until 20 LPM is indicated on flowmeter (3). Manometer (2) shall indicate between +0.5 and +2.0 inches (+12.7 and +50.8 mm) H_2O.
(g) Open needle valve until 100 LPM is indicated on flowmeter (3). Manometer (2) shall indicate between +0.5 and +2.0 inches (+12.7 and +50.8 mm) H_2O.

(h) Slowly close needle valve until 10 cc/min is indicated on flowmeter (3). Manometer (2) shall indicate between +0.5 and +2.5 inches (+12.7 and +63.5 mm) H_2O.

(i) Shut off the supply at slow opening valve (12) and disconnect regulator (7) from the test setup.

F. 5510 Series Regulator Adjustment and Test.

NOTE: Before testing the regulator assembly, make sure it is completely assembled with tested components.

(1) Remove relief valve from regulator and install a 0-100 psig (0.69 MPa) pressure gauge in its place.

(2) Turn the regulator on-off valve to the "ON" position then turn the valve to the "OFF" position.

(3) Vent the upper section of the regulator by engaging a mask plug-in into an outlet and letting the oxygen vent. If no constant flow outlet is used on the regulator, attach a threaded adapter and needle valve to one of the plugged outlet ports. Vent through the needle valve.

(4) Repeat steps (2) and (3) a total of ten times.

(5) Adjust the regulator outlet pressure by turning screw (35, IPL figure 9) as necessary to obtain 55 $\pm$ 2 psi (0.38 $\pm$ 0.01 MPa) pressure as indicated on the gauge attached to the regulator relief valve port. Regulator must be flowing through an outlet while the pressure is being adjusted. If no outlet is being used, use an adapter and needle valve (cleaned for oxygen service) and flow approximately 4 LPM.

(6) Connect a 10 liter per minute flow meter to a suitable mask plug-in and turn the on-off valve to the "ON" position, then connect the mask plug-in to an outlet. Flow, as indicated on the attached flowmeter, must be in accordance with figure 102.

(7) Remove the mask plug-in and check the regulator outlet pressure. Lock-up pressure shall not exceed 75 psi (0.52 MPa).

(9) Turn the regulator on-off valve to the "OFF" position and replace the 0-100 psi (0-0.69 MPa) pressure gauge with the regulator valve.

(10) Repeat steps (1) through (9) a total of three times at 24 hour intervals. Then torque the relief valve per Table 801.

NOTE: The 24-hour time interval is recommended to permit component parts to settle.

(11) Turn the regulator on-off valve to the "ON" position.

(12) Use leak test solution to leak test all regulator joints and outlet ports. Manipulate mask plug-in to simulate use during test. No leakage is allowed. If outlets, gauge or relief valve joints leak, retorque until leak is eliminated. Maximum torque must not exceed values listed in Table 801. If charging valve assembly leaks, retorque until leak is eliminated. Maximum torque must not exceed value listed in Table 801.

NOTE: Always relieve pressure when retorquing fittings.

G. Final Test of Complete Unit.

(1) Turn the regulator on-off valve to the "ON" position.

(2) Use leak test solution to leak test all regulator joints, connections and outlet ports. Check On-Off valve stem area for leakage while turning valve from fully "ON" to "OFF" position and from fully "OFF" back to "ON" position. Manipulate mask plug-in to simulate use during test. No leakage is allowed.

(3) Perform a functional test of the unit by connecting a mask to each of the outlets to assure flow of oxygen. If the unit is a 5600, connect a mask to the demand regulator and don the mask and breathe to assure regulator operation.

2. Fault Isolation

A. See figure 105 for a chart containing troubles, probable causes and remedies.

TROUBLE	PROBABLE CAUSE	REMEDY
A. Leakage		
(1) Leakage at joint between outlet assembly (26, IPL figure 2), relief valve (32, IPL figure 9), or gauge (31 or 31A) and body (49)	(a) Units not assembled to body using sealing tape	Reassembly to body per Assembly, paragraph 2.B, 2.E or 2.F
	(b) Units not tight enough in body	Retorque per Table 801
(2) Leakage at joint between charging valve assembly (24) body and body (49)	(a) Unit not assembled to body using sealing tape	Reassemble to body per Assembly, paragraph 2.C
	(b) Unit not tight enough in body	Retorque per Table 801
(3) Leakage at joint between safety plug (28) and body (49)	(a) Unit not tight enough in body	Retorque per Table 801
	(b) Defective disc (29, IPL figure 9) or washer (30)	Inspect periphery of washer and disc for smoothness. Replace if necessary and retorque per Table 801
(4) Leakage past core of charging valve assembly (24)	(a) Loose or defective core	Replace charging valve assembly
(5) Leakage at joint between bushing (19) and body (49)	(a) Unit not tight enought in body	Retorque per Table 801
	(b) Defective packing (18)	Replace packing

Trouble Shooting Chart
Figure 105 (Sheet 1 of 4)

TROUBLE	PROBABLE CAUSE	REMEDY
A. Leakage (Cont'd)		
(6) Leakage between bushing (19, IPL figure 9) and nut (13)	(a) Loose nut (13, IPL figure 9)	Tighten nut
	(b) Defective packing (14)	Replace packing per Assembly, paragraph 2.K
(7) Leakage between stem assembly (15) and nut (13)	(a) Faulty seat (16)	Replace seat
	(b) Contamination	Clean seal
(8) Demand regulator (7, IPL figure 2) leaks	(a) Contamination on gasket (24, IPL figure 3)	Disassemble demand valve assembly and clean
	(b) Defective demand valve assembly (20) or gasket (24)	Replace demand valve assembly and/or gasket
B. Relief Pressure		
(1) Relief valve (32, IPL, figure 9) does not relieve at proper pressure	(a) Worn parts or contamination	Replace relief valve
C. Oxygen Shut Off		
(1) On-Off valve fails to shut off oxygen in "OFF" position	(a) Faulty head assembly (17 or 17A, IPL figure 9)	Replace head assembly per Assembly, paragraph 2.I

Trouble Shooting Chart
Figure 105 (Sheet 2 of 4)

TROUBLE	PROBABLE CAUSE	REMEDY
D. Outlet Pressure		
(1) Regulator assembly (38, IPL figure 2) fails to provide proper outlet pressure	(a) Regulator assembly not adjusted properly	Readjust regulator assembly per Testing, paragraph 1.F
(2) Regulator assembly (38) fails to hold proper outlet pressure	(a) Defective seat (44 or 44A, IPL figure 9) or pin (45)	Inspect seat and pin per Assembly, paragraph 2.O
	(b) Diaphragm (41) defective	Replace diaphragm
	(c) Diaphragm not sealed to body	Reassemble diaphragm per Assembly, paragraph 2.Q
E. Draft and Flow Requirements		
(1) Outlet assembly (28, IPL figure 2) does not allow proper flow	(a) Worn parts	Inspect parts; replace as necessary
	(b) Parts not properly assembled	Disassemble parts and reassemble properly per Assembly, paragraph 1
(2) Demand regulator (7, IPL figure 2) fails to meet draft and flow requirements	(a) Demand valve assembly (20, IPL figure 3) sticking	Replace demand valve assembly
	(b) Diaphragm (10) punctured	Install new diaphragm per assembly, paragraph 3.E
	(c) Diaphragm (10) not properly assembled to case (28)	Reinstall diaphragm per Assembly, paragraph 3.E

Trouble Shooting chart
Figure 105 (Sheet 3 of 4)

TROUBLE	PROBABLE CAUSE	REMEDY
F. Plug-In Retention		
(1) Outlet assembly (28, IPL figure 2) does not hold plug-in securely	(a) Worn parts	Inspect parts; replace as necessary
	(b) Parts improperly assembled	Disassemble outlet and reassemble properly per Assembly, paragraph 1

Trouble Shooting Chart
Figure 105 (Sheet 4 of 4)

DISASSEMBLY

WARNING: THE OXYGEN CYLINDER SHALL BE COMPLETELY DISCHARGED PRIOR TO PERFORMING ANY DISASSEMBLY.

NOTE: The instructions in paragraphs 1 and 2 list the steps necessary to disassemble each of the Portable Oxygen Breathing Assemblies into major components. Instructions for disassembly of the components are listed in paragraphs 3 through 5.

CAUTION: TO PREVENT POSSIBILITY OF THREAD GALLING, THE REGULATOR BODY SHOULD NOT BE REMOVED FROM THE CYLINDER UNLESS THE CYLINDER IS DUE FOR HYDROSTATIC RETESTING, OR CYLINDER CONTAMINATION IS SUSPECTED.

NOTE: See Testing and Fault Isolation, to establish the condition of the unit or most probable cause of its malfunction. This is to determine the extent of disassembly required without completely tearing down and rebuilding the unit.

1. 5500 Series. (See IPL figure 2.)

   A. Do not attempt to remove regulator (38) from cylinder (60) until all external components have been removed from the regulator.

   B. Identification plate (35) is attached to regulator (38) with drive screws (37). Plates (43, 44 and 44A) are attached by an adhesive. Removal of these plates is not ordinarily required.

   C. Remove clamp (24) and sling (17).

   D. Unscrew and remove outlet assemblies (28).

2. 5600 Series. (See IPL figure 2.)

   A. Remove clamp (24) and sling (17).

   B. Do not attempt to remove regulator (38) from cylinder (60) until all components have been removed from the regulator.

   C. Remove screws (11). Remove clamp (14) to remove bracket (13).

   D. Unthread nut of connector assembly (3). Unthread connector assembly (3) from regulator (7).

E. Unthread elbow assembly (4) and outlet assembly (28) from regulator (38).

F. Identification plate (35) is attached to regulator (38) with two drive screws (37). Instruction plates (43, 44 and 44A) are attached by an adhesive. Removal of these plates is not ordinarily required.

3. 6379 and 800649 Series Demand and Pressure Demand Oxygen Regulators, (See IPL figure 3.)

A. Remove screws (7), and pull cover assembly (6) or cover (14) off case (28). Removal of plates (8, 11 or 12) is not normally required. If removal is necessary, drill out rivets (10 or 13). Remove plate (9) only if damaged.

B. Slightly compress spring (13A) and remove from cover (15) and the lever of plate and lever assembly (13B), then remove the plate and lever assembly.

C. Disconnect and remove spring (13C) from button (13D) then remove the button from cover (15).

D. Remove cord (17) and take diaphragm assembly (16) off case (28).

E. Unthread screws (19), and remove deflector (18).

F. Remove screws (21) and washers (22 and 23). Pull valve assembly (20) out of case (28). Remove gasket (24).

G. Remove screen (27) from the inlet port of case (28) only if necessary.

H. Unscrew adapter (25 or 26) from the outlet port of case (28).

I. If bracket on case (28) appears damaged, drill out attaching rivets. Do not remove the bracket if it is undamaged.

4. Outlet Assemblies.

A. Part No. 5041. (See IPL figure 4.) Unthread screw (6). Remove screen (7), and pick glass cord (8) out of body (12). Remove screen (9), if necessary. Unscrew nut (3), and remove cover (2). Slide cap (4) and washer (5) off case (18). Remove screw (11). Unthread body (12) from case (18). Take spring (13), valve (14), and seat (15) out of case (18). Remove latch springs (16) and pins (17).

B. Part No. 5009. (See IPL figure 5.) Remove cover (3). Remove screw (4), screen (5) and pick glass cord (6) out of stud (8). Unthread stud (8) from receptacle (19). Remove valve (11), spring (13), and gasket (10). Thread flow port (14) out of stud (8). Remove gasket (18). Snap ring (16) out of flow port (14) and remove filter (17).

C. Part No. 800503-00. (See IPL figure 5.) Remove cover (3). Unscrew stud (8) from receptacle (19). Remove valve (11), spring (13) and gasket (10). Thread flow port (15) out of stud (8). Remove gasket (18) from stud (8).

D. Part No. 5507 and 5533. (See IPL figure 7.) Remove screw (2) and screen (4). Remove glass cord (3) and screen (4) from body (12). Unthread guide assembly (6). Remove washer (7) from guide assembly (6). Remove washers (8 and 9), seat (10), and spring (11) from body (12).

E. Part No. 5052. (See IPL figure 8.) Remove screw (2). Remove screen (4), and pick glass cord (3) out of base (7). Take screen (4) and washer (5) out of base (7). Unthread base (7) from body (13). Remove gasket (8). Unthread seat (10). Remove gasket (11). Take retainer (12) and spring (9) out of body (13).

F. Part No. 8572. (See IPL figure 6.) Unscrew body assembly (2) from adapter (9). Remove gasket (5), poppet (6), spring (7), and filter (8) from adapter (9).

G. Part No. 802863-02. (See IPL figure 10.) Disassemble as follows:
   (1) Unthread nipple (2) from body (15) only if damaged or leakage has been noted.
   (2) Push in and turn plug assembly (4 through 6) counterclockwise to remove. Pull cover (4) off plug (6) and body (15) then remove packing (5) from the plug and discard the packing.
   (3) Unthread sleeve and pin assembly (8 and 9) from body (15). Remove pins (8) from sleeve (9).

   NOTE: Use of plug (6) may aid in unthreading the sleeve and pin assembly.

(4) Remove seal (10), retainer (11) and packing (12) from sleeve (9) and discard the seal and packing.
(5) Remove poppet (13) and spring (14) from body (15).

5. 5510 Series Regulator Assembly. (See IPL figure 9.)

NOTE: The regulator should not be removed from the cylinder for disassembly. Disassembly of the regulator body from the cylinder should not be attempted until completion of the disassembly instructions listed below.

A. Unthread screws (34) and remove plate (33). Remove screw (35).

B. Unthread and remove case (36 or 36A). Lift guide (37), spring (38), plate (39), ring (40), diaphragm (41), and plate (42) out of body (49 or 49A).

C. Unscrew and remove holder (43). Remove seat (44 or 44A), pin (45), guide (46), and spring (47).

D. Unthread and remove plug (28). Remove disc (29) and washer (30).

E. Remove on-off valve by unthreading it from the regulator body. Use a wrench on the flats of the hexagonal portion of the valve body. Remove filter (21), if necessary, or plug (20).

F. Peel plate (7) off handle (8). Remove nut (9) and washer (10). Pull handle (8) off stem assembly (15).

G. Remove washers (11 and 12).

H. Unthread nut (13). Remove packing (14 or 14A) and seat (16).

I. Using stem assembly (15), back head assembly (17 or 17A) out of bushing (19).

J. Remove packing (18 or 18A).

K. Unthread relief valve (32) from body (49 or 49A).

L. Remove the sealing tape compound on threads of relief valve (32).

M. Remove cap (22). Seat (23) is cemented to the cap. Unthread and remove charging valve assembly (24), then remove filters (25 and 27).

N. Remove gauge (31 or 31A) by using a thin wrench on the flats of the square at the rear of the case.

O. Removal of regulator body (49 or 49A) from the cylinder is not recommended and is not usually required. If removal is essential, install the unit in a suitable holding fixture and use wrench (1) to remove the regulator body from the cylinder. Remove drain tube (48, IPL figure 9) only if it is damaged.

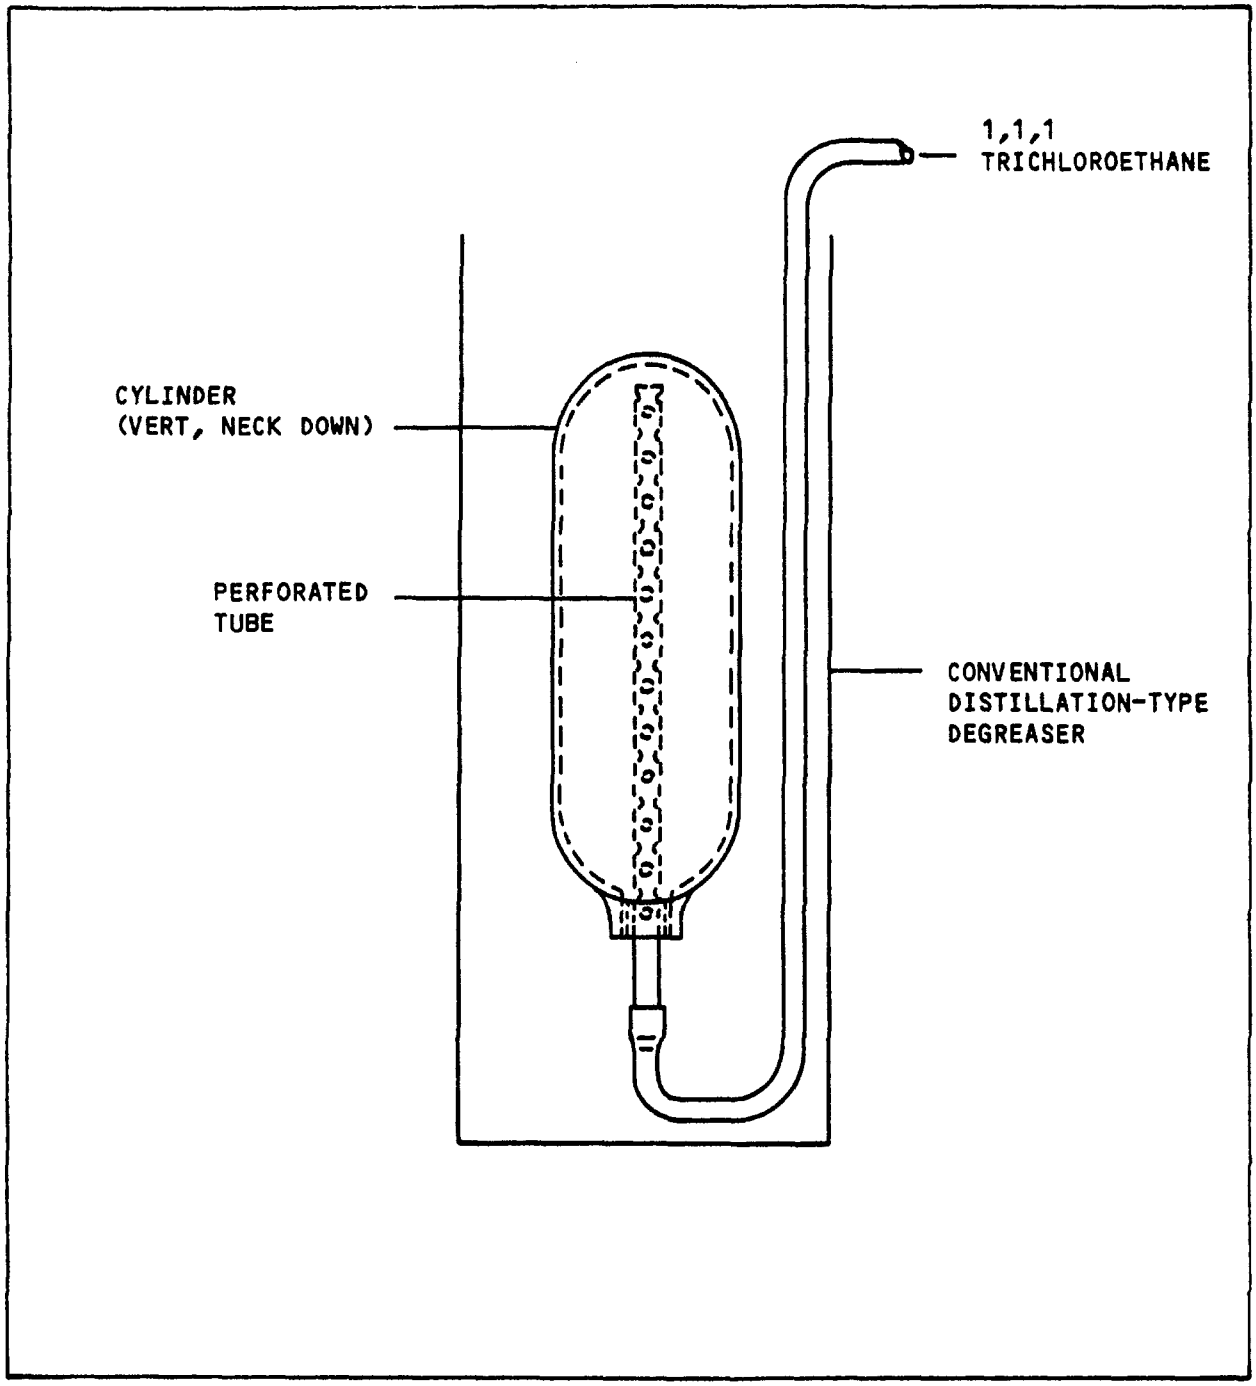
CLEANING

WARNING: DO NOT ALLOW OIL, GREASE, FLAMMABLE SOLVENTS, OR OTHER COMBUSTIBLE MATERIALS TO COME IN CONTACT WITH PARTS THAT WILL BE EXPOSED TO PRESSURIZED OXYGEN. SUCH MATERIALS, AS WELL AS DUST, LINT, AND FINE METAL FILINGS ARE ALL POTENTIAL COMBUSTIBLES WHICH MIGHT, WHEN EXPOSED TO OXYGEN UNDER PRESSURE, IGNITE AND RESULT IN AN EXPLOSION.

1. Using the material listed in Table 401, perform the cleaning procedures outlined in the following paragraphs.

NOTE: Equivalent materials may be used.

MATERIAL	DESCRIPTION	MANUFACTURER*	REFER TO PARAGRAPH
Acid/Odor Neutralizer	Fisan-Enzodent	V44389	1.A.(5)
Phosphoric - Isopropyl Mixture	Phosphoric Acid Isopropyl Alcohol (50% of each by Vol)	V70829 NOTE: Purchased separately	1.A.(3)
1,1,1 Trichloro-ethane	MIL-T-81533 FED SPEC. O-T-620	V71984	1.A.(4) 1.A.(8) a., b., c. 1.B.(2)



*Refer to Illustrated Parts List, paragraph 1.E for Vendor's Code.

List of Cleaning Materials
Table 401

A. After inspecting cylinder in accordance with Check perform the following cleaning procedure:

NOTE: This procedure will remove any organic impurities which are soluble in 1,1,1 Trichloroethane.

(1) Wire brush the cylinder neck threads to remove sealing compounds or rust.
(2) Shake out cylinder to remove any loose foreign matter.
(3) Apply a solution (50% by volume of phosphoric acid isopropyl alcohol) by brush to the area wire brushed, exercising care to prevent excessive application from running into the cylinder.

Cleaning Setup
Figure 401

WARNING: USE 1,1,1 TRICHLOROETHANE IN A WELL VENTILATED AREA ONLY. AVOID PROLONGED OR REPEATED CONTACT WITH SKIN AND INHALATION OF TOXIC VAPORS

(4) Utilizing a cleaning setup as illustrated in figure 401, place the cylinder, with neck down, in vertical position over the perforated tube (the diameter and length of the tube will be determined by the particular size of the cylinder being cleaned). Pump 1,1,1 Trichloroethane, slightly below its boiling point, through the tube thoroughly spraying the interior of the cylinder being cleaned for a period of three minutes. Remove cylinder from tube and allow complete drainage of 1,1,1 Trichloroethane into drain.

(5) After completion of step (4), and using a cleaning setup similar to the setup illustrated in figure 401, pump a solution of Fisan-Enzodent (8 ounces (.227 kg) per each gallon (3.8 l) of water), at a temperature of 180°F (82.2°C), through the tube, thoroughly spraying the interior of the cylinder being cleaned for a period of three to five minutes. Accomplishment of step (5) will neutralize any acid constituents and destroy odor.

(6) After completion of step (5), and using a cleaning setup similar to the setup illustrated in figure 401, pump water (at city pressure) at 160°F (71.1°C), through the tube, thoroughly spraying the interior of the cylinder being cleaned for a period of two minutes to remove any traces of alkaline residue.

(7) After completion of step (6), and using a cleaning setup similar to the setup illustrated in figure 401, dry the interior of the cylinder with forced air heated to a temperature of 212°F (100.0°C), for a period of three to five minutes.

(8) After completion of step (7), and after the cylinder has cooled to room temperature, reinspect the cylinder in accordance with Check.

NOTE: The cleaning process used should be checked initially and periodically as follows:

a. Pour 50cc of anhydrous, chemically pure, 1,1,1 Trichloroethane into the processed cylinder. Cap and shake well for one to two minutes.

b. Remove cap and pour flushings into a clean Erlenmeyer flask. Distill the 1,1,1 Trichloroethane in a water bath. After the 1,1,1 Trichloroethane has been distilled, examine residue in flask. If oil marks are visible, check cleaning solutions, implements and pressure.

c. After completion of steps (a) and (b), and using a cleaning setup similar to the setup illustrated in figure 401, clear all traces of 1,1,1 Trichloroethane from the interior of the cylinder by blowing with dry, clean, oil-free air.

B. After inspecting the valve assembly in accordance with Check, perform the following cleaning procedure.

WARNING: DO NOT ALLOW OIL, GREASE, FLAMMABLE SOLVENTS, OR OTHER COMBUSTIBLE MATERIALS TO COME IN CONTACT WITH PARTS THAT WILL BE EXPOSED TO PRESSURIZED OXYGEN. SUCH MATERIALS, AS WELL AS DUST, LINT, AND FINE METAL FILINGS ARE ALL POTENTIAL COMBUSTIBLES WHICH MIGHT, WHEN EXPOSED TO OXYGEN UNDER PRESSURE, IGNITE AND RESULT IN AN EXPLOSION.

(1) Remove dirt and foreign particles from equipment by wiping with a clean lint-free cloth, or by blowing with clean oil-free air or nitrogen.

WARNING: USE 1,1,1 TRICHLOROETHANE IN A WELL VENTILATED AREA ONLY. AVOID PROLONGED OR REPEATED CONTACT WITH SKIN AND INHALATION OF TOXIC VAPORS.

(2) Metal parts which come in contact with oxygen and have become contaminated with grease can be cleaned by using a vapor degreasing method with 1,1,1 Trichloroethane. Blow clean and dry with a stream of clean dry, oil-free air.

(3) Non-metallic parts such as silicone and rubber components may be cleaned by using an ultrasonic detergent and water cleaning system. Rinse parts in clean water and dry thoroughly before reassembly.

CHECK

1. Inspect exterior of cylinder for indications of abuse, dents and bulges.

2. Inspect neck of cylinders for cracks and distortion or damaged threads.

3. Inspect all cylinders for peeling external paint and obscure markings.

4. Inspect all high pressure cylinders for last date of hydrostatic test and type. If hydrostatic testing is required, tests shall be in accordance with prescribed procedures by facilities holding a current, valid DOT Approval.

   NOTE: DOT Type 3HT cylinders require hydrostatic retesting every 3 years. DOT type 3A and 3AA cylinders require hydrostatic retesting every 5 years. Under certain usage conditions, DOT type 3A and 3AA cylinders may be retested at 10 year intervals. Refer to the current tariff of the "HAZARDOUS MATERIAL REGULATIONS OF THE DEPARTMENT OF TRANSPORTATION" (49 CFR 170) paragraph 173.34 (e) (15) for eligibility requirements.

   NOTE: For Cylinder Inspection and Hydrostatic Retest, the use of Compressed Gas Association (CGA) pamphlets C-1, C-5, C-6, C-8 are recommended. These are available from:

   CGA, INC.
   1235 Jefferson Davis Highway
   Arlington, VA 22202

5. Inspect the interior for defects which might render the cylinder unsafe.

6. Inspect the interior of cylinders for rust spots, improper parkerizing, or surface blemishes.

7. Inspect valves and/or regulator for cracks, nicks, dents, or burrs which might cause malfunction.

8. Inspect valve seats for scoring.

9. Inspect all threads of valves and/or regulators for damage.

10. Inspect overall condition of all components.

REPAIR

NOTE: Table 601 lists the consumable materials required for repair. Equivalent materials may be used.

MATERIAL	DESCRIPTION	MANUFACTURER*	REFER TO PARAGRAPH
Chromic Acid	Chromic Acid	V72658	4.E
Phosphoric Acid	Phosphoric Acid	V70829	4.C, 4.E
Phosphate Coating	Zn PO_4	V44389	4.C

*Refer to Illustrated Parts List, paragraph 1.E for Vendor's Code.

Consumable Materials for Repair
Table 601

1. Repair of parts, other than removing burrs, is not recommended. If a part is in need of repair, discard it and replace the part.

2. Replace all gaskets, washers, packings, diaphragms, non-metallic valve seats and filter screens at each overhaul.

3. Replace cylinders that show signs of abuse, dents, bulges, cracks, distortion, damaged threads, and/or defects which might render the cylinder unsafe (refer to Check, steps 3, 4, 5 and 7).

   NOTE: DOT 3HT Type cylinders must be discarded at the end of twenty-four years from original test date or 4,380 pressurizations, whichever occurs first.

4. Cylinders that require interior protective treatment may be reparkerized as follows: (Refer to Check, step 6).

   A. Sandblast cylinders internally and externally using fine grit shot.

   B. Rinse cylinder in clean water.

C. Apply a phosphate coating to the interior of the cylinder either by dipping or spraying. For dip-coating, a three minute minimum dip is recommended; for spray-coating, one minute minimum is recommended.

NOTE: The balanced aqueous solution of phosphoric acid, phosphates, and accelerating agents produces a uniform water insoluble crystalline coating varying from gray to black in color.

D. Rinse cylinder in clean water.

E. Rinse cylinder in hot chromic acid (140 to 210°F) (60.0 to 98.9°C).

NOTE: The pH of the chromic acid rinse will be maintained between 2 and 4 by the addition of flake chromic acid of a mixture of chromic and phosphoric acids.

F. Dry the cylinder by using warm air or a drying oven.

NOTE: For maximum corrosion resistance, coating weights of 400 mg/sq. ft. (0.43 mg/cm^2) are usually adequate. This coating weight may be reduced to 200 mg/sq. ft. (0.22 mg/cm^2) if an activator (titanium salts) is used. The coating weight may be deceptive if loosely adherent deposits are obtained, since loosely adherent deposits give inferior performance. Finely crystalling zinc phosphate coatings provide the best corrosion resistance.

G. If the exterior finish is removed, it must be recoated with 1000 mg/sq. ft. min. (1.08 mg/cm^2 min.) phosphate, and primed per MIL-P-8585A, color Y.

5. Remark and/or repaint cylinders in acccordance with information outlined in figure 2.

ASSEMBLY

NOTE: Table 701 lists the consumable materials necessary for assembly. Equivalent materials may be used except for oxygen lubricant.

MATERIAL	DESCRIPTION	MANUFACTURER*	REFER TO PARAGRAPH
Thread Sealing Tape	Permacel No. 412	V99742	1.G(5), 2.A, 2.B, 2.C, 2.E, 2.F, 4.B, 4.C
Adhesive	Insa-Lute Adhesive No. 1	V80703	2.D
Loctite Sealant	Loctite, Grade C	V05972	2.R
Dow Corning Adhesive	Dow Corning Adhesive No. A-4000	V71984	3.E
Oxygen Lubricant	Krytox 240AC	V18873	1.G (2), 1.G (4), 2.G, 2.H, 2.I, 2.K
Loctite Sealant	Loctite 222	V05972	1.G (3)
Oxygen	MIL-O-27210, Type I	V07098	3.C
Lockwire	MS20995C20	-----	2.K

*Refer to Illustrated Parts List, paragraph 1.E for Vendor's Code

List of Consumable Materials for Assembly
Table 701

1. Outlet Assemblies

   A. Part No. 8572. (See IPL figure 6.) Place filter (8), spring (7), poppet (6) and gasket (5) in adapter (9) and thread body assembly (2) into adapter (9).

   B. Part No. 5052. (See IPL figure 8.) Place retainer (12) and spring (9) in body (13). Place gasket (11) on seat (10), and thread base (7) onto the body. Install washer (5) and screen (4) in base (7). Pack glass cord (3) into the opening of base (7). Install screen (4) and screw (2).

   C. Part No. 5507. (See IPL figure 7.) Place spring (11), seat (10) and washers (8 and 9) in body (12). Place washer (7) in guide assembly (6), and screw guide assembly (6) into body (12). Place screen (4) into body (12), and pack glass cord (3) into the body. Install screen (4) and screw (2).

   D. Part 5009. (See IPL figure 5.) Place filter (17) on flow port (14), and hold in place by installing ring (16). Install gasket (18) in stud (8), and thread flow port (14) into stud (8). Install gasket (10), valve (11), and spring (13) into receptacle (19). Thread stud (8) into receptacle (19). Pack glass cord (6) into stud (8). Thread screw (4) into stud fitting (8) and install cover (3).

   E. Part No. 800503-00. (See IPL figure 5.) Install gasket (18) in stud (8) and thread flow port (15) into stud (8). Install gasket (10), valve (11), and spring (13) into receptacle (19). Thread stud (8) into receptacle (19). Place plug of cover (3) into open port of receptacle (19).

   F. Part No. 5041. (See IPL figure 4.) Position pins (17) on case (18), and hook springs (16) over the grooved ends of the pins. Install seat (15), valve (14), and spring (13) in case (18). Slide washer (5) and cap (4) onto case (18). Assemble nut (3) and cover (2); then thread nut (3) onto case (18). Place screen (9) into the opening of body (12). Pack glass cord (8) into the opening and install screen (7) and screw (6).

G. Part No. 802863-02. (See IPL figure 10). Reassemble as follows:

(1) Place spring (14) in poppet (13); install in body (15).
(2) Sparingly apply a wipe coat of Krytox to packing (12) and install in sleeve (9). Install insert (11) and seal (10) in sleeve (9).
(3) Insert pins (8) in sleeve (9). Apply Loctite 222 to the external threads of sleeve (9) and thread the sleeve into body (15), being sure the pins remain in the sleeve.

NOTE: Use of plug (6) will aid in threading the sleeve into the body.

(4) Sparingly apply a wipe coat of Krytox to packing (5) and install in the groove in plug (6). Install cover (4) on body (15) and plug (6), then install and seat plug (6) in sleeve (9).
(5) Apply 1-1/2 turns of thread sealing tape to nipple (2) in the direction of the thread spiral, beginning at the first thread. In no case shall the tape extend beyond the first thread. Trim off excess tape. Thread nipple (2) into body (15).

2. 5510 Series Regulator Assemblies. (See IPL figure 9.)

NOTE: Regulator body (49 or 49A)) must be assembled to a cylinder before assembly of the regulator.

A. If regulator body (49 or 49A)) was removed from a cylinder, make sure drain tube (48) is pressed into body (49 or 49A). Place the appropriate cylinder in a suitable holding fixture and wrap 1-1/2 turns of thread sealing tape to body (49 or 49A), in the direction of the thread spiral, beginning with the first thread. Trim off excess tape. Tighten body (49 or 49A) into cylinder using wrench (1, figure 901). Torque all bodies per Table 801. Position body so that writing on cylinder will be in appropriate position when unit is assembled.

B. Wrap 1-1/2 turns of thread sealing tape to gauge (31 or 31A, IPL figure 9) in the direction of the thread spiral, beginning with the first thread. In no case shall the tape extend beyond the first thread. Trim off excess tape. Thread gauge (31 or 31A) into body (49 or 49A). Use a thin wrench on the gauge pipe connection square. Torque per Table 801.

C. Wrap 1-1/2 turns of thread sealing tape to valve assembly (24) in the direction of the thread spiral, beginning with the first thread. In no case shall the tape extend beyond the first thread. Trim off excess tape. Assemble valve assembly (24) to regulator body (49 or 49A) after installing filters (25) and (27). Torque per Table 801.

D. If necessary, cement seat (23) to cap (22) using adhesive. Coat seat (23) and cap (22) with Insa-Lute adhesive, then join and allow parts to air dry. Thread cap (22) with seat (23) onto charging valve assembly (24) after adhesive has thoroughly dried.

E. Wrap 1-1/2 turns of thread sealing tape to relief valve (32) in the direction of the thread spiral, beginning with the first thread. In no case shall the tape extend beyond the first thread. Trim off excess tape. Install valve in body (49 or 49A). Do not tighten valve at this time. It is necessary to remove relief valve when testing regulator assembly. When valve is finally installed, torque per Table 801.

F. Wrap 1-1/2 turns of thread sealing tape to appropriate outlet assemblies in the direction of the thread spiral, beginning with the first thread. In no case shall the tape extend beyond the first thread. Trim off excess tape. Install the appropriate outlet assemblies at this time. Torque outlets per Table 801.

G. Insert filter (21) in opening of body (49 or 49A) such that opening in filter is over the raised portion of seat. Apply a wipe coat of Krytox to packing (18) then install bushing (19) or plug (20) in opening of body (49 or 49A). Tighten bushing until it bottoms on body (49 or 49A). Observe that filter (21) is not wrinkled.

H. Apply a wipe coat of Krytox to stem of stem assembly (15).

I. Apply a wipe coat of Krytox to threaded area of head assembly (17) and install head assembly (17) in bushing (19) using stem assembly (15) to thread head assembly (17) into bushing (19).

J. Install seat (16) on stem assembly (15) and push seat (16) into bushing (19).

K. Apply a wipe coat of Krytox to packing (14 or 14A), then assemble packing (14 or 14A) on nut (13) and thread nut (13) into bushing (19). Lockwire nut (13) to body (49 or 49A) per the applicable instructions of MS33540.

L. Place washers (11 and 12) on stem assembly (15). Assemble handle (8) and attach it to stem assembly (15) with washer (10) and nut (9). Press plate (7) on handle (8).

M. Position washer (30) and disc (29) in the opening of body (49) and torque safety plug (28) per Table 801.

N. Place spring (47) and guide (46) in body (49 or 49A).

O. Inspect the center hole of seat (44) and the seating area of pin (45) with a magnifying glass or microscope. These areas must be smooth and clean without cracks, nicks, or burrs. Insert pin (45) in seat (44) and place the assembly into body (49 or 49A).

P. Inspect the thread of holder (43) with a magnifying glass or microscope. Make sure that the first thread does not have a sharp leading edge and that the entire thread is free of burrs and rough edges. Torque holder (43) into body (49 or 49A) per Table 801. Over-torquing may result in damage to seat (44).

Q. Place plate (42), diaphragm (41), three rings (40), plate (39), spring (38) and guide (37) in position in the regulator body.

NOTE: Three slip rings (40) are normally required to properly seal diaphragm (41) while engaging a maximum number of threads of case (36). The number of rings (40) may be altered if necessary to accomplish this.

R. Thread case (36) onto body (49 or 49A). Tighten case (36) until it bottoms on body (49 or 49A)). Install screw (35) loosely. When ready to test unit, apply Loctite, Grade C to setscrew (35) then adjust unit before Loctite sets up.

NOTE: Do not install plate (33) and screws (34) until completion of Testing.

3. Part No. 6379 and 800649 Series Demand and Pressure/Demand Oxygen Regulators. (See IPL figure 3).

A. Thread adapter (25 or 26) onto the outlet port of case (28).

B. Install screen (27) in the inlet port of case (28).

C. Install gasket (24) and attach valve assembly (20) to case (28), using washers (22 and 23) and screws (21). Connect a supply of oxygen to the inlet port, and adjust oxygen pressure to 85 psi (0.59 MPa). Cover sealing area of valve assembly (20) with a small amount of clean water. Bubbles indicate leakage which must be corrected. After successful completion of this test, remove the oxygen source, dry the regulator by blowing with clean, dry, water-pumped air, and continue reassembly.

D. Attach deflector (18) to case (28) with screws (19). Clearance must be noted between the demand valve and the deflector. Lack of clearance will cause the demand valve to open.

E. Install diaphragm assembly (16) over case (28) so that diaphragm edge extends to edge of machined surface beyond groove. Wrap cord (17) around diaphragm at groove in case four full turns and tie securely. The diaphragm must lay smoothly without wrinkles or folds. Apply Dow Corning adhesive over knot tied in cord (17).

F. Rivet plates (8, 11 and/or 12) to cover (14 and/or 15) with rivets (10 and 13). Install plate (9) if it was removed.

G. Install button (13D) in cover (15), then attach spring (13C) to the narrow slots in the button inside the cover.

H. Install plate and lever assembly (13B) in cover (15) with the lip of the lever in the recess slot in cover (15). Place one end of spring (13A) in the hole in the lever of plate and lever assembly (13B) and the other end in the hole nearest the closed face of cover (15).

NOTE: Spring (13A) shall measure 3-1/4 in. (8.25 cm), tip-to-tip, prior to installation.

I. Assemble cover assembly to case (28) with screws (7).

4. 5600 Series. (See IPL figure 2.)

NOTE: All components of the 5600 Series must be completely tested prior to assembly. Instructions for the testing of components are listed under Testing.

A. With regulator (38) assembled to cylinder (45), place loop of sling (17) over regulator (38) onto neck of cylinder (45).

B. Wrap 1-1/2 turns of thread sealing tape to elbow assembly (4) in the direction of the thread spiral, beginning with the first thread. In no case shall the tape extend beyond the first thread. Trim off excess tape. Thread the elbow assembly into regulator (38).

C. Wrap 1-1/2 turns of thread sealing tape to connector assembly (3) in the direction of the thread spiral, beginning wih the first thread. In no case shall the tape extend beyond the first thread. Trim off excess tape. Thread the connector assembly into regulator (7).

D. Assemble bracket (13) to regulator (7) with screws (11) and washers (12), then align this unit on the cylinder and unite elbow assembly (4) to connector assembly (3).

E. Connect bracket (13) to cylinder (45) by installing clamp (14), then secure loose end of sling (17) to the cylinder with clamp (24).

F. If necessary, attach identification plate (35) to regulator with screws (37). Affix instruction plates (43, 44 and 44A) to cylinder (45), if necessary.

NOTE: Outlet assemblies (28) are normally assembled to regulator (38) when regulator is reassembled.

5. 5500 Series. (See IPL figure 2.)

NOTE: All components of the 5500 Series must be completely tested prior to final assembly. Refer to Testing instructions.

A. With regulator (38) assembled to cylinder (45), place loop of sling (17) over regulator (38) onto neck of cylinder (45). Secure loose end of sling (17) to cylinder (45) with clamp (24).

B. If necessary, attach identification plate (35) to regulator with screws (37). Affix instruction plates (43, 44 and 44A) to cylinder (45), if necessary.

NOTE: Outlet assemblies (28) are normally assembled to regulator (38) when regulator is reassembled.

6. Storage Instructions

A. Make sure on-off valve assembly is completely closed prior to placing the assembly in storage.

B. Plug all openings with suitable dust caps and wrap the unit in a clean plastic bag to prevent dust accumulation. Do no use preservative coatings of any type.

C. Make sure that cylinder pressure is always a minimum of 200 psi (1.38 MPa).

FITS AND CLEARANCES

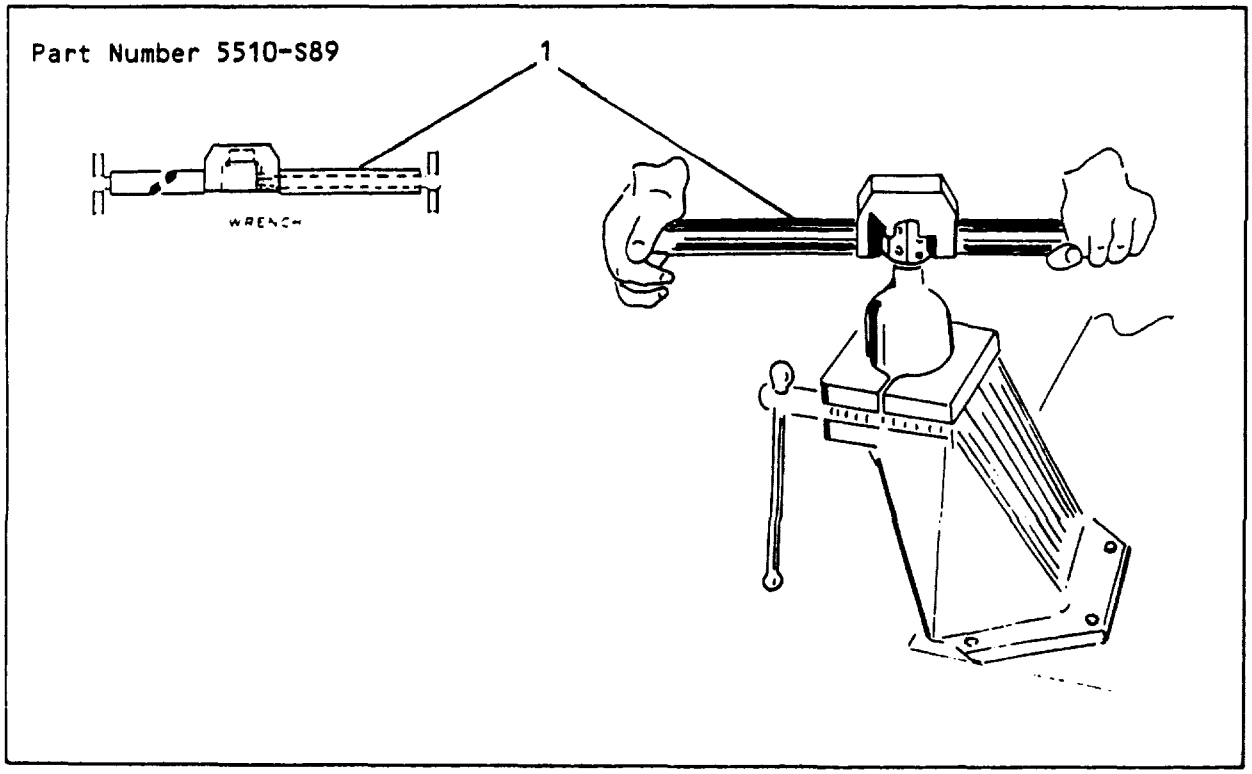
1. Table 801 presents the torque values necessary to assemble the unit.

UNIT	TORQUE lbf• in. (N•m)
Outlet assemblies (28, IPL figure 2)	*40-80 (4.5-9.0)
Charging Valve Assembly (24, IPL figure 9)	*60-250 (6.8-28.2)
Safety Plug (28, IPL figure 9)	150 (16.9)
Gauge (31 or 31A, IPL figure 9)	**40 (4.5)
Relief Valve (32, IPL figure 9)	*25-50 (2.8-5.6)
Seat Holder (43, IPL figure 9)	*50-125 (5.6-14.1)
Regulator Body (49, IPL figure 9) All except P/N 5053-03 & 5053-13 (1/2 ANPT)	1200 (135.6)
P/N 5053-03 & 5053-13 (1 ANPT)	1800 (203.4)

*Torque to minimum values. If leakage occurs, retorque to a higher value but do not exceed the maximum.

***Determined by orientation.*

Assembly Torque Values
Table 801



SPECIAL TOOLS, FIXTURES AND EQUIPMENT

1. All special tools required to overhaul the portable oxygen breathing equipment are listed in figure 901 and illustrated in figure 902. Equivalent tools may be used.

INDEX NO.	PART NO.	NOMENCLATURE	USE
1	5510-S89	Wrench	Used to turn regulator body (49 or 49A, IPL figure 9) into cylinder (43, IPL figure 2)
2	Deleted		

NOTE: All special tools listed are manufactured by Scott Aviation, Lancaster, New York.

Special Tools

Special Tools
Figure 902

ILLUSTRATED PARTS LIST

1. This Illustrated Parts List lists and describes the parts of the 5500 Series and 5600 Series, Portable Oxygen Breathing Units.

   A. The Illustrated Parts List consists of nine parts listings and nine completely indexed drawings. The breathing units are followed immediately by their component parts, properly indented thereunder, to show their relationship to the units.

   B. The quantities listed in the "UNITS PER ASSY" column are, in the case of assemblies, the total quantity used per breathing unit at the location indicated, while the component parts indented under the assemblies are the quantity used per assembly. The quantities specified, therefore, are not necessarily the total used per breathing unit. See the Numerical Index for the total used per breathing unit. It should be noted that the index quantity only reflects the use of one outlet assembly. If more than one outlet is present, quantitites must be adjusted accordingly.

   C. The part numbers listed in the "PART NUMBER" column are Scott Aviation part numbers except standard parts, which are listed by "MS" and "AN" part numbers, and vendor items which are listed by vendor part numbers.

   D. When the quantity of a part is to be selected as required, the abbreviation "AR" will appear in the "UNITS PER ASSY" column.

   E. A six place code following the description of a part indicates the manufacturer of that part. Standard parts and parts carried under Scott part numbers have no six place vendor code. The following list contains the codes, and names and addresses of manufacturers supplying items or articles for the breathing unit. This listing includes the vendor's code presented in Table 101, 401, 601 and 701.

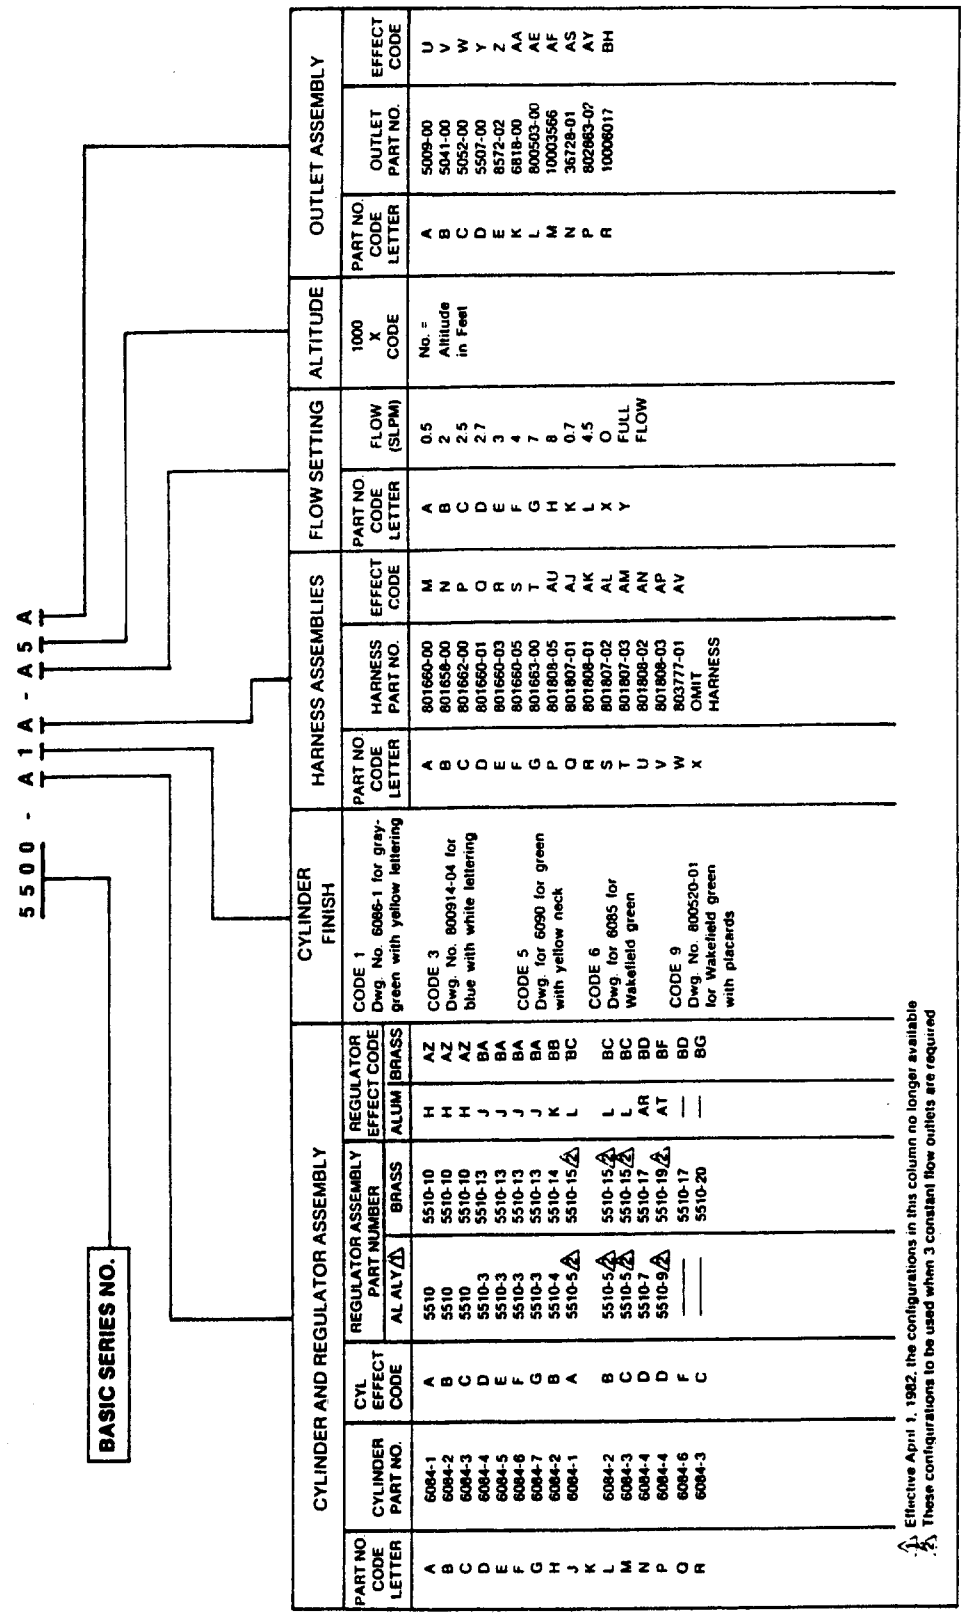
VENDOR'S CODE

CODE	NAME AND ADDRESS
V00287	CEM Co., Inc. Danielson, Conn.
V05972	American Sealants Co. Hartford, Conn.
V07098	Linde Division of Union Carbide Tonawanda, New York
V14674	Corning Glass Works Corning, New York
V18034	Nupro 4800 East 345th St. Willoughby, Ohio
V18873	E.I. DuPont DeNemours & Company, Inc. Petroleum Chemicals Division Wilmington, Delaware
V21343	Owens-Corning Fiberglass Corp. Huntington, Pennsylvania
V44389	Oakite Products Berkeley Heights, New Jersey
V45722	Parker Kaylon Division of General American Transportation Corp., Clifton, New Jersey
V49315	Puritan Equipment, Inc. Lenexa, Kansas
V66295	Wittek Manufacturing Co. Chicago, Illinois
V71984	Dow Corning Corp. Midland, Michigan
V78189	Shakeproof Division of Illinois Tool Works Inc. Elgin, Illinois
V80703	Sauereisen Cements Co. Pittsburgh, Pennsylvania

VENDOR'S CODE - continued

CODE	NAME AND ADDRESS
V81168	Linear, Inc. Philadelphia, Pennsylvania
V99742	Johnson and Johnson Inc. Permacel Division New Brunswick, New Jersey

F. The following effect codes have been assigned to the items contained in IPL figure 1.



PART NO.	EFFECT CODE
5500 SERIES & 5600 SERIES	Select applicable codes from listings in IPL figure 1.
Select effect code from IPL figure 1	1
Used on 5600 Series	2
Used on 5600 Series with 6084-1, 6084-2 and 6084-3 cylinders	3
Used on 5600 Series with 6084-4 cylinder	4
Used on 5600 Series with 6084-5 cylinder	5
Used on 5600 Series with 6084-6 and 6084-7 cylinder	6
Used on 5500 and 5600 Series with 6084-1, 6084-2 and 6084-3 cylinders	7
Used on 5500 and 5600 Series with 6084-4 cylinder	8
Used on 5500 & 5600 Series with 6084-5, 6084-6 and 6084-7 cylinders	9
Used on 5500 Series with 801663-00 Strap Assembly	10
Used on 5500 Series	11

2. How to use this Illustrated Parts List

A. If neither the part number nor the nomenclature is known, the part can be found by comparison with the exploded view illustration. When located on the illustration, the item number will refer to the line in the Illustrated Parts List with the part number and the nomenclature.

B. If the part number is known, refer to the Numerical Index and find the part number. Opposite the part number is the figure and item number which refers to the Illustrated Parts List. Proper nomenclature is opposite the item number on the Group Assembly Parts List page.

IMPORTANT WARNINGS

The following WARNINGS are presented to inform the user of this manual of the requirements which shall be adhered to when performing service procedures on this equipment. Additional WARNINGS will be found in the procedural steps in the manual.

WARNING: ANY SERVICE OR OVERHAUL PERFORMED ON THIS APPARATUS SHALL BE DONE ONLY BY THOSE FACILITIES EXPERIENCED IN, OR BY PERSONNEL KNOWLEDGEABLE IN AVIATION OXYGEN EQUIPMENT. IF NONE ARE KNOWN, CONTACT SCOTT AVIATION OR ITS DISTRIBUTORS FOR NAMES OF AUTHORIZED SERVICE CENTERS.

WARNING: ALL PROCEDURES DESCRIBED IN THIS MANUAL SHALL BE PERFORMED IN AN AREA FREE OF OIL, GREASE, FLAMMABLE SOLVENTS OR OTHER COMBUSTIBLE MATERIALS. SUCH MATERIALS, AS WELL AS DUST, LINT, AND FINE METAL FILINGS ARE ALL POTENTIAL COMBUSTIBLES WHICH MIGHT, WHEN EXPOSED TO OXYGEN UNDER PRESSURE IGNITE AND RESULT IN AN EXPLOSION AND/OR FIRE.

WARNING: DO NOT ALLOW OIL, GREASE, FLAMMABLE SOLVENTS, OR OTHER COMBUSTIBLE MATERIALS TO COME IN CONTACT WITH PARTS THAT WILL BE EXPOSED TO PRESSURIZED OXYGEN. SUCH MATERIALS, AS WELL AS DUST, LINT, AND FINE METAL FILINGS ARE ALL POTENTIAL COMBUSTIBLES WHICH MIGHT, WHEN EXPOSED TO OXYGEN UNDER PRESSURE, IGNITE AND RESULT IN AN EXPLOSION.

CYLINDER AND VALVE ASSEMBLY

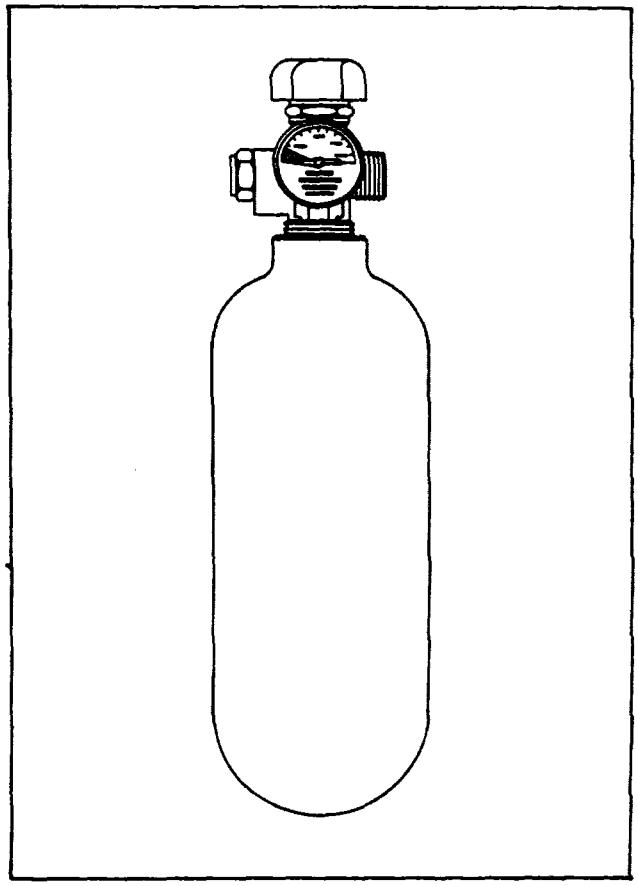
1. Description and Operation

A. General

(1) This manual provides maintenance instructions for the 6350 Series Cylinder and Valve Assemblies (see figure 1). The complete part number of any particular cylinder and valve assembly is an eight to eleven place combination of numbers and letters. An example part number and an explanation of the various numbers and letters which make up a part number are shown in figures 2, 3, and 4.

The cylinder and valve assemblies, although similar in design and appearance, are used for various applications. The major applications are to supply oxygen at altitudes where oxygen is required for breathing.

B. Purpose of Equipment



(1) To furnish a predetermined supply of oxygen, dependent on the size of the cylinder.

(2) The valves covered in this manual are manually operated "on-off" oxygen valves which are designed with a slow opening feature. The valves are nominally rated for 2000 psi service.

(3) To furnish a shut-off valve for turning the oxygen supply "ON" or "OFF".

(4) To furnish a safety device to vent excessive pressure in oxygen cylinders.

(5) To furnish, on some models, a gauge to visually monitor the supply of oxygen.

NOTE: 1. Designation AK and AM are identical except for positioning of stenciled information.

Cylinder Finish
Figure 4

C. Typical Installation

(1) A typical installation of the cylinder valve is shown in figure 5. A slow opening cylinder valve assembly is installed on each high pressure oxygen cylinder (1). The valves provide for manual, positive opening and closing of the oxygen system.

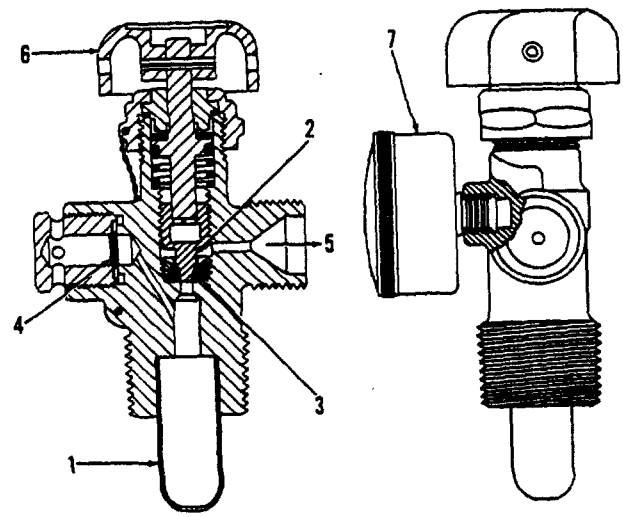
5. ANEROID OPERATED OXYGEN SYSTEM RELEASE VALVE
6. ELECTRICALLY OPERATED OXYGEN SYSTEM RELEASE VALVE
7. AUTOMATIC CONSTANT FLOW PRESSURE REGULATOR
8. PASSENGER MASK COMPARTMENT DOOR
9. CHECK VALVE

Typical Installation
Figure 5

D. Operation

(1) Operation of all cylinder and valve assemblies is identical. The high pressure air or oxygen within the cylinder is released at the fitting when the shut-off valve is opened. The oxygen supply is maintained within the cylinder when the shut-off valve is closed.

(2) The cross section illustrated in figure 6 is representative of all the slow opening oxygen cylinder valve assemblies. With the valves installed in a high pressure oxygen cylinder, and valve handle (6) closed (full clockwise), the oxygen is contained in the cylinder through the action of valve plug (2) and valve seat assembly (3). When valve handle (6) is opened (full counter-clockwise), valve seat assembly (3) is raised away from inlet (1) thereby allowing oxygen flow to outlet (5). The valves are equipped with safety outlet assemblies (4). The safety outlet assemblies are preset to rupture at 2500 to 2775 psi in order to vent oxygen in the event of system overpressurization. A cylinder pressure gauge (7) is provided on some cylinder valve assemblies to indicate cylinder pressure.



(3) These valves restrict flow only during the initial opening phase, and will prevent a downstream dead-ended system from being brought up to system pressure too rapidly.

NOTE: Rapid pressurization of a system is adiabatic in nature and may result in a potentially hazardous temperature rise.

There is no appreciable increase in flow through the valve when opened more than 3 turns. As with all valves, it should be opened fully and then backed off about 1/4 of a turn. Note, however, that the valve can be forced open more than 3-1/2 turns, but this begins to compress the sealing spring and results in an immediate increase in torque required to operate the valve. This should be avoided. Similarly, from a shut-off position, the valve handle can be further tightened approximately another 1/4 turn. This too is accompanied by an increase in torque required and does not enhance the sealing of the valve. This is the result of the KEL-F seat which will cold-flow with the application of additional torque. The packing on the rotating stem seals by the combined action of a spring and internal gas pressure. Application of sufficient axial force (push) on the valve handle can result in unseating of this seal and ensuing leakage, but only as long as this unseating force is maintained.

VALVE CHARACTERISTICS:

1.	Torque to open or close	15 inch pounds (1.7N·m) (Maximum)
2.	Torque to operate	7 inch pounds (.8N·m) (Average)
3.	Full open position	3-1/2 turns (Approximate)

2. VALVE PLUG
3. VALVE SEAT ASSEMBLY
4. SAFETY OUTLET ASSEMBLY
5. VALVE OUTLET
6. VALVE HANDLE
7. CYLINDER PRESSURE GAUGE

Slow Opening Oxygen Cylinder Valve Assembly
Figure 6

2. Trouble Shooting

A. Do not attempt to repair a defective cylinder and valve assembly in the field. If the assembly is defective (leakage, or failure to open or close) return the assembly to a qualified overhaul depot.

3. Maintenance Practices

A. Servicing

(1) No servicing is required.

B. Removal/Installation

WARNING: DO NOT ATTEMPT TO REMOVE A VALVE ASSEMBLY THAT IS PRESSURIZED AT ANY PORT. DEPLETE OXYGEN PRESSURE BEFORE DISCONNECTING THE FITTINGS AT ANY PORT. DO NOT REMOVE CYLINDER VALVES FROM CYLINDERS. IF OVERHAUL IS REQUIRED, RETURN THE ENTIRE ASSEMBLY TO A QUALIFIED OVERHAUL DEPOT.

(1) All valves are mounted by threading the valve directly into a high pressure oxygen cylinder. An oxygen line connection is made from the outlet port. On some valves containing a safety outlet assembly, piping is installed from this assembly to a safe disposal point (over board).

(2) Use care to prevent distortion of fittings or tubing when removing or installing the cylinder and valve assembly.

C. Adjustment/Test

(1) There are no adjustments for the cylinder and valve assembly.

(2) Tests are listed under Inspection/Check.

D. Inspection/Check

(1) Note the pressure on the pressure gauge. The gauge must indicate the oxygen pressure inside the cylinder.

(2) Apply leak test solution, Specification MIL-L-25567, to the valve stem opening in the valve body and at all connections. Bubbles indicate leakage. Leakage at fittings may be corrected by tightening the applicable fitting. Always bleed pressure before retightening any fitting. If leakage still exists, do not attempt to repair the assembly in the field. Replace the assembly, and send the defective unit to a qualified overhaul depot.

(3) Every cylinder is metal stamped near the threaded opening with the date (month-year) of manufacture and last hydrostatic test. The cylinder should be retested at those intervals specified in the hazardous materials regulations of the Department of Transportation (DOT), Current Tariff No. Return to overhaul if retest is indicated.

4. Cleaning/Painting

A. Clean the outside of the cylinder and valve assembly with a dry cloth. Touch up to cover nicks or scratches may be accomplished in accordance with standard practice. However, all ports and threads must be plugged or masked to prevent solvent, paint or other foreign material from entering the valve.

5. Approved Repairs

A. Do not attempt to repair a defective cylinder and valve assembly in the field. Replace the assembly and return the replaced assembly to a qualified overhaul depot.

OVERHAUL MANUAL

IMPORTANT WARNINGS

The following WARNINGS are presented to inform the user of this manual of the requirements which shall be adhered to when performing service procedures on this equipment. Additional WARNINGS will be found in the procedural steps in the manual.

WARNING: ANY SERVICE OR OVERHAUL PERFORMED ON THIS APPARATUS SHALL BE DONE ONLY BY THOSE FACILITIES EXPERIENCED IN, OR BY PERSONNEL KNOWLEDGEABLE IN AVIATION OXYGEN EQUIPMENT. IF NONE ARE KNOWN, CONTACT SCOTT AVIATION OR ITS DISTRIBUTORS FOR NAMES OF AUTHORIZED SERVICE CENTERS.

WARNING: ALL PROCEDURES DESCRIBED IN THIS MANUAL SHALL BE PERFORMED IN AN AREA FREE OF OIL, GREASE, FLAMMABLE SOLVENTS OR OTHER COMBUSTIBLE MATERIALS. SUCH MATERIALS, AS WELL AS DUST, LINT, AND FINE METAL FILINGS ARE ALL POTENTIAL COMBUSTIBLES WHICH MIGHT, WHEN EXPOSED TO OXYGEN UNDER PRESSURE IGNITE AND RESULT IN AN EXPLOSION AND/OR FIRE.

WARNING: DO NOT ALLOW OIL, GREASE, FLAMMABLE SOLVENTS, OR OTHER COMBUSTIBLE MATERIALS TO COME IN CONTACT WITH PARTS THAT WILL BE EXPOSED TO PRESSURIZED OXYGEN. SUCH MATERIALS, AS WELL AS DUST, LINT, AND FINE METAL FILINGS ARE ALL POTENTIAL COMBUSTIBLES WHICH MIGHT, WHEN EXPOSED TO OXYGEN UNDER PRESSURE, IGNITE AND RESULT IN AN EXPLOSION.

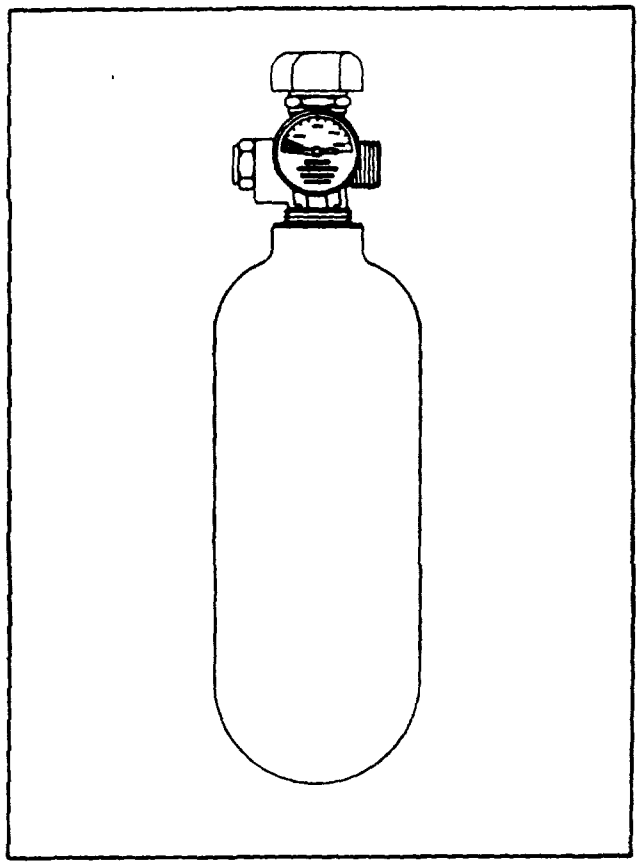
CYLINDER AND VALVE ASSEMBLY

1. Description and Operation

A. General

(1) This manual provides overhaul instructions with illustrated parts list for the 6350 Series Cylinder and Valve Assemblies (see figure 1). The complete part number of any particular cylinder and valve assembly is an eight to eleven place combination of numbers and letters. An example part number and an explanation of the various numbers and letters which make up a part number are shown in figures 2, 3, and 4.

The cylinder and valve assemblies, although similar in design and appearance, are used for various applications. The major applications are to supply oxygen at altitudes where oxygen is required for breathing.



B. Purpose of Equipment

(1) To furnish a predetermined supply of oxygen, dependent on the size of the cylinder.

(2) The valves covered in this manual are manually operated "on-off" oxygen valves which are designed with a slow opening feature. The valves are nominally rated for 2000 psi service.

(3) To furnish a shut-off valve for turning the oxygen supply "ON" or "OFF".

(4) To furnish a safety device to vent excessive pressures in oxygen cylinders.

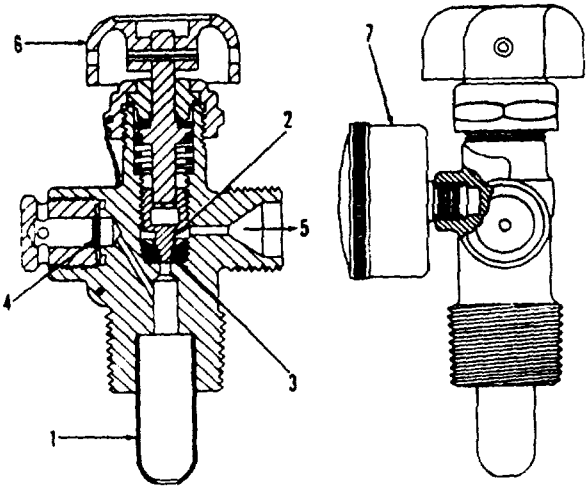
D. Operation



(1) Operation of all cylinder and valve assemblies is identical. The high pressure air or oxygen within the cylinder is released at the fitting when the shut-off valve is opened. The oxygen supply is maintained within the cylinder when the shut-off valve is closed.

(2) The cross section illustrated in figure 6 is representative of all the slow opening oxygen cylinder valve assemblies. With the valves installed in a high pressure oxygen cylinder, and valve handle (6) closed (full clockwise), the oxygen is contained in the cylinder through the action of valve plug (2) and valve seat assembly (3). When valve handle (6) is opened (full counterclockwise), valve seat assembly (3) is raised away from inlet (1) thereby allowing oxygen flow to outlet (5). The valves are equipped with safety outlet assemblies (4). The safety outlet assemblies are preset to rupture at 2500-2775 psi in order to vent oxygen in the event of system overpressurization. A cylinder pressure gauge (7) is provided on some cylinder valve assemblies to indicate cylinder pressure.

(3) These valves restrict flow only during the initial opening phase, and will prevent a downstream dead-ended system from being brought up to system pressure too rapidly.

NOTE: Rapid pressurization of a system is adiabatic in nature and may result in a potentially hazardous temperature rise.

There is no appreciable increase in flow through the valve when opened more than 3 turns. As with all valves, it should be opened fully and then backed off about 1/4 of a turn. Note, however, that the valve can be forced open more than 3-1/2 turns, but this begins to compress the sealing spring and results in an immediate increase in torque required to operate the valve. This should be avoided. Similarly, from a shut-off position, the valve handle can be further tightened approximately another 1/4 turn. This too is accompanied by an increase in torque required and does not enhance the sealing of the valve. This is the result of the KEL-F seat which will cold-flow with the application of additional torque. The packing on the rotating stem seals by the combined action of a spring and internal gas pressure. Application of sufficient axial force (push) on the valve handle can result in unseating of this seal and ensuing leakage, but only as long as this unseating force is maintained.

2. Disassembly

WARNING: DISCHARGE CYLINDER PRESSURE PRIOR TO REMOVAL OF VALVE ASSEMBLY.

NOTE: Refer to the "EFFECT CODE" column of the Group Assembly Parts List for the parts applicable to the part number valve assembly being disassembled. Disregard instructions concerning parts that are not used on the valve being disassembled.

A. Disassemble any 6350 Series Cylinder and Valve Assembly by unthreading valve assembly (7 or 8, IPL figure 1) from cylinder (9). Remove indentification plate (2) from the cylinder if required.

B. Disassemble the 802777 and 802780 Oxygen Valve Assemblies as follows (see IPL figure 2).

(1) Unthread and remove gauge (7) and safety relief assembly (8 or 20); then adaptor (9) and insert (10).

(2) Unthread connection (12); then remove gasket (13) and disc (14), only if the disc is ruptured.

(3) Disassemble valve assembly (20 through 35) as follows:

a. Unthread cap (21); then remove washer (22) and disc (23), only if the disc is ruptured.

b. Remove handwheel (24) by removing nut (25) and cup (26); then remove spring (27).

c. Remove washer (28) from body (35).

d. Unthread and remove nut (29); then remove follower (30) and packings (31 and 32) from nut (29).

e. Unthread and remove stem assembly (33) and plug assembly (34) from body (35).

C. Disassemble the 810850 or 10850 Slow Opening Oxygen Valve Assemblies as follows (see IPL figure 3).

(1) Remove gauge (3 or 4) from body (100 or 101) by removing screws (5) and washers (7).

(2) Remove ring (8), packing (9) and sleeve (10).

(3) Remove safety plug assembly (12 through 14), if applicable. Remove plug (12), disc (13 or 13A) and gasket (14) from body (100 or 101).

NOTE: Use driver (3 or 4, figure 1001), as applicable, to remove retainers in steps (4) through (12) below.

(4) Remove safety outlet assembly (16 through 20), if applicable. Remove gasket (20), disc (19 or 19A), retainer (18), and insert (17) from nut (16).

(5) Remove safety outlet assembly (25 through 29), if applicable. Remove gasket (29), disc (28 or 28A), retainer (27), and insert (26) from nut (25).

(6) Remove safety outlet assembly (31 through 37), if applicable and disassemble as follows:

a. Unthread cap assembly (31) from the safety outlet assembly and remove screw (32).

b. Remove gasket (37), disc (36 or 36A), retainer (35) and insert (34) from nut (33).

(7) Remove safety outlet assembly (39 through 43), if applicable. Remove gasket (43), disc (42 or 42A), retainer (41), and insert (40) from nut (39).

(8) Remove safety outlet assembly (45 through 49), if applicable. Remove gasket (49), disc (48 or 48A), retainer (47), and insert (46) from nut (45).

(9) Remove safety outlet assembly (51 through 55), if applicable. Remove gasket (55), disc (54 or 54A), retainer (53), and insert (52) from fitting (51).

(10) Remove safety outlet assembly (57 through 63), if applicable and disassemble as follows:

a. Unthread cap assembly (57) from the safety outlet assembly and remove screw (58).

b. Remove gasket (63), disc (62 or 62A), retainer (61), and insert (60) from nut (59).

(11) Remove safety outlet assembly (65 through 71), if applicable and disassemble as follows:

a. Unthread cap assembly (65) from the safety outlet assembly and remove screw (66).

b. Remove gasket (71), disc (70 or 70A), retainer (69), and insert (68) from nut (67).

(12) Remove safety outlet assembly (73 through 77), if applicable. Remove gasket (77), disc (76 or 76A), retainer (75) and insert (74) from nut (73).

(13) Disassemble body assembly (82 through 101) as follows:

a. Remove plate (82).

b. Remove handle (83) by driving out pin (84).

c. Unthread and remove retainer (85). Remove guide (86) and packing (88) or washer (89).

d. Remove stem assembly (90) from body (100 or 101).

e. Remove washers (92 and 93), spring (94) and washer (95) from body (100 or 101).

f. Unthread valve plug (96) and valve seat assembly (97).

NOTE: Use tee wrench (1, figure 1001) to remove plug (96, IPL figure 3). Use valve seat wrench (2, figure 1001) to remove valve seat assembly (97, IPL figure 3).

g. Unthread plug (98) from body (100 or 101).

h. Unthread gauge guard (99) from body (100).

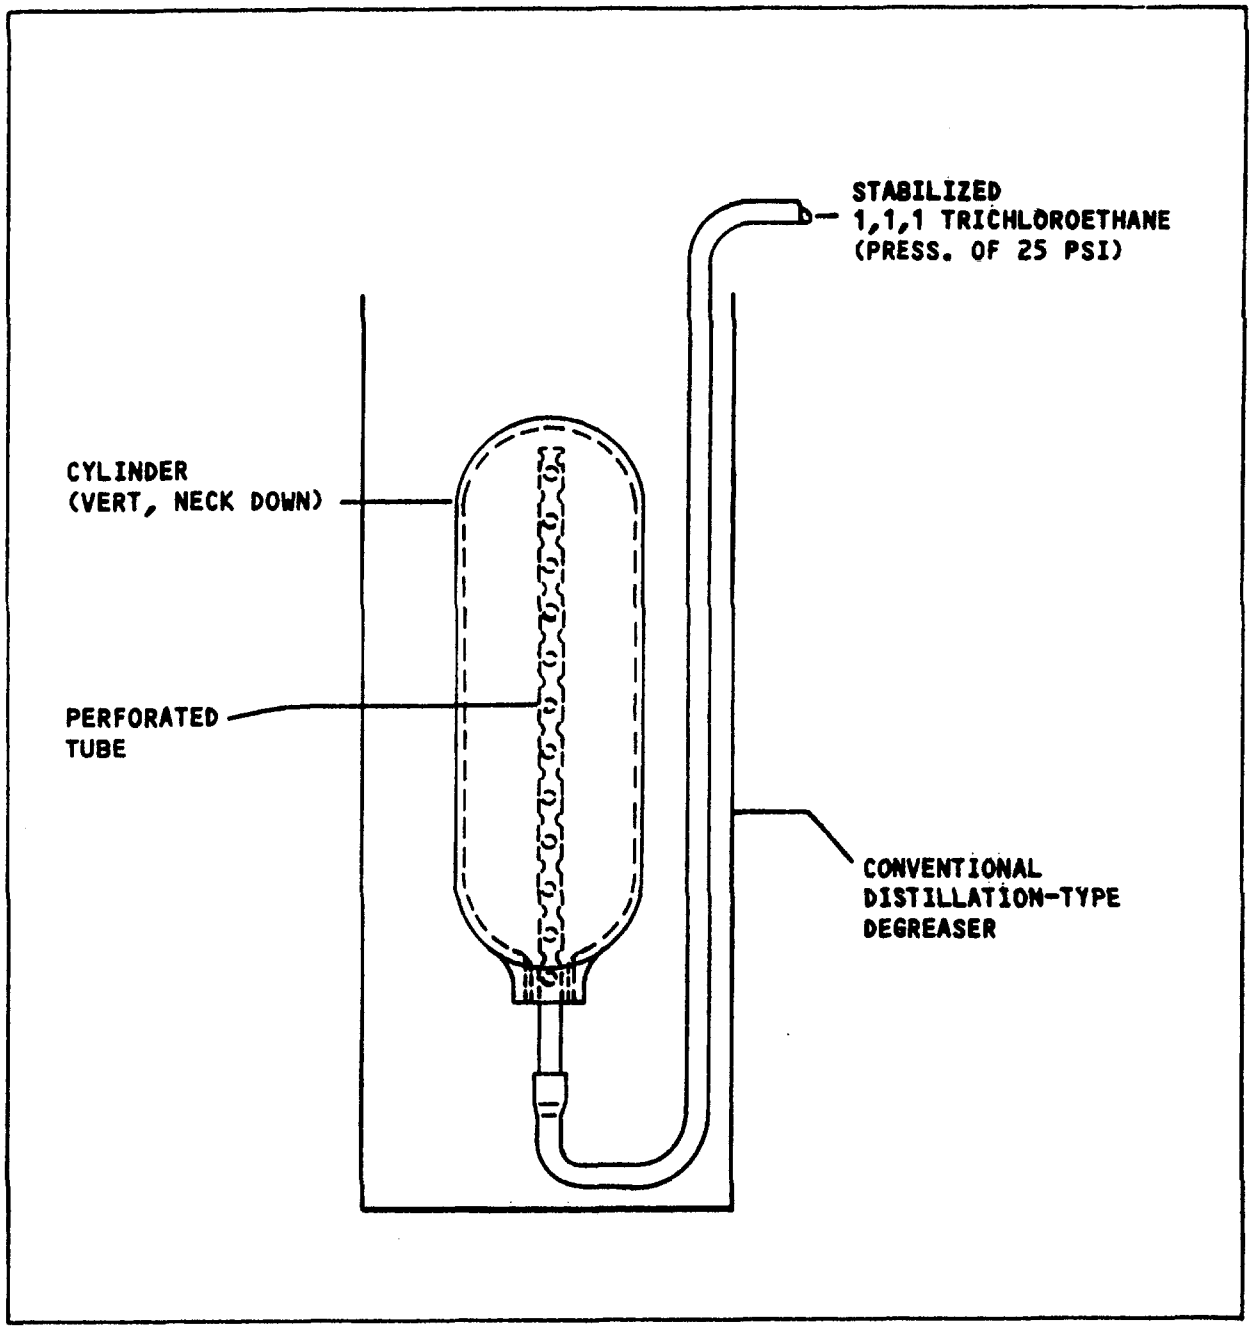
3. Cleaning

Note: Using the cleaning materials listed in Table I, perform the cleaning procedures outlined in the following paragraphs. Equivalent materials may be used.

MATERIAL	DESCRIPTION	MANUFACTURER*	REFER TO PARA.
Neutralizing Agent	Fisan Enzodent	V44389	3.A.(5) 3.B.(2)
Degreasing Agent	1,1,1 Trichloroethane (MIL-T-81533)	V91784	3.A.(4) 3.A.(8)(a)
Corrosion Inhibitor	Phosphoric Acid Isopropyl Alcohol (50% of each by Vol.)	V70829 NOTE: Purchased Separately	3.A.(3)

*Refer to Illustrated Parts List, paragraph 12.A.(4) for Vendor's Codes.

List of Cleaning Materials
Table I



A. After inspecting cylinders in accordance with Inspection/Check, perform the following cleaning procedure.

NOTE: This procedure will remove any organic impurities which are soluble in 1,1,1 Trichloroethane.

(1) Wire brush the cylinder neck threads to remove sealing compounds or rust.

(2) Shake out cylinder to remove any loose foreign matter.

(3) Apply a solution (50% by volume of phosphoric acid/isopropyl alcohol) by brush to the area wire brushed, exercising care to prevent excessive application from running into the cylinder.

Cleaning Setup
Figure 201

WARNING: USE 1,1,1 TRICHLOROETHANE IN A WELL VENTILATED AREA ONLY. AVOID PROLONGED OR REPEATED CONTACT WITH SKIN AND INHALATION OF TOXIC VAPORS.

(4) Utilizing a cleaning setup as illustrated in figure 201, place the cylinder, with neck down, in vertical position over the perforated tube (the diameter and length of the tube will be determined by the particular size of the cylinder being cleaned). Pump stabilized 1,1,1 trichloroethane, slightly below its boiling point, through the tube, thoroughly spraying the interior of the cylinder being cleaned for a period of three minutes. Remove cylinder from tube and allow complete drainage of 1,1,1 trichloroethane into drain.

(5) After completion of step (4), and using a cleaning setup similar to the setup illustrated in figure 201, pump a solution of Fisan Enzodent (8 ounces per each gallon of water), at a temperature of 180°F, through the tube thoroughly spraying the interior of the cylinder being cleaned for a period of three to five minutes. Accomplishment of this step will neutralize any acid constituents and destroy odor.

(6) After completion of step (5), and using a cleaning setup similar to the setup illustrated in figure 201, pump water (at city pressure) at 160 to 180 degrees F, through the tube thoroughly spraying the interior of the cylinder being cleaned for a period of two minutes to remove any traces of alkaline residue.

(7) After completion of step (6), and using a cleaning setup similar to the setup illustrated in figure 201, dry the interior of the cylinder with forced air heated to a temperature of 212°F, for a period of three to five minutes.

(8) After completion of step (7), and after the cylinder has cooled to room temperature, reinspect the cylinder in accordance with Inspection/Check.

NOTE: The cleaning process used should be checked initially and periodically as follows.

a. Pour 50cc of anhydrous, chemically pure, 1,1,1 Trichloroethane into the processed cylinder. Cap and shake well for one to two minutes.

b. Remove cap and pour flushings into a clean Erlenmeyer flask. Distill the 1,1,1 Trichloroethane in a water bath. After the 1,1,1 Trichloroethane has been distilled, examine residue in flask. If oil marks are visible, check cleaning solutions, implements and pressure.

c. After completion of steps (a) and (b), and using a cleaning setup similar to the setup illustrated in figure 201, clear all traces of the 1,1,1 Trichloroethane from the interior of the cylinder by blowing with dry, clean, oil-free air.

B. After inspecting the valve assembly or regulator assembly in accordance with Inspection/Check, perform the following cleaning procedure.

WARNING: DO NOT ALLOW OIL, GREASE, FLAMMABLE SOLVENTS, OR OTHER COMBUSTIBLE MATERIALS TO COME IN CONTACT WITH PARTS THAT WILL BE EXPOSED TO PRESSURIZED OXYGEN. SUCH MATERIALS, AS WELL AS DUST, LINT, AND FINE METAL FILINGS ARE ALL POTENTIAL COMBUSTIBLES WHICH MIGHT, WHEN EXPOSED TO OXYGEN UNDER PRESSURE, IGNITE AND RESULT IN AN EXPLOSION.

(1) Remove dirt and foreign particles from equipment by wiping with a clean lint-free cloth, or by blowing with clean oil-free air or nitrogen.

WARNING: USE 1,1,1 TRICHLOROETHANE IN A WELL VENTILATED AREA ONLY. AVOID PROLONGED OR REPEATED CONTACT WITH SKIN AND INHALATION OF TOXIC VAPORS.

(2) Metal parts which come in contact with oxygen and have become contaminated with grease can be cleaned by using a vapor degreasing method with stabilized 1,1,1 Trichloroethane. Blow clean and dry with a stream of clean, dry, oil-free air or nitrogen.

(3) Non-metallic parts such as silicone and rubber components may be cleaned by using an ultrasonic detergent and water cleaning system. Rinse parts in clean water and dry thoroughly before reassembly. Do not use chlorinated solvents with non-metallic parts.

4. Inspection/Check

NOTE: For Cylinder Inspection and Hydrostatic Retest, the use of Compressed Gas Association (CGA) pamphlets E-1, C-5, C-6, C-8 are recommended. These are available from:

CGA, INC.
1235 Jefferson Davis Highway
Arlington, VA 22202

A. Inspect exterior of cylinder for indications of abuse, dents and bulges.

B. Inspect neck of cylinders for cracks and distortion or damaged threads.

C. Inspect all cylinders for peeling external paint and obscure markings.

D. Inspect all high pressure cylinders for last date of hydrostatic test and type. If hydrostatic testing is required, test in accordance with Testing, step A.

NOTE: DOT Type 3HT cylinders require hydrostatic retesting every 3 years. DOT type 3A and 3AA cylinders require hydrostatic retesting every 5 years. Under certain usage conditions, DOT type 3A and 3AA cylinders may be retested at 10 year intervals. Refer to the current tariff of the "HAZARDOUS MATERIAL REGULATIONS OF THE DEPARTMENT OF TRANSPORTATION" (49 CFR 170) paragraph 173.34 (e) (15) for eligibility requirements.

E. Inspect interior of cylinders for defects which might render the cylinder unsafe.

NOTE: Inspect the interior of cylinders with the aid of a small electric light to give complete visibility of interior.

F. Inspect the interior of cylinders for rust spots, improper parkerizing, or surface blemishes.

G. Inspect valve and/or regulator for cracks, nicks, dents, or burrs which might cause malfunction.

H. Inspect valve seats for scoring.

I. Inspect all threads of valves and/or regulator for damage.

J. Inspect overall condition of all components.

5. Repair

NOTE: Table II lists the consumable materials for repair. Equivalent materials may be used.

MATERIAL	DESCRIPTION	MANUFACTURER*	REFER TO PARA.
Chromic Acid	Chromic Acid	V72658	5.B(5)
Phosphoric Acid	Phosphoric Acid	V70829	5.B(3)
Phosphate	Zn PO_4	V44389	5.B(3)

*Refer to Illustrated Parts List, paragraph 12.A(4) for Vendor's Codes.

List of Consumable Materials for Repair
Table II

A. Replace cylinders that show signs of abuse, dents, bulges, cracks, distortion, damaged threads, and/or defects which might render the cylinder unsafe (refer to Inspection/Check, steps A,B,C, and E).

NOTE: DOT type 3HT Type cylinders must be discarded and replaced at the end of twenty-four years following date of original test or 4,380 pressurizations, whichever occurs first.

B. Cylinders that require interior protective treatment may be reparkerized as follows (refer to Inspection/Check, step F).

(1) Sandblast cylinders internally and externally using fine grit shot.

(2) Rinse cylinder in clean water.

(3) Apply a phosphate coating to the interior of the cylinder either by dipping or spraying. For dip-coating, a three minute minimum dip is recommended; for spray-coating, one minute minimum is recommended.

NOTE: The balanced aqueous solution of phosphoric acid, phosphates, and accelerating agents produce a uniform water insoluble cyrstalline coating varying from gray to black in color.

(4) Rinse cylinder in clean water.

(5) Rinse cylinder in hot chromic acid (140 to 210°F) (60 to 99°C).

NOTE: The pH of the chromic acid rinse will be maintained between 2 and 4 by the addition of flake chromic acid or a mixture of chromic and phosphoric acids.

(6) Dry the cylinder by using warm air or a drying oven.

NOTE: For maximum corrosion resistance, coating weights of 400 mg/sq. ft. are usually adequate. This coating weight may be reduced to 200 mg/sq. ft. if an activator (titanium salts) is used. The coating weight may be deceptive if loosely adherent deposits are obtained, since adherent deposits give inferior performance. Finely crystalline zinc phosphate coatings provide the best corrosion resistance.

C. Remark and/or repaint cylinders in accordance with information outlined in figure 4.

D. 802777 and 802780 Oxygen Valve Assemblies (see IPL figure 2).

(1) Repair of parts is not recommended. Replace washer (28), follower (30), packings (31 and 32), plug assembly (34) and obviously defective parts at overhaul.

E. 10850 or 810850 Slow Opening Oxygen Cylinder Valve Assembly (see IPL figure 3).

(1) Repair of parts is not recommended. Replace packing (9), disc (13, 13A, 19, 19A, 28, 28A, 36, 36A, 42, 42A 48, 48A, 54, 54A, 62, 62A, 70, 70A, or 76), gasket (14, 20, 29, 37, 43, 49, 55, 63, 71, or 77), identification plate (82), pin (84), packing (88), washers (89 and 92), stem assembly (90) and valve seat assembly (97).

6. Assembly

NOTE: Table III lists the consumable materials required for reassembly.

MATERIAL	DESCRIPTION	MANUFACTURER	REFER TO PARA.
Sealing Tape	Permacel Tape No. 412	V99742	6.A.(2) 6.A.(20) 6.B.(5) 6.C.
Alpha Molykote	No. 106	V94499	6.A.(4)
Oxygen Lubricant	Krytox 240AC	V19898	6.A.(6) 6.A.(7) 6.A.(8) 6.A.(10)b 6.A.(11)b 6.A.(12)b 6.A.(13)b 6.A.(14)b 6.A.(15)b 6.A.(16)b 6.A.(17)b 6.A.(18)b 6.A.(19)b
Lock Wire	MS20995C20	------	6.A.(9)
Temp-Alarm Paint	Torque Paint Temperature-Alarm Type 43E	V82682	6.A.(20)

*Refer to Illustrated Parts List, paragraph 12.A(4) for Vendor's Codes.

NOTE: Equivalent materials may be used, except for oxygen lubricant.

Recommended Consumable Materials for Assembly
Table III

NOTE: Refer to the "EFFECT CODE" column of the Group Assembly Parts List for the parts applicable to the part number valve assembly being reassembled. Disregard instructions concerning parts that are not used on the valve assembly being reassembled.

A. Assemble the 810850 or 10850 Slow Opening Oxygen Cylinder Valves as follows (see IPL figure 3).

(1) Thread gauge guard (99) onto body (100).

(2) Wrap 1-1/2 turns of thread sealing tape to plug (98) in the direction of the thread spiral, beginning with the first thread. In no case shall the tape extend beyond the first thread. Trim off excess tape. Thread the plug into body (101).

(3) Thread valve seat assembly (97) into the valve body until seated. Torque tighten the valve seat assembly per Table IV, using valve seat wrench (2, figure 1001).

(4) If threads of valve plug (96, IPL figure 3) are uncoated or coating is worn off, apply a very light coat of molykote to the threads and bake at 260°F for one hour. Thread valve plug (96) into body (100 or 101). Thread valve plug (96) into valve body using tee wrench (1, figure 1001).

(5) Place washer (95, IPL figure 3) and spring (94) into body (100 or 101).

(6) Apply a thin film of oxygen lubricant to surfaces of washers (92 and 93) and place the washers on top of spring (94).

NOTE: Observe correct order of washers (92 and 93); washer (92) is non-metallic.

(7) Apply a thin film of oxygen lubricant to face of gasket on stem assembly (90) and place the stem assembly into body (100 or 101). Place washer (89) on stem assembly (90).

(8) Apply a wipe coat of oxygen lubricant to packing (88) and place packing into groove of guide (86).

(9) Position guide (86) and secure in place by threading retainer (85) into body (100 or 101). Torque retainer (85) per Table IV. Lockwire the retainer to the body per applicable instructions of MS33540.

CAUTION: THE TORQUE VALUES LISTED IN TABLE IV SHALL BE STRICTLY ADHERED TO WHEN INSTALLING RETAINERS. TORQUE VALUES DEPEND ON THE TYPE OF SAFETY DISC BEING INSTALLED.

(10) Reassemble safety outlet assembly (73 through 77) as follows:

a. Position disc (76 or 76A) and gasket (77) into retainer (75).

b. Apply a wipe coat of oxygen lubricant to exposed surface of gasket (77).

c. Thread retainer (75) into body (100 or 101) using driver (3 or 4, figure 1001) and torque per Table IV.

d. Position insert (74, IPL figure 3) in nut (73) and thread nut (73) into body (100 or 101). Lockwire the nut into the valve body per applicable instructions of MS33540.

(11) Reassemble safety outlet assembly (65 through 71) as follows:

a. Position gasket (71) and disc (70 or 70A) into retainer (69). Convex side of gasket (71) shall be out.

b. Apply a wipe coat of oxygen lubricant to exposed surface of gasket (71).

c. Thread retainer (69) into body (100 or 101) using driver (3 or 4, figure 1001) and torque per Table IV.

d. Position insert (68, IPL figure 3) in nut (67) and thread nut (67) into body (100 or 101). Lockwire the nut into the valve body per applicable instructions of MS33540.

e. Secure cap assembly (65) to nut (67) with screw (66). Thread the cap assembly onto end of nut (67) after completion of testing.

(12) Reassemble safety outlet assembly (57 through 63) as follows:

a. Position gasket (63) and disc (62 or 62A) into retainer (61).

b. Apply a wipe coat of oxygen lubricant to exposed surface of gasket (63).

c. Thread retainer (61) into body (100 or 101) using driver (3 or 4, figure 1001) and torque per Table IV.

d. Position insert (60, IPL figure 3) in nut (59) and thread nut (59) into body (100 or 101). Lockwire the nut into the valve body per applicable instructions of MS33540.

e. Secure cap assembly (57) to nut (59) with screw (58). Thread the cap assembly onto end of nut (59) after completion of testing.

(13) Reassemble safety outlet assembly (51 through 55) as follows:

a. Postion gasket (55) and disc (54 or 54A) into retainer (53).

b. Apply a wipe coat of oxygen lubricant to exposed surface of gasket (55).

c. Thread retainer (53) into body (100 or 101) using driver (3 or 4, figure 1001) and torque per Table IV.

d. Position insert (52, IPL figure 3) in fitting (51) and thread fitting (51) into body (100 or 101). Lockwire the fitting into the valve body per applicable instructions of MS33540.

(14) Reassemble safety outlet assembly (45 through 49) as follows:

a. Position gasket (49) and disc (48 or 48A) into retainer (47).

b. Apply a wipe coat of oxygen lubricant to exposed surface of gasket (49).

c. Thread retainer (47) into body (100 or 101) using driver (3 or 4, figure 1001) and torque per Table IV.

d. Position insert (46, IPL figure 3) in nut (45) and thread nut (45) into body (100 or 101). Lockwire the nut into the valve body per the applicable instructions of MS33540.

(15) Reassemble safety outlet assembly (39 through 43) as follows:

a. Position gasket (43) and disc (42 or 42A) into retainer (41).

b. Apply a wipe coat of oxygen lubricant to exposed surface of gasket (43).

c. Thread retainer (41) into body (100 or 101) using driver (3 or 4, figure 1001) and torque per Table IV.

d. Position insert (40, IPL figure 3) in nut (39) and thread nut (39) into body (100 or 101). Lockwire the nut into the valve body per the applicable instructions of MS33540.

(16) Reassemble safety outlet assembly (31 through 37) as follows:

a. Position gasket (37) and disc (36 or 36A) into retainer (35).

b. Apply a wipe coat of oxygen lubricant to exposed surface of gasket (37).

c. Thread retainer (35) into body (100 or 101) using driver (3 or 4, figure 1001) and torque per Table IV.

d. Position insert (34, IPL figure 3) in nut (33) and thread nut (33) into body (100 or 101). Lockwire the nut into the valve body per the applicable instructions of MS33540.

e. Secure cap assembly (31) to nut (33) with screw (32). Thread the cap assembly onto end of nut (33) after completion of testing.

(17) Reassemble safety outlet assembly (25 through 29) as follows:

a. Position gasket (29) and disc (28 or 28A) into retainer (27).

b. Apply a wipe coat of oxygen lubricant to exposed surface of gasket (29).

c. Thread retainer (27) into body (100 or 101) using driver (3 or 4, figure 1001) and torque per Table IV.

d. Position insert (26, IPL figure 3) in nut (25) and thread nut (25) into body (100 or 101).

(18) Reassemble safety outlet assembly (16 through 20) as follows:

a. Postion gasket (20) and disc (19 or 19A) into retainer (18).

b. Apply a wipe coat of oxygen lubricant to exposed surface of gasket (20).

c. Thread retainer (18) into body (100 or 101) using driver (3 or 4, figure 1001) and torque per Table IV.

(19) Reassemble safety plug assembly (12 through 14) as follows:

a. Position gasket (14) and disc (13 or 13A) into plug (12).

b. Apply a wipe coat of oxygen lubricant to exposed surface of gasket (14).

c. Thread plug (12) into body (100 or 101) and torque per Table IV.

(20) Apply a wipe coat of oxygen lubricant to packing (9). Place ring (8), packing (9) and sleeve (10) on stem of gauge (3). Secure gauge (3) to body (101) with screws (5 or 6) and washers (7). Cover screw (5 or 6) heads with Temp-Alarm paint.

(21) Wrap 1-1/2 turns of thread sealing tape to gauge (4) in the direction of the thread spiral, beginning with the first thread. In no case shall the tape extend beyond the first thread. Trim off excess tape. Thread the gauge into body (101).

(22) Test the partially assembled slow opening oxygen cylinder valve assembly in accordance with Testing.

(23) Complete assembly by securing handle (83) to stem assembly (90) with roll pin (84). Secure identification plate (82) to handle (83).

B. Assemble the 802777 and 802780 Oxygen Valve Assemblies as follows (see IPL figure 2).

(1) Assemble valve assembly (20 through 35) as follows:

a. Thread plug assembly (34) into body (35).

b. Place stem assembly (33) in body (35); then place packing (32) in nut (29) and thread the nut into the body.

c. Install packing (31) and follower (30) on stem assembly (33) and carefully depress into nut (29). Place washer (28) over nut (29).

d. Place handwheel (24) on stem assembly (33); then place spring (27) over the stem into the handwheel. Secure handwheel with cup (26) and nut (25).

e. If disassembled, insert disc (23) and washer (22) in cap (21) and thread the cap onto body (35). Thread cap (20) onto body (35).

(2) If disassembled, insert disc (14) and gasket (13) in connection (12). Thread the connection onto body (35) and torque per Table IV.

(3) Place insert (10) in adaptor (9) and thread the adaptor into connection (12).

(4) Thread safety relief assembly (8) onto body (35).

(5) Wrap 1-1/2 turns of thread sealing tape to gauge (7) in the direction of the thread spiral, beginning with the first thread. In no case shall the tape extend beyond the first thread. Thread the gauge into body (35).

C. Assemble the 6350 Series Cylinder and Valve Assembly as follows (see IPL figure 1).

NOTE: Wrap thread sealing tape to valves, prior to mating with cylinders in the direction of the thread spiral, beginning with the first thread. In no case shall the tape extend beyond the first thread. Trim off excess tape. Wrap two turns of tape on threads of valves requiring 100 pound-feet torque and three turns on threads of valves requiring 150 pound-feet.

(1) Secure plate (2) to cylinder (9).

(2) Thread appropriate valve assembly (7 or 8) into appropriate cylinder (9), torque the valve assembly per Table IV.

7. Fits and Clearances

A. Table IV presents the torque values necessary to assemble the units.

UNIT	TORQUE (Newton meters)
Plug (12, IPL figure 3)	*100 to 400 pound-inches (11,3-45,2)
Retainer (18, IPL figure 3)	**275/375 pound-inches (31/42) max.
Retainer (27, IPL figure 3)	**275/375 pound-inches (31/42) max.
Retainer (35, IPL figure 3)	**275/375 pound-inches (31/42) max.
Retainer (41, IPL figure 3)	**275/375 pound-inches (31/42) max.
Retainer (47, IPL figure 3)	**275/375 pound-inches (31/42) max.
Retainer (53, IPL figure 3)	**275/375 pound-inches (31/42) max.
Retainer (61, IPL figure 3)	**275/375 pound-inches (31/42) max.
Retainer (69, IPL figure 3)	*300 to 400 pound-inches (33,9-45,2)
Valve Body (19, IPL figure 2)	150 pound-feet (204)
Valve Body (100, IPL figure 3)	150 pound-feet (204)
Valve Body (101, IPL figure 3)	150 pound-feet (204)
Valve Seat Assy (97,IPL figure 3)	140 pound-inches (15,8)
Retainer (75, IPL figure 3)	**275/375 pound-inches (31/42)max.
Retainer (85, IPL figure 3)	300 pound-inches (33,9)
Connection (12, IPL figure 2)	300 pound-inches (33,9) maximum

*Torque components to minimum values. If leakage occurs, retorque to a higher value, but do not exceed the maximum.

**Torque retainer to 275 pound-inches (31N.m) maximum when installing disc, P/N 10003742 (silver) or to 375 pound-inches (42.3 N.m) when installing disc, P/N 10006001 (bronze).

Assembly Torque Values
Table IV

8. Testing

WARNING: IN ALL PROCEDURES LISTED BELOW, OXYGEN IS SPECIFIED AS THE TEST GAS. WATER PUMPED NITROGEN OR OIL-FREE AIR MAY BE SUBSTITUTED, BUT RESULTS MUST BE CONVERTED PRIOR TO BEING COMPARED WITH THE RESULTS SPECIFIED FOR OXYGEN. DO NOT, UNDER ANY CIRCUMSTANCES, USE OIL PUMPED GAS AS THIS WILL CAUSE CONTAMINATION OF THE VALVE AND TEST EQUIPMENT. OIL, EVEN IN MINUTE QUANTITY, COMING IN CONTACT WITH OXYGEN MAY CAUSE AN EXPLOSION OR FIRE.

NOTE: Table V lists the consumable materials for testing. Equivalent materials may be used.

MATERIAL	DESCRIPTION	MANUFACTURER*	REFER TO PARAGRAPH
Oxygen	MIL-O-27210, *Type 1*	V07098	All Testing
Leak Test Solution	Sodium Chromate; 5cc per gallon of water	V72658	8.C(3), 8.D(4), 8.D(6), 8.E(3)

*Refer to Illustrated Parts List, paragraph 12.A(4) for Vendor's Codes.

List of Consumable Materials for Testing
Table V

A. If required, subject the cylinders to hydrostatic testing in accordance with CGA Pamphlet C-1 and Hazardous Materials Regulations of Department of Transportation (DOT), Current Tariff No.

B. Facilities performing such tests shall hold a current, valid DOT Approval.

C. After reassembly of the 802777 and 802780 Oxygen Valve Assemblies perform a leak test in accordance with the following procedure.

(1) Close the valve.

(2) Apply pressure to the valve inlet (cylinder port).

(3) Submerge the valve in a leak test solution. No leakage shall be evident.

D. After reassembly of the 10850 or 810850 Oxygen Cylinder Valve, perform the following test:

(1) Attach a 2000 psi oxygen source to the inlet of the oxygen valve assembly through a suitably attached flexible hose or equivalent. Air or nitrogen, equivalent in dryness and cleanliness to MIL-O-27210 may be substituted for oxygen.

(2) Manually close (full clockwise) the valve at control stem (90, IPL figure 3) fingertight.

(3) If the valve is equipped with a pressure gauge, remove the gauge bezel and lens before continuing.

(4) Completely submerge the valve in leak test solution.

(5) With the valve submerged, apply 1850 $^{+0}_{-50}$ psi to the inlet. Check the valve for leakage for two minutes. Leakage as indicated by bubbles must be corrected before continuing.

(6) Remove the valve from the leak test solution, suitably cap the valve outlet, open the valve (two revolutions counterclockwise) and completely submerge the valve for three minutes. Leakage as indicated by bubbles must be corrected before continuing.

(7) Remove the valve from the solution, manually close the valve and remove the outlet cap or plug installed in step (6).

(8) Check the torque required to open and close the pressurized valve from cracked to full open. The torque shall not exceed 15 pound-inches (1,70 N.m).

(9) Shut off and remove the external oxygen source.

(10) Dry the valve thoroughly with a stream of clean, dry, oil-free air. Insure that inside gauge mechanism is dry. Replace the gauge lens and bezel if required.

(11) Complete assembly of the oxygen valve assembly (refer to Assembly, Step A.(15)).

E. After reassembly of cylinder and valve assembly, perform a leakage test in accordance with the following procedure.

(1) Charge cylinder to full operating pressure at a rate not to exceed 300 psi per minute.

(2) Allow cylinder to cool to room temperature and "top off" if necessary.

(3) Submerge the valve assembly and cylinder neck in leak test solution for two minutes, and check for leakage. No leakage shall be evident.

NOTE: If cylinder and valve assembly is equipped with a gauge, remove the gauge bezel and lens prior to submerging in leak test solution.

(4) Check accuracy of valve or regulator gauge to master gauge. Accuracy to be ± 50 psi.

(5) Record valve gauge indication and date of charging.

(6) Store cylinder and valve assembly for a minimum of 72 hours. During this period check gauge indication against recorded indication. These indications shall be identical.

(7) Check gauge indication against recorded indication. These indications shall be identical.

(8) Dry cylinder and valve assembly thoroughly with low pressure oil-free air. Be sure gauge is dry internally.

9. Trouble Shooting

A. See Figure 801 for trouble shooting chart.

TROUBLE	PROBABLE CAUSE	REMEDY
Improper indication on pressure gauge of 802777 or 802780 oxygen valve assembly	Faulty pressure gauge (3, IPL figure 2)	Replace pressure gauge
Leakage at gauge (3, IPL figure 2)	Pressure gauge (3) loose	Tighten pressure gauge
Leakage at valve stem (14)	Faulty washer (11)	Replace washer
	Faulty valve stem (14)	Replace valve stem
	Faulty valve plug assembly (17)	Replace valve plug assembly
Leakage at cylinder neck when oxygen valve assembly is mated with cylinder	Damaged cylinder threads	Replace cylinder
	Damaged threads on oxygen valve assembly	Replace oxygen valve assembly
Leakage between stem assebly (90, IPL figure 3) and guide (86)	Faulty stem assy (90, IPL figure 3) or spring (94)	Replace defective part
	Faulty seat on guide (86)	Replace guide
Leakage between guide (86) and retainer (85)	Faulty packing (88) or washer (89)	Replace packing; retorque retainer
Leakage past valve seat assembly (97)	Faulty valve seat assembly (97)	Replace valve seat assembly
	Faulty plug (96)	Replace plug
	Defect in body (100 or 101)	Replace body
	Valve seat assembly (97) insufficiently torqued	Torque per Table IV

Trouble Shooting Chart (Sheet 1 of 2)
Figure 801

TROUBLE	PROBABLE CAUSE	REMEDY
Leakage at safety outlet assembly	Ruptured disc (13, 13A, 19, 19A, 28, 28A, 36, 36A, 42, 42A, 48, 48A, 54, 54A, 62, 62A, 70, 70A, 76 or 76A)	Replace disc
	Loose plug (12), fitting (51) or nut (16, 25, 33, 39, 45, 59, 67, or 73)	Tighten plug, fitting or nut
	Defective gasket (14, 20, 29, 37, 43, 49, 55, 63, 71 or 77)	Replace gasket
Leakage at gauge connection	Faulty packing (9)	Replace packing
	Loose gauge (4)	Tighten gauge
	Loose gauge (3)	Tighten screws (5)

Trouble Shooting Chart (Sheet 2 of 2)
Figure 801

10. Storage Instructions

A. Seal all valve/regulator ports with clean metal or polyvinyl chloride (PVC) caps or plugs to prevent foreign matter from entering the valve. Store in sealed polyethylene or polyvinyl bag.

B. Do not use any preservative coating on valves.

C. Charge cylinders until a gauge indication is available (approximately 150 psi).

11. Special Tools, Fixtures and Test Equipment

A. All special tools, fixtures and test equipment required for overhaul are listed in figure 1001 and illustrated in figure 1002 and are manufactured by Scott Aviation, Lancaster, New York.

FIGURE 1002 ITEM NO.	PART NUMBER	PART NAME	APPLICATION
1.	10850-T91-1	Tee Wrench	Used to install/remove valve plug (96, IPL figure 3)
2.	10850-T91-2	Valve Seat Wrench	Used to install/remove valve seat assembly (97, IPL figure 3)
3.	10850-T91-3	Driver	Used to install/remove retainers (18, 27, 35, 41, 47, 53, 61, 69 and 75, IPL figure 3) in valve assemblies using discs (19, 28, 36, 42, 48, 54, 62, 70 and 76)
4.	2786-S52-1	Driver	Used to install/remove retainers (18, 27, 35, 41, 47, 53, 61, 69 and 75, IPL figure 3) in valve assemblies using discs (19A, 28A, 36A, 42A, 48A, 54A, 62A, 70A and 76A)

Special Tools, Fixtures and Test Equipment List

Illustration of Special Tools, Fixtures and Test Equipment
Figure 1002

12. Illustrated Parts List

NOTE: Some models of the slow opening valve assemblies have been discontinued, but repair parts are available. The complete new replacement assemblies are directly interchangeable with the superseded assemblies.

MODEL	SUPERSEDED BY
27876	810850-10
58537	810850-1A
58538	810850-1B
6449M	802777 and 802780

A. This Illustrated Parts List lists and describes the parts for the 6350 Series Cylinder and Valve Assemblies (see IPL figure 1), the 802777 and 802780 Series Oxygen Valve Assemblies (see IPL figure 2), and 10850, 810850 Series Slow Opening Oxygen Cylinder Assemblies (see IPL figure 3).

(1) The Group Assembly Parts List consists of parts listings and completely indexed drawings. The particular valve/regulator assembly is followed immediately by its component parts, properly indented thereunder, to show their relationship to the assembly.

(2) The quantities listed in the "UNITS PER ASSY" column are, in the case of assemblies, the total quantity used per cylinder and valve assembly at the location indicated, while the component parts indented under the assemblies are the quantity used per assembly. The quantities specified, therefore, are not necessarily the total used per cylinder and valve assembly.

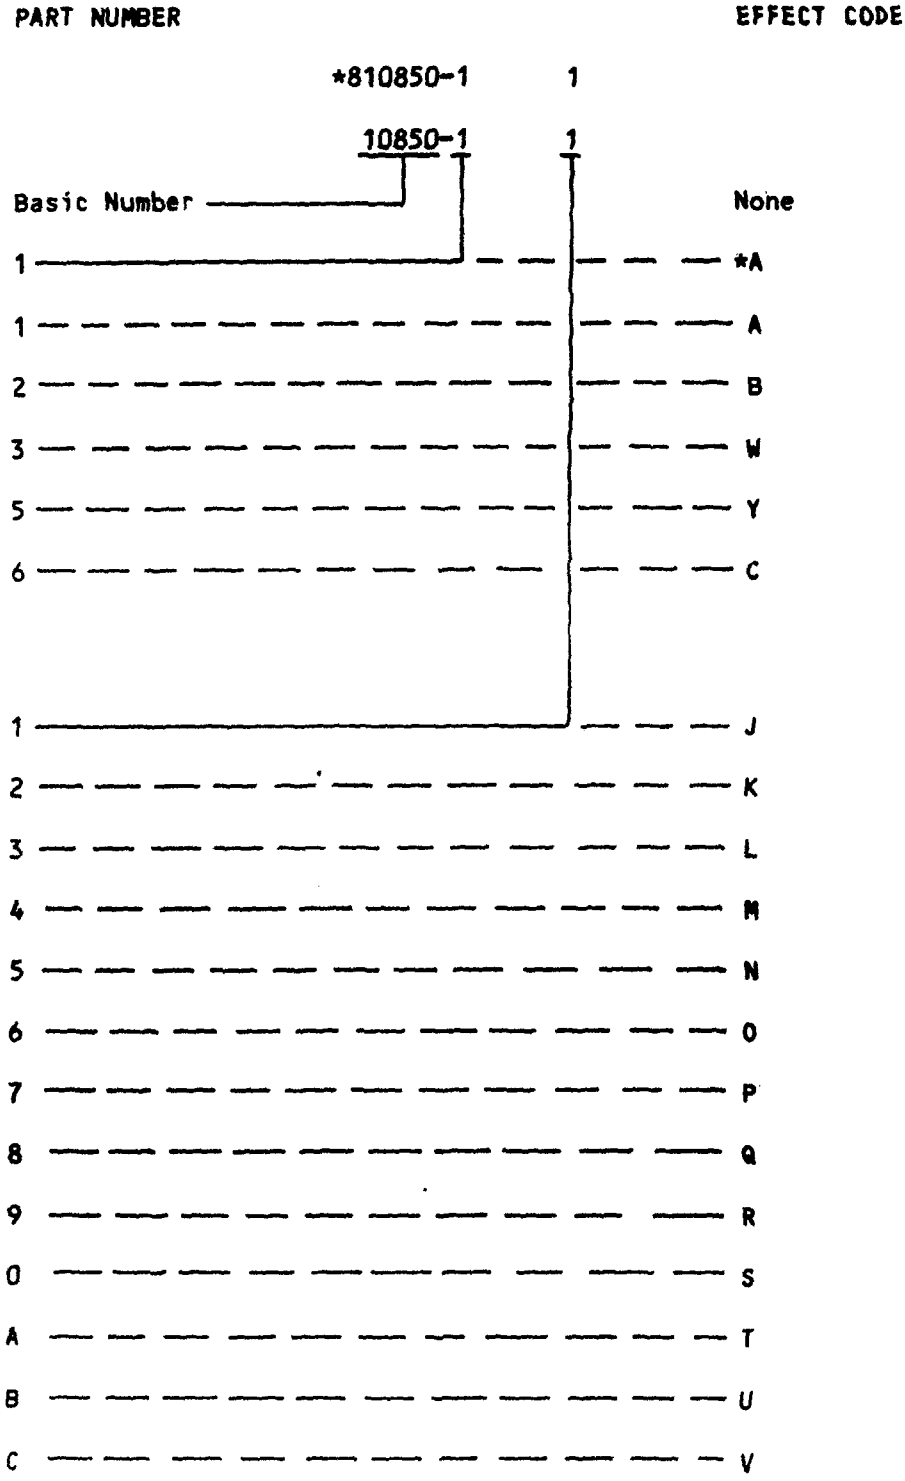
(3) The part numbers listed in the "PART NUMBER" column are Scott Aviation part numbers except standard parts, which are listed by "MS" and "AN" part numbers, and vendor items, which are listed by vendor part numbers. Commercial hardware available at commercial sources is identified by the abbreviation "COML" in the "PART NUMBER" column.

(4) A six place code, following the description of a part, indicates the manufacturer of that part. Standard parts and parts carried under Scott part numbers have no vendor's code. The following list contains the codes, and names and addresses of manufacturers supplying items or articles for the cylinder and valve assemblies. This listing includes the vendor codes presented in Tables I, II, III and V.

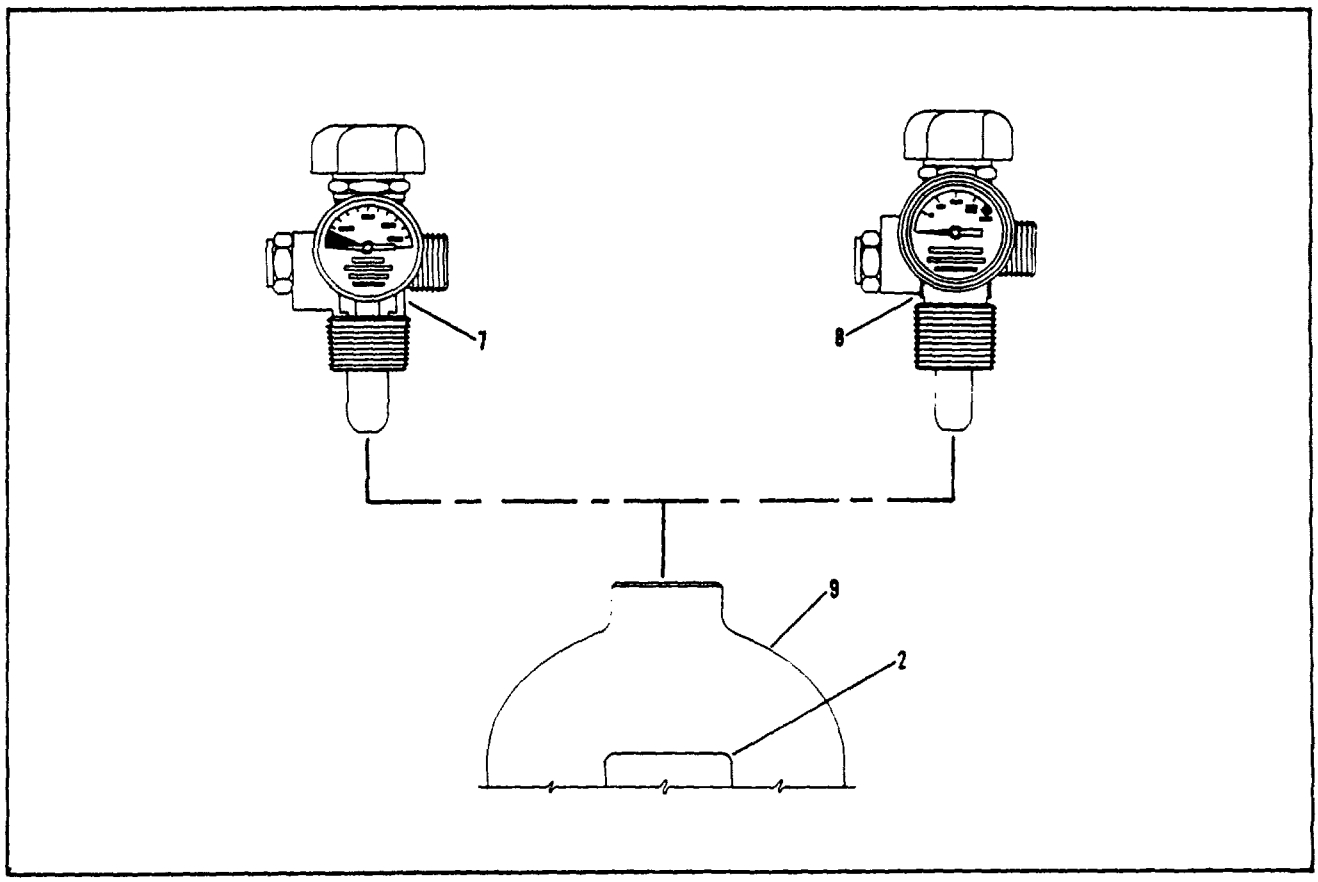
VENDOR'S CODE

CODE	NAME AND ADDRESS
V02697	Parker Seal Co. Division of Parkerhannifin Corp. Lexington, Kentucky
V04666	Robbins Aviation, Inc. Vernon, California
V07098	Union Carbide Corp. Linde Division Tonawanda, New York
V19898	E.I. DuPont De Nemours and Co., Inc. Wilmington, Delaware
V31879	Thermo Valves Corp. Mountain View, California
V44389	Oakite Products, Inc. Berkeley Heights, New Jersey
V70829	J.T. Baker Chemical Co. N. Phillipsburg, New Jersey
V72658	Allied Chemical Corp. Industrial Chemical Division Morristown, New Jersey
V72962	Elastic Stop Nut Division of Amerace Esna Corp. Union, New Jersey
V82682	Tempil Div. Big Tree Industries Inc. South Plainfield, New Jersey
V91784	Hooker Chemical Corp. Niagara Falls, New York
V94499	Dow Corning Corp. Alpha Molykote Plant Stamford, Connecticut
V99742	Johnson and Johnson, Inc. Permacel Division New Brunswick, New Jersey

B. How to use this Illustrated Parts List.



(1) If neither the part number nor the nomenclature is known, the part can be found by comparison with the exploded view illustration. When located on the illustration, the index number will refer to the line in the Group Assembly Parts List with the part number and the nomenclature.



C. How to determine the applicable "EFFECT CODE".

(1) Parts used on only one part number oxygen valve assembly (see IPL figure 2) are indicated by a letter symbol immediately following the description of a part in the "EFFECT CODE" column. An explanation of the letter symbols used is outlined below. In cases when the "EFFECT CODE" column has been left blank, parts listed are common to all oxygen valve assemblies.

PART NUMBER	EFFECT CODE
802777-02	A
802777-03	B
802777-05	C
802777-06	D
802780-05	E
802780-06	F

(2) Note the part number of the particular Slow Opening Valve Assembly (see IPL figure 3) being overhauled, and determine the "EFFECT CODE" letters applicable. For example, if the part number is 10850-11, the "EFFECT CODE" letters are A and J in the "EFFECT CODE" column. In addition to those parts, the particular assembly would use all parts having a blank "EFFECT CODE" column.

OVERHAUL INSTRUCTIONS

FOR

ZEP AERO

HIGH PRESSURE CYLINDER

TYPE ZC 268-111-30

ZEP AERO
111 Penn Street
El Segundo, California 90245, U.S.A.

June 15, 1965
Rev. "A" Jan 1966
Rev. "B" June 1966

RECOMMENDED PROCEDURE FOR RECONDITIONING HIGH PRESSURE CYLINDERS PER ICC REGULATIONS

1. Inspect cylinders visually to determine advisability of reconditioning.

2. OVERHAUL - Disassembly

   A. Clamp the cylinder in a suitable holding device, with the valve upward.

   B. Slowly open the valve handle to bleed off the cylinder pressure.

   Caution: Never attempt to remove or tighten a cylinder valve when there is pressure in the cylinder.

   C. Overhaul valve, and test.

3. Inspect threads and interior.

4. Inspect cylinder interior and exterior for dents and corrosion with inspection light.

5. TESTING

   A. All light weight cylinders must be tested every 3 years and must be destroyed after 12 years use. Date stamp and hydrostatic test stamp must be inserted around the top of dome very lightly.

   B. All standard weight cylinders must be hydrostatic tested every 5 years. Date stamp, hydrostatic test stamp will be stamped under the last test dates.

6. If interior is rusty, the procedure outlined below shall be followed:

   A. Pour in a solution containing 1 gallon Solar Scale Remover D4-08 Compound diluted with 2 to 3 parts water. Leave for a period of 10 to 15 minutes; empty, and flush with hot water. (NOTE: D4-08 compound can be re-used until it becomes weak.)

   B. Pour in a second solution comprised of 3 ounces of Solar Neutralizer A-6 Compound diluted with 1 gallon of hot water, and leave for a period of 2 minutes. Flush with hot water.

   C. Use a third solution composed of 3 ounces of Solar Phosphate Compound A-7 diluted with 1 gallon hot water, and leave for a period of 2 minutes. Empty, but do not flush. Place on drier and allow to dry completely.

7. Inspect interior with inspection light.

8. Purge and install reconditioned valve, torque down, and clean off excess lubricant.

9. Charge, leak check, halogen test, and prepare for paint.

10. Paint with 1 coat Zinc Chromate Primer and 2 coats of light green lacquer.

11. Stencil with correct stencil, stamp off, top off, and leak check; apply overhaul decal.

THE Bendix CORPORATION

1. DISASSEMBLY

Disassembly in the same order as the key index numbers assigned to the exploded view illustration. Figure 1.

a. Remove nuts (1), washers (3) and bolts (2) from housing (25).

b. Remove adapters (4), gaskets (5) from housing (25).

c. Disassembly of cover (10) with items (11) and (12) intact can be accomplished by holding unit in hand and removing bolts (6) and washers (7).

NOTE

Springs (15) and (17) under cover (10) create no hazard since their load will be dissipated when bolts (6) are backed out.

d. Hold unit in an upright position. Remove cover (8) and gasket (9).

Lift cover (10) from housing (25). Remove items (13) through (18).

e. Hold rod (20) with a suitable device being sure not to damage it while removing nut (19).

f. Remove rod (20) and items (21) through (24).

g. Remove ring (26) from rod (20).

NOTE

Item 4A is a check valve peculiar to the 38E59-3A only.
Item 22 is a spacer peculiar to the 38E59-4A only. This is used in place of item (13).
Item 27 is a mounting bracket peculiar to the 38E59-2A only.

2. CLEANING

a. Thoroughly wash all parts with a suitable cleaning solvent. Dry all parts with a clean cloth.

3. INSPECTION

Inspect all parts for damage. Check rod (20) for scratches.

Check retainer seat for smoothness of surface.

Check springs for distortion or damage.

Check all threads for condition and cleanliness.

Check diaphragm (23) for punctures or distortion.

4. REPAIR AND REPLACEMENT

a. Replace all worn or damaged parts.

b. Replace all "O" Rings and gaskets.

5. REASSEMBLY

a. Reassembly is basically the reverse of disassembly.

CAUTION

When replacing nut (19) on rod (20) use care when holding rod to avoid damage while tightening nut.

b. When installing cover (10) be sure adjusting screw is lined up properly in retainer (14) before tightening bolts (6).

c. Reassembly of item 4 is the same in all models with the exception of the 38E59-3. This model incorporates a flapper valve assembly.

If flapper valve is damaged replace complete assembly.

The position of the flapper valve assembly (4A) is shown in the exploded view.

6. TEST PROCEDURE

Install Valve Assembly in test set up shown in Figure 2.

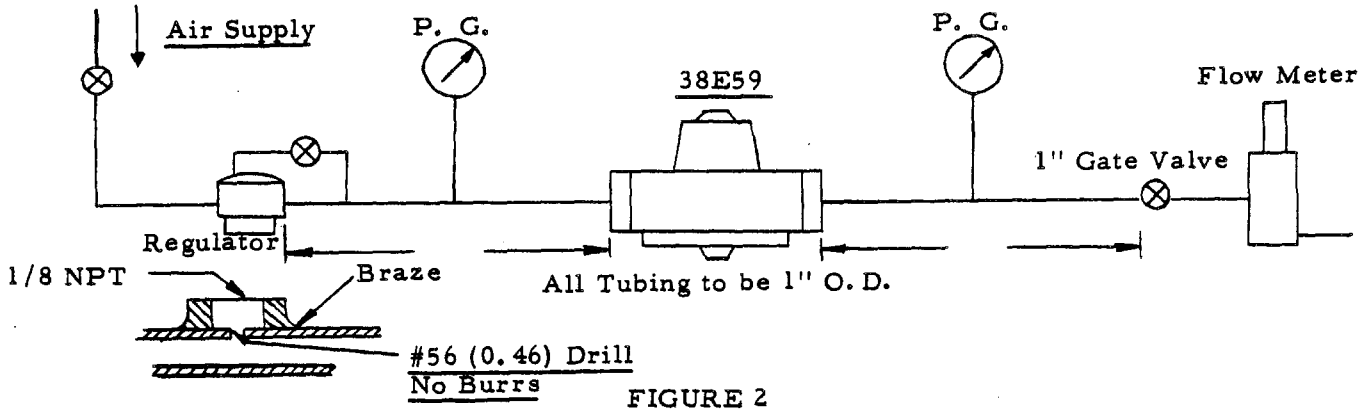

FIGURE 2

a. CALIBRATION

The valve setting stated in Initial Setting is for guidance only in making initial setting. Readjustment will be necessary to meet the requirements of minimum flow.

b. SETTING (INITIAL)

Adjust the power spring adjustment screw to maintain the following regulated or discharge pressure when flowing 20 ±1/2 scfm at inlet pressure of 30 ±1 psig:

17.5 ±.5 psig	38E59-1, 2 & 3
16.5 ±.08 psig	38E59-4
10.0 ±0.5 psig	38E59-5
15.0 ±.05 psig	38E59-6

c. MINIMUM FLOW

With inlet pressure of 90 $\pm$1 psig and flow of 5 $\pm$1/2 scfm the regulated pressure should be:

18.0 $\pm$0.75 psig	38E59-1, 2 & 3
16.5 $\pm$.08 psig	38E59-4
10.0 $^{+.080}_{-.050}$ psig	38E59-5
15.0 $^{+.080}_{-.050}$ psig	38E59-6

d. FINAL SETTING

With inlet pressure of 30 $\pm$1 psig and air flow of 5 $\pm$1/2 scfm the regulated pressure should be:

18 $\pm$1 psig	38E59-1, 2 & 3
16.5 $\pm$.08 psig	38E59-4
10.0 $^{+.080}_{-0}$ psig	38E59-5

With inlet pressure of 50 $\pm$1 psig and flow of 5 $\pm$1/2 scfm the regulated pressure should be:

15 $^{+.080}_{-0.5}$ psig	38E59-6

e. CRACK AND RESEAT PRESSURE TEST

38E59-1, 2, 3 & 4

Install valve assembly as shown in Figure 3.

Gradually increase the pressure to 22 psig and the relieving flow should be 12 scfh minimum.

Decrease the pressure to 18 psig and the leakage flow will be 5 scfh maximum.

38E59-5

Install valve assembly as shown in Figure 3.

Gradually increase the pressure to 13 psig and the relieving flow should be 12 scfh minimum.

Decrease the pressure to 10 psig and the leakage flow will be 5 scfh maximum.

38E59-6

Install valve assembly as shown in Figure 3.

Gradually increase the pressure to 20 psig and the relieving flow should be 12 scfh minimum.

Decrease the pressure to 15 psig and the leakage flow will be 5 scfh maximum.

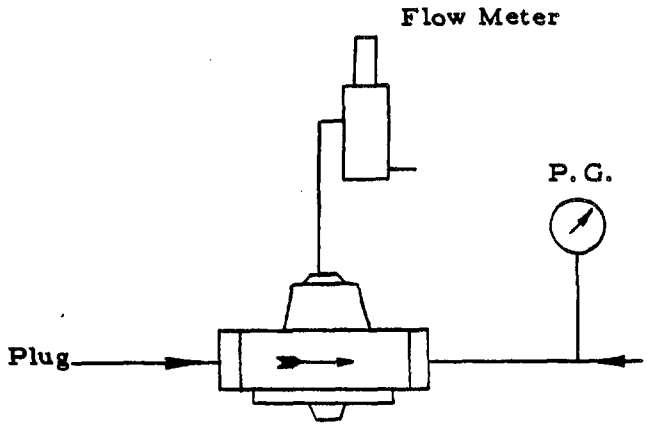

FIGURE 3

f. CHECK VALVE TEST

38E59-3 only

Install valve assembly as shown in Figure 4.

The flapper valve must open freely when pushed lightly with a blunt rod.

The flapper valve must remain closed regardless of position when not in operation.

Plug the outlet of the 38E59 and connect the inlet to a pressure line. Apply 18 psig pressure. Using liquid soap check around the check valve flanges for leakage. This should not exceed one bubble per second at any point.

Remove the plug from the outlet connection and connect the inlet to a suction source.

Apply 6" Hg. suction and close the shut-off valve. The mercury in the manometer must not fall faster than 0.25" Hg. in one minute - equivalent to 2.5 cc/min. leakage of sea level free air.

1. SPECIAL TOOLS. None.

2. DISASSEMBLY. (Refer to Figure 2).

A. Hold the adjusting nut (2) and unscrew the self-locking nut (1) from the adjusting screw (13) with a suitable wrench.

B. Remove the adjusting nut (2), from the adjusting screw (13).

C. Unscrew the valve seat retainer (3), from the valve housing (15).

D. Remove the screen (4), from the valve seat retainer (3).

E. Remove the valve seat (5), the gasket (6), the valve (7), and the valve spring (8), from the housing (15).

F. Remove the guide assembly (11), together with the adjusting screw (13), with the assembled spring retainer (12), from the valve housing (15).

G. Remove the sealing washer (9), and "O" Ring (10), from the top of the adjusting screw (13).

NOTE

Do not disassemble the guide assembly. If either the spring guide or self-locking clinch nut is damaged replace the entire guide assembly.

H. If necessary, unscrew the guide assembly (11), from the bottom of the adjusting screw (13).

I. Unscrew spring retainer (12), from the adjusting screw (13).

J. If necessary, take out screws (14), and remove the two nameplates.

3. CLEANING. Wash all parts of the suction relief valve in unleaded gasoline or any other suitable solvent.

CAUTION

Do not use Carbon Tetrachloride; its use results in corrosion of the parts.

4. INSPECTION. Inspect the valve housing for cracks, breaks and scored or corroded chambers. Check the "O" Ring, sealing washer, and gasket for cracks and breaks. Examine all threaded parts for stripped threads. Inspect the hollow valve for scored surfaces. Inspect the screen for punctures.

5. REPAIR OR REPLACEMENT. Replace any damaged parts found; replace all gaskets at every overhaul.

6. LUBRICATION.

A. For all valves - Prior to reassembly apply a film of Pioneer No. 8 Instrument oil to "O" ring. Also apply Parker Threadlube 6PB to housing threads before reassembling seat retainer.

B. For Model 691-2B only - In addition to the above, lubricate the 691-2B valve with #60 oil.

CAUTION

On models other than the 691-2B, all parts except those indicated in paragraph 6A above, must be reassembled dry.

7. REASSEMBLY.

A. Replace the spring retainer (12), on the adjusting screw (13), shoulder upward. Replace the guide assembly (11), on the bottom of the adjusting screw (13).

B. Replace the sealing washer (9), and "O" ring (10), on top of the adjusting screw (13). See paragraph 6.

C. Insert the adjusting screw (13), with the assembled spring retainer (12), guide assembly (11), "O" ring (10), and sealing washer (9), into and through the valve housing (15), so that the top of the adjusting screw (13), protrudes above the top of the housing (15).

D. Assemble the adjusting nut (2), over the protruding adjusting screw key (13). Secure the adjusting nut in place with the self-locking nut (1).

E. Place the gasket (6), over the valve seat (5).

F. Insert the valve spring (8), into the interior of the valve housing and over the circular shoulder on the bottom of the spring retainer (12).

CAUTION

Be sure to fit the valve spring properly over the spring retainer shoulder.

G. Place the hollow valve (7), over the valve spring (8). Carefully compress the valve and spring until the valve enters the chamber. Hold in place with the index finger of one hand.

H. Thrust the index finger of the other hand through the valve seat (5), to control the valve (7), and valve spring (8).

I. Place the screen (4), against the valve seat (5).

J. Screw the valve seat retainer (3) on the valve housing (15).

K. If nameplates were removed, replace and secure with screws (14).

8. TEST PROCEDURE.

A. At any time that adjustment of the Suction Relief Valve is specified during the test procedure, proceed as follows: hold the knurled adjusting nut tightly with the left hand to prevent it from turning. Then loosen the upper self-locking nut about one-quarter turn with a suitable wrench. Turn the adjusting nut counterclockwise to increase suction or clockwise to decrease suction.

NOTE

During all tests, the valve adjusting nut and top self-locking nut must be drawn tight. The nameplate screw holes must be airtight and the valve seat and screw retainer must be tightened to normal position. Check for stability at each setting by partially blocking off the inlet screen by hand to increase suction approximately one inch. The suction should immediately return to original setting without hunting or fluctuating when the hand is removed.

B. With the exception of model 691-2B, the 691 type suction relief valve must be assembled dry and tested in a room free of oil vapors to preclude the entrance of oil vapor either into the suction relief valve or the companion dry air pump. An AN 6237-1 Filter must be connected between the Suction Relief Valve and the pump inlet port to preclude entrance of dust and dirt into the pump.

NOTE

For all tests run the pump at 27.5 ± 0.25 Volts.

C. Model 691-2B.

C-1 Set up unit as per schematic with Bendix Dry Air Pump 1511. (Refer to Figure 1).

C-2 Adjust the suction to 4.5 ± 0.1 Hg. with no flow through the air flowmeter. The suction gage should not increase more than 1.3 in. Hg.

C-3 Adjust the suction to 6.1 ± 0.1 in. Hg. with 1.125 ± 0.125 CFM flowing through the air flowmeter. The suction gage should not fluctuate more than 0.5 in. Hg.

C-4 Adjust the suction to 7.0 ± 0.2 in. Hg. with 1.125 ± 0.125 CFM flowing through the air flowmeter. The suction gage should not fluctuate more than 0.5 in. Hg.

C-5 Adjust the suction to 5.0 ± 0.1 in. Hg.

NOTE

This is the final setting of this model valve.

D. Models 691-11, 691-15, and 691-17.

D-1 Set up unit as per schematic with Bendix Dry Air Pump 1511. (Refer to Figure 1).

D-2 Adjust the suction to 2.0 ± 0.25 in. Hg. with no flow through the air flowmeter. The suction gage should not fluctuate more than ± 0.1 in.. Hg.

D-3 Adjust the suction to 4.5 ± 0.25 in. Hg. with no flow through the air flowmeter. The suction gage should not fluctuate more than ± 0.1 in. Hg.

D-4 Adjust the suction to 2.8 ± 0.1 in. Hg. for the 691-11 valve; 3.9 ± 0.1 in. Hg. for the 691-15 valve; 2.8 ± 0.1 in. Hg. for the 691-17 valve; with 2.3 ± 0.1 CFM flowing through the air flowmeter. The suction gage should not fluctuate more than ± 0.1 in. Hg.

NOTE

This is the final setting of these model suction relief valves.

D-5 After making setting of 2.8 ± 0.1 in. Hg. for the 691-11 valve; 3.9 ± 0.1 in. Hg. for the 691-15 valve; 2.8 ± 0.1 in. Hg. for the 691-17 valve; increase the air flow in the pipe leading to the valve until the valve suction is 1.8 ± 0.1 in. Hg. Clamp on adapter to the valve relief port and measure leakage flow by means of a suitable air flowmeter. Maximum allowable leakage is 0.20 CFM.

E. Models 691-12, 691-13 and 691-14.

E-1 Set up unit as per schematic with Bendix Dry Air Pump 1511. (Refer to Figure 1).

E-2 Adjust the suction to 4.0 ± 0.25 in. Hg. with no flow through the air flowmeter. The suction gage should not fluctuate more than ± 0.1 in. Hg.

E-3 Adjust the suction to 7.0 ± 0.25 in. Hg. with no flow through the air flowmeter. The suction gage should not fluctuate more than ± 0.1 in. Hg.

E-4 Adjust suction to 5.0 ± 0.1 in. Hg. for models 691-12 and 691-13; 6.0 ± 0.1 in. Hg. for the 691-14 valve; with 0.85 ± 0.1 CFM flowing through the air flowmeter. The suction gage should not fluctuate more than ± 0.1 in. Hg.

NOTE

This is the final setting for these model valves.

E-5 After making setting of 5.0 ± 0.1 in. Hg. for models 691-12 and 691-13; 6.0 ± 0.1 in. Hg. for the 691-14 valve; increase air flow in pipe leading to the valve until the valve suction is 4.0 ± 0.1 in. Hg. Clamp an adapter to the valve relief port and measure leakage flow by means of a suitable air flowmeter. Maximum allowable leakage is 0.25 CFM.

F. Model 691-16.

F-1 Set up unit as per schematic with Bendix Dry Air Pump 1511. (Refer to Figure 1).

F-2 Adjust the suction to 8.5 ± 0.25 in. Hg. with no flow through the air flowmeter. The suction gage should not fluctuate more than ±0.1 in. Hg.

F-3 Adjust the suction to 11.0 ± 0.25 in. Hg. with no flow through the air flowmeter. The suction gage should not fluctuate more than ± 0.1 in. Hg.

F-4 Adjust the suction to 10 ± 0.1 in. Hg. with 0.85 ± 0.1 CFM flowing through the air flowmeter. The suction gage should not fluctuate more than ± 0.1 in. Hg.

NOTE

This is the final setting for the 691-16.

F-5 After making setting of 10 ± 0.1 in. Hg. increase air flow in pipe leading to the valve until the valve suction is 8.5 ± 0.1 in. Hg. Clamp adapter to the valve relief port and measure leakage flow by means of suitable air flowmeter. Maximum allowable leakage is 0.25 CFM.

NOTE

Adapter for leakage test should cover tie wire holes in screen cap.

GAGE PRESSURE SWITCH 1G198, -2, -3 OVERHAUL MANUAL

1. DESCRIPTION AND OPERATION

Models 1G198, 1G198-2, and 1G198-3 are pressure actuated switches designed to sense gage pressure. Pressure is applied to a diaphragm. The resultant force created by the gage pressure on the diaphragm is conveyed to a negative rate disc spring by the diaphragm. When the increasing gage pressure reaches a preset actuation point, the disc spring snaps over center allowing the pressure plate to actuate the electrical assembly. Upon decreasing gage pressure, at a preset value below the actuation point, the disc spring snaps back to its original position returning the pressure plate and electrical assembly to their original positions.

TABLE I LEADING PARTICULARS

Service Media.....Air
Actuation Points:

Model	Increasing Pressure	Decreasing Pressure
1G198	At 20 ±2 PSIG	At 15 ±2 PSIG
1G198-2	At 17 ±1 PSIG	At 14 ±1 PSIG
1G198-3	At 1.5 ±.5 PSIG	At .5 ±.5 PSIG

Proof Pressure.....262 PSIG
Ambient Temperature Range.....-54°C to +121°C
-65°F to +250°F
Pressure Port.....Per AND10050-4
7/16-20 UNF-3B
Mounting Provisions.....Two .199 inch dia. holes
on 1.25 inch centers
Electrical Data:
Switching Element.....SPDT
Current.....5 amps resistive at 28 VDC
Receptacle.....Per MS3102-10SL-3P
mates with MS3106-10SL-3S
Overall Dimensions:
Height.....3.50 inches max
Width & Depth.....1.87 inches typ
Weight.....4 ounces est

GAGE PRESSURE SWITCH 1G198, -2, -3 OVERHAUL MANUAL

2. DISASSEMBLY (See Figures 3 and 4)

A. Cut and remove lockwire from electrical assembly [13], port cap [2], and body [11].

NOTE: Observe method used to lockwire unit. Use same method to replace lockwire during assembly.

B. Using a 66-4 tool, remove electrical assembly [13] from body [11]. Remove O-ring [12] from electrical assembly [13].
C. Using a 66-1 tool and a 66-56 tool, remove body [11] from port cap [2].
D. Remove pressure plate [8], disc spring [9], register ring [10], diaphragm [7], O-ring [6], adjustment shoe [5], and helical spring [4] from port cap [2] or body [11].
E. Using a 66-5 tool, remove adjustment screw [3] from port cap [2].

3. CLEANING

A. Clean all metal parts with dry cleaning solvent per Federal Specification P-D-680, Type 1, or equivalent; use a stiff bristle brush and/or a clean, lint-free cloth.

WARNING: AVOID SOLVENT CONTACT WITH SKIN AND AVOID BREATHING SOLVENT VAPORS. OBSERVE FIRE PRECAUTIONS.

B. Dry parts thoroughly with moisture free, compressed air, and/or allow to air dry.

4. INSPECTION/CHECK (See Figures 1, 2, and 4)

A. Inspect all machined surfaces for cracks, burrs, nicks, corrosion, or any other condition which could cause a malfunction in service.
B. Inspect all threaded parts for crossed or stripped threads.
C. Check all plated parts for deterioration.
D. Check helical spring [4] for distortion, length, and rate.
(1) Roll spring on flat surface; there must be no wobble.
(2) Free length should be .360/.390 inch.
(3) With spring deflected to solid height, reaction force should be approximately 4.2 pounds.
E. Using an ohmmeter or other suitable device, check electrical circuitry of electrical assembly [13].
(1) With electrical assembly [13] in the deactuated position there must be a closed circuit between receptacle pins A and B, also an open circuit between pins A and C.

(2) Actuate electrical assembly [13] by applying slight pressure to actuating plunger of assembly.
(3) With electrical assembly [13] actuated there must be a closed circuit between receptacle pins A and C; also an open circuit between pins A and B.

F. Test dielectric strength of electrical assembly [13].
(1) With output limited to 18 milliamperes, apply 1000 volts RMS 60 cycles between each receptacle pin and the receptacle shell for a period not to exceed one minute.

CAUTION: THE OUTPUT CURRENT MUST BE LIMITED DURING THIS TEST AS A PRECAUTIONARY MEASURE IN ORDER TO PREVENT PERMANENT DAMAGE TO THE ASSEMBLY.

(2) There must be no arcing.
(3) Maximum permissible leakage is 2 milliamperes.

G. Inspect nameplate [14] for legibility and security of attachment to body [11].

5. REPAIR (See Figure 4)

A. Adjustment screw [3] and electrical assembly [13] contain nylon locking inserts. If required, these inserts should be removed and replaced with new nylon pellets of appropriate size.
B. Remove any minor nicks, corrosion, or burrs from aluminum parts with an aluminum oxide abrasive cloth per Federal Specification P-C-451.
C. Remove defects from stainless steel parts using crocus cloth per Federal Specification P-C-458, grade 600 or finer.
D. Repair minor thread damage by carefully chasing threads with an appropriate tap or die.
E. Replace any parts on which the plating has deteriorated.
F. Replace all parts that cannot be made serviceable by steps 5.A. thru 5.D.

6. ASSEMBLY (See Figures 1 thru 4)

A. Apply a thin film of lubricant to O-rings [6 and 12].

NOTE: Recommended lubricant is FS1281 manufactured by Dow Corning Corp., Midland, Michigan (V71984).

B. Using a 66-5 tool, thread adjustment screw [3] into port cap [2]. Thread as far as possible; then back off 1/4 turn.
C. Install helical spring [4], adjustment shoe [5], O-ring [6], and diaphragm [7] into port cap [2].
D. Install register ring [10], disc spring [9], and pressure plate [8] into body [11].
E. Using 66-1 and 66-56 tools, assemble body [11] to port cap [2]. Tighten to 15 foot pounds torque.

CAUTION: DO NOT EXCEED 15 FOOT POUNDS TORQUE.

F. Install and synchronize electrical assembly [13].
(1) Place O-ring [12] around electrical assembly [13].
(2) Connect the partially assembled unit to a test setup such as shown in Figure 2.
(3) Increase test pressure to actuate disc spring [9] and hold pressure.
(4) Using a 66-4 tool, thread electrical assembly [13] into body [11] until assembly actuates.

CAUTION: INTERNAL DAMAGE TO ELECTRICAL ASSEMBLY [13] CAN RESULT IF IT IS THREADED TOO FAR.

(5) Reduce test pressure to zero.
(6) Thread electrical assembly [13] an additional 1/6 turn (60°) into body [11].

NOTE: Electrical assembly [13] is now synchronized and should not be rotated again.

G. After unit has been tested and adjusted per paragraph 8, lockwire electrical assembly [13] and port cap [2] to body [11]. Use wire per MS20995C32 or MS20995F32 installed per MS33540.

7. FITS AND CLEARANCES (Not Applicable)

8. TESTING (See Figures 1 thru 4)

A. Connect the completely assembled unit between the valves of a test setup such as shown in Figure 2. The inlet manifold should be connected to a source of clean, dry, compressed air which delivers at least 262 PSIG.
B. Test unit for leakage by slowly applying 262 PSIG to pressure port. Shut off inlet valve and maintain a static pressure head for one minute. If leakage occurs, refer to paragraph 9, TROUBLE SHOOTING.

CAUTION: DO NOT EXCEED MAXIMUM INLET PRESSURE OF 262 PSIG.

C. Test unit operating limits.
(1) With test lamp circuit connected to receptacle, slowly increase test pressure to pressure port until the circuit between receptacle pins A and B opens (A-C closes). Note the exact gage reading the instant this occurs.
(2) Slowly decrease the test pressure until the circuit between receptacle pins A and B closes (A-C opens). Note the exact gage reading the instant this occurs.
(3) If required, adjust unit operation to conform with data given in Table II. Using a 66-5 tool, rotate adjustment screw [3] in small increments and repeat steps 8.C.(1) and 8.C.(2). To increase pressure settings, rotate adjustment screw [3] counterclockwise; to decrease settings, turn clockwise.

D. Test dielectric strength of electrical assembly [13].
(1) With output limited to 18 milliamperes, apply 1000 volts RMS 60 cycles between each receptacle pin and the receptacle shell for a period not to exceed one minute.

CAUTION: THE OUTPUT CURRENT MUST BE LIMITED DURING THIS TEST AS A PRECAUTIONARY MEASURE IN ORDER TO PREVENT PERMANENT DAMAGE TO THE ASSEMBLY.

(2) There must be no arcing.
(3) Maximum permissible leakage is 2 milliamperes.

TABLE II UNIT OPERATING CHARACTERISTICS

MODEL	TEST PRESSURE	PRESSURE PSIG	CIRCUIT	
			A-B	A-C
1G198	Increasing	At 20 ±2	Opens	Closes
	Decreasing	At 15 ±2	Closes	Opens
1G198-2	Increasing	At 17 ±1	Opens	Closes
	Decreasing	At 14 ±1	Closes	Opens
1G198-3	Increasing	At 1.5 ±.5	Opens	Closes
	Decreasing	At .5 ±.5	Closes	Opens

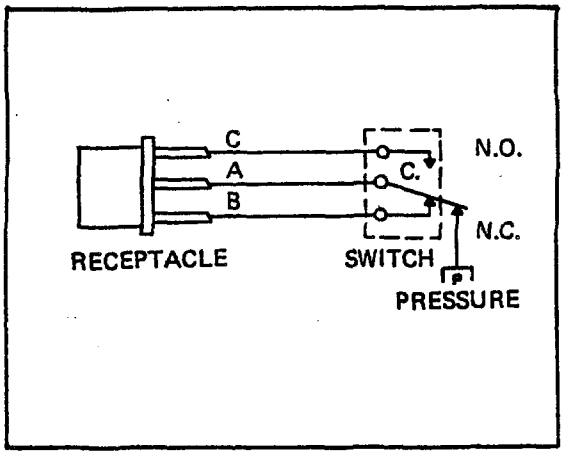

FIGURE 1 ELECTRICAL SCHEMATIC

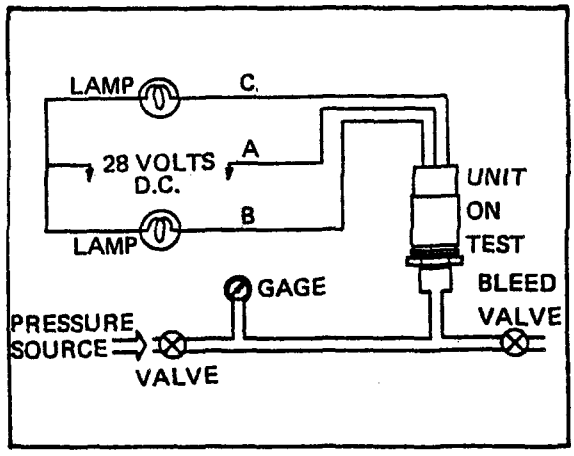

FIGURE 2 SUGGESTED TEST SETUP

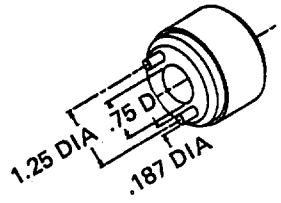
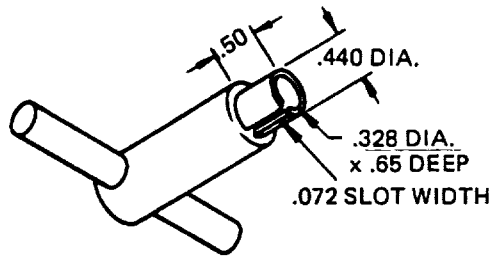
9. TROUBLE SHOOTING (See Figure 4)

TABLE III



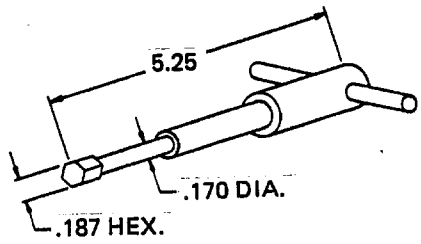
TROUBLE	PROBABLE CAUSE	REMEDY
Leakage	Defective O-ring [6]	Replace O-ring [6].
	Ruptured diaphragm [7]	Replace diaphragm [7].
Unit fails to operate or operate within pressure limits	Defective electrical assembly [13]	Check per paragraphs 4.E. and 4.F. If defective, replace electrical assembly [13].
	Defective disc spring [9]	Replace disc spring [9].
	Improper adjustment screw [3] setting	Readjust adjustment screw [3] per paragraph 8.C.
	Incorrect synchronization of electrical assembly [13]	Resynchronize electrical assembly [13] per paragraph 6.F.

10. STORAGE INSTRUCTIONS

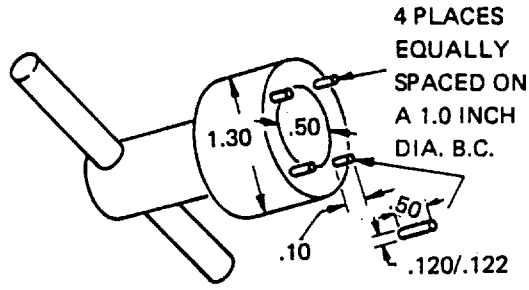


Cap pressure port and electrical receptacle with closures per MIL-C-5501. Place unit in a suitable plastic bag and/or corrugated cardboard container.

11. SPECIAL TOOLS (See Figure 3)



Tools similar to those shown in Figure 3 will aid in the assembly, disassembly, and adjustment of the unit. These tools may be made in the average machine shop, or they may be procured from Custom Aviation Supply under part numbers 66-1, 66-4, 66-5, and 66-56.



66-1 PORT CAP TOOL

66-4 ELECTRICAL ASSEMBLY TOOL

66-5 ADJUSTMENT SCREW TOOL

66-56 BODY ASSEMBLY TOOL

VACUUM PRESSURE SWITCH 32V29 OVERHAUL MANUAL

1. DESCRIPTION AND OPERATION

Model 32V29 is a pressure actuated switch designed to sense pressures below ambient pressure. Varying pressures are applied to opposite sides of a diaphragm. The resultant force, created by the difference between vacuum and ambient pressure on the diaphragm, is conveyed to a negative rate disc spring by a pressure plate. When the pressure difference increases to a preset actuation point, the disc spring snaps over center allowing the pressure plate to move the switch actuator assembly which actuates the electrical switching element. When the pressure difference decreases to a preset value below the actuation point, the disc spring snaps back to its original position returning the pressure plate, switch actuation assembly, and electrical switching element to their original positions.

This model is used on DeHavilland DHC-6 Twin Otter aircraft to provide warning of low suction for vacuum driven instruments.

TABLE I. LEADING PARTICULARS

Service Medium	Air
Actuation Points:	
Increasing Vacuum	By 4.7 inches Hg
Decreasing Vacuum	By 4.2 inches Hg
Proof Vacuum	10 inches Hg
Ambient Temperature Range	-65°F to +160°F
Pressure Connection	Per AND10050-4 7/16-20 UNF-3B THD
Electrical Data:	
Switching Element	SPDT hermetically sealed
Current	4 amps resistive at 28 VDC
Receptacle	Per MS33678-10SL-3P mates with MS3106-10SL-3S
Mounting Provisions	Two .195/.200 inch dia. holes on 3.00 inch centers
Overall Dimensions:	
Height	3.75 inches
Width	3.52 inches
Depth	3.12 inches
Weight	15 ounces

2. DISASSEMBLY (See Figure 3)

A. Cut and remove lockwire from screws [2 and 4], vent plug [13], lock [9], and port cap [14].

NOTE: To facilitate reassembly, observe method used to lockwire switch. Use same method to replace lockwire during final assembly.

B. Remove screws [2 and 4] and nuts [5] from port cap [14] and mounting bracket [3]. Detach mounting bracket [3] and upper half of unit from port cap [14].
C. Remove diaphragm [7], O-ring [6], adjustment shoe [15], helical spring [12], and lock [9] from port cap [14].
D. Using a 3/16 inch Allen wrench, remove adjustment screw [10] from port cap [14]. Remove O-ring [11] from adjustment screw [10].
E. Remove O-rings [6 and 16] and tube [17] from body assembly [23]. Carefully disengage lower arm of switch actuator assembly from undercut at top of pressure plate assembly [8]. Remove pressure plate assembly [8] and disc spring [22] from body assembly [23].

NOTE: It is recommended that O-rings [6, 11, and 16] and diaphragm [7] be replaced at each overhaul.

F. Do not disassemble unit further unless repair or replacement of a component is indicated by INSPECTION/CHECK, paragraph 4, or TROUBLE SHOOTING, paragraph 9. If disassembly is required, continue with steps 2.G. thru 2.I.
G. Unsolder and separate case [25] from body assembly [23]. Unsolder and remove screw [27] and safety wire eyelet [26]. Unsolder leads between switch [18] and receptacle [21].
H. If receptacle [21] requires replacement, unsolder and remove from case [25].
I. If switch [18] requires replacement, carefully break the epoxy bonds between screws [19], nuts [24], switch [18], and switch holder on body assembly [23]. Remove screws [19] and nuts [24] holding switch [18] to switch holder.

3. CLEANING

A. Clean all metal parts with dry cleaning solvent per Federal Specification P-D-680, Type 1, or equivalent; use a stiff bristle brush and/or a clean, lint-free cloth.

WARNING: AVOID SOLVENT CONTACT WITH SKIN AND AVOID BREATHING SOLVENT VAPORS. OBSERVE FIRE PRECAUTIONS.

B. Dry parts thoroughly with moisture free compressed air, or allow to air dry.

4. INSPECTION/CHECK (See Figures 1, 2, and 3)

A. Inspect all machined surfaces for cracks, nicks, burrs, corrosion, or any other condition which could cause a malfunction in service.
B. Inspect all threaded parts for crossed or stripped threads.
C. Check all plated parts for deterioration.

D. Check helical spring [12] for distortion, length, and rate.
(1) Roll spring on flat surface; there must be no wobble.
(2) Free length should be .485/.515 inches.
(3) With spring deflected to solid height, reaction force should be 5.5 pounds.

E. Using an ohmmeter or other suitable device, check switch [18] and/or electrical circuitry.
(1) With switch [18] in the deactuated position, there must be a closed circuit between "NC" and "C" terminals (circuit A-B), and an open circuit between "NO" and "C" terminals (circuit B-C).
(2) Gradually depress actuating plunger of switch [18] until it actuates.

CAUTION: INTERNAL DAMAGE TO SWITCH [18] CAN RESULT IF ACTUATING PLUNGER IS DEPRESSED TOO FAR.

(3) With switch [18] actuated, there must be a closed circuit between "NO" and "C" terminals (circuit B-C) and an open circuit between "NC" and "C" terminals (circuit A-B).

F. Test dielectric strength of receptacle [21].
(1) With current limited to 18 milliamperes, apply 1000 volts RMS 60 cycles between receptacle pins and receptacle shell for a period not to exceed one minute.

CAUTION: OUTPUT CURRENT MUST BE LIMITED TO PREVENT PERMANENT DAMAGE TO PART.

(2) There must be no arcing.
(3) Maximum permissible leakage is 2 milliamperes.

5. REPAIR (See Figure 3)

A. Adjustment screw [10] contains a nylon locking insert. If required, this insert should be removed and replaced with a new nylon pellet of equal size.
B. Remove any minor nicks, corrosion, or burrs from aluminum parts with aluminum oxide abrasive cloth per Federal Specification P-C-451.
C. Remove defects from stainless steel parts using crocus cloth per Federal Specification P-C-458, grade 600 or finer.
D. Repair minor thread damage by carefully chasing threads with an appropriate tap or die.
E. Replace any parts on which the plating has deteriorated.
F. Replace all parts that cannot be made serviceable by steps 5.A. thru 5.D.

6. ASSEMBLY (See Figures 1, 2, and 3)

A. If switch was completely disassembled continue with step 6.B., otherwise skip to step 6.Q.

B. Solder leads to receptacle [21]. Use 95% Sn/5% Sb solder and wire per specification MIL-W-16878, Type E, size 20.

C. If receptacle was removed, insert leads through hole in case [25]. Solder switch [18] to leads using Figure 1 as reference for circuitry. Use 60% Sn/40% Pb solder.

D. Check dielectric strength and circuitry using steps 4.E. and 4.F.

E. Mount switch [18] to switch holder on body assembly [23] using screws [19] and nuts [24].

NOTE: Screws [19] should be snug, not tight, in order to facilitate final positioning of switch [18].

F. Apply lubricant (See Table II, Item 1) to O-rings [6, 11, and 16].

G. Install tube [17], O-rings [6 and 16], disc spring [22] and pressure plate assembly [8] in body assembly [23].

NOTE: Make certain that lower arm of switch actuator assembly is registered in undercut at top of pressure plate.

H. Install O-ring [6] and diaphragm [7] in port cap [14].

I. Assemble port cap [14] and mounting bracket [3] to body assembly [23] using screws [2 and 4] and nuts [5].

J. Install O-ring [11] on adjustment screw [10]. Using a 3/16 inch Allen wrench, thread adjustment screw [10] into port cap [14] far enough to provide a pressure seal.

K. Mount the partially assembled unit in a test setup such as shown in Figure 2 and adjust switch [18] actuation.

(1) Slowly apply sufficient negative pressure to actuate disc spring [22] and hold.

(2) With disc spring [22] maintained in the actuated position, move switch [18] toward actuator arm until switch [18] actuates, as indicated by test light circuit. Advance switch [18] an additional .004-.008 inch toward actuator arm. Tighten mounting screws [19] being careful that switch [18] does not move.

CAUTION: INTERNAL DAMAGE TO SWITCH [18] CAN RESULT IF THE .008 INCH OVERTRAVEL LIMIT IS EXCEEDED.

(3) If switch mounting holes do not provide sufficient movement, carefully bend actuator arm(s) as required.

CAUTION: DO NOT APPLY ANY FORCE TO WOBBLEFRAM (SMALL DIAPHRAGM IN SWITCH ACTUATOR ASSEMBLY) WHILE BENDING ACTUATOR ARM(S).

(4) Increase pressure to ambient and remove unit from test setup.

L. Use epoxy (See Table II, Item 2) to bond switch [18] and nuts [24] to switch holder, and heads of screws [19] to switch [18]. Cure epoxy per manufacturer's instructions.

M. Remove screws [2 and 4]. Detach upper half of unit from port cap [14]. Remove diaphragm [7], O-rings [6 and 16], tube [17], pressure plate assembly [8], and disc spring [22] from port cap [14].

N. If receptacle [21] was removed, solder it to case [25] using 60% Sn/40% Pb solder.

O. Solder case [25] to body assembly [23] using 60% Sn/40% Pb solder.

P. Before installing screw [27] and safety wire eyelet [26], place switch housing unit in an oven and bake at 250°F for 30 minutes to remove all moisture. To prevent contamination install safety wire eyelet [26] and screw [27] immediately after unit cools to handling temperature. Solder screw [27] and safety wire eyelet [26] to case [25]. Use 60% Sn/40% Pb solder to hermetically seal unit.

Q. Install disc spring [22], pressure plate assembly [8], tube [17], and O-rings [6 and 16] in body assembly [23].

NOTE: Make certain that lower arm of switch actuator assembly is registered in undercut at top of pressure plate assembly [8].

R. Install adjustment shoe [15], O-ring [6], and diaphragm [7] into port cap [14].

S. Using screws [2 and 4] and nuts [5], secure mounting bracket [3] and port cap [14] to body assembly [23]. Tighten screws [2 and 4] to 22-24 inch pounds torque.

CAUTION: DO NOT EXCEED 24 INCH POUNDS TORQUE.

T. Install helical spring [12] into port cap [14].

U. Using a 3/16 inch Allen wrench, thread adjustment screw [10], with O-ring [11] on it, into port cap [14].

V. After unit has been tested and adjusted per paragraph 8, install vent plug [13] into pressure port marked "VENT".

TABLE II RECOMMENDED MATERIALS

ITEM	DESCRIPTION	MANUFACTURER
1	G624 Compound Lubricant	General Electric Co. Waterford, N.Y. (V01139)
2	Stycast 2651 & Catalyst 9 Epoxy	Emerson & Cuming, Inc. Canton, Mass. (V04552)

W. Install lock [9] into adjustment screw [10] and lockwire lock [9] to port cap [14]. Lockwire vent plug [13] to heads of a pair of screws [4]. Also lockwire screws [2 and 4] in groups of two. Use lockwire per MS20995C32.

7. FITS AND CLEARANCES (Not applicable)

8. TESTING (See Figures 1, 2, and 3)

A. Connect the completely assembled unit between the valves of a test setup such as shown in Figure 2. The "VAC" pressure port should be connected to a negative pressure source which delivers at least 10 inches mercury vacuum.

B. Test unit for leakage by applying 10 inches mercury vacuum to pressure port marked "VAC". Shut off inlet valve and maintain a static pressure head for one minute. If leakage occurs, refer to paragraph 9, TROUBLE SHOOTING.

CAUTION: DO NOT EXCEED MAXIMUM INLET VACUUM OF 10 INCHES MERCURY.

C. Test unit operating limits.
(1) With test light circuit connected to receptacle [21], slowly increase vacuum to "VAC" port until circuit connected between receptacle pins B and C closes (A-B opens). Note the exact gage reading the instant this occurs.
(2) Reduce vacuum slowly until circuit connected between receptacle pins A and B closes (B-C opens). Note the exact gage reading the instant this occurs. Reduce vacuum to ambient.
(3) If required, adjust switch operation to conform with the data given in Table III by rotating adjustment screw [10] in small increments and repeating steps 8.C.(1) and 8.C.(2). To increase pressure settings, turn adjustment screw counterclockwise; to decrease settings, turn clockwise.

D. Test dielectric strength of receptacle [21] per paragraph 4.F.

TABLE III SWITCH OPERATING CHARACTERISTICS

TEST VACUUM	VACUUM INCHES OF MERCURY	CIRCUIT	
		A-B	B-C
Increasing	By 4.7	Opens	Closes
Decreasing	By 4.2	Closes	Opens

VACUUM PRESSURE SWITCH 32V29 OVERHAUL MANUAL

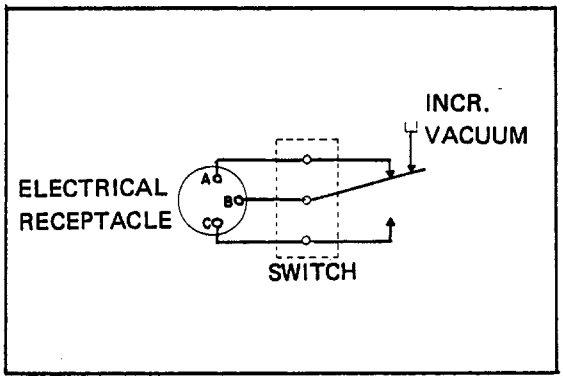

FIGURE 1 ELECTRICAL SCHEMATIC

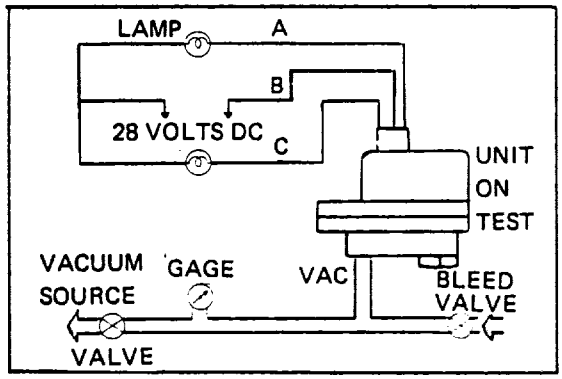

FIGURE 2 SUGGESTED TEST SETUP

9. TROUBLE SHOOTING (See Figure 3)

TABLE IV

TROUBLE	PROBABLE CAUSE	REMEDY
Leakage	Loose screws [2 and 4]	Tighten screws [2 and 4] per paragraph 6.S.
	Defective O-ring(s) [6, 11, and/or 16]	Replace defective O-ring(s).
	Defective diaphragm [7].	Replace diaphragm [7].
	Defective body assembly [23]	Replace body assembly [23].
Switch fails operate or operate within pressure limits	Defective electrical circuitry	Check circuitry per paragraphs 4.E. and 4.F. Replace or repair defective component.
	Improper adjustment screw [10] setting	Readjust adjustment screw [10] per paragraph 8.C.
	Defective diaphragm [7]	Replace diaphragm [7].
	Incorrect synchronization of switch [18]	Resynchronize switch [18] per para. 6.K.
	Defective disc spring [22]	Replace disc spring [22].

10. STORAGE INSTRUCTIONS

Cap pressure port and electrical receptacle with closures per MIL-C-5501. Place switch in a suitable plastic bag and/or corrugated cardboard container.

11. SPECIAL TOOLS

No special tools are required.

12. ILLUSTRATED PARTS LIST

A. The Illustrated Parts List provides identification and spare parts ordering information. Order parts by part number and nomenclature.
B. Supplier codes in the parts list nomenclature column are obtained from the Federal Cataloging Handbook H4-1. Table V cross-references these codes with the manufacturer's name and location.

HOW TO ORDER

Peri-Seal products are available for immediate shipment from stock direct from the General Connectors Corporation factory, 233 W. Orange Grove Avenue (P. O. Box 575), Burbank, California, U.S.A. Phone: Area Code 213-842-7151; Cable address: Genaero, Burbank, California, U.S.A.

GENERAL CONNECTORS CORPORATION

Peri-Seal Flexible Pneumatic Duct Connectors & Bulkhead Seals

GENERAL DESCRIPTION

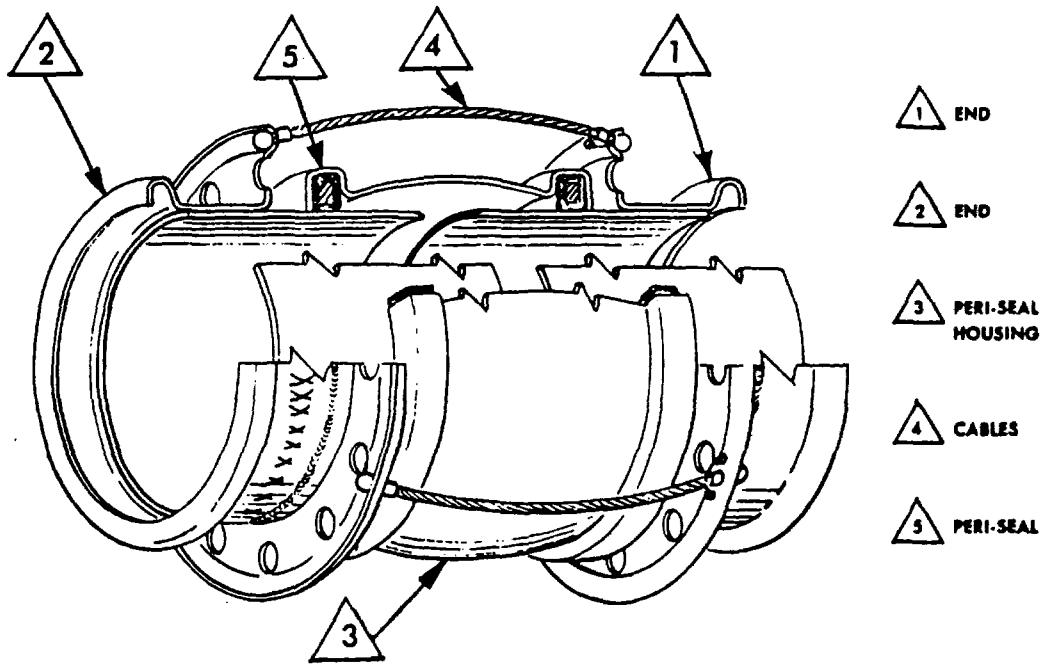
1. The Peri-Seal Connector, designed and built by General Connectors Corporation, is a flexible, 95% metallic duct connector, approved for use in pneumatic/air conditioning/ice protection systems of the Douglas DC-8, DC-9, Boeing 727 and other aircraft. The major design consideration was safety. The Peri-Seal was also designed to create a simple device to replace bellows type duct connectors which eliminated the possibility of a catastrophic failure. These assemblies may be easily serviced at the user's facility.

2. Peri-Seal sealing elements are interchangeable for use on any aircraft equipped with the connector or bulkhead seal where nominal duct sizes are similar.

3. These connectors are designed to withstand dynamic movement under all operating conditions. They are used to compensate for misalignment and to absorb contraction and expansion due to heating, cooling and system vibration.

4. The Peri-Seal Connector assembly for the DC-8, 727 and 707 is joined to the aircraft duct system by means of stainless steel end flanges welded to sleeves on which the seal is accomplished. End flanges are of several types as required to mate to the aircraft ducting. In the DC-9 version of the Peri-Seal connector, sealing is accomplished directly on the aircraft duct ends.

5. The Peri-Seal Connector consists of two fiberglass reinforced silicone rubber sealing elements (Peri-Seals) retained in a stainless steel housing. A flared center section housing permits deflection of either the duct or housing body. This unique construction, mostly of metal, is not subject to the degree of failure and damage of bellows type connectors. The Peri-Seals are symmetric and interchangeable. Expansion and contraction of the connector is accomplished by sliding of sleeves or ducting within the inside periphery of the Peri-Seals.



6. Part identification is electro-etched on the outer surface of the housing and includes the General Connector trademark, part number and the applicable airframe manufacturer's part number.

7. Peri-Seals are lubricated prior to assembly and packaged in individual plastic envelopes. Further lubrication prior to installation is not required. Lubrication should not be removed prior to installation.

8. Assemblies and Peri-Seals should be stored in a clean, dry area in their individual plastic wrappings. When so stored, they have an indefinite shelf life.

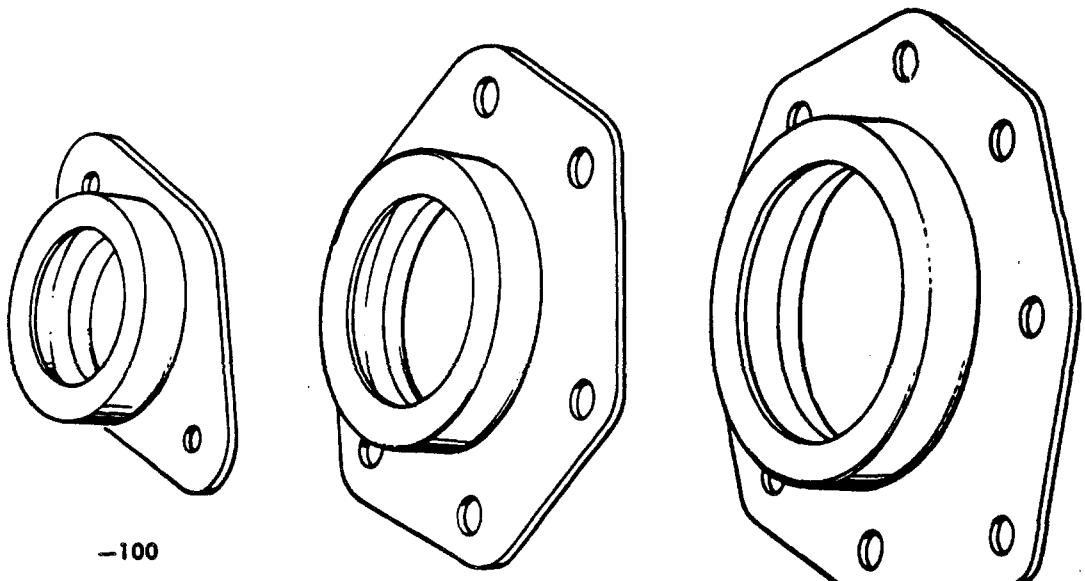
GENERAL DESCRIPTION



The DC-9 Peri-Seal Connector is a simplified version of the DC-8 design, consisting of a stainless steel housing and two Peri-Seal sealing elements. The assembly is intended to be installed directly on the ducting installed in the aircraft.

Peri-Seals are interchangeable, size for size, for DC-8 Peri-Seals and carry the same part numbers

Overhaul and installation procedure is the same as detailed for the DC-8 Peri-Seal housing.

GENERAL DESCRIPTION

A Bulkhead Seal consists of a stainless steel housing with a flange for attachment to the bulkhead. The housing contains a single Peri-Seal. Sealing is accomplished on the outer surface of the aircraft ducting. Peri-Seals are replaceable by removing the bulkheal seal housing at the adjacent duct joint.

GENERAL DESCRIPTION

This Peri-Seal application consists of a single Peri-Seal sealing element in a stainless steel, flanged housing. Sealing is accomplished on the surface of a mating sleeve, similarly flanged. The unit is restrained by an internal cable assembly positioned between a vane in each flanged component.

OVERHAUL INSTRUCTIONS

The overhaul of a "Peri-Seal" Connector is accomplished by replacement of the worn "Peri-Seals". Replacement can be accomplished with ordinary hand tools by semi-skilled personnel.

The "Peri-Seals" are the only components which require periodic maintenance and replacement.

1. *Connector Disassembly into Component Parts*
   a. Cut and remove safety wires on one end only. (DC-8 only.)
   b. Remove the three retaining cables from detent slots. (DC-8 only.)
   c. Carefully extract ends from housing.
   d. Remove "Peri-Seals".
      Note: Exercise care not to damage surface of seal retaining groove.

2. *Cleaning of all components.*
   a. Use toluene or a ketone based solvent.
   b. Wipe all components dry with a non-linting cloth.
      Note: Make sure all foreign matter is removed from seal housing.

3. *Inspection of metal components.*
   Examine metal components for scratches, burrs, or other defects which might interfere with proper operation of the "Peri-Seal" Connector. Examine the flanges per manufacturer's maintenance instructions.

4. *Installation of new "Peri-Seals".*
   a. Remove "Peri-Seals" from plastic envelope. Avoid contamination. "Peri-Seals" are prelubricated and require no further lubrication.
   b. Insert "Peri-Seals" into seal retaining grooves. "Peri-Seals" are identical and symmetrical. No special instructions are required as to position and seating of "Peri-Seals".

5. *Reassembly of Connector.* (All except DC-9)
   a. Place one flange face down on a clean surface (plastic flange cover or other suitable protective material must be used). Center housing over sleeve and push down evenly. Under certain combinations of tolerances, the fit will be tight. By slightly canting the housing and using the fingers inside the housing to depress the seal, assembly is easily accomplished.
   b. Repeat operation (a) on other end.
   c. Rotate ends to align cable keyhole slots with alignment marks on housing. (DC-8 only)

d. Insert retaining cable shank terminal partially through hole in end collar. Position cable terminal in slot with end collar between the ball and shank. (DC-8 only)

e. Insert safety wire through collar holes and twist to lock. Be sure safety wire is installed between cable terminal and collar keyhole. Repeat on all retaining cables. (DC-8 only)

INSTALLATION PROCEDURE

1. *Offset* — Offset should be kept to an absolute minimum per specifications given in individual part description pages.

2. *Torque* — Any torque or twist in the retaining cables on DC-8 "Peri-Seals" will reduce the elongation capabilities of the unit. After the "Peri-Seal" Connector is lightly secured in place, align cables with lines scribed on "Peri-Seal" housing and complete tightening of connector. Torque is not a factor in other versions of the "Peri-Seal" connector.

3. *"Peri-Seal" Condition* — "Peri-Seals should be free from all signs of cuts and abrasion indicating damage to the fiberglass fabric. Avoid contacting the "Peri-Seal" with any sharp tools or instruments while making visual check. "Peri-Seals" are prelubricated. Do not contaminate or remove lubricant from the sealing surfaces.

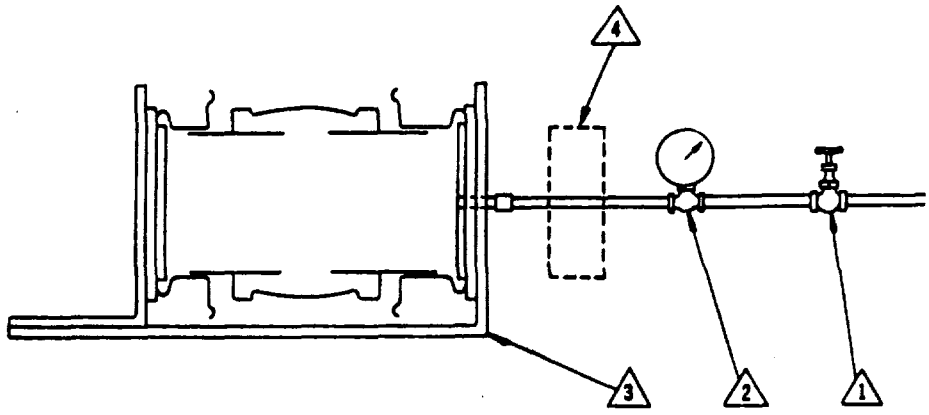
4. *End Flange Condition* — Inspect flanges per their manufacturers' respective overhaul manuals. CAUTION: Avoid contact with any sharp tools, instruments, or abrasives on the sealing surfaces during installation of duct connectors to assure maximum service life from connector.

5. *Tightening End Flanges* — Cable collars on DC-8 "Peri-Seals" are provided with spanner wrench holes to facilitate torquing of NUCO threaded flanges. CAUTION: Apply the adjustable Spanner Wrench (P/N26A440) from the flange side only.

6. *Installation Guides* — (DC-8 Parts)

   a. Electroetched on the "Peri-Seal" Housing.

   b. Electroetched on Sleeve O.D.



c. Electroetched on "Peri-Seal" Housing.

BEFORE CLAMP ALIGN ▮ IS TIGHTENED CABLE

It is important that these guides be followed to facilitate proper installation and operation of the DC-8 units.

PRESSURE TESTING (DC-8 "Peri-Seals")

Tests for leakage of new connectors or connectors containing new "Peri-Seals" may be performed as listed below. Testing of connectors containing used seals should only be performed at the appropriate system operating temperature as leakage may be above normal if testing is performed with cold air.

(1) PRESSURE REGULATOR 0 TO 100 PSIG

(2) PRESSURE GAGE 0 TO 100 PSIG

(3) TEST FIXTURE

(4) FLOWMETER (Optional test method)

INSTRUCTIONS

1. Install "Peri-Seal" Connector in test fixture as indicated in the Figure. Part must be restrained at the installed length.
2. Set pressure regulator above 90 PSIG.
3. Close valve! Use stop watch to time pressure drop from 90 psig until the minimum time specified in the table below is reached. If the pressure is above 60 psig, the part is satisfactory.
4. When using flowmeter, read leakage and refer to DC-8 Specification Table, where applicable.

NOTE: It is suggested that the test fixture be provided with a protective cage for safety.

26A430-33	4.50	26A430-69	8.25

Peri-Seals are individually packaged and lubricated. No further lubrication is required.

WARRANTY

The metallic components of all Peri-Seal Connectors and Bulkhead seals are warrantied for 2,000 service hours to be free from defects due to material and workmanship. Under normal usage the metallic components should last the life of the airframe. The non-metallic Peri-Seals are warrantied for a minimum of 1500 service hours when installed per the limits as outlined by the airframe manufacturer, or for 2 years from the date of delivery. Warrantees will terminate upon the earliest expiration of service hours or storage date.

Any Peri-Seal, together with the Connector, which fails under the hours of operation defined above, should be tagged with the number of service hours and returned to General Connectors Corporation, 233 W. Orange Grove Ave., Burbank, California, U.S.A. Upon inspection approval at the factory, General Connectors Corporation will repair or replace with a new part. No charge will be made for the returned item when under the warranty.

MAINTENANCE INSTRUCTIONS FOR :

REGULATOR VALVE ASSEMBLY

PART NO. B40D85

JANITROL AERO

COLUMBUS , OHIO

HEAT TRANSFER AND CONTROL PRODUCTS FOR THE AEROSPACE INDUSTRY

LITHO IN USA 1E 65

№ B40D85.

TABLE I. LEADING PARTICULARS

Envelope size (inches)	3.250 x 2.375 x 4.250
Weight (pounds)	0.90 lb (max.)
Ambient air temperature range	0°F to 160°F
Altitude range (feet)	Sea level to 40,000
Air inlet pressure range	5.0-80 psig
Downstream pressure range (in. Hg)	4.5-5.5
Inlet and outlet size	1/2 in. tube

1. INTRODUCTION.

2. GENERAL. These instructions provide overhaul procedures for Regulator Valve Assembly, Part No. B40D85, manufactured by Janitrol Aero Division, Midland-Ross Corporation, Columbus, Ohio.

3. DESCRIPTION.

4. GENERAL. The B40D85 Valve (see figure 1) is designed for use in a system providing positive ambient pressure to aircraft instruments. It regulates against a nominal fixed flow of 0.3 pounds per minute. With inlet pressures of 5 to 80 psig it reduces to 4.5 to 5.5 in. Hg.

5. DISASSEMBLY. (See figure 2.)

NOTE

It is recommended that the valve assembly be overhauled after every 500 hours of operation.

a. Disassemble the valve assembly in the same order as the index numbers assigned to the exploded view illustration, figure 2, observing the following special instructions:

b. Attaching parts have been assigned index numbers immediately following parts they attach. For example, it will be necessary to remove the screws (2) to free the cap (1).

c. All O-ring packings (10 and 11) must be replaced at each overhaul.

d. The inlet valve stem (8) and inlet valve seat (9) are matched parts and must be replaced as an assembly.

6. CLEANING. (See figure 2.)

a. Wash all metal parts in dry-cleaning solvent, Federal Specification P-D-680. If foreign material is difficult to remove, use a soft bristle brush to aid in the cleaning process. Dry parts thoroughly with filtered, compressed air.

b. Wipe the diaphragm assembly with a clean, dry, lint-free cloth.

CAUTION

Do not use any type of solvent on the diaphragm assembly (6).

Figure 2. Exploded View of Regulator Valve Assembly

7. INSPECTION. (See Table II.)

8. LUBRICATION. No lubrication is required.

9. REASSEMBLY. (See figure 2.)

a. Reassembly is the reverse of disassembly.

b. Install plug jet (14) in body (15) before reassembly of entire valve assembly.

10. TESTING.

11. TEST EQUIPMENT REQUIRED.

a. Inlet Air Regulator, 0-160 psig

b. Pressure Gage, 0-160 psig

c. Mercury Manometer

d. Orifice, ~~0.169 - 0.178~~ 0.160 - 0.163 in. diameter

e. Approximately 3 feet of 1/2-inch diameter tubing

f. A 150 psig air pressure source capable of delivering 0.5 lb/min flow

12. TEST PROCEDURE. (See figure 3.)

a. With valve installed in test setup, introduce air at a pressure of 5.0 psig at the valve inlet port.

b. Maintain 5.0 psig pressure at valve inlet and adjust regulator to obtain a downstream pressure of 4.7 in. Hg.

c. Without further adjustment of valve, increase inlet pressure to 80 psig. Downstream pressure shall not exceed 5.5 in. Hg.

TABLE II. INSPECTION PROCEDURES

INDEX NO. (See Fig. 2)	NOMENCLATURE	INSPECTION PROCEDURES
1	Regulator Cap	Inspect for distortion, cracks and rough sealing surface. Inspect for damaged screw threads. Replace for any of these conditions.
3	Spring	Check visually for cracks. Replace if cracks are found.
4	Spring Guide	Check for wear or visible damage. Replace for either condition.
5	Adjusting Screw	Check for broken or stripped threads. Replace for either condition.
6	Diaphragm Assy	Check for distortion or visible damage. Replace for either condition.
8, 9	Inlet Valve Assy	Check valve stem (8) and seat (9) for visible wear patterns. Replace entire inlet valve assembly if either part is damaged.
14, 15	Body Assembly	Check body (15) for cracks, distortion, damaged threads and rough sealing surface. Inspect jet (14) for visible damage. Replace body assembly for any of these conditions.
ALL	Hardware	Check for visible damage. Replace as required.

d. Decrease inlet pressure to 5.0 psig. Downstream pressure shall not be less than 4.5 in. Hg.

e. Increase inlet pressure to 80 psig. Downstream pressure shall not be less than 4.5 in. Hg or more than 5.5 in. Hg.

NOTE

In instances where the tolerance range of the valve is significantly less than 5.0 ±0.5 in. Hg, the final adjustment should place the actual tolerance an equal amount from the upper and lower allowable limits.

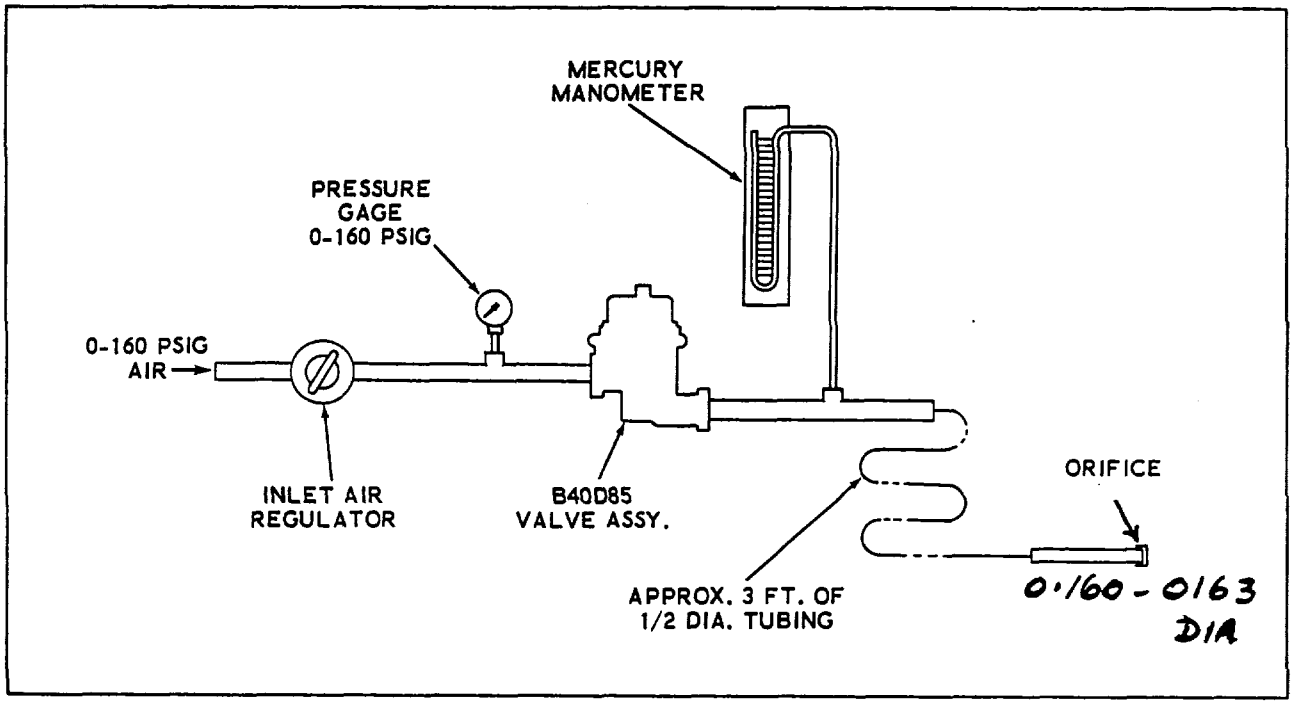

Figure 3. Test Setup

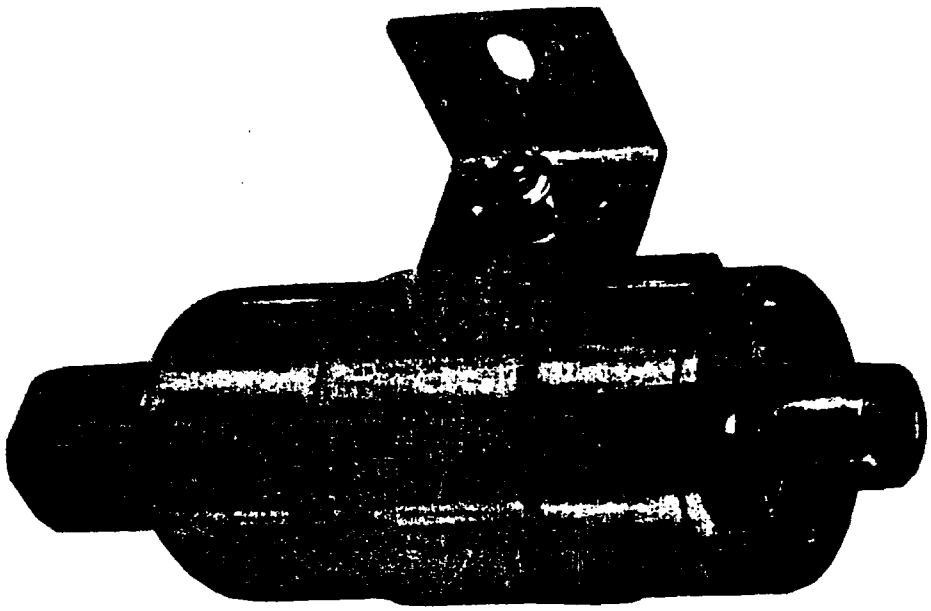
OVERHAUL INSTRUCTIONS FOR

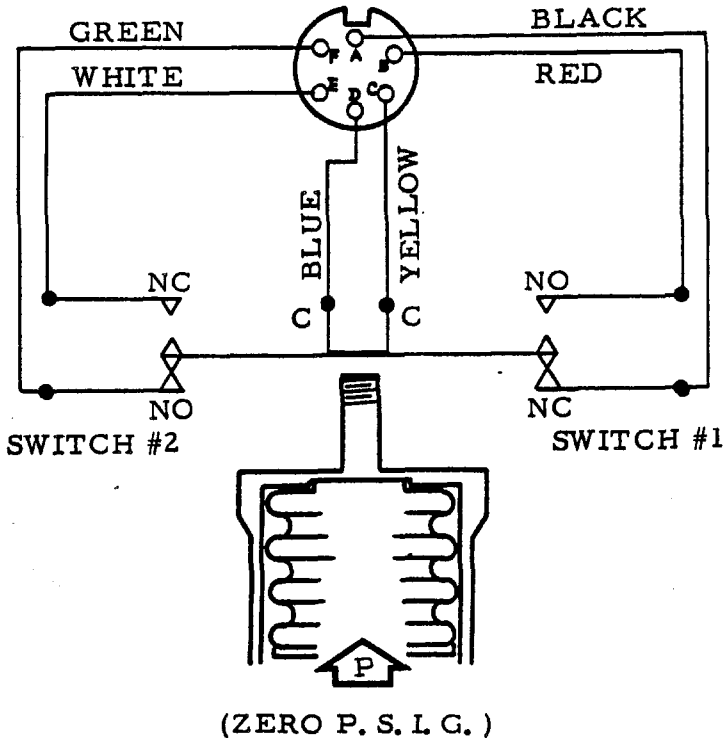


U. O. P. INSTRUMENTS PRESSURE SWITCH

TYPE MDB-620-1

PRESSURE SWITCH NO. MDB-620-1, OVERHAUL INSTRUCTIONS

DESCRIPTION



1 The pressure switch covered by these overhaul instructions is a pneumatically operated type with a pressure port on the lower end of the main housing and an electrical connector receptacle on top of the main housing (see Figure 1). Installed within the main housing are two independently wired microswitches (see Figure 2), adjusted to operate as follows: No. 1 switch to actuate between 23 and 27 p. s. i. g. decreasing pressure and reset at 30 p. s. i. g., on increasing pressure. No. 2 switch to actuate between 18 and 22 p. s. i. g. decreasing pressure, and reset by 25 p. s. i. g. on increasing pressure. A removable mounting bracket is provided with an insulator between the bracket and main housing to protect the switch from excessive vibration and shock.

Pressure Switch

TABLE OF LEADING PARTICULARS

TEMPERATURE RATING	-	-65°F to +250°F
ELECTRICAL RATING	-	1 AMP @ 28 V. D. C.
SYSTEM PRESSURE	-	80 P. S. I. G.
PROOF PRESSURE	-	160 P. S. I. G.
OPERATING CHARACTERISTICS	-	No. 1 switch actuates at 23/27 p. s. i. g. on decreasing pressure, reset by 30 p. s. i. g. No. 2 switch actuates at 18/22 p. s. i. g., reset by 25 p. s. i. g.

Wiring Schematic
Figure 2

DISASSEMBLY (see Figure 3)

NOTE

Do not attempt to remove bellows assembly (B.) or to disassemble beyond step J. below, as specialized equipment is necessary to reinstall and calibrate.

2 A. Cut lockwire (1) and remove screws (2).

B. Lift electrical connector receptacle (4) to allow access to pin wiring (3).

C. Disconnect wires (3) from connector pins. Remove electrical connector receptacle (4).

D. Remove housing top cap (5).

E. Remove cap (6) from switch head (10).

F. Carefully remove switch actuator (7) from piston cup assembly (13). Remove and discard heli-coil insert (8) from switch actuator (7).

G. Slacken set screw (9) in switch head (10), unscrew and remove switch head (10).

H. Remove micro-switches (11) from switch head (10), by removing two screws (12) retaining each micro-switch.

I. Disconnect wiring (3) from each micro-switch.

J. Do not attempt any further disassembly.

CLEANING

3 A. Clean all metal parts in dry cleaning solvent and dry with compressed air.

INSPECTION

4 A. Visually inspect all metal parts for damage affecting serviceability.

(1) Check housing for cracks or distortion.

(2) Check surfaces of all parts having relative motion for scoring or uneven wear.

REPAIR

5 Repair is limited to replacement of micro-switches, wiring, or electrical connector receptacle.

ASSEMBLY (see Figure 3)

6 A. Install micro-switches (11) to switch head (10) using four screws (12). Lock screws (12) using Loctite "C".

B. Solder wires (3) to micro-switch contacts (see Figure 2).

C. Install switch head (10) to main housing. Adjust switch head (10) to its approximate final position. Do not lock.

D. Using a new heli-coil lock insert (8), install switch actuator (7). Adjust to approximate final position.

E. Before proceeding with further assembly, carry out calibration procedure outlined in paragraph 7.

F. Reinstall switch head cap (6) and main housing cap (5).

G. Draw wires (3) through hole in cap (5) and resolder wires to electrical connector receptacle (4), (see Figure 3).

H. Install electrical connector receptacle (4) to main housing using four screws (2). Wirelock screws (2).

CALIBRATION

7 A. Apply controlled and gaged pressure, and by adjustment of switch head (10), adjust until actuation of micro-switch No. 1 occurs before 30 p.s.i.g. on increasing pressure, and resets between 23 and 27 p.s.i.g. on decreasing pressure.

B. Decrease pressure below 15 p.s.i.g., then increase pressure and adjust switch actuator (7) until actuation of micro-switch No. 2 occurs before 25 p.s.i.g., and resets between 18 and 22 p.s.i.g. on decreasing pressure.

C. Return pressure to zero.

D. Apply proof pressure of 160 p.s.i.g.

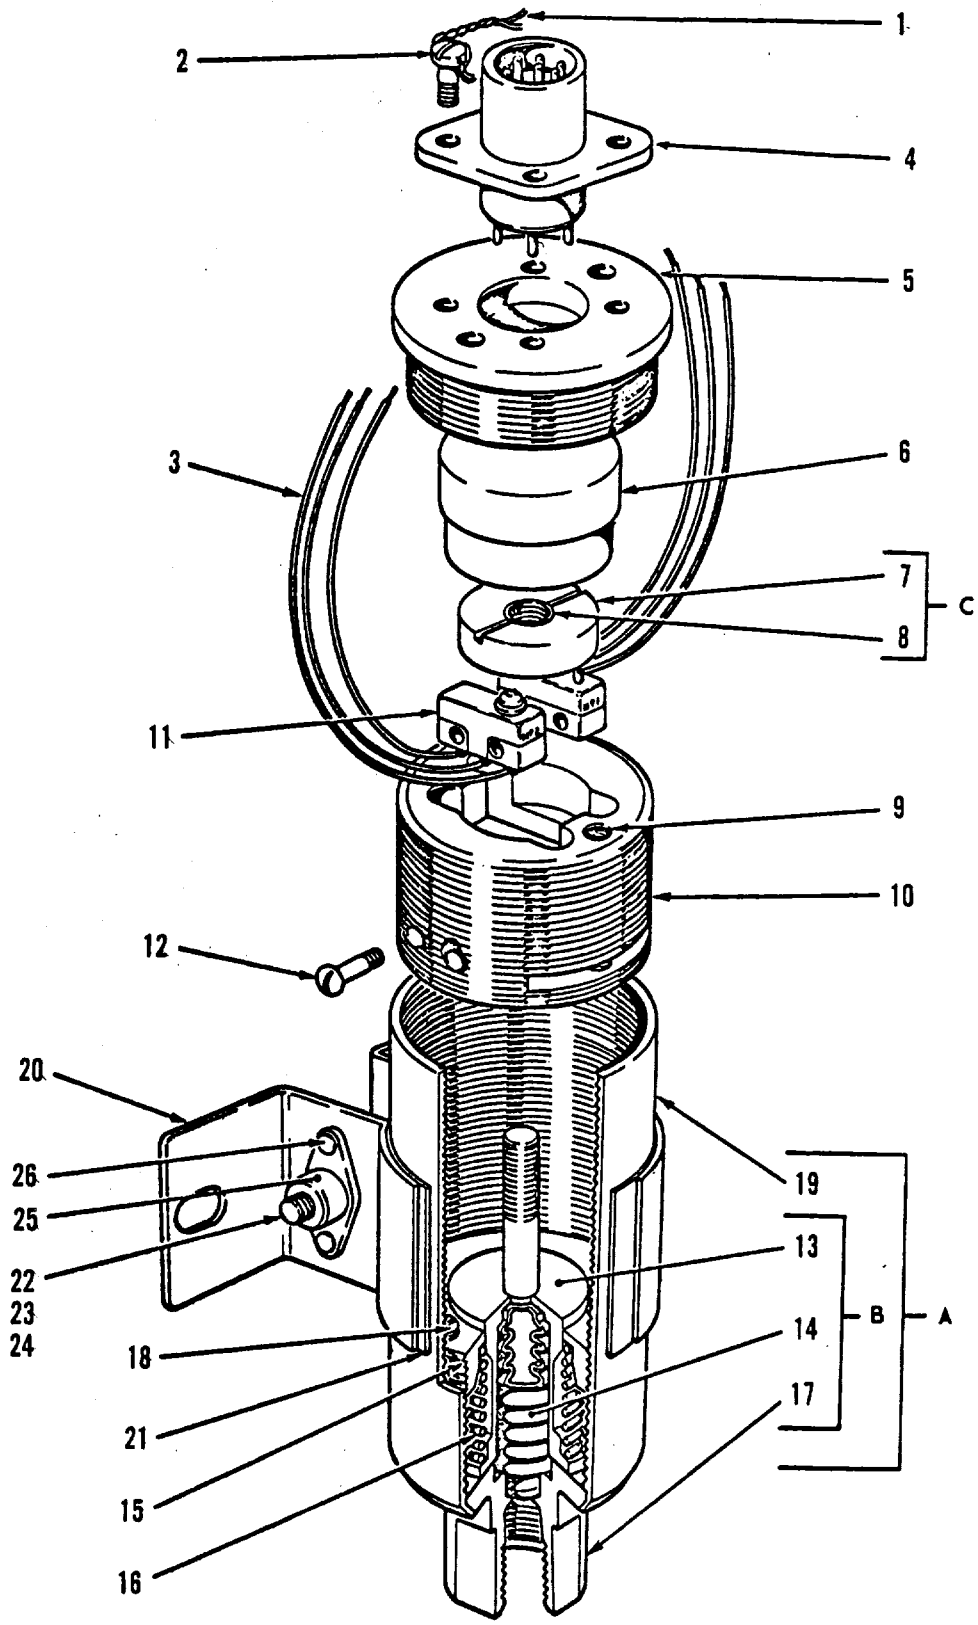
E. Return pressure to zero.

F. Repeat steps A. and B.

G. Return pressure to zero and tighten set screw (9) to lock switch head (10).

TROUBLE SHOOTING

8 Due to the basic simplicity of this switch no special trouble shooting is required.



STORAGE INSTRUCTIONS

9 Cap pressure port and electrical connector receptacle to keep out foreign matter during storage.

INSPECTION—MAINTENANCE

INSPECTION, TESTING, QUALITY CONTROL

Our products are best known for quality. A quality control system in accordance with MIL-Q-5923 is maintained under a Chief of Quality Control. The regular facilities of all U.S. Government Inspectors are available.

MAINTENANCE—ROUTINE

Maintenance of our aircraft hardware generally consists of simple lubrication, checking for visible signs of wear and tightening screws, approximately every 500 flight hours (for Overhaul instructions see procedures described with each repairable item):

(1) Tighten all screws including cover-plate screws, handle set-screws, cylinder set-screws and mounting screws, or threaded fittings.

(2) Lubricate:

Bolts—generously apply grease (ANG-21 or equivalent) to exposed surfaces. Work bolt in and out of case several times then wipe off excess grease.

Hubs—apply 2 or 3 drops of light weight oil between exposed hub and case. Rotate hub several times and wipe off excess oil from exposed surfaces.

Cylinder Assemblies—apply small amount of graphite through keyway to internal parts of cylinders. NEVER USE OIL OR GREASE TO LUBRICATE CYLINDERS.

Valve Assemblies—no lubrication required.

HOW TO ORDER

Please order all items by part number, including complete dash numbers, type, finish, keying and strikes required, all of which are explained in Leading Particulars for every item in this manual.

See the Glossary of "Lockwords" immediately following the Introduction for explanation of technical terms applied to locks, latches and hand hardware.

FINISHES:

Finishes are usually indicated and are the most suitable for each item described. If we have not shown a finish, or if you wish to deviate from the finishes normally called out, we will work to your specification, wherever possible.

KEYING:

Key numbers are specified for some of the items in this manual to indicate that these items will always be furnished with the same keying. When key numbers are not shown, it is necessary that you tell us whether you want lock cylinders on your orders "keyed alike", "keyed different" or "master keyed". See Glossary of "Lockwords", page viii. One key supplied with locks unless otherwise specified. Spare keys available on order.

DELIVERY DATES:

Our customers' delivery requirements differ widely and therefore we seldom stock complete assemblies; however, we do maintain a substantial inventory of basic components. Please allow sufficient lead time in placing your orders to provide for completion of the items you require.

TERMS OF SALE:

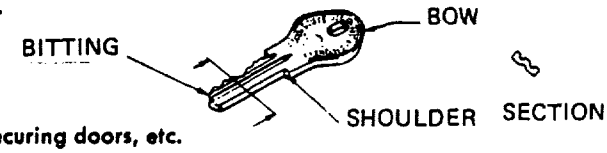
Net 30 days FOB our plant, Glendale, California. Extra charge may be made for export packing or special preservation packing.

MODIFICATION SERVICE:

Should modification specifications call for replacements not covered in our Master Index, please consult us. Our design group is eminently qualified to show you how to adapt existing Adams Rite products to your needs, or if necessary, to design new products to your specifications.

ADAMS RITE MANUFACTURING COMPANY
540 W. CHEVY CHASE DR., GLENDALE 4, CALIF.

KEY — For operating cylinders.



CHANGE KEY: Key for individual cylinders.

KEYED ALIKE: All cylinders may be operated by same key.

KEYED DIFFERENT: Each cylinder or group of cylinders uses different key.

MASTER KEY: Key to open a cylinder or group of cylinders which may be set to different change keys.

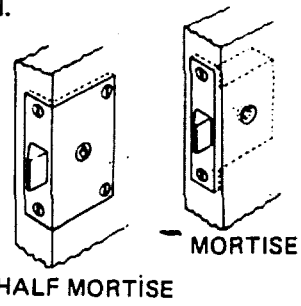
MASTER KEYED: All cylinders in a group operated by one master key although all cylinders may be keyed different.

LAZY CAM — *See Cylinder*

LATCH — Non-locking spring-loaded fastener for securing doors, etc.

DEAD LATCH: Latch in which bolt can be positively stopped.

LEVER — *See Handle*



LOCK — Fastener operated primarily or secondarily by key or equivalent, for securing doors, etc.

DEAD LOCK: Lock in which bolt can be positively stopped.

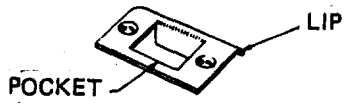
LOCK BAR — Part used to stop bolt or handles from operating.

MORTISE — To set a lock, etc., flush into the edge of the door, etc.

HALF-MORTISE: To set a lock, etc., into the face of a door, etc., may be flush to face, or with flange on surface.

PULL — A fixed hand or finger grip.

SHAFT — *See Spindle*



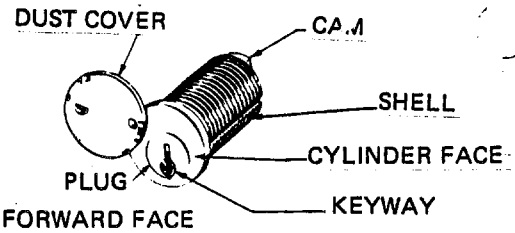
SPINDLE — Central shaft or square bar used to operate mechanism; usually fastened to handle and inserted in hub to operate lock or latch.

SPRING — Flat, coil, tension, compression and torsion used to actuate or retain bolts and other parts of locks.

STRIKE — Plate usually mounted on door jamb to accept bolt and protect jamb from damage.

THUMB TURN — Small Handle

TONGUE — *See Bolt*

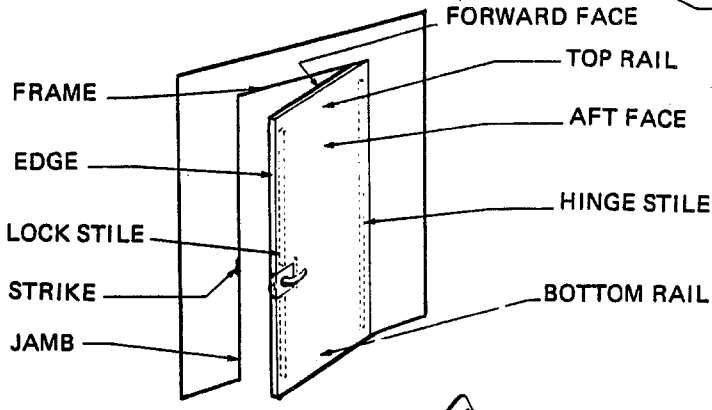


TUMBLER — Part of a cylinder see cylinder

GLOSSARY OF LOCKWORDS

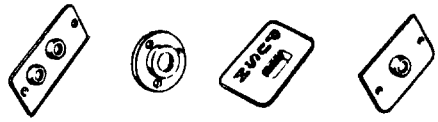
CYLINDER *(continued)*

SLABBING: Flat milled on one or both sides of shell to prevent rotation.



DEAD BOLT *See Bolt*

DEAD LATCH *See Latch*



DEAD LOCK *See Lock*

DOOR

ESCUTCHEON Trim plate or handle mounting plate.

FLAP A flush handle usually of the push-pull type.

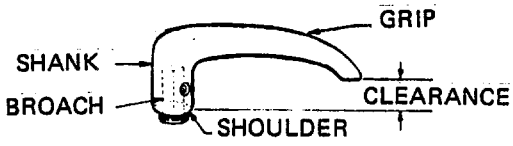
FREE-TURNING Feature of design which permits disengagement of a handle from spindle or shaft.

HAND OF DOOR The description of the door operation. Taken from position **Inside** airplane **looking forward.**

LEFT HAND: Door hinges on or slides toward left.

RIGHT HAND: Door hinges on or slides toward right.

SWING: Door may swing forward, (or away from), or aft, (or toward), the viewer.

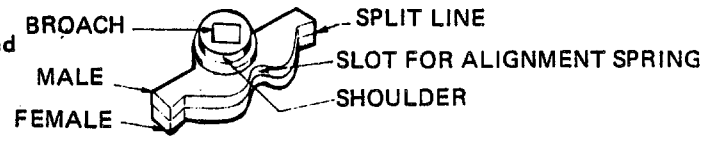


Illustrations shown with viewer looking forward.

LEFT HAND, FWD. | LEFT HAND, AFT. | RIGHT HAND, FWD. | RIGHT HAND, AFT

HANDLE Hand or finger grip for operating lock of door as lever, tee, ring, drop, offset, etc.

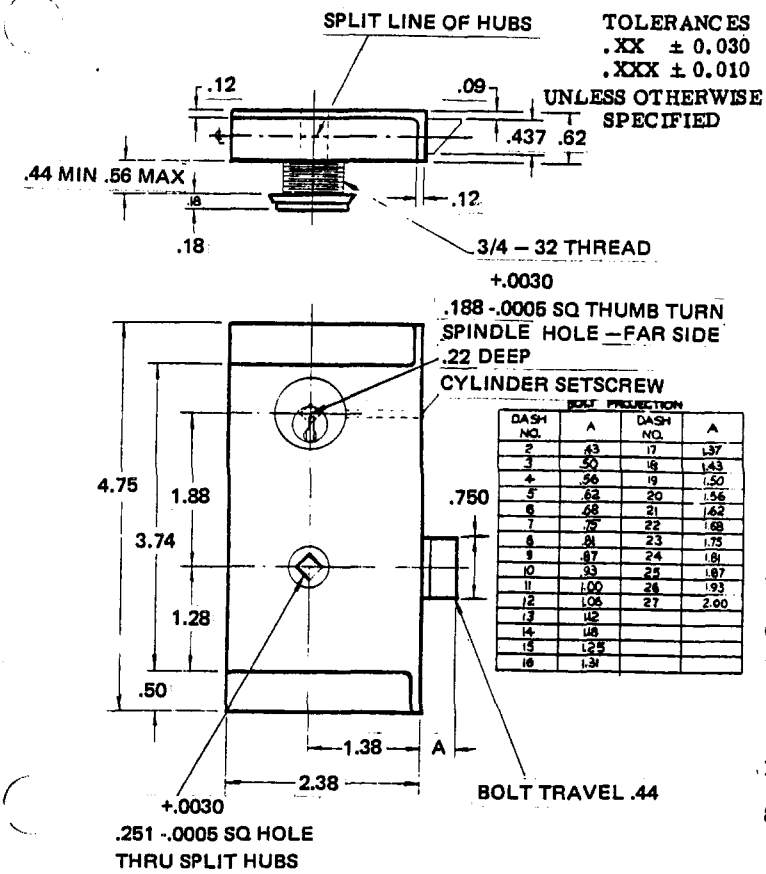
HUB Component of mechanism used for actuating bolt, lockbar, etc., into which spindle is inserted.



DOUBLE-ACTION: Turns both directions to actuate bolt.

SINGLE-ACTION: Turns in one direction to actuate bolt.

SOLID: One Piece.



SPLIT: Two piece, male and female, for independent actuation from either side.

KEEPER *See Strike*

LEADING PARTICULARS

USE: . . . . . Heavy duty installations on interior or exterior doors. Adaptable to almost universal installation with wide variety of handles and escutcheons.

MATERIALS: . Case and cover - aluminum alloy; bolt and hubs - steel; cylinder - brass.

FINISH: . . . . Bolt face - polished; cylinder - chrome plated; unless otherwise specified.

OPERATION: . Rotate hubs approximately 35 degrees either direction to retract bolt. Lock or unlock by key or thumb-turn. Use with separate spindles meeting at split-line of hubs when locking of outer handle only required. Inner handle remains operable. When solid spindle is used, handles work together. Bolt always free to latch. Hubs support handles against dropping.

WEIGHT: . . . Approximately 0.62 lb.

EXAMPLE OF PART NUMBERS: . . AR24-2 TY 1: Lock with 0.43 inch bolt projection; bevel and case type as shown in drawing.
AR24B2 TY 1: same as above, reverse bevel bolt.

KEYING: . . See Introduction; Keying paragraph, page iv.

STRIKE: . . . See AR52 (page 1-47). Not included.

OVERHAUL PROCEDURE

1. Disassemble in order of keyed index numbers as shown on exploded view illustration.

NOTE

Insert key in locked cylinder; retract key one notch; key may then be used to unscrew cylinder from case. Do not exert extreme pressure. Be sure setscrew is fully disengaged from cylinder.

2. Wash all parts in solvent per Federal P-S-661, or equivalent.

CAUTION

Do not immerse cylinders in any liquid to clean. Use air hose.

3. Inspect all parts for signs of visible wear.
4. Replace worn or damaged parts.
5. Polish out scratches on exposed surfaces.
6. Lubricate with grease per MIL-G-3278A, or equivalent.

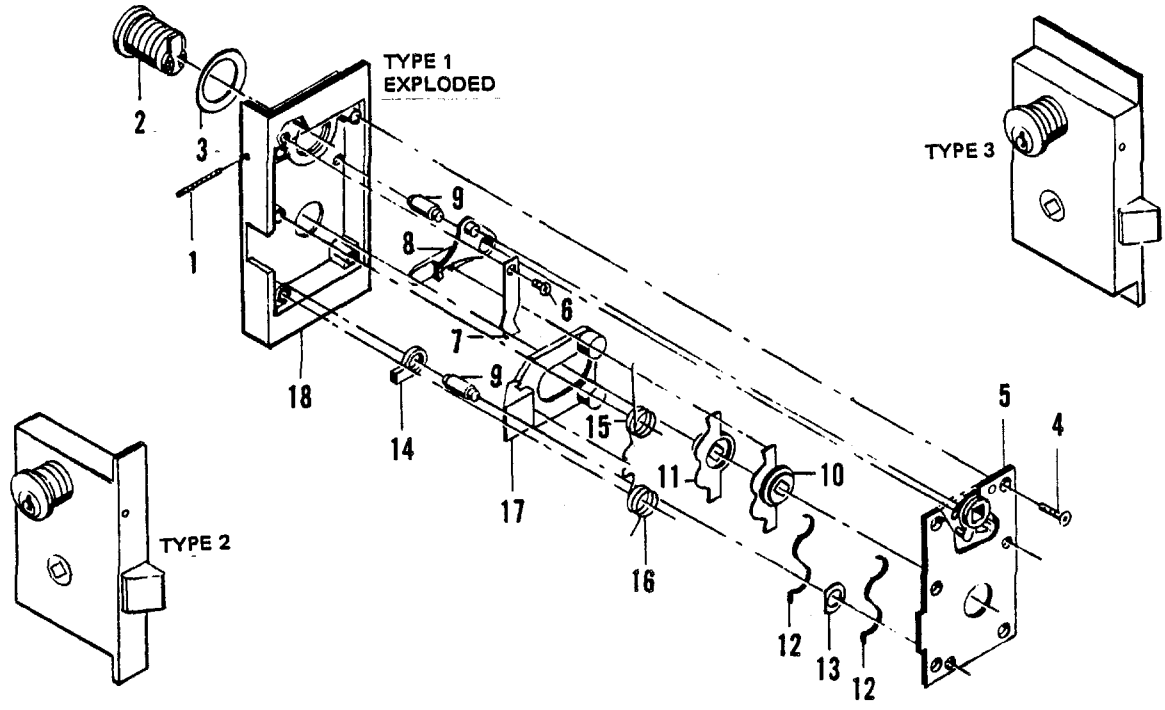
WARNING

Do not use oil or grease as a lubricant for cylinder - use powdered graphite only.

7. Reassemble in the reverse order of disassembly.

NOTE

Be sure stirrup on cover assembly (5) mates with pin on lockbar (8).

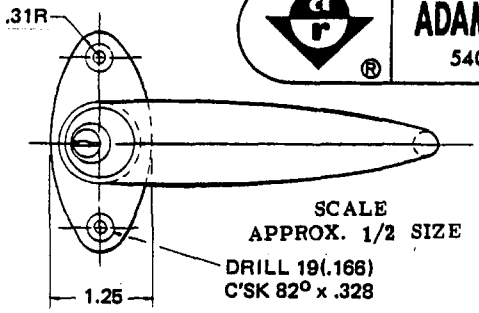


8. Check operation for conformance to Leading Particulars Operation.

CAUTION

Be sure both hubs can operate independently when separate spindles used.

MAINTENANCE



See Introduction; Maintenance paragraph, page iii.

FOR SPINDLE LENGTHS BETWEEN OR BEYOND VALUES GIVEN, EQUATE IN UNIFORM INCREMENTS AS INDICATED

LEADING PARTICULARS

USE: . . . . . Heavy-duty locking handles to operate locks or latches, including those shown elsewhere in this catalog, on interior or exterior doors. Also non-locking handles.

MATERIALS: . . Handle and escutcheon - aluminum alloy; pin cylinder - brass, disc cylinder - zinc; spindle - steel.

FINISH: . . . . . Handle and escutcheon - full polish; cylinder face - chrome plated.

OPERATION: . . Dead-locking handle and spindle securely locks to escutcheon; free-turning handle disengages from spindle when locked, with handle and spindle turning independently in escutcheon. Free-turning handle retained in locked position by light spring.

WEIGHT: . . . . Approximately 0.52 lb. (AR83-2-0)

EXAMPLE OF PART NUMBERS: . . . AR83-2-24: Dead-locking handle locking perpendicular to escutcheon, 1.500 inches between mounting holes, 0.38 inch spindle projection.
AR83-2-24F: Free-turning handle, 1.500 inches between mounting holes, 0.38 inch spindle projection.
AR83C2-24F: Free-turning handle with cylinder dust cover, 1.500 inches between mounting holes, 0.38 inch spindle projection.
AR83-8-0: Non-locking handle, broached for spindle, 2.125 inches between mounting holes.

KEYING: . . . . Must be specified on order. See Introduction, Keying paragraph, page iv.

(NOTE: Suffix "F" for Free-turning handle; insert "C" for cylinder with dust-cover.)

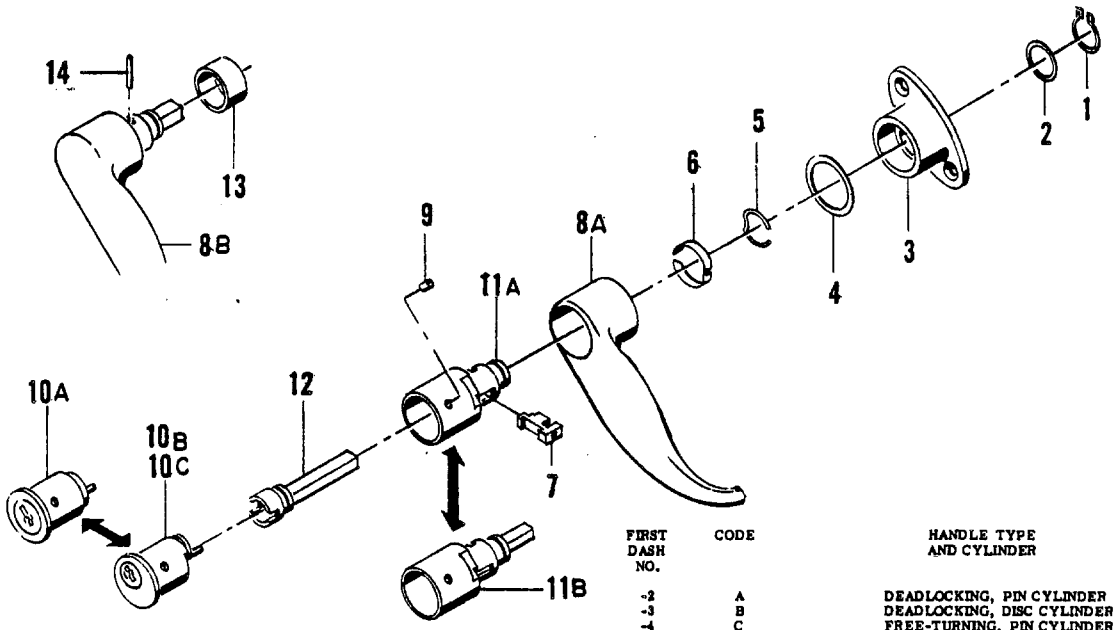
OVERHAUL PROCEDURE

1. Disassemble in order of keyed index numbers as shown on exploded view illustration.
   1a1. Code AW thru FW and AX thru FX: To remove lockbar (7) from FREE-TURNING assemblies, first rotate key in cylinder until spindle is engaged with handle; remove springs (5 and 6); lockbar (7) will slide free through large opening in case (11).
   1a2. Code AS thru FS and AT thru FT: To remove lockbar (7) from DEAD-LOCKING assemblies, first remove cylinder (10) from case asssembly (11).
   1b. To remove case-pins (9) use small drill in drill-press or hand drill motor.
2. Wash all parts in solvent per Federal P-S-661, or equivalent.

WARNING

Do not immerse cylinders in any liquid to clean. Use compressed air.

3. Inspect all parts for signs of visible wear.
4. Replace worn or damaged parts.
5. Polish out scratches on exposed surfaces.
6. Lubricate with grease per MIL-G-3278A, or equivalent.



WARNING

Do not use oil or grease as a lubricant for cylinder - use powdered graphite only.

7. Reassemble in the reverse order of disassembly.
8. Check operation for conformance to Leading Particulars Operation.

FOR SPINDLE LENGTHS BETWEEN OR BEYOND VALUES GIVEN, EQUATE IN UNIFORM INCREMENTS AS INDICATED

LEADING PARTICULARS

USE: . . . . . Heavy-duty locking handles to operate locks or latches, including those shown elsewhere in this catalog, on interior or exterior doors. Also non-locking handles.

MATERIALS: . . Handle and escutcheon - aluminum alloy; pin cylinder - brass, disc cylinder - zinc; spindle - steel.

FINISH: . . . . Handle and escutcheon - full polish; cylinder face - chrome plated.

OPERATION: . . Dead-locking handle and spindle securely locks to escutcheon; free-turning handle disengages from spindle when locked, with handle and spindle turning independently in escutcheon. Free-turning handle retained in locked position by light spring.

WEIGHT: . . . Approximately 0.40 lb.

EXAMPLE OF PART NUMBERS: . . AR87-2-24: Dead-locking handle locking perpendicular to escutcheon, 1.500 inches between mounting holes, 0.38 inch spindle projection.
AR87-2-24F: Free-turning handle, 1.500 inches between mounting holes, 0.38 inch spindle projection.
AR87C2-24F: Free-turning handle with cylinder dust cover, 1.500 inches between mounting holes, 0.38 inch spindle projection.
AR87-9-0: Non-locking handle, broached for spingle, round escutcheon.
(NOTE: Suffix "F" for Free-turning handle; insert "C" for cylinder with dust cover.)

KEYING: . . . . Must be specified on orders. See Introduction, Keying paragraph, page iv.

OVERHAUL PROCEDURE

1. Disassemble in order of keyed index numbers as shown on exploded view illustration.
   1a1. Code AW thru DW and GW; AX thru DX and GX: To remove lockbar (7) from FREE-TURNING assemblies, first rotate key in cylinder until spindle is engaged with handle; remove springs (5 and 6); lockbar (7) will slide free through large opening in case (11).
   1a2. Code AS thru DS and GS; AT thru DT and GT: To remove lockbar (7) from DEAD-LOCKING assemblies, first remove cylinder (10) from case assembly (11).
   1b. To remove case-pins (9), use small drill in drill-press or hand drill motor.
2. Wash all parts in solvent per Federal P-S-661, or equivalent.

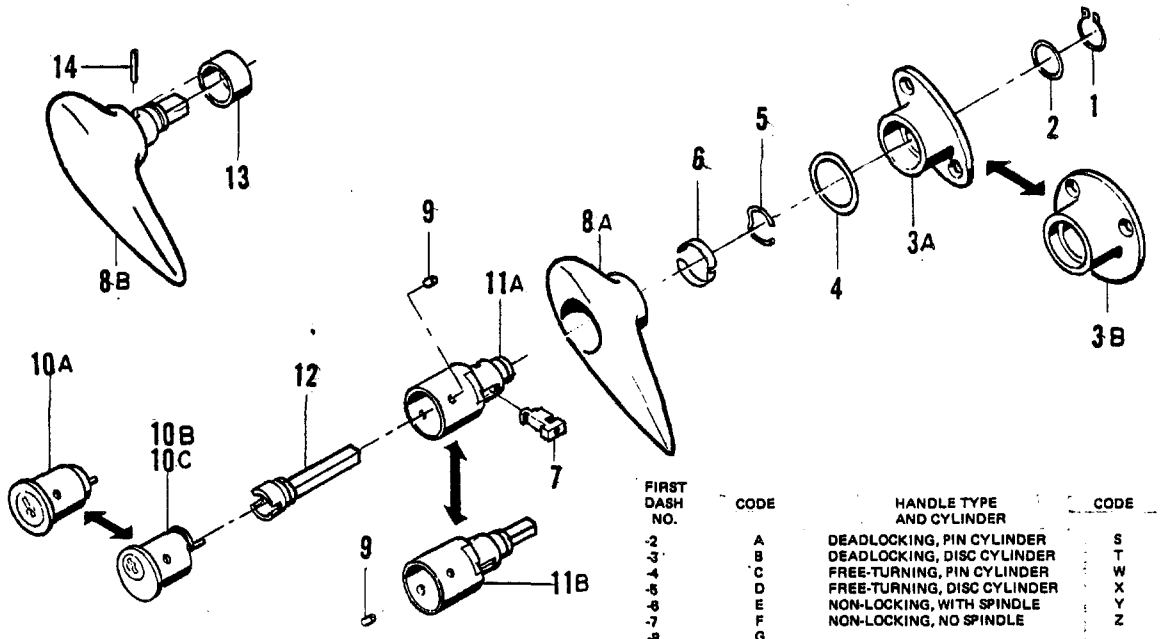
WARNING

Do not immerse cylinders in any liquid to clean. Use compressed air.

3. Inspect all parts for signs of visible wear.
4. Replace worn or damaged parts.
5. Polish out scratches on exposed surfaces.
6. Lubricate with grease per MIL-G-3278A, or equivalent.

WARNING

Do not use oil or grease as a lubricant for cylinder - use powdered graphite only.



7. Reassemble in the reverse order of disassembly.
8. Check operation for conformance to Leading Particulars Operation.

MAINTENANCE

See Introduction: Maintenance paragraph, page iii.

ADAMS RITE MANUFACTURING COMPANY

(NOT REPAIRABLE)

USE: . . . . . With bolt type latches and locks shown elsewhere in this catalog.
MATERIAL: . . Corrosion resistant steel, except AR61 - cold-roll steel.
FINISH: . . . . AR50, AR51, AR52 - polish; AR61 - cadmium plated.

EXAMPLE OF PART NUMBER: . . . AR52-3: Strike for latch installed in center of 0.75 inch thick door and having 0.437 x 0.750 inch bolt.

ADAMS RITE MANUFACTURING COMPANY
540 W. CHEVY CHASE DR., GLENDALE 4, CALIF.

LEADING PARTICULARS

USE: . . . . . Sturdy, pop-up type drain valves for lavatory and galley basins.
MATERIALS: . Brass; gaskets - synthetic rubber.
FINISH: . . . . Exposed surfaces - chrome plated.
OPERATION: . Actuate lever-arm with conventional lift or lever, or by remote control, to close or open drain valve. AR41 plug is removable for cleaning by turning counterclockwise and lifting. Valve seat must be tightened down to the limit to allow full indicated travel of lever.

WEIGHT: . . . . AR41 - 0.88 lb; AR43 - 1.19 lbs.

OVERHAUL PROCEDURE

1. Disassemble in order of keyed index numbers as shown on exploded view illustration.

NOTE

VL251 plug (4B) may be removed for cleaning without disassembling valve by turning 90 degrees counterclockwise and lifting out.

2. Wash all parts in solvent per Federal P-S-661, or equivalent.
3. Inspect all parts for signs of visible wear.
4. Replace worn or damaged parts.
5. Polish out scratches on exposed surfaces.
6. Reassemble in the reverse order of disassembly.
7. Check operation for conformance to Leading Particulars Operation.

POLICY STATEMENT

1. The overhaul instructions contained in this manual provide descriptive information, special procedures, and data pertaining to work done on the units identified on the title page. These instructions pertain to the units after they have been removed from the aircraft. The manual has been prepared for the experienced shop mechanic who normally performs shop work and not for the aircraft service mechanic who normally works on units while they are installed in the aircraft.

2. Every effort has been taken to provide complete and accurate overhaul instructions. However, if a situation should arise that is not adequately covered by this manual, please contact ELDEC Corporation for specific information at the following address:

Service Representative
ELDEC Corporation
P.O. Box 100

Telex: 328-959
TWX: 910-449-2855

8-240 Proximity Switch
Figure 1

1. Description and Operation

A. Description

(1) The ELDEC Proximity Switch Assembly, PN 8-240-04, shown in Figure 1, is an all solid state self-contained unit that changes state (switches) when a moveable metal target (actuator) comes within the actuating point of the fixed sensor. The proximity switch (hereafter referred to as assembly) performs the same function as a mechanical switch, but does not require physical contact.

(2) The entire assembly is contained within a single molded epoxy case. Electrical interface is provided through three separate leads, 3 feet in length. The output, depending on part number and requirements, consists of a normally open or normally closed switch closure to ground (see Figure 2 for leading particulars).

B. Operation

The assembly contains a sensor coil driven by an oscillator. As a target is brought into the proximity of the magnetic field generated by and surrounding the sensor coil, eddy currents are produced in the target. These eddy currents result in losses, absorbing energy from the magnetic field. When these losses increase beyond a set value (as the target is brought nearer the sensor coil), the oscillator is disabled. A detector/comparator circuit detects the presence or absence of oscillation and switches the output transistor on or off.

2. Disassembly

Sealed assembly, disassembly not required.

3. Cleaning

Clean dirt, oil, or grease from assembly with a clean cloth dampened with commercial Stoddard solvent.

WARNING: VENTILATE WORK AREA WHEN USING SOLVENT. AVOID CONTACT WITH SKIN. WEAR RUBBER GLOVES. OBSERVE ALL SAFETY AND FIRE PRECAUTIONS.

4. Inspection

Inspect assembly for damage, wear, broken leads, corrosion and deterioration.

OPERATING CHARACTERISTICS

5. Repair

Sealed assembly. Repair not required. Replace if defective.

6. Assembly

Not required.

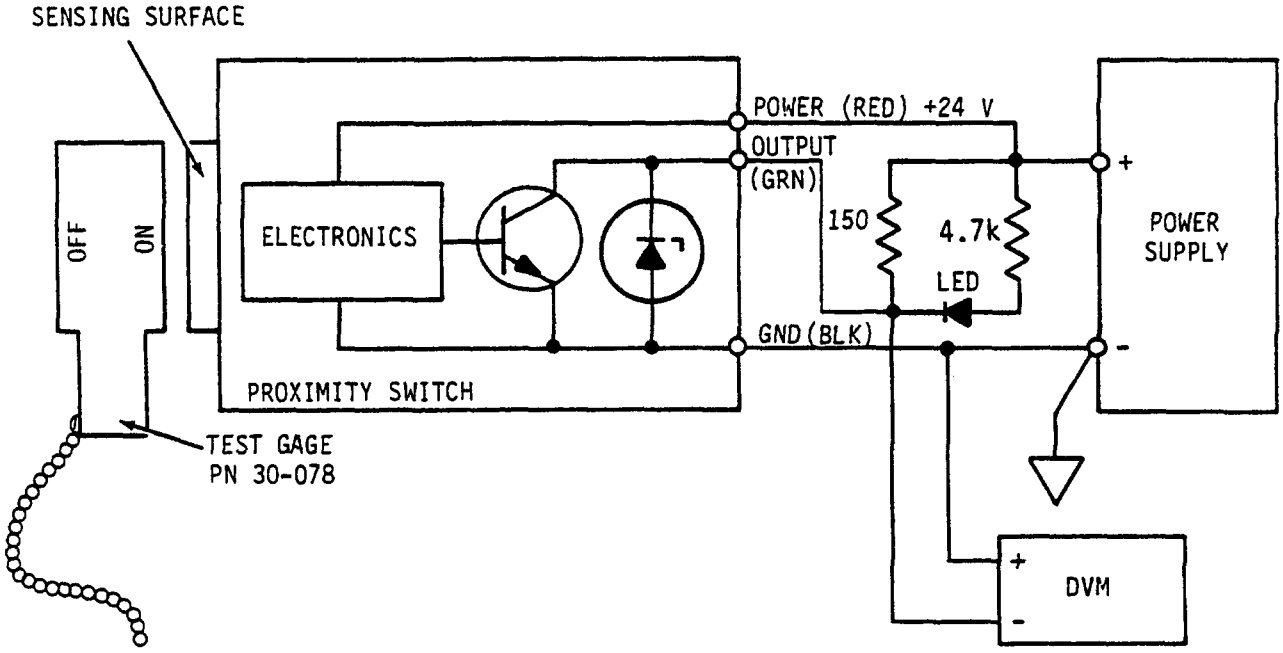
7. Fits and Clearances

Special fits and clearances not required.

8. Testing

This section provides functional test procedures for the assembly. If any out-of-limit conditions are observed, replace switch assembly.

A. Test Equipment Required



NOTE: Equipment of equivalent accuracy or specifications may be used.

ITEM	NAME	MODEL	MFR.
1	Proximity Switch Test Gage	30-078	ELDEC
2	Power Supply, 30 Vdc, 1 Amp		
3	Diode, Light Emitting (LED)	550-0405	DIALCO
4	Resistor, 4.7K, 1/4W, 5%	RCR07G472JS	ALLEN-BRADLEY
5	Resistor, 150 Ohm, 10W, 5%	HL-10, 150 ±5%	DALE
6	DVM	8000A	Fluke

Test Equipment List
Figure 3

B. Test Setup

Connect equipment as shown in Figure 4. Energize power supply and set its output to +30V dc (max.) with a 200mA load. The LED shall be illuminated when target is not present.

Test Set-Up
Figure 4

C. Proximity Switch Functional Test Procedures

(1) Place the OFF side of the test gage against the sensor face. Verify that the output is equal to or less than 2V and the LED remains illuminated.

(2) Place the ON side of the test gage against the sensor face. The LED should extinguish.

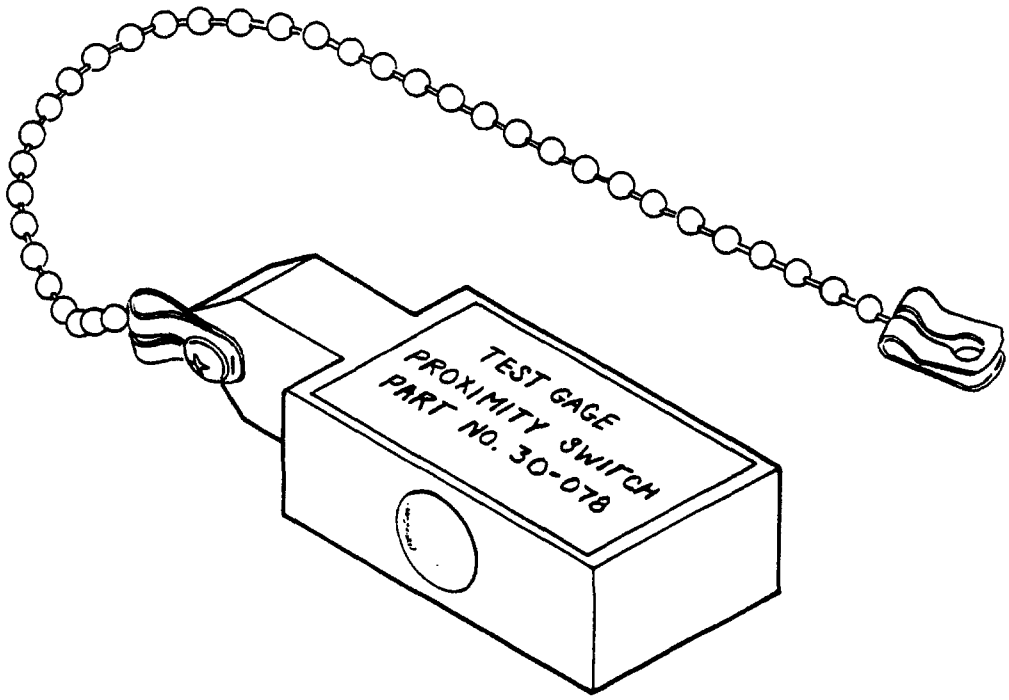
(3) Set power supply voltage to 18V dc (min.) and repeat Steps 1 and 2, disregarding voltage check in step (1).

(4) Testing is complete. Turn off power supply and disconnect assembly.

9. Troubleshooting

Not required. Replace if assembly does not meet requirements under TESTING (Paragraph 8).

10. Storage Instructions



Package assembly in a polyethylene bag or wrap. Seal in a commercial carton and store in a cool, dry place.

11. Special Tools, Fixtures, and Equipment

A. The following special tool is suggested for testing the assembly.

(1) Test Gage, Proximity Switch, ELDEC PN 30-078.

B. The Test Gage (Figure 5) may be purchased from ELDEC, or fabricated locally using two plastic shims, 0.08" (actuate) and 0.12" (deactuate) thick laminated to a 1/2" X 1/2" X 0.05" steel target.

Test Gage, Part No. 30-078

PROPELLERS/ PROPULSORS

MANUFACTURE	COMPONENT	PART NUMBER	ATA NO.	REV. STATUS	S.B./T.R.
Bendix	Tachometer Indicator (Propeller) Old P/N New P/N	34108C1AF13-1A3 & 34108CIAL-13-1A3 3571260-8002		Jun 16/1970	
Woodward	*Governor*	*Bulletin 33528E*			

THIS PAGE INTENTIONALLY LEFT BLANK.

Overhaul data for propellers is contained in Hartzell Propeller Overhaul Instructions No. 118B supplied separately.

Overhaul data for Woodward propeller governors is not included in this volume, since overhaul requires special test equipment and must be performed at airworthiness - authority approved facilities only. the following facilities have been approved and have the necessary test equipment to overhaul Woodward governors:

Airwork Corporation, Millville, New Jersey, U.S.A.

Hamilton Standard West Coast Division, Long Beach, California, U.S.A.

Hoffman Gm b H and Co. KG, Rosenheim, Germany.

Southwest Airmotive Company, Dallas, Texas, U.S.A.

United Aircraft of Canada Limited, Longueuil, Quebec, Canada.

Woodward Governor Company, Rockford, Illinois, U.S.A.

It is suggested that any operator, who has airworthiness - authority approved facilities for propeller governor overhaul, should contact the Woodward Governor Company directly for any required overhaul information.

Woodward also has a factory exchange replacement program, details of which are given in Bulletin 33528E included in this Chapter.

THIS PAGE INTENTIONALLY LEFT BLANK.

TACHOMETER INDICATOR 34108C1AF13-1A3

This manual also applies to Part No. 34108C1AL13-1A3 and Part No. 3571260-8002, the radial markings being the only difference.

OVERHAUL INSTRUCTIONS WITH PARTS BREAKDOWN

34108C1AF13-1A3

1. Description and Operation.

The 34108C1AF13-1A3 tachometer indicator is a hermetically sealed, unlighted instrument. It consists of a synchronous motor, a gear train assembly, a drag cup, two pointers and a graduated dial mounted in a 2 inch diameter case.

The indicator is normally connected electrically to a remotely located tachometer generator to form a complete system. Any change in the frequency of the generator (caused by the function being measured) will cause the synchronous motor to change speed. The pointers are mounted on shafts driven by the gear train assembly and the drag cup, which acts as a slipping clutch. In moving over the dial range, the pointers provide a visual indication of the function being measured.

The sub-dial facilitates reading indications between the main dial divisions.

The clamp-on mounting feature used allows the indicator to be rotated in order that all pointers on the instrument panel will be aligned under normal operating conditions with all pointers horizontal to the left. Any deviation from normal (indicated by a pointer dropping out of alignment) will be readily apparent.

The indicator will withstand vibration up to 2 g's.

Table 1. Leading Particulars

Operating Temperature . . .	-54°C to +71°C
Power Requirements	Generator to MIL-G-26611 or MIL-G-9398
Weight	0.9 lbs.
Accuracy	.5%

2. Disassembly.

A. Disassemble the indicator according to the following procedure: (refer to figure 2)

(1) Remove screw (2).

(2) Lift identification plate (1) over connector (4).

(3) Unsolder eyelet (3) and remove from end cover (6).

(4) Heat edge of case and glass assembly (8) around end cover (6) to melt solder holding end cover in place, and with a wire hook or other suitable tool inserted into eyelet hole, pull cover from case and glass assembly.

NOTE: Do not disassemble connector (4) or nameplate nut (5) from end cover unless necessary to replace a damaged part.

(5) Unsolder wires from connector (4).

(6) Remove compression ring.

(7) Clean excess solder from inner diameter of case and glass assembly (8) and withdraw indicator mechanism from assembly.

NOTE: Do not disassemble case and glass assembly (8) unless necessary to replace a damaged part.

(8) Remove dial spacer (12) from case and glass assembly (8).

(9) Remove pointer and hub assembly (13) by turning pointer against stop and gently continuing rotation and pulling pointer and hub assembly away from dial (15).

CAUTION: USE CARE TO AVOID BENDING POINTER STOP WHEN REMOVING POINTER AND HUB ASSEMBLY (13).

(10) Remove two dial screws (16).

(11) Insert a strip of thin, flat steel beneath dial (15) directly under pointer assembly (14) and carefully pry pointer assembly loose.

(12) Remove two screws (18) and washers (19) to separate gear train assembly (16) from motor housing (39).

CAUTION: USE CARE IN REMOVING GEAR TRAIN ASSEMBLY (17) TO AVOID DAMAGE TO THE PROTRUDING ENDS OF SHAFTS.

(13) Loosen screw (21) to remove return path assembly (26).

NOTE: Magnet assembly (27) should not be exposed to an open circuit. To avoid such exposure during disassembly, slide the magnet assembly directly from the indicator into magnet keeper 1489036-1. Place magnet and keeper in a non-magnetic container or on a non-magnetic surface.

(14) Remove screw (28) and disc (29) and slide magnet assembly (27) off starter and shaft assembly (35).

NOTE: Do not disassemble magnet assembly (27) unless it is necessary

to replace a damaged part.

(15) Slide spacer (36), motor rotor assembly (37), and ball bearings (39) from shaft of starter and shaft assembly (35).

NOTE: Stator assembly (38) is secured in housing by shrink fit. If removal is necessary the housing must be heated.

B. Disassemble the gear train assembly (17) according to the following procedure: (refer to figure 3)

(1) Remove three screws (2) and lock washers (3) and loosen rear plate assembly (1).

(2) Unsolder outer end of hairspring (10) from hairspring plate (6).

(3) Remove screw (7) and washer (8) to release hairspring plate (6).

NOTE: Do not disassemble jewel (4) from rear plate (5) unless necessary to replace a damaged part.

(4) Slide hub, gear and shaft assembly (9) out of front plate assembly (14).

CAUTION: USE CARE IN DISASSEMBLING GEAR TRAIN ASSEMBLY TO AVOID DAMAGE TO SHAFT PIVOTS, JEWELS, AND TEETH OF GEAR AND PINION.

(5) Remove hairspring (10) from shaft (13).

(6) Balance spring (11) need not be removed.

(7) Remove roll pin (15) and bushing and shaft assembly (17).

NOTE: Do not disassemble jewel (16) from plate assembly (22) unless necessary to replace a damaged part.

Do not disassemble bushing and shaft assembly (17) unless necessary to replace a damaged part.

3. Cleaning.

A. Clean main assembly of indicator according to the following instructions:

WARNING: USE SOLVENT IN A WELL VENTILATED AREA. DO NOT INHALE SOLVENT VAPORS OR ALLOW SOLVENT TO COME IN CONTACT WITH THE SKIN. KEEP SOLVENT AWAY FROM OPEN FLAME.

(1) Clean all metal parts with an approved solvent or use Naptha.

(2) Wash the dial (15) and cover glass (10) with a pure soap and water using care not to damage dial markings. Rinse and dry.

(3) Clean ball bearings (39) with Naptha or an approved solvent. Dry thoroughly. Do not handle ball bearings with bare fingers.

(4) Keep parts clean and free from dust particles.

B. Clean gear train assembly according to the following instructions:

(1) Clean pivots of shafts by inserting them into a piece of pithwood.

(2) Clean jewels (7 and 16) with a piece of soft pegwood freshly tapered for each jewel.

(3) Clean the teeth of pinion (18) and gear and cup assembly (12) with a stiff hair brush or glass fiber brush.

(4) Clean metal parts with Naptha or an approved solvent. Dry in accordance with standard shop practice.

(5) Keep parts clean and free from dust particles until reassembled.

4. Inspection/Check.

A. Inspect main assembly of indicator according to following steps:

(1) Inspect all parts for visible wear, damage, or defects.

(2) Inspect washers for scratches, scoring or damage.

(3) Inspect threads for stripping or burrs.

(4) Inspect lead wires for breaks.

(5) Inspect insulation for damage, breakdown or frayed material.

(6) Inspect pins of connector (4) for bending, breaks or loosening.

(7) Inspect case and glass assembly (8) for leaks, corrosion, dents or damage to case.

(8) Inspect glass (10) for chips or cracks.

(9) Inspect dial (15) and pointers (13 and 14) for chipped paint.

(10) Inspect bearings (39) for damage, wear or foreign material.

B. Inspect gear train assembly according to the following steps:

(1) Inspect jewels (7 and 16) under magnification for cracks or wear.

(2) Inspect teeth of pinion (18) for breaks, stripping, burrs or foreign material.

(3) Inspect teeth of gear and cup assembly (12) for breaks, stripping, burrs or foreign material.

(4) Inspect hairspring (10) for twisting or distortion, or improperly wound convolutions.

5. Repair.

No repair of any parts is recommended. Replace any parts found in inspection to be defective.

6. Assembly.

A. Assemble the gear train assembly according to the following instructions: (refer to figure 3)

CAUTION: USE CARE IN HANDLING AND ASSEMBLING GEAR TRAIN ASSEMBLY. TEETH OF PINION (18), TEETH OF GEAR AND CUP ASSEMBLY (12), PIVOTS OF SHAFTS (13 and 20), AND JEWELS (4 and 16) ARE DELICATE AND CAN BE EASILY DAMAGED.

(1) Assemble jewels (19) with high surface toward bottom jewel housings in bushing (21). Assemble pinion (18) on end of bushing with tapered end. Adjust opposite jewel for end play of shaft of 0.003 to 0.005 inch. Press on pinion (18) to allow clearance of 0.025 inch between inner face of pinion and opposing face of bushing (21). Hand taper ream hub of pinion if necessary.

(2) Press in bushing and shaft assembly (17) flush to 0.002 inch below rear surface of front plate (22).

(3) Press shaft (13) into gear and cup assembly (12) with 0.215 inch length pivot extending from gear on the side on which balance wheel is staked. Press in shaft (13) until shoulder of large diameter of shaft at front extends 0.401 inch beyond front surface of washer on front of hub of gear and cup assembly (12).

(4) Position hairspring (10) into gear and cup assembly (12) with 0.215 inch length pivot extending from gear on side on which balance wheel is staked (toward rear in exploded view illustration). Press in shaft (13) until shoulder of large diameter of shaft at front extends 0.401 inch beyond front surface of washer on front of hub of gear and cup assembly (12).

(5) Position hairspring (10) on shaft (13) as follows:

(a) View cup and gear assembly (12) from rear with the center of hole, which has been pressed into one of three gear spokes in a vertical position. Place hairspring (10) on shaft (13) so that free end of hairspring points clockwise from vertical.

(b) Maintain this position and press hub of hairspring (10) against hub of gear and cup assembly (12). Hairspring must be parallel to main gear; in free condition hairspring must be centered with shaft.

(c) Locate outer end of hairspring so that coils are equally spaced when the spring is wound up approximately 150 degrees. This adjustment is made by bending outer end of spring while free and after soldered to hairspring plate (6).

(6) Press in pin (15) so that they extend 0.130 inch from rear surface of plate assembly (22).

(7) Press in bushing and shaft assembly (17) flush to 0.002 inch below rear surface of front plate assembly (14).

(8) If jewel (16) was removed, press in place with high point of jewel toward rear of front plate assembly (14).

(9) If jewel (4) was removed press in with high point of jewel toward front of rear plate (5).

(10) Assemble front plate assembly (14), hub, gear and shaft assembly (9), and rear plate assembly (1).

(11) Adjust jewel (16) for 0.0013 to 0.0020 inch end play of shaft (13).

(12) Solder end of hairspring (10) to hairspring plate (6). Bend and readjust as necessary to insure that coils are equally spaced when hairspring is wound up approximately 150 degrees.

B. Assemble the main indicator assembly according to the following instructions: (refer to figure 2)

(1) If stator assembly (38) was removed from housing (40), reassemble as follows:

(a) Place housing in oven at 200°F (±20°F) for a period of two hours.

(b) Immerse stator assembly in dry ice for a period of two hours.

(c) Within five minutes after removal of parts from oven and dry

ice, insert stator into housing.

(2) Completely demagnetize motor rotor assembly (37) with magnetreater model 990. Using magnet charger 107A with fixture 1489486, fully remagnetize motor rotor assembly. Fixture 1449486 must be used in order to obtain desired magnetic path to assure proper motor starting characteristics. Demagnetize to a field strength of 380 to 420 gauss. Insert motor rotor assembly into magnet keeper 1489071 or install it immediately into motor assembly.

(3) Install spacers (36) and motor rotor assembly (37) on shaft of starter and shaft assembly (35).

(4) Place one bearing (39) on shaft of starter and shaft assembly (35) with flanged edge of bearing against spacer (36).

(5) Insert bearing mounted on shaft into seat at rear of motor housing (40).

(6) Place second bearing (39) on shaft on front side of motor housing (40) with flanged edge of bearing toward front of indicator.

(7) If magnet assembly (27) has been exposed to an open magnet circuit, it must be remagnetized. First demagnetize magnet assembly completely using model 990 magnetreater. Then place magnet assembly in magnet charger model 107A with fixture 1489041-1 and charge to full strength. Discharge maximum dc current through magnet charger winding. Remove magnet assembly from magnet charger directly into magnet keeper 1489036-1. Take care to avoid exposure to an open magnetic circuit. Do not remove magnet assembly from magnet keeper until ready to place in return path (26) in indicator.

NOTE: In order to stabilize magnet assembly (27), immerse magnet assembly (in its keeper) in dry ice for two hours, then immerse in boiling water for ten minutes. Repeat cycle a minimum of four times.

NOTE: If compensating discs (31 and 32) are replaced, they must be replaced with equal diameter discs to those removed.

(8) Assemble magnet assembly (27) on shaft extending through housing (40). To avoid demagnetization, place magnet assembly directly on to shaft from magnet keeper.

(9) Adjust end play of motor 0.0013 to 0.0020 inch with 8 oz. reversing gage load and tighten setscrew (28) against disc (29).

(10) Fit drag cup assembly (20) on shaft of gear train assembly (17). A replacement drag cup assembly may require reaming.

(11) Fasten gear train assembly (17) to motor housing (40) using screws (18) and washers (19).

(12) Install dial (15) on gear train assembly using dial screws (16).

NOTE: Apply purple glyptal lacquer to dial screw holes in gear train assembly by placing a drop of glyptal lacquer to end of a wire and placing it in screw hole. Spread glyptal in hole with wire. Add a second drop of glyptal to hole in same manner.

(13) Press pointers (13 and 14) in place on their respective shafts. If new pointers are used they may require reaming with a 3 degree, 3 flute standard taper reamer to achieve a positive fit on shaft.

(14) Connect leads of stator to connector (4) according to wiring diagram (see figure 1)

NOTE: If drag cup magnet has been remagnetized and thermocycled, before recalibrating, the return path should be positioned forward against the rear plate, connected to a generator and operated at 4200 RPM. In this condition, demagnetize the drag cup magnet until the pointer indicates 92 to 93% RPM. Recalibrate.

(15) Connect indicator to tachometer generator TT3 or equivalent. Adjust smoothness of motor when running at low (75 to 100 rpm) speeds. This is accomplished by adjusting screw (24). Lock screw in place after adjustment with locking nut (25).

(16) Place entire mechanism into case and glass assembly (8). Position rear cover in place and tape securely together.

(17) Conduct tests outlined under section 8, Testing, for room temperature starting, scale error, friction error and position error.

(18) If indicator meets all test requirements, remove tape, clean case and cover of any tape residue. If connector (4) was removed solder in place in end cover (6).

(19) Line up end cover so that polarizing key of connector (4) is within 2 degrees of top centerline of dial (15).

(20) Solder end cover (6) in place in case (11).

(21) Connect indicator to dual valve manifold that is connected to both a vacuum pump and a source of helium. Evacuate indicator to a pressure of 50 microns. With vacuum maintained, bake indicator at 71° to 79°C (160° to 175°F) for twelve hours.

(22) Switch valve to dry helium source, backfill and seal indicator by

soldering eyelet (3) in place.

NOTE: Helium used shall be at least 98 percent pure, dust free and shall contain not more than 0.006 milligrams of water vapor per liter (dew point -65°C (-85°F) at filling pressure.

7. Fits and Clearances.

All applicable fits and clearances are called out in assembly procedures.

8. Testing.

A. Unless otherwise specified for an individual test following conditions shall be observed for testing:

(1) All tests shall be conducted at atmospheric pressure (approximately 29.9" Hg.) and at room temperature (approximately +25°C).

(2) Indicator shall be tested in its normal operating position (dial surface shall be held in a vertical plane).

(3) All voltages noted herein are alternating current root-mean-square values. Voltmeter used to measure voltages shall be of a type which is free from frequency error.

(4) Indicator shall be gently tapped or vibrated before a test reading is taken.

B. The indicator shall be subjected to the following tests:

(1) Room temperature starting.

Connect indicator to TT3 generator or an equivalent variable frequency power supply. Supply voltage shall be a maximum of 0.0035 times frequency in cycles per minute. Frequency of supply shall be increased from 0 cycles per minute to a maximum of 150 cycles per minute. Reading shall not be less than 2.5 percent RPM at 150 cycles per minute input.

(2) Scale error.

Connect indicator to TT3 generator and test at points of scale listed in table 2. Test shall be made by setting generator at speed shown and reading error from indicator, or by setting the indicator at desired reading and reading error in generator speed whichever is more convenient. Errors at test points shall not exceed tolerances specified in table 2. When speed is held constant at any point of scale (above 5.0 percent RPM) pointer shall not oscillate over a range greater than 0.5 percent RPM from 3.5 to 15

percent RPM and 0.3 percent RPM from over 15 to 100 percent RPM as shown on indicator.

(3) Friction error.

Indicator shall be set at 5, 20, 40, 85, and 100 percent RPM graduations. After each setting indicator shall be gently tapped and change in indication noted. Change shall not exceed 1.5 percent RPM at 5 percent RPM graduation, and 0.5 percent RPM at 40, 70, 85 and 100 percent graduations. This test may be combined with scale error test.

(4) Position error.

Indicator shall be operated at 100 percent RPM while indicator is in normal operating position. Indicator reading shall be noted. Maximum deviation from normal position reading, when tested in the following positions, shall not exceed 0.3 percent RPM.

(a) Rotated from normal position through 45 degrees to rear (dial tilted 45° back from vertical position).

(b) Rotated from normal position through 45 degrees to front (dial tilted 45° forward from vertical position).

(c) Rotated from normal position through 45 degrees to right (dial vertical).

(d) Rotated from normal position through 45 degrees to left (dial vertical).

(5) Pointer alignment.

Indicator shall be operated so main pointer will indicate 90 and 96 percent RPM respectively. Sub-dial pointer shall then correspondingly indicate 0 and 6 respectively, within 0.2 percent RPM.

(6) Sealing.

Indicator shall be tested for leaks by means of a mass spectrometer type of helium leak detector. Total leak rate shall not exceed 0.1 micron-cubic foot per hour.

(7) Fogging.

Indicator shall be placed in a controlled ambient temperature of 85°C +5°C for minimum period of two hours. Within ten seconds after removal from oven, immerse indicator to depth of ¾ inch (cover glass down) in ice water bath maintained at 0° to 5°C. After 5 minutes remove indicator and quickly wipe dry. Inspect cover glass and dial

immediately for evidence of fog. Evidence of fog is cause for rejection.

As an alternate method, indicator may be placed in a controlled oven with temperature maintained at 71°C ±2°C for a minimum of one hour. Remove indicator and while still at this temperature, rub an ice cube on indicator glass for a period of one to two minutes. Wipe glass dry and inspect indicator for evidence of water or oil fog. Evidence of fog is cause for rejection.

Table 2. Calibration Data

Generator Speed RPM	Current Indication Percent RPM	Scale Error Percent RPM ± Indicated	Tolerance Generator RPM Limits
0	0	0.5	
210	5	0.5	189 - 231
420	10	0.5	339 - 441
630	15	0.5	609 - 651
840	20	0.5	819 - 861
1260	30	0.6	1235 - 1285
1680	40	0.8	1647 - 1713
2100	50	0.8	2067 - 2133
2520	60	0.8	2487 - 2553
2940	70	0.8	2907 - 2973
3150	75	0.5	3129 - 3171
3360	80	0.5	3339 - 3381
3570	85	0.5	3549 - 3591
3780	90	0.5	3759 - 3801
3990	95	0.5	3969 - 4011
4200	100	0.5	4179 - 4221
4410	105	0.5	4389 - 4431
4620	110	0.5	4599 - 4641

9. Trouble Shooting.

Table 3 contains a list of possible defects that may become evident in the indicator. It lists possible causes and steps to correct them.

Table 3. Trouble Shooting

Trouble	Probable Cause	Remedial Steps
Indicator fails position error test. Right or left.	Hairspring out of position.	Reposition hairspring.
Indicator does not meet minimum starting speed requirement.	Screw (24) out of position in return path (26).	Adjust screw (24) until proper speed is obtained.
	Motor rotor assembly (37) demagnetized.	Remagnetize as called out in paragraph.
Indicator fails scale error test.	Incorrect balance, hairspring out of position.	Reposition hairspring.
Indicator fails friction error test.	Dirt on shaft or pivots.	Clean properly.
Indicator fails fogging test.	Moisture or excessive oil.	Open indicator, bake in oven at 71°C to 79°C (160°F to 175°F) for 12 hours.

DIRECTION OF ROTATION OF MAGNET FOR PHASE SEQUENCE B-A-C WHEN VIEWED FROM REAR END OF MOTOR

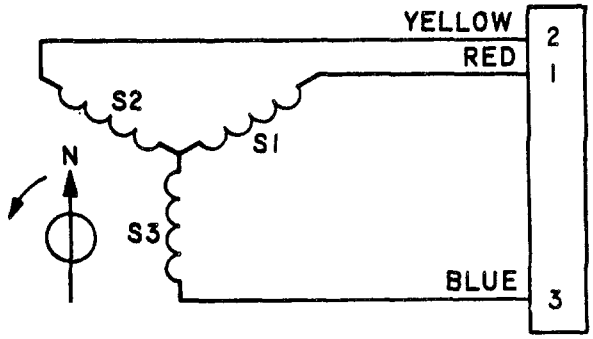

Figure 1. Wiring Diagram

10. Storage Instructions.

Prepare indicator for storage or shipment by placing protective cap, part no. 1489206-12 over connector (4). Using a cardboard box of suitable size, cushion indicator with a sufficient amount of dunnage to prevent any damage during shipment. Make certain that glass (10) is well protected. Seal box with a standard cloth or paper tape.

11. Special Tools, Fixtures and Equipment.

The following listing contains special tools required to overhaul and test indicator. If listed tools are not available, a suitable equivalent may be used. Unless otherwise indicated tools listed are manufactured by The Bendix Corporation.

Table 4. Special Tools and Test Equipment

Part No.	Nomenclature	Application
1489036-1	Magnet Keeper	To hold magnet assembly (27) at disassembly.
1489041-1	Magnetizing Fixture	To hold magnet assembly (27) in magnet charger model 107A.
1489071	Magnet Keeper	To hold motor rotor assembly (37) at disassembly.
1489486	Magnetizing Fixture	To hold motor rotor assembly (37) in magnet charger.
Model 107A	Magnet Charger Radio Frequency Lab. Boonton, N.J.	To remagnetize magnet assembly (27) and motor rotor assembly (37).
Model 990	Magnetreater Radio Frequency Lab. Boonton, N.J.	To demagnetize magnet assembly (27) and motor rotor assembly (37).
MIL-G-26611 MIL-G-9398	Generator	To supply power for indicator tests.

Table 4. Special Tools and Test Equipment (Continued)

Part No.	Nomenclature	Application
Model 24-120A	Helium Leak Detector Consolidated Electro-Dynamics Corp. Pasadena, Calif.	To perform helium leak check.

WOODWARD

AIRCRAFT PROPELLER GOVERNOR,

SYNCHRONIZER AND UNFEATHERING ACCUMULATOR

APPLICATION, MODERNIZATION AND EXCHANGE GUIDE

Outdated or worn propeller governors, unfeathering accumulators and automatic synchronizer components may be exchanged at a flat cost for factory remanufactured models that have newest improvements for best speed control.

To order exchange replacements, issue your purchase order to Rockford for the desired items, indicating that these are to replace old units (specifying part numbers and preferably the aircraft/engine/propeller hub model designations). Fresh exchange units will be shipped immediately and you will be invoiced at the flat rate. Return the old units prepaid to our main plant at 5001 North Second Street, Rockford, Illinois 61101. You can reuse our shipping container if you wish.

For twin engine aircraft, replace both governors if we specify pairs only. There is a notable difference in response rate (stability, sensitivity, etc.) between some governor models, if mixed. Matched governor pairs will be furnished. For less common and foreign governor models not listed, please contact Rockford for information.

Factory remanufactured controls carry the standard new part warranty. This provides for F.O.B. factory repair of any defects resulting from improper material or workmanship when installed and used in the manner intended and for as long as it is so used. Governor and accumulator TBO is the same as that specified for the engine except turboprop governor TBO is 1500 hours for the first overhaul and 2200 hours thereafter.

All prices are list per unit, F.O.B. Rockford, Illinois, subject to change without notice (May 1969). Exchange prices presume returned units are in usable condition.

WOODWARD GOVERNOR COMPANY

ROCKFORD, ILLINOIS

Woodward Propeller Governors

Overhaul of Woodward propeller governors requires special test equipment and must be performed at airworthiness-authority approved facilities only. The following facilities have been approved and have the necessary test equipment to overhaul Woodward governors:

Airwork Corporation, Millville, New Jersey, U.S.A.

Hamilton Standard West Coast Division, Long Beach, California, U.S.A.

Hoffman GmbH and Co., KG, Rosenheim, Germany.

Southwest Airmotive Company, Dallas, Texas, U.S.A.

United Aircraft of Canada Limited, Longueuil, Quebec, Canada.

Woodward Governor Company, Rockford, Illinois, U.S.A.

It is suggested that any operator, who has airworthiness-authority approved facilities for propeller governor overhaul, should contact the Woodward Governor Company directly for any required overhaul information.

Woodward also has a factory exchange replacement program, details of which are given in Bulletin 33528E attached.

INTRODUCTION

This manual contains instructions for the overhaul of the De Havilland Intake Deflector Actuators (Part of C6EC1055-3).

INTAKE DEFLECTOR ACTUATORS PART OF C6EC1055-3

1. Description and Operation

A. Physical Characteristics

The intake deflector actuator consists of a cylinder, which includes a threaded spigot suitable for connection of 1/4-inch flared tube fittings, a piston with two sets of piston rings, an adapter to permit mounting of the actuator on an engine intake duct, and a turnbuckle assembly for connection to an intake deflector.

LH and RH actuators are similar except that the adapters are handed and the bores of the threaded spigots differ in diameter. The spigot used on the LH actuator has a bore of 0.125 inch. That used on the RH actuator has a bore of 0.093 inch.

B. Operation

The unit is used to position a snow deflector in an engine air intake duct. One LH and one RH actuator is required to operate the deflector in each engine nacelle. Each actuator is extended by air pressure and is retracted by the integral compression spring which returns the piston to the head end of the cylinder when the air pressure is released.

The difference in bore between the threaded spigots used on the LH and RH actuators compensates for the difference in length of the air pressure supply lines to insure that the actuators operate at approximately the same speed.

C. Leading Particulars

The leading particulars of the actuator are shown in Table 1.

Table 1

Leading Particulars

Operating Air Pressure	35 ± 5 psi
Stroke	3.26/3.34 in.

2. Disassembly

A. Disassemble Intake Deflector Actuator (Figure 3)

(1) Cut and remove lockwire from cylinder (3, 4, 5, 6, 14A) and adapter (25, 26, 27, 28).

(2) Unscrew and remove cylinder from adapter, using a suitable strap wrench positioned at the top or bottom of the cylinder.

CAUTION: WRENCH MUST NOT BE POSITIONED AT ANY INTERMEDIATE POINT ALONG THE CYLINDER AS THIS MAY RESULT IN DEFORMATION OF CYLINDER WALLS.

(3) Do not remove label (7, 8, 9, 10) or spigot (11, 12) from cylinder unless replacement is required after inspection. Do not remove nipple (14B) from cylinder (14A) unless replacement is required.

(4) If label requires replacement, remove by softening with methyl ethyl ketone (refer to Table 2) and scraping off with a wooden or plastic scraper. Remove all traces of old adhesive using a lint-free cloth moistened with xylene.

WARNING: USE METHYL ETHYL KETONE AND XYLENE IN A WELL-VENTILATED AREA. AVOIDS BREATHING FUMES. AVOID SKIN CONTACT. KEEP AWAY FROM FLAME.

(5) If spigot requires replacement, remove attaching rivets (13) and soften sealant between faying surfaces of spigot and cylinder with methyl ethyl ketone. Remove spigot and remove all traces of old sealant from cylinder using methyl ethyl ketone.

(6) Slide adapter (25, 26, 27, 28) and spring (15) off turnbuckle assembly (16).

(7) Disconnect turnbuckle assembly from piston (24) by removing bolt (17), washers (18) and nut (19).

(8) Do not disassemble turnbuckle assembly unless inspection shows that a rod end (21) requires replacement. In which case, remove rivet (20) locking defective rod end to turnbuckle (22) and unscrew rod end from turnbuckle.

(9) Do not remove ring sets (23) from piston (24) unless replacement is required after inspection. If a ring set requires replacement, carefully lift piston rings and corrugated expander out of piston groove and slide off piston.

(10) Lift plate (29) out of alternative adapter (26, 28).

Table 2

Disassembly Materials and Compounds

MATERIAL	SPECIFICATION OR MANUFACTURER
Methyl Ethyl Ketone Xylene	TT-M-261 TT-X-916

3. Cleaning

A. General

(1) Clean all parts with a lint-free cloth moistened with solvent (refer to Table 3).

WARNING: USE SOLVENT IN A WELL-VENTILATED AREA. AVOID BREATHING FUMES. AVOID SKIN CONTACT. KEEP AWAY FROM FLAME.

(2) Use a soft-bristle brush moistened with solvent to clean areas difficult to reach with a cloth.

CAUTION: DO NOT IMMERSE ROD ENDS (21, FIGURE 3), CYLINDER ASSEMBLIES (3, 5), OR RING SETS (23) IN SOLVENT.

(3) After cleaning, dry parts thoroughly using a clean, lint-free cloth.

Table 3

Cleaning Materials and Compounds

MATERIAL	SPECIFICATION OR MANUFACTURER
Solvent	P-D-680

4. Inspection/Check (Figure 3)

A. General

(1) Inspect all parts for obvious wear, damage or corrosion.

(2) Inspect threaded parts for damaged, stripped or crossed threads.

(3) Check label (7, 8, 9, 10) for security and legibility.

(4) Inspect anodized surfaces for scratches and abrasions.

(5) Inspect bore of cylinder for scoring.

(6) Check that bearings of rod ends (21) rotate freely with no binding or roughness.

(7) Check spring (15) for distortion by rolling on a flat surface and for squareness of ground ends. Check that load rate is approximately 36 lb with a deflection of 4.5 inches.

(8) Check that ring sets (23) rotate freely in grooves of piston (24). If rings do not rotate freely, inspect piston grooves for burrs or other damage, and for dirt. Clean as necessary (refer to paragraph 3).

5. Repair

A. General

(1) Replace all parts that do not pass inspection and are damaged beyond simple repair.

(2) Lightly hone out scores from cylinder bore to maximum diameter of 2.010 inches.

(3) Smooth out minor damage to other surfaces of aluminum alloy parts using fine aluminum oxide or silicon carbide abrasive cloth (refer to Table 4).

(4) Touch up aluminum alloy surfaces with chemical film Alodine 1200S in accordance with manufacturer's directions.

NOTE: Touched-up areas will be golden-brown instead of the original blue.

Table 4

Repair Materials and Compounds

MATERIAL	SPECIFICATION OR MANUFACTURER
Abrasive Cloth (Grit No. 320)	P-C-451

6. Assembly

A. Assemble Intake Deflector Actuator (Figure 3)

(1) Insert plate (29) into alternative adapter (26, 28) to provide a seat for spring (15).

(2) Lightly smear piston rings (23) with silicone grease (refer to Table 5), and assemble to piston (24) by carefully sliding one expander and piston ring over piston into piston ring groove. Following same procedure install expander and piston ring into second groove of piston. Check that rings rotate freely in grooves of piston and then align rings so that gaps in rings are approximately 180° apart.

(3) Assemble rod ends (21) to turnbuckle (22) as shown in Figure 1. Lock rod ends in place using rivets (20).

(4) Connect turnbuckle assembly (16) to piston (24) using bolt (17), washers (18) and nut (19).

(5) Assemble spigot (11, 12) to cylinder (14), as follows:

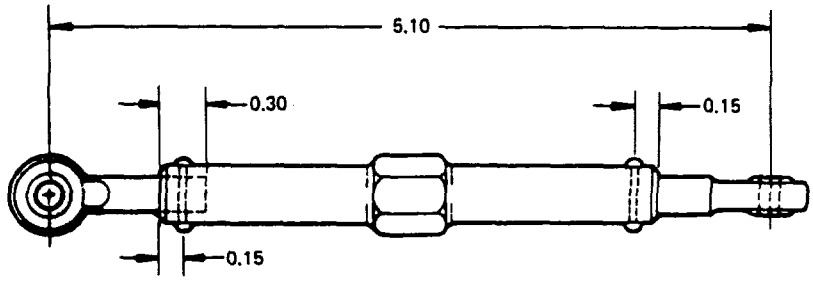
(a) Remove all traces of old sealant from faying surfaces using methyl ethyl ketone.

WARNING: USE METHYL ETHYL KETONE AND TRICHLORETHYLENE IN A WELL-VENTED AREA, AVOID BREATHING FUMES, AVOID SKIN CONTACT, KEEP AWAY FROM FLAME.

(b) Thoroughly clean faying surfaces of spigot and cylinder with a soft bristle brush or lint-free cloth moistened with trichloroethylene, and dry with a clean, lint-free cloth before trichloroethylene evaporates.

(c) Apply a thin layer of sealant to faying surface of spigot and secure spigot to cylinder using rivets (13).

WARNING: USE SEALANT IN A WELL-VENTILATED AREA, AVOID BREATHING FUMES, AVOID SKIN CONTACT, KEEP AWAY FROM FLAME.



(d) Remove any excess sealant from spigot and cylinder using methyl ethyl ketone.

(5A) Install nipple (14B) in top of cylinder (14A).

(6) Install replacement label (7, 8, 9,10) as follows:

(a) Thoroughly clean surface of cylinder where label is to be installed, using a lint-free cloth moistened with trichlorethylene, and dry with a clean, lint-free cloth before trichloroethylene evaporates.

(b) Remove paper backing from new label. Apply label to cylinder, rubbing down carefully with a plastic applicator to remove all air trapped under label.

NOTES:

SCREW ROD ENDS INTO TURNBUCKLE TO OBTAIN INSERTION AND PIN-CENTRE DIMENSIONS INDICATED, WITH ROD ENDS AT 90° TO ONE ANOTHER.

DRILL NO. 51 (0.067 IN. DIA) THROUGH ROD ENDS AND TURNBUCKLE TO INSTALL LOCKING RIVETS AT POSITIONS INDICATED.

ALL LINEAR DIMENSIONS IN INCHES; TOLERANCE ±0.01.

Assembly of Rod Ends to Turnbuckle

Figure 1

(c) Seal all edges of label with a light, overlapping ribbon of edge sealer.

WARNING: USE EDGE SEALER IN A WELL-VENTILATED AREA. AVOID BREATHING FUMES. AVOID SKIN CONTACT. KEEP AWAY FROM FLAME.

(7) Insert piston (24) with attached turnbuckle assembly (16) fully into cylinder (3, 4, 5, 6, 14A), compressing ring sets (23) to facilitate entry into cylinder bore.

(8) Slide spring (15) over turnbuckle assembly and into cylinder bore.

(9) Apply a small quantity of anti-galling compound to threads of cylinder, check that plate (29) is installed in alternative adapter (26, 28) if appropriate. Screw cylinder (14A) into adapter and hand tighten insuring that not less than six full threads are engaged. Screw cylinder (3, 4, 5, 6) into adapter using a suitable strap wrench positioned at the top or bottom of the cylinder.

CAUTION: WRENCH MUST NOT BE POSITIONED AT ANY INTERMEDIATE POINT ALONG THE CYLINDER AS THIS MAY RESULT IN DEFORMATION OF CYLINDER WALLS.

(10) Lock cylinder to adapter using wire MS20995C51.

(11) Perform functional test procedure after reassembly.

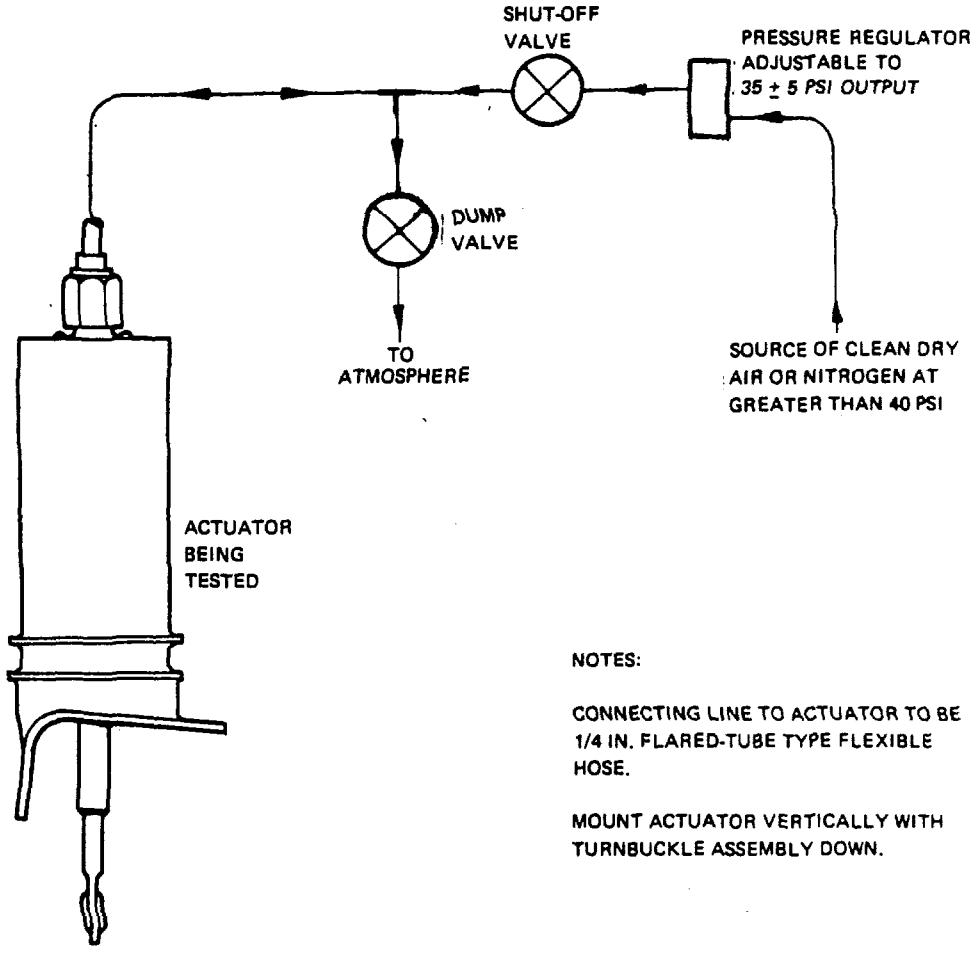
7. Fits and Clearances

Not applicable.

8. Testing



NOTE: It is recommended that the actuator be subjected to the functional test procedure before installation into an aircraft.

A. Test Equipment

Test equipment required to perform the functional test procedure is indicated in Figure 2.

B. Preparation for Test (Figure 2)

(1) Close shutoff valve and open dump valve.

Schematic Test Setup

Figure 2

(2) Connect actuator to test setup.

(3) Apply air or nitrogen pressure to test setup and set pressure regulator to 35 ± 5 psi.

(4) Close dump valve.

C. Test Procedure

(1) Measure projection of turnbuckle assembly beyond adapter and record for use in steps (7) and (8).

(2) Open shutoff valve.

(3) Actuator must extend smoothly to reach full extension in less than 3 seconds.

(4) Measure extended projection of turnbuckle assembly beyond adapter, using the same reference points as in step (1), and record for use in step (8).

(5) Check for leaks between spigot and cylinder using detergent (refer to Table 6).

(6) Close shutoff valve and open dump valve.

(7) Actuator must retract smoothly until projection of turnbuckle assembly beyond adapter is the same as that recorded in step (1).

(8) Check stroke by subtracting projection recorded in step (1) from that recorded in step (4). Stroke must be between 3.26 and 3.34 inches.

D. Shut-down After Test

(1) Shut off air or nitrogen pressure to test setup and close pressure regulator.

(2) Open shutoff valve.

(3) Disconnect actuator from test setup.

E. Test Results

(1) Actuators which meet the requirements of the functional test procedure, may be put into service.

(2) If any actuator fails to meet the requirements of the functional test procedure, refer to the trouble shooting procedure.

Table 6

Test Materials and Compounds

MATERIAL	SPECIFICATION OR MANUFACTURER
Detergent, Leak-Tec, Formula No. 277C	American Gas and Chemicals Co. Inc.

9. Trouble Shooting

A. If the actuator fails to meet the requirements of the functional test procedure, refer to Table 7 to determine the possible cause and correction for the malfunction.

Table 7

Trouble Shooting Information

TROUBLE	POSSIBLE CAUSE	CORRECTION
1. Actuator fails to extend, or extension is not smooth or too slow.	Dirt in cylinder bore.	Clean cylinder bore.
	Cylinder bore scored.	Lightly hone cylinder bore, or replace cylinder.
	Rings tight in piston grooves.	Clean rings and piston grooves.
		Deburr piston grooves.
		Lightly polish sides of rings.
	Rings incorrectly assembled in piston grooves.	Check that each groove has one ring and a corrugated expander, and that ring gaps are approximately 180° apart.
2. Leakage between spigot and cylinder.	Breakdown of sealant film between spigot and cylinder.	Disassemble spigot from cylinder. Clean, apply fresh sealant, and reassemble.
3. Actuator fails to retract or retraction is not smooth.	Broken spring.	Replace spring.
	Piston jamming in cylinder bore.	Refer to Trouble 1.
4. Stroke out of tolerance.	Dirt in actuator.	Disassemble, clean and reassemble actuator.

10. Storage Instructions

A. Preparation

(1) Cap threaded spigot or nipple.

(2) Wrap intake deflector actuator in water vapor resistant barrier material, including a desiccant (refer to Table 8).

(3) Affix label giving following information:

(a) Identification.

(b) Date of overhaul.

(c) Inspection.

Table 8

Storage Materials and Compounds

MATERIAL	SPECIFICATION OR MANUFACTURER
Barrier Material	MIL-B-121
Desiccant	MIL-D-3464

11. Special Tools

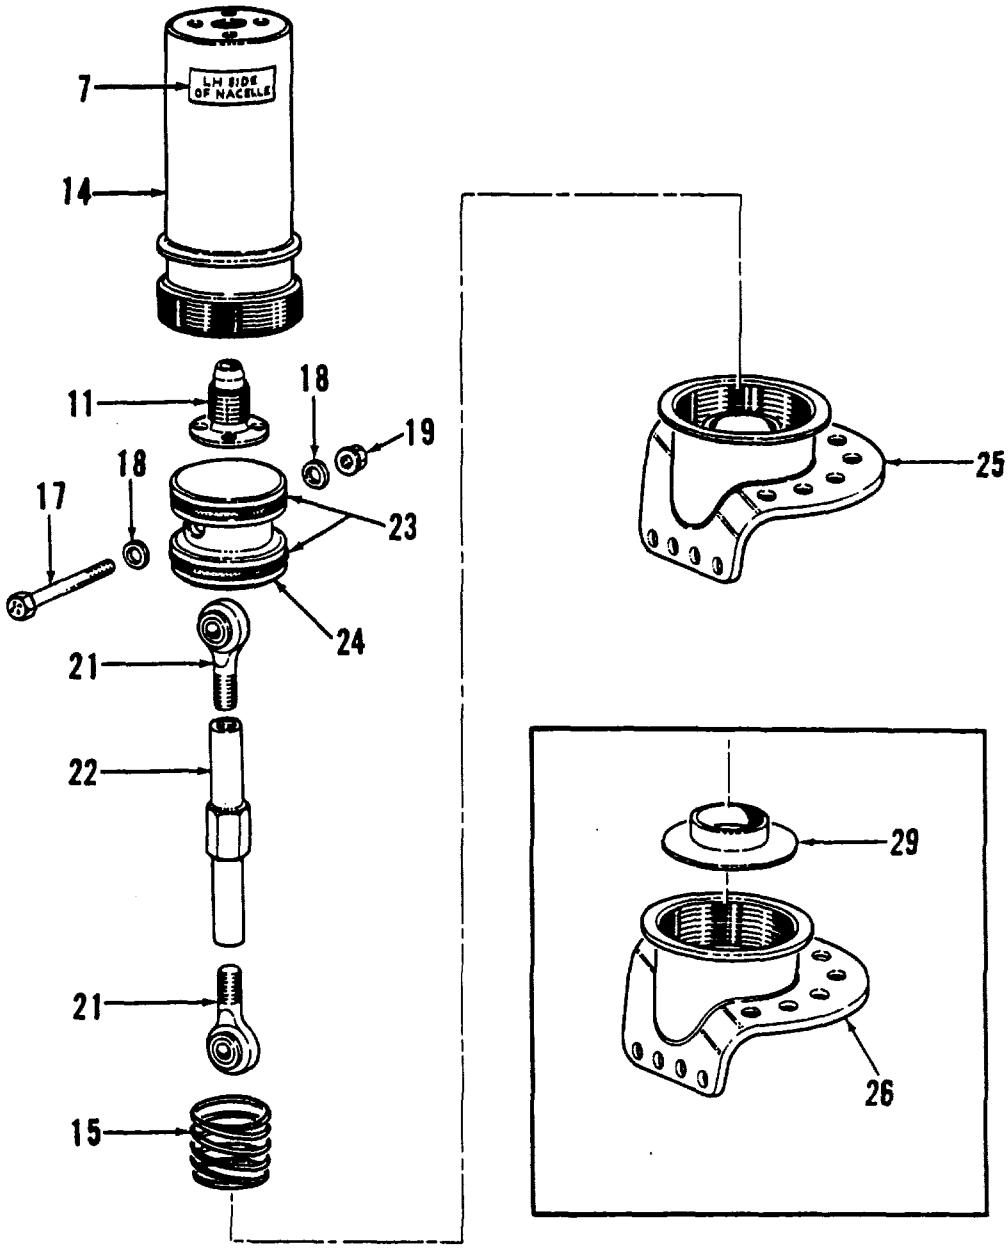
No special tools are required. Overhaul of the actuator can be accomplished with the use of tools, fixtures and other equipment normally available at overhaul facilities.

12. Illustrated Parts List

A. For explanation of vendor codes used in the illustrated parts list, refer to Table 9.

Table 9

Vendor Codes



CODE	VENDOR NAME AND ADDRESS

INTRODUCTION

1. SCOPE OF THIS MANUAL

This manual has been prepared by Barry Controls Division of Barry Wright Corporation, Burbank, California, in accordance with Air Transport Association (ATA) Specification 100. Contained in this manual are shop verified procedures to enable a qualified mechanic to restore the Type 7350721 engine vibration isolator to serviceable condition. This manual is intended for shop overhaul and not line maintenance. Refer to the aircraft manufacturer's maintenance manual for removal and installation procedures.

2. SERVICE OR OVERHAUL LIFE

Barry Controls has determined from analysis of isolators that were removed from service at various flight hours and through laboratory tests that isolator service life is consistent with the PT6A engine overhaul cycle - based on normal aircraft useage. Operators who consistently get high time from their engines have good flight and maintenance procedures which are also beneficial to isolator service life.

The isolators will provide good service for engine TBO but they rarely last twice engine TBO. Therefore, it is suggested that these isolators be removed at engine overhaul and replaced with new isolators, or overhauled in accordance with the detailed procedures specified in this manual. This is economical because the engine is already off the aircraft and the isolators can easily be changed. It also assures optimum isolator performance when the overhauled engine is installed.

Barry Controls has set up an exchange program for these isolators where used isolators which are acceptable for overhaul will be replaced on an exchange basis with overhauled, zero time, fully warranted isolators.

DESCRIPTION AND OPERATION

1. DESCRIPTION

A. Barry Controls Type 7350721 Engine Vibration Isolators provide attachment for Pratt and Whitney PT6A-20 and PT6A-27 turboprop engines to the de Havilland DHC-6 Twin Otter and other aircraft. They minimize the transmission of powerplant/propeller noise and vibration to the airframe and also reduce airframe vibration transmitted to engine. Three isolators are required for each engine. All isolators on an aircraft should have the same part number.

NOTE: Isolator 7350721-7 supersedes isolators 7350721-1, 7350721-5, and 7350721-6 used on the PT6A-20 engine. Isolator 7350721-7 is alternate and replacement for 7350721-8 on the PT6A-20 engine.

Isolator 7350721-8 can be substituted for isolator 7350721-7 for use on the PT6A-20 engine, but isolator 7350721-8 cannot be substituted for isolator 7350721-7 on the PT6A-27 engine.

B. Each isolator consists of two matched resilient cores installed on a steel housing so that the cores can be visually inspected. The cores are manufactured from Butyl elastomer vulcanize bonded between two metal plates. All primary structural components are passivated stainless steel. The isolator is held together by a stud that is flared on one core and press fit into the other core.

C. The isolator housing is connected to the engine with four bolts. A gasket must be used between the isolator and engine pad to prevent bottoming out of attach bolts or shear pilot which could damage isolator or engine. A single mounting bolt through the stud and core assemblies connects the isolator to the airframe.

2. OPERATION

Engine propulsive forces are transmitted from the engine pad to the isolator housing, through the core assemblies to the mounting bolt, and into the airframe. Propeller/powerplant shock and vibration are reduced by the controlled spring rate and damping properties of the core assemblies, while the propulsive forces are passed to the airframe.

3. VISUAL CHECK OF INSTALLED ISOLATORS

A. The isolators can be visually checked for condition and installation on the aircraft as follows (Ref: IPL Figure 1 for component nomenclatures):

3.A. (Continued)

(1) Visually check core assemblies for indications of bond failure, separations, excessive deflection, or elastomer damage.

(2) Check mounting bolts for tightness and safety.

(3) Visually check housing for damage and cracks.

COMPONENT	LENGTH	WIDTH	HEIGHT	WEIGHT
7350721-7	2.35 INCH	4 INCH	2.88 INCH	1.6 LBS.
7350721-8	2.35 INCH	4 INCH	2.88 INCH	1.6 LBS.

LEADING PARTICULARS
FIGURE 1

DISASSEMBLY

1. GENERAL

The exploded view illustration (Ref: IPL Fig. 1) provides the basic component information to disassemble the 7350721-7 and 7350721-8 engine vibration isolators. Read all notes and procedures to simplify disassembly and prevent equipment damage or personal injury.

2. REQUIRED SPECIAL TOOLS FOR DISASSEMBLY

None

3. DISASSEMBLY PROCEDURE

A. Disassemble the isolator as follows (Ref: IPL, Fig. 1):

(1) The core (2) is press fit on stud (3). Pull core off stud by hand or use soft mallet to tap housing away from core.

(2) Remove core (8) and stud (3) from housing (4).

(3) Remove bumper tube (6) from stud (3).

(4) Hold protruding end of stud (3) and drill out flared portion of stud (3) in core (8) and discard stud.

CAUTION: WHEN DRILLING, BE CAREFUL NOT TO DAMAGE CORE (8) OR THE CORE MAY HAVE TO BE REPLACED.

(5) Remove gasket (5) and discard.

(6) Remove spring pin (-7) from housing where applicable.

CLEANING

1. CLEANING MATERIALS REQUIRED

Refer to Fig. 201 for required cleaning materials.

MATERIAL/EQUIPMENT	SOURCE
Isopropyl Alcohol	Commercially Available
Brush, Stiff-bristle Non-metallic	Commercially Available
Cloth, Lint-free	Commercially Available
Cloth, Crocus	Federal Spec. P-C-458
Methyl-Ethyl-Ketone	Federal Spec. TT-M-261
Pad, Bronze Wool, Fine	Commercially Available
Pads, Scotch Brite, General Purpose, 7447	Minnesota Mining & Mfg.
Pads, Scotch Brite, Ultra Fine, 7448	Minnesota Mining & Mfg.
Solvent, Stoddard	Federal Spec. P-D-680, Type I

NOTE: When listed items are not available, equivalent substitutes may be used.

Cleaning Materials
Figure 201

2. CLEANING PROCEDURE

A. Cleaning of core assembly and nylon bumper tube.

CAUTION: DO NOT USE TOLUENE, OR SIMILAR SOLVENTS FOR CLEANING. NEVER IMMERSE BONDED PARTS IN CLEANING COMPOUNDS OR DAMAGE TO THE ELASTOMER AND THE ELASTOMER-TO-METAL BOND MAY RESULT.

WARNING: ISOPROPYL ALCOHOL IS FLAMMABLE AND MUST NOT BE USED NEAR HEAT OR OPEN FLAME. IT IS A TOXIC SOLVENT. INHALATION OF VAPORS OR PROLONGED CONTACT WITH LIQUID SHOULD BE AVOIDED.

(1) Clean oil, grease, and grime from the core assembly and bumper tube with a clean cloth or stiff-bristle brush moistened with isopropyl alcohol.

NOTE: Fine bronze wool pads or crocus cloth may be used to remove stubborn accumulations of foreign material.

(2) Immediately dry with a clean, dry, lint-free cloth.

B. Cleaning of non-bonded all metal parts.

WARNING: STODDARD SOLVENT AND METHYL-ETHYL-KETONE (MEK) ARE FLAMMABLE AND MUST NOT BE USED NEAR HEAT OR OPEN FLAME. THESE ARE TOXIC SOLVENTS. INHALATION OF VAPORS OR PROLONGED CONTACT WITH THESE LIQUIDS SHOULD BE AVOIDED.

(1) Clean metal parts by vapor degreasing or washing in clean Stoddard solvent or MEK.

(2) Use a stiff-bristled non-metallic brush to remove foreign matter accumulations. Use fine bronze wool pads, Scotch Brite pads, or crocus cloth to remove stubborn foreign matter accumulations.

(3) Repeat step (1) above.

(4) Dry metal parts with a clean lint-free cloth or oil-free compressed air at 20 psig maximum.

(5) If further cleaning is necessary, clean metal surfaces by vapor blasting in accordance with the following procedures.

(a) Vapor blast to remove heavy residue or corrosion.

(b) After vapor blasting, clean parts by vapor degreasing or washing in clean Stoddard solvent or MEK per step (1) of this paragraph.

(c) Dry parts with a clean, lint-free cloth or oil-free compressed air at 20 psig maximum.

INSPECTION/CHECK

1. GENERAL

A. Inspect all parts for nicks, cracks, scratches, corrosion, fretting, and galling.

NOTE: Conduct inspections under a strong light, preferably using a 10X magnification.

B. Inspect applicable detail parts of the engine vibration isolator in accordance with requirements contained in FITS AND CLEARANCES.

C. Perform dimensional inspections using standard inspection equipment. REFER TO FIG. 301 FOR SPECIFIC INSPECTION/CHECKS.

NOTE: In Fig. 301, where magnetic particle inspection is specified, perform inspection in accordance with Military Specification MIL-I-6868 or equivalent procedure.

NOMENCLATURE FIGURE AND ITEM NUMBER	METHOD OF INSPECTION	CHECK	REQUIREMENTS
Spring Pin	Visual	Distortion	Replace if damaged
NOTE: Spring pin is applicable only to early model housing. Current housing has cast pin. Both have same part number and are interchangeable.			
Bumper Tube	Visual	Nicks, burrs, scratches.	If significant visual damage, replace.
Housing	Dimensional	Wear	Refer to FITS AND CLEARANCES. If limits are exceeded, replace.
	Visual	Scratches, nicks, burrs	Reworked area cannot exceed 0.020 inch depth or 15% of any surface or perimeter after removal of scratches, nicks and burrs.

INSPECTION REQUIREMENTS
FIGURE 301 (SHEET 1 OF 2)

NOMENCLATURE FIGURE AND ITEM NUMBER	METHOD OF INSPECTION	CHECK	REQUIREMENTS
Housing (Continued)	Magnetic particle	Indications	Surface indications within requirements of visual inspection may be reworked. If exceeded, discard part.
Core	Dimensional	Wear	Refer to FITS AND CLEARANCES; if limits are exceeded replace core assemblies. NOTE: New cores are not to be mixed with inservice cores.
	Test	Wear	Refer to TESTING; if deflection is not within tolerance, replace both core assemblies.
	Visual	Separation	Separations between metal plate and elastomer must not exceed 1 inch length or 1/16 inch depth. Replace if exceeded.
		Sponginess or swelling of elastomer	Replace the core assembly if any evidence of sponginess or swelling is noted. This condition is generally caused by prolonged contact of the isolator with noncompatible fluids.
		Elastomer for abrasion, cuts, tears or gouges.	Minor abrasion is acceptable. Replace core if there is major abrasion or any evidence of cuts, tears or gouges.
Stud			Replace at each overhaul
Gasket			Replace at each overhaul

INSPECTION REQUIREMENTS
FIGURE 301 (SHEET 2 OF 2)

REPAIR

1. GENERAL

A. Replace all worn or damaged parts which cannot be reworked to meet inspection requirements. Only spare parts of the latest configuration are available. These parts upgrade the assembly and are compatible with all previous components. Isolator assemblies and some components may be returned to Barry Controls for overhaul.

B. Identification may become obliterated during rework; if needed, identify or tag items prior to rework.

C. All magnetic particle inspection is in accordance with Military Specification MIL-I-6868 or equivalent.

CAUTION: ALL REWORK TO DAMAGED AREAS MUST BE ACCOMPLISHED WITH HAND TOOLS. GRINDING OR MACHINING IS PROHIBITED EXCEPT WHEN SPECIFICALLY CALLED OUT IN THE PROCEDURE.

ITEM	PART NUMBER	MANUFACTURER/SPEC.
Bronze Wool Pads	Fine	Brillo Manufacturing Co. Brooklyn, New York
File	Fine	Optional
Sandpaper	Fine	Optional
Whetstone (not Oilstone) or Carborundum		Optional

NOTE: Equivalent substitutes may be used for above listed items.

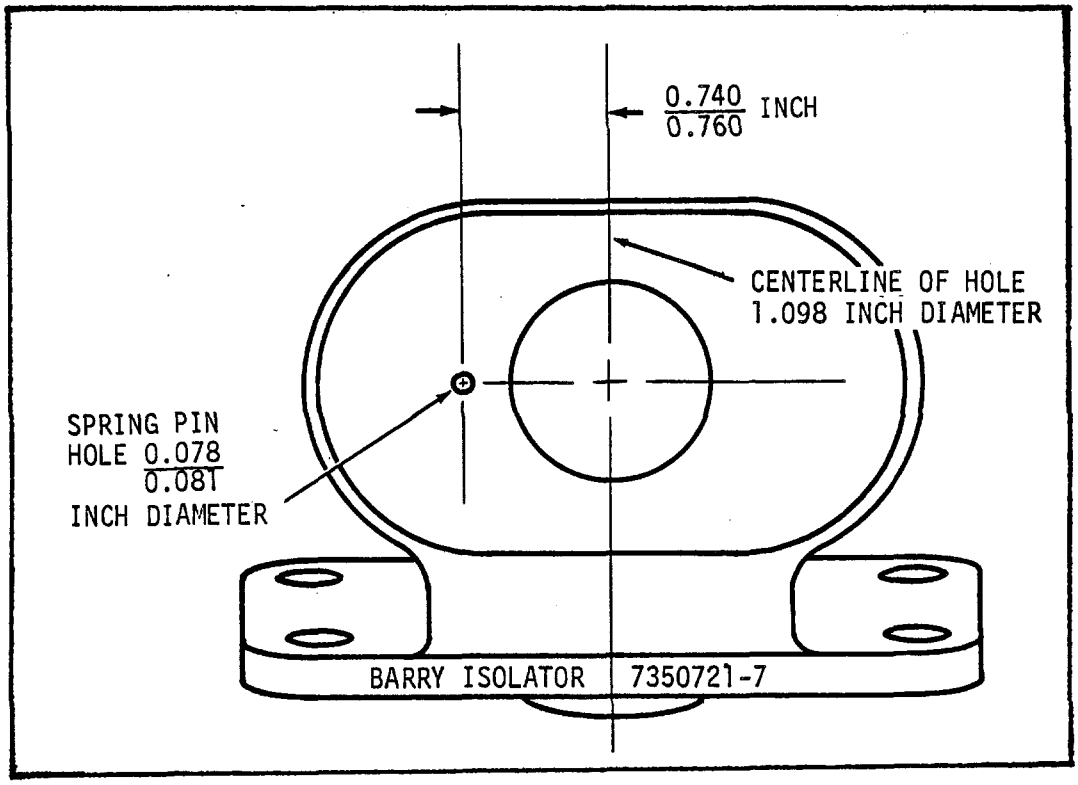
REPAIR MATERIALS
FIGURE 401

2. HOUSING

A. Remove cracks, nicks and burrs using a file, whetstone, fine sandpaper or crocus cloth, maintaining a 125 RMS finish. Reworked areas must not exceed 0.020 inch depth or 15% of any surface or perimeter.

B. There are two types of housings, one with a spring pin inserted through the body and the latest production type with the pin cast on the housing. Part number 7351256-2 is used for both types. Should the cast pin become worn beyond tolerances shown in FITS AND CLEARANCES the housing can be reworked as follows:

(1) Grind or machine remnants of cast pin flush to both surfaces of housing.



(2) Machine a spring pin hole as shown in Figure 402. Break sharp edges .010 inch.

C. Clean as specified in CLEANING.

D. Magnetic particle inspect.

E. Passivate in accordance with Federal Specification QQ-P-35, or equivalent.

NOTE: Passivate all housings whether or not repairs are made to the housing.

HOUSING REWORK
FIGURE 402

ASSEMBLY

1. GENERAL

   A. The engine vibration isolator assembly instructions are for the latest configuration. It is suggested that all isolators be modified to these configurations. However, older components can be used if they conform to the inspection and tolerance requirements. Therefore, it is possible that some instructions will not apply. Item numbers in these instructions refer to the exploded view illustrations of Figure 1 of the Illustrated Parts List.

   B. Read all notes and cautions to help simplify assembly and prevent equipment damage or personal injury.

2. SPECIAL TOOLS REQUIRED

   A. None required.

3. ASSEMBLY PROCEDURE

   NOTE: Install only mated pairs of cores. Reference TESTING in this manual. Any pair of new cores is considered mated without testing.

   A. Press the spring pin (7) into the housing (4) for all housings without the cast pin on housing. See Figure 501.

   B. Insert small end of stud (3) into core (8) as shown in Figure 501.

      (1) Flare the stud in the countersink of core (8) with 100° flare tool. See Figure 501.

   NOTE: FLARE STUD ONLY ENOUGH TO HOLD CORE SO IT WILL NOT COME OFF THE STUD. TOO MUCH FLARE COULD CRACK THE STUD. THE DEEP COUNTERSINK IN THE CORE IS TO ENSURE THE FLARED END OF THE STUD IS BELOW THE SURFACE OF THE CORE.

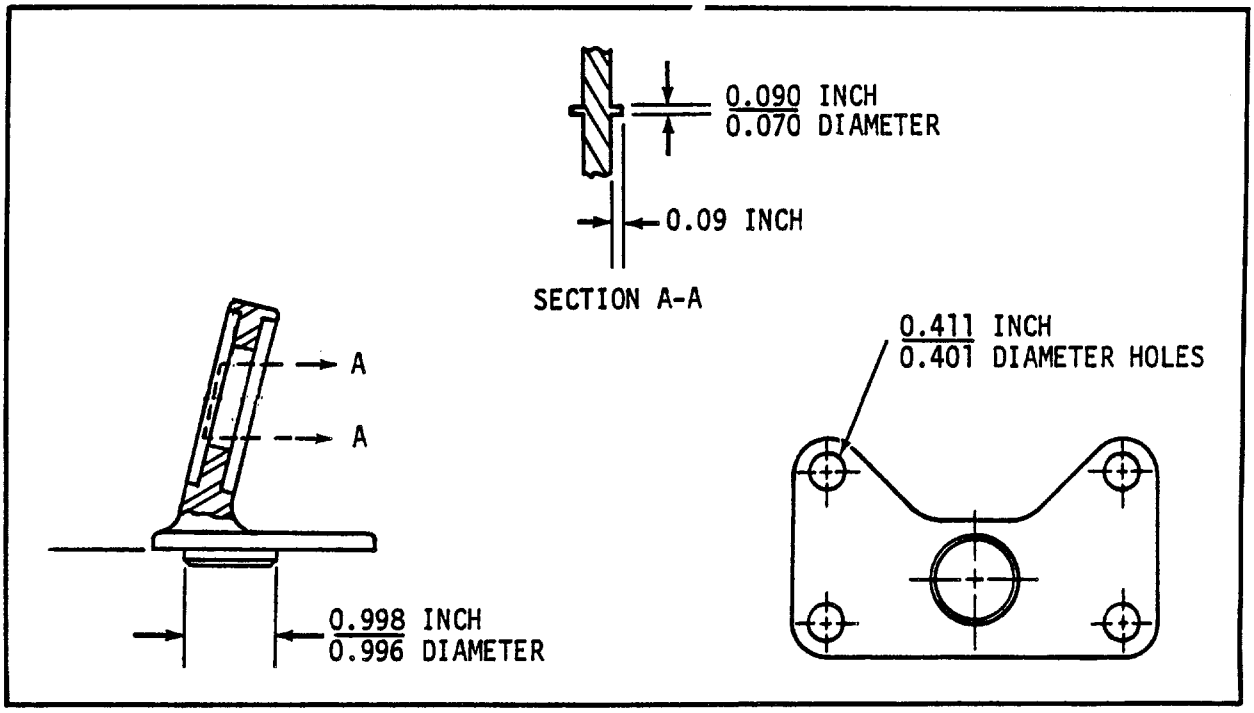
   C. Install bumper tube (6) over stud and place subassembly on housing (4) as shown in Figure 501, aligning the pin on the housing with the hole in the core.

ASSEMBLY
FIGURE 501

NOTE: The spring pin used on housing P/N 7351256-2 (Ref: 4, IPL Fig. 1) and the cast pin used on the current production housing assure correct sub-assembly orientation and do not carry load. The blind hole in the current production core assemblies has been enlarged to simplify assembly. If core assemblies with a smaller diameter blind hole are to be installed on the cast pin housing, enlarge blind hole with a 5/32 inch drill to facilitate installation.

D. Press fit the core (2) onto stud (3).

E. To keep the press fit core (2) on the stud (3) for handling and storage purposes, place a plastic bonding tie strap or equivalent through the stud hole and secure it around the two cores. In some instances the press fit is not sufficient to hold the isolator together. This happens occasionally and is considered normal. The isolator can be used as is if this occurs.



F. Install new gasket (5) on housing.

FITS AND CLEARANCES

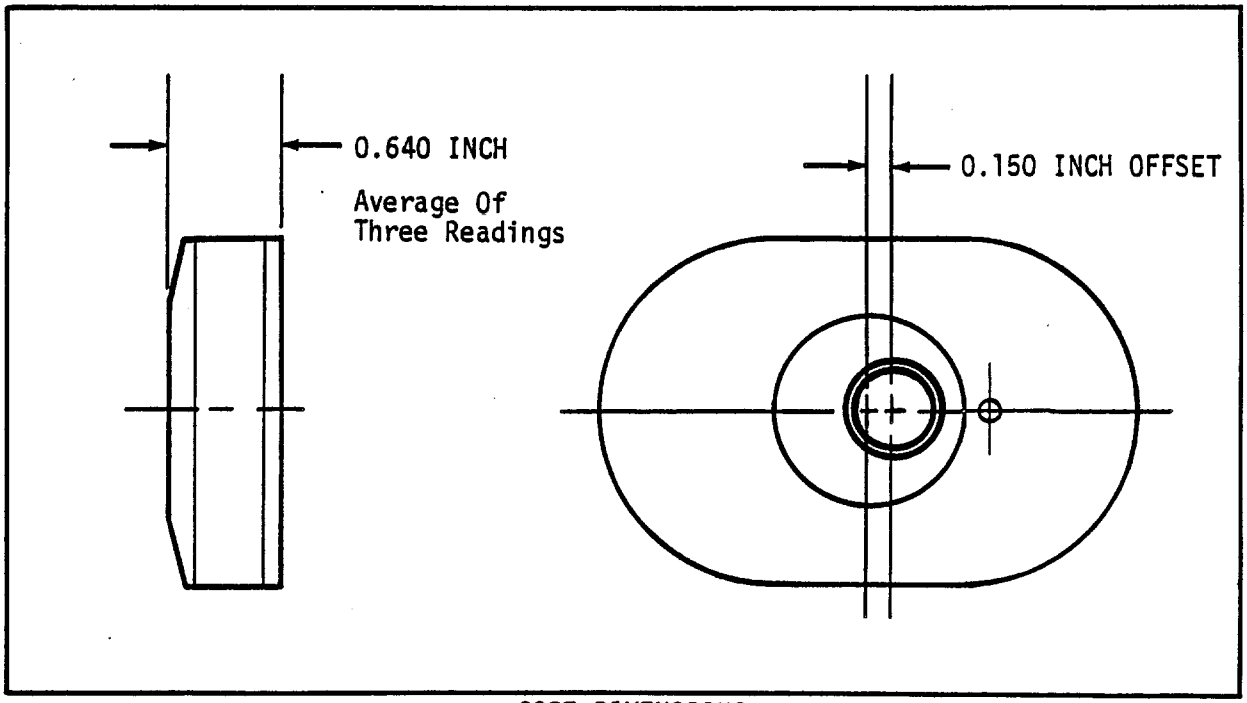


Figure 601 contains the fits and clearances for the 7350721-7 and 7350721-8 Engine Vibration Isolators.

NOMENCLATURE, ITEM NUMBER AND FIGURE NUMBER	DESIGN MANUFACTURING LIMITS (INCHES) DIMENSION		SERVICE WEAR LIMITS (INCHES) DIMENSION

FIGURE 604

TESTING

1. GENERAL

The following test procedure is for used core assemblies to establish serviceable cores when rebuilding isolators(REF: IPL 2, 8, Fig. 1).

NOTE: Core assemblies removed from an isolator are to be retained as a matched pair, tested and, if qualified reinstalled as a matched pair. It is recommended if one of the pair fails inspection or test, both cores be replaced.

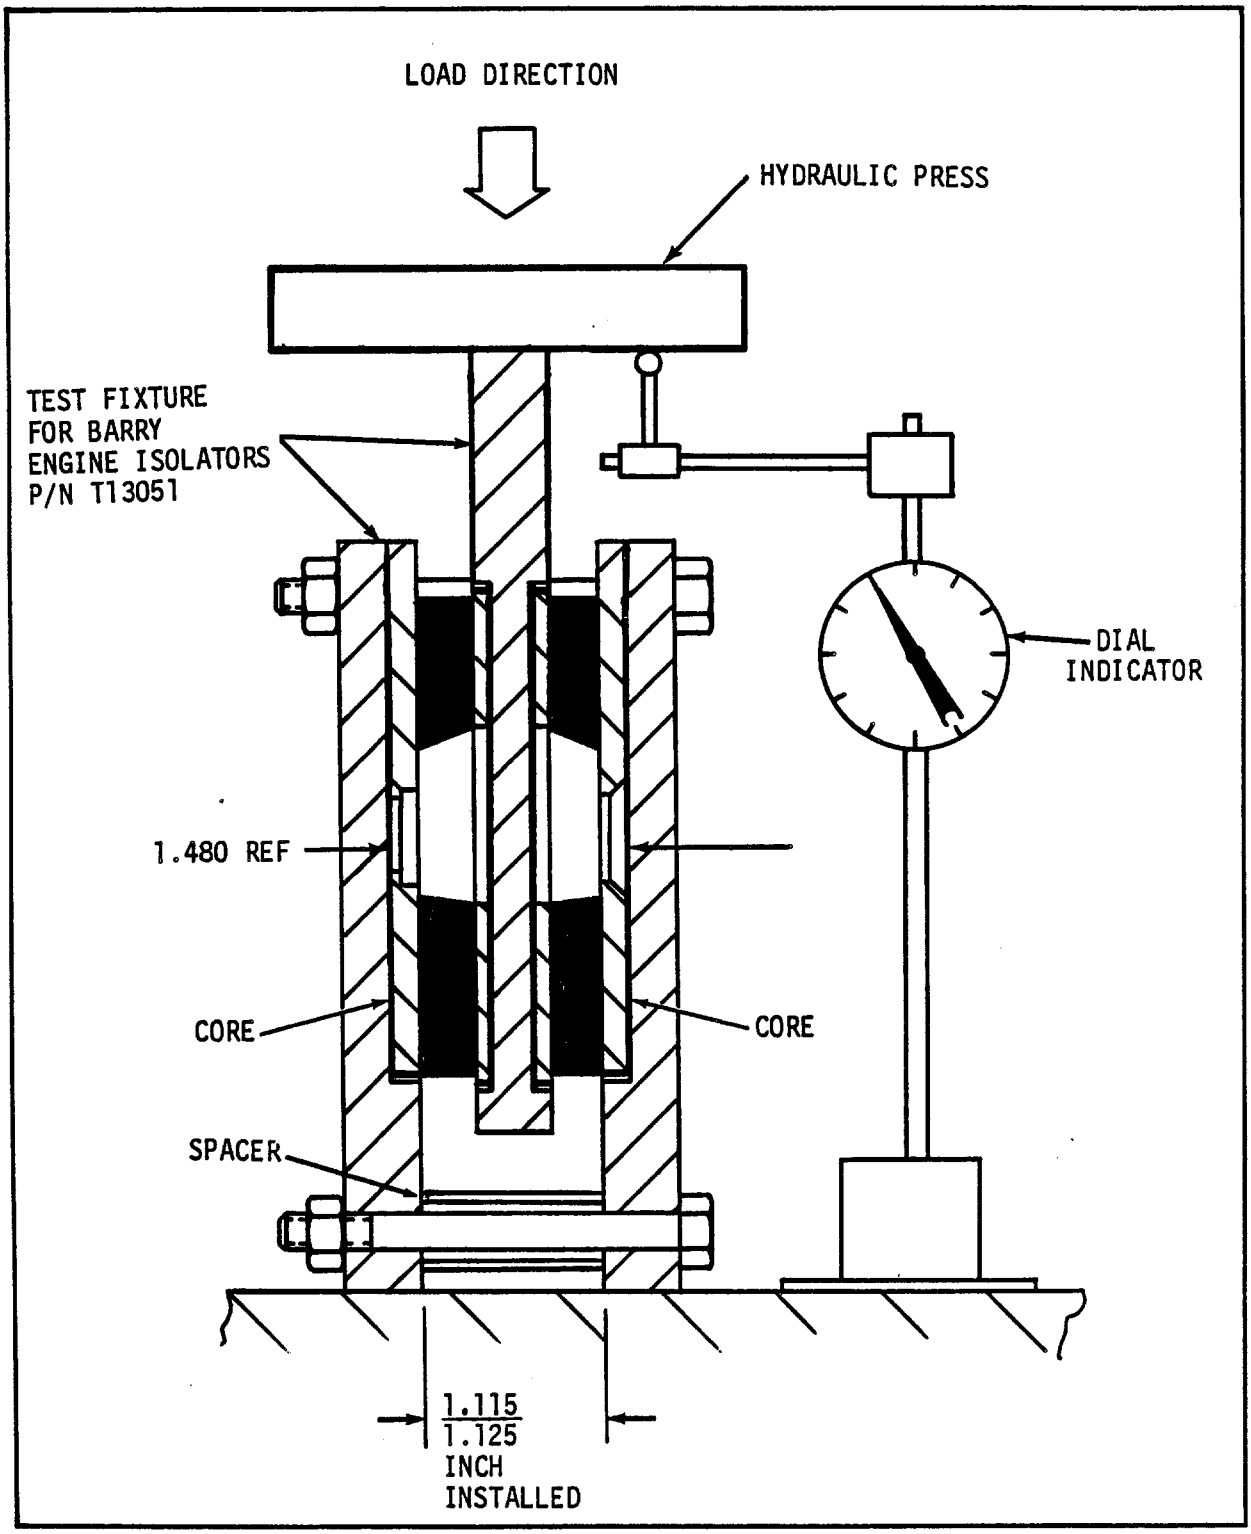
2. TEST PROCEDURE

A. Test procedure for a matched pair of core assemblies consisting of P/N 7351257-7 and P/N 7351257-9, one each.

1) Install a pair of core assemblies in Test fixture T13051 as shown in Figure 701. Tighten the three 1/4 inch bolts which hold the fixture together so that the spacer tubes are clamped between the two outer plates of the fixture. This controls the 1.115/1.125 inch dimension and assures that the cores are properly pre-compressed for Test.

B. Flex core assemblies to 600 pounds, three times.

C. Apply 200 pound preload. Set dial indicator to zero while maintaining preload.



D. Increase load to 600 pounds. Hold cores in this position for one minute. Note that the load will slowly drop below 600 pounds.

E. Return load to 600 pounds. Read deflection on dial indicator.

1) Deflection between 200 pound and 600 pound load should be 0.108-0.140 inches one minute after loading. If deflection is outside of tolerance, replace core assemblies.

F. Visually inspect the core assemblies while the 600 pound load is applied. Reject core if any separations in elastomer or at elastomer to metal bond exceed 1.0 inch length or 1/16 inch depth.

G. Tag or bag core assemblies as a matched pair.

CORE ASSEMBLY TEST
FIGURE 701

3. TEST PROCEDURE

A. Test procedure for a matched pair of core assemblies consisting of P/N 7351257-10 and P/N 7351257-11, one each.

1) Install a pair of core assemblies in Test fixture T13051 as shown in Figure 701. Tighten the three 1/4 inch bolts which hold the fixture together so that the spacer tubes are clamped between the two outer plates of the fixture. This controls the 1.115/1.125 inch dimension and assures that the cores are properly pre-compressed for Test.

B. Flex core assemblies to 400 pounds, three times.

C. Apply 40 pound preload. Set dial indicator to zero while maintaining preload.

D. Increase load to 400 pounds. Hold cores in this position for one minute. Note that load will slowly drop below 400 pounds.

E. Return load to 400 pounds. Read deflection on dial indicator.

1) Deflection between 40 pound and 400 pound load should be 0.138-0.168 inches one minute after loading. If deflection is outside of tolerance, replace core assemblies.

F. Visually inspect the core assemblies while the 400 pound load is applied. Reject core if any separations in elastomer or at elastomer to metal bond exceed 1.0 inch length or 1/16 inch depth.

G. Tag or bag core assemblies as a matched pair.

STORAGE INSTRUCTIONS

1. Storage is estimated at five years under ideal conditions. Ideal conditions are defined as follows:

   A. Individually wrap isolators in a flexible, waterproof, grease proof barrier material MIL-B-121 or equivalent commercially available material or paper.

   NOTE: Plastic bags should not be used for long term storage to avoid the possibility of moisture condensation.

   B. No contact with petroleum-based fluids or solvents.

   C. No exposure to direct sunlight.

   D. No exposure to extremes in temperature or humidity.

2. Storage is estimated at four years under normal conditions.

SPECIAL TOOLS, FIXTURES AND EQUIPMENT

1. Only one special fixture is required for overhaul of the 7350721-7 and 7350721-8 engine vibration isolator. This fixture is required to test used cores as described in the TESTING section of this manual.

ILLUSTRATED PARTS LIST

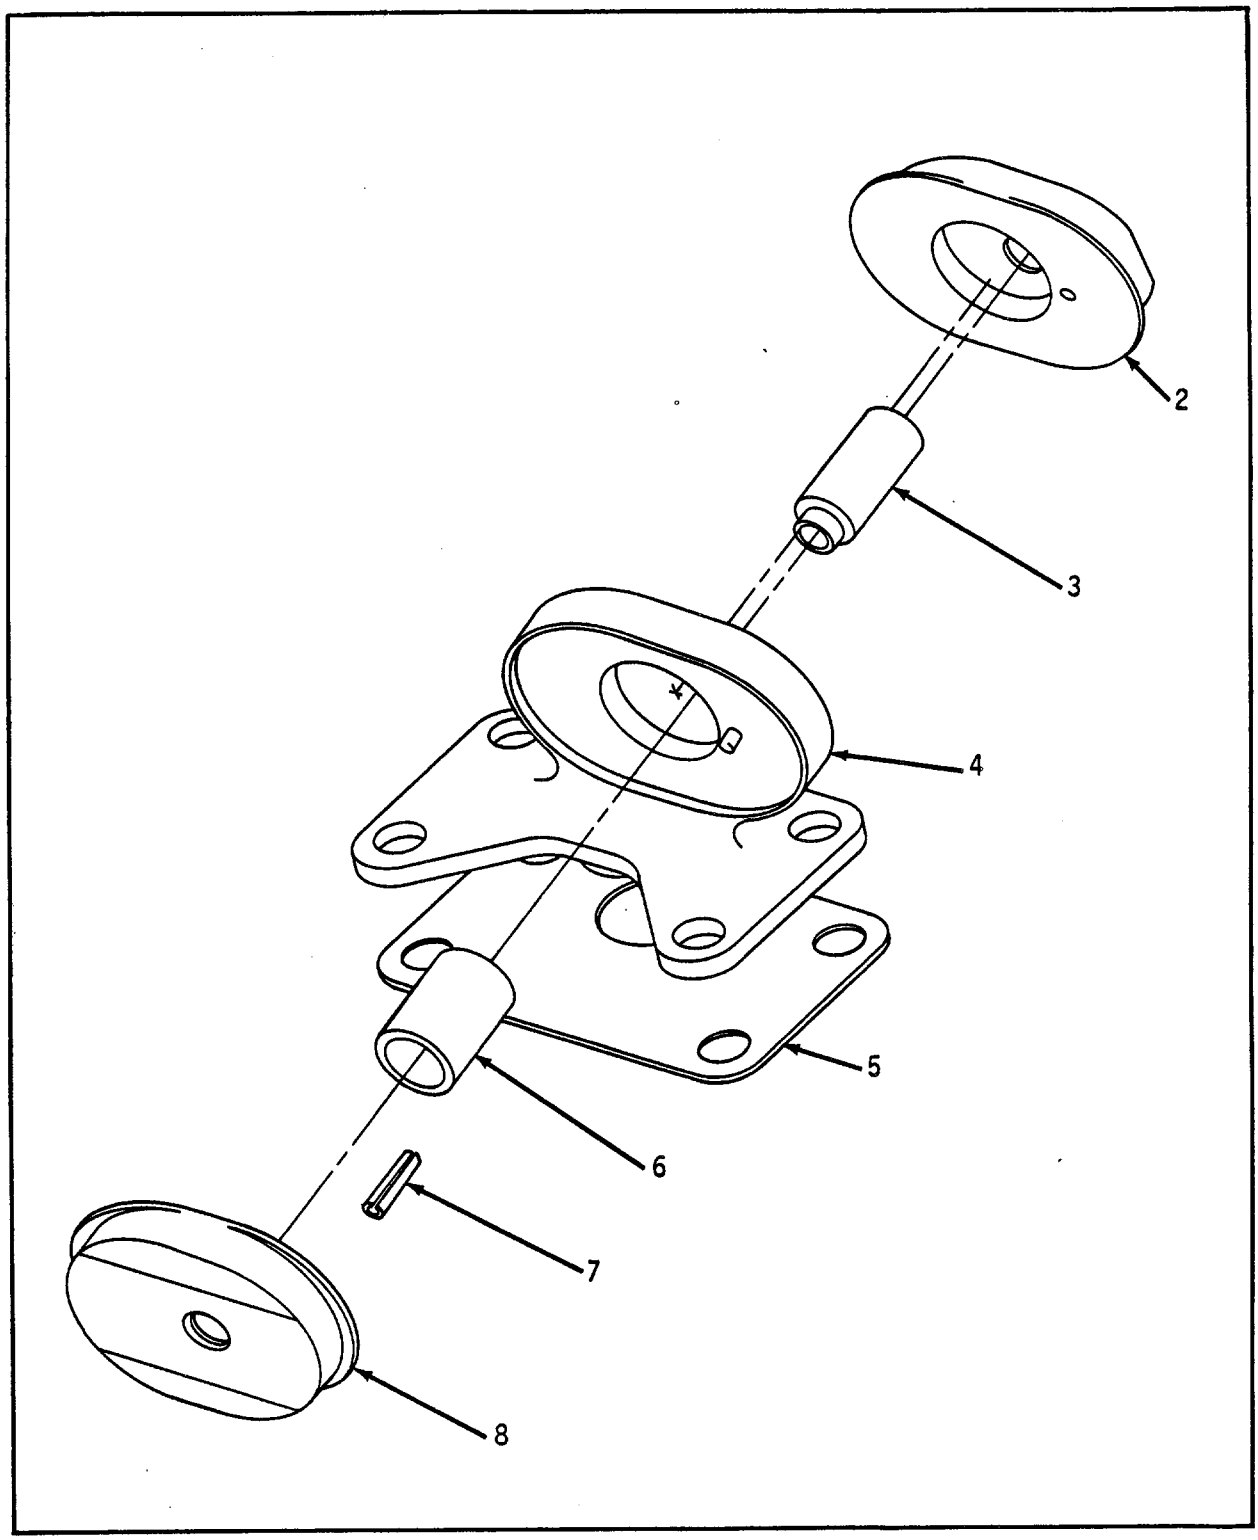
1. GENERAL

The illustrated parts list consists of an itemized parts breakdown which is illustrated as necessary to identify the parts.

2. FIGURE ITEM COLUMN

The number listed under "Figure" is the figure number of the exploded view that illustrates the listed parts. The numbers listed under "Item" identify the parts in the illustration. Where a part is not illustrated, the item number of that part will be preceded with a dash (-). Item numbers with alpha varients show modification or configuration differences from the basic item number.

3. NOMENCLATURE COLUMN



The nomenclature used for each part is the same as that given for the title of the manufacturer's drawing with any necessary qualifying description. Nomenclatures listed are intended to show the relationship of a part with its assembly.

4. EFFECT CODE COLUMN

When two or more main assembly variations are listed, a different "usable on" code letter is assigned to each main assembly and is listed in the Effect Code Column. All components peculiar to an assembly are identified by the same code letter as the appropriate main assembly. Components with different code letters are not interchangeable between main assemblies unless designated interchangeable in the Nomenclature column. The column is left blank opposite a part that is common to all main assemblies.

5. UNITS PER ASSEMBLY COLUMN

The quantities listed in this column are the number of units required per assembly. For bulk items, the letters "AR" are entered to indicate "as required". The letters "RF" are entered to indicate that item is listed only for reference purposes.

WRIGHT COMPONENTS INC.

OVERHAUL INSTRUCTIONS

VALVE NO. 15328

1. DESCRIPTION AND DATA

A DESCRIPTION

(Refer to Fig. 1)

The valve covered by these overhaul instructions is a solenoid operated three way valve with a supply port on the lower end of the valve body, a control port on one side of the valve, and an exhaust port to atmosphere. The solenoid coil assembly is attached to the headplate of the valve. With the coil assembly de-energized, the supply port is closed by the action of a spring and plunger assembly holding the ball on to its valve seat. When the coil assembly is energized, the plunger assembly is withdrawn clear of the ball, supply pressure seats the ball on to its valve seat closing the exhaust port to atmosphere, and allowing supply pressure to pass through the control port.

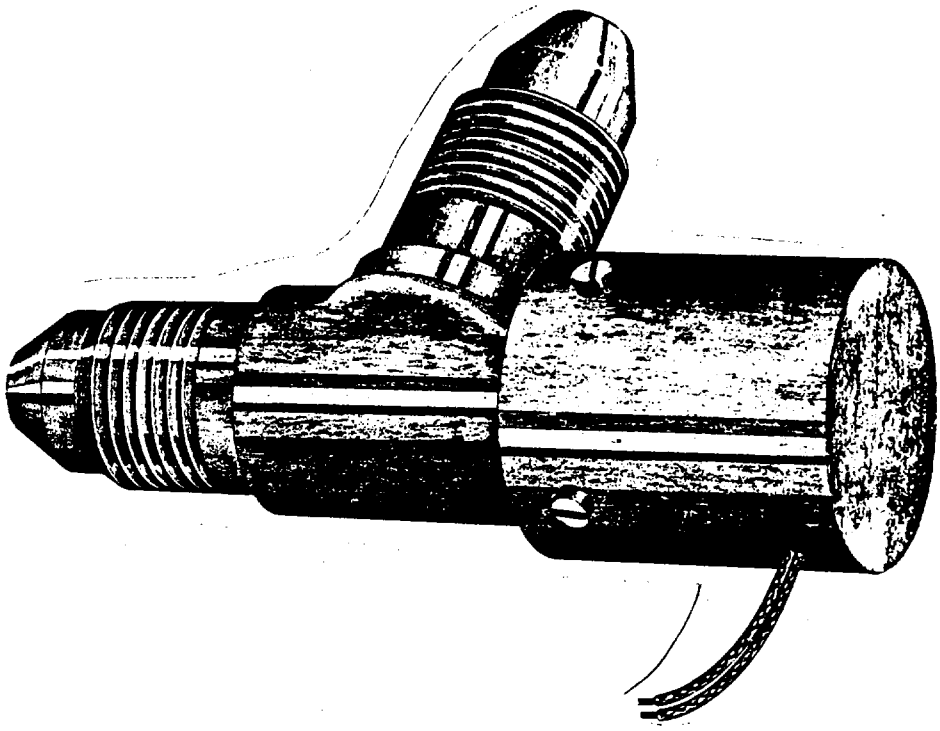

FIGURE 1 SHUTOFF VALVE No. 15328

B DATA

Type - Solenoid operated valve

Fluid Media - Air

Operating Pressure - 35/70 PSI

Proof Pressure - 140 PSI

Burst Pressure - 210 PSI

Temperature - +400 to 450°F

Voltage - 18 - 28V DC.

Current - 1.5 amp max at 30V DC and 76°F.

Duty - 7 seconds on, 1 hour off.

2. DISASSEMBLY

A PROCEDURE

(Refer to Fig. 2)

(1) Remove four screws (1) and slide coil assembly (2) from headplate (7).

(2) Remove shim (3), spring (4) and plunger assembly (5) from headplate (7).

(3) Remove four screws (6) and lift out headplate (7) from valve body.

(4) Carefully remove O-ring (8) valve seat (9), ball (10) spacer (11) valve seat (12), O-ring (13) and spacer (14) from valve body (15).

3. CLEANING

A Clean all metal parts (except coil assembly) in trichlorethylene or similar cleaning solution, and dry with compressed air.

4. INSPECTION

A PROCEDURE

(1) Inspect plunger assembly, valve seats and ball for damage such as visible score marks or pitting. Replace defective parts.

(2) Inspect coil assembly for obvious damage. Measure resistance of coil Allowable limits 38 - 42 ohms at 76°F.

(3) Check spring value rated at 6.7 lb/inches (0.36 lb at .25 ± .005 inch).

5. REPAIR

A Repair is limited to replacement of defective parts.

6. ASSEMBLY

A PROCEDURE

(Refer to Fig. 2)

(1) Install spacer (14) to valve body (chamferred inside diameter must face supply port). Assemble new O-ring (13) to valve seat (12) and carefully insert into valve body ensuring that seat faces top.

(2) Install spacer (11) and ball (10) on valve seat.

(3) Assemble new O-ring (8) to valve seat (9) and carefully insert into valve body ensuring that seat faces down.

(4) Install headplate (7) and secure to valve body with four screws (6).

(5) Install plunger assembly (5), spring (4) and shim (3) to headplate.

NOTE: If plunger assembly (5) was replaced, stone or trim the end of push-rod to .297/.296 inches.

(6) Slide coil assembly (2) on headplate and valve body, and secure to headplate with four screws (1).

7. TESTING

A PROCEDURE

(Refer to Fig. 2)

(1) Connect coil wires to electrical power source 18 - 28 volts DC.

(2) Connect supply port to a gauged clean air supply.

(3) Connect 0 - 200 PSI gauge to control port.

(4) Apply air pressure at 35 - 70 PSI to supply port. Energise coil assembly.

Check that gauge reading at control port is within 5 PSI of pressure applied at supply port, and that gauge shows balanced pressure within 1 - 3 seconds. A valve that is sluggish should be rejected.

(5) De-energize coil assembly. Increase pressure at supply port to 140 PSI and ensure that valve remains closed at applied pressure. Allowable leakage is .001 lbs/min at control port and .10 lbs/min at exhaust port.

8. TROUBLE SHOOTING

A No special trouble shooting instructions are required.

9. STORAGE INSTRUCTION

A Cap supply port and control port. Tape exhaust port on valve body. Tape assembly coil wires.

10. ILLUSTRATED PARTS LIST

FUEL FLOW INDICATOR

PART NUMBER 25514-B25A-3-A3

DESCRIPTION AND OPERATION

The fuel flow indicator 25514-B25A-3-A3 is a precision instrument designed to provide readings of rate of fuel flow in terms of pounds per hour. The indicator operates from electrical signals generated by a mating synchro type transmitter which monitors the actual flow of the fuel.

Simplified construction contributes to the accuracy and reliability of the indicator. The dial is attached to a mounting plate that, in turn, is directly secured on the front end of the Autosyn synchro assembly powering the unit. The shaft of the synchro extends through the dial; the pointer is affixed directly on the shaft. The pointer, mounted on the synchro shaft, constitutes sole moving component of indicator.

TABLE I

LEADING PARTICULARS

Operating Voltage	26 volts
Rated Frequency	400 cps
	single-phase
Range	60 to 500 pph
Dial Spread	240 degrees
Temperature Range	-65 to +159.8°F
	(-54 to +71°C)

DISASSEMBLY

(Refer to figure 1.)

A. Remove protective cap (1).

B. Identification plate (2) is cemented to end cover (7). Do not remove identification plate unless it is defective. To remove a defective identification plate, loosen edge with knife; then peel plate free.

C. Attach a mating connector (DM9700-7S of Deutsch Co., Electronics Components Division, Banning, Calif., Federal Supply Code No. 11139 or equivalent) to the receptacle (6) of the indicator. Place indicator on a hot plate or in an induction coil to heat the soldered bond joining outer edge of end cover (7) to inner circumference at rear end of case and glass assembly (9). When the solder has melted sufficiently that the plating will not be peeled from plated surfaces of end cover or case (12), use the mating connector to pull the end cover assembly free. Do not use excessive heat or force which could result in separating receptacle from end cover which is unnecessary unless one of these components is defective. Remove all excess solder from inside of case.

D. Withdraw mechanism straight out from case and glass assembly (9) and remove the spacer (13).

E. Unsolder and remove eyelet (3), but do not disassemble the end cover assembly (5) or the case and glass assembly (9) unless necessary to replace a defective part.

F. Unsolder leads from terminal pins of receptacle (6), remove all excess solder.

G. Remove the pointer assembly (14) by pulling it straight away from dial (16) with fingers or use a suitable tool. Do not pry pointer sideways: this might result in damage to the pointer, dial, or shaft.

H. Remove screws (17) and detach dial plate (18) from synchro assembly (19).

CLEANING

A. Clean all metal parts, except as noted in the following procedures, in solvent. Dry thoroughly. Keep parts free from dust particles.

WARNING

Use solvent in a well ventilated area. Do not inhale vapors or allow solvent to come in contact with the skin. Keep solvent away from open flame.

CAUTION

Do not immerse the synchro assembly (19) in solvent or allow solvent to enter interior portions of synchro assembly.

B. Be certain no deposits of grease or other foreign matter remain on terminal pins or insulation of receptacle (6).

C. Wash cover glass (11) and dial (16) in pure soap and water taking care to avoid damage to dial markings. Dry parts thoroughly. Polish cover glass with a soft lint free cloth. Keep parts free from finger marks.

D. Clean pointer assembly (14) with art gum or other similar soft eraser.

E. Clean exterior surfaces as well as the leads of synchro assembly (19) with solvent. Wipe away all film residue which remains as solvent dries.

INSPECTION

A. Inspect all parts for cracks, breaks, wear and any other obvious defects or damage.

B. Inspect the receptacle (6) for bent, broken, or loosened terminal pins for cracked or loosened insulation and for bent or damaged shell.

C. Inspect end cover (7) for damaged edges.

D. Inspect cover glass (11) for chips, cracks, and discoloration.

E. Inspect case (12) for distortion and for damaged ends.

F. Examine spacer (13), pointer assembly (14), and dial (16) for pin holes, scratches, or other damage to paint. Be sure parts are free from stains and discoloration.

G. Inspect leads of synchro assembly (19) especially at points of entry into synchro housing for crimps, breaks, and damaged insulation.

H. Dielectric Test of Synchro Assembly (19). Test dielectric strength of synchro assembly as follows. Using insulation breakdown test set 13700-1-C, apply a potential of 500 volts (rms) at a commercial frequency for a minimum period of five seconds across a stator lead and ground (housing) and then across a rotor lead and ground (shaft). There shall be no electrical breakdown of insulation. Failure of test requires replacement of the synchro assembly.

I. Leak Test of Case and Glass (9) and End Cover (5) Assemblies. Use components of hermetic sealing stand 13693-1-B to seal off rear end of assembly. Evacuate interior of the assembly to 50 microns or less absolute pressure. Use the helium leak detector, Model 24-120A, to measure rate of helium leakage through the assembly. The leak rate shall not exceed 1.0 micron-cubic-foot per hour. If leak rate is excessive, repair as required by reworking the faulty soldered joint or by replacing the defective component.

REPAIR AND REPLACEMENT

A. No repair of components is recommended. Replace any part disclosed by inspection or testing to be defective.

B. Replace identification plate if removed.

ASSEMBLY

A. If case assembly (9) was disassembled, proceed as follows. While inserting cover glass (11) and case (12) into front ring (10) insert a ring of solder under cover glass along edge joining front ring and case; use solder conforming to Specification QQ-S-571, Comp SN63, Form W, 0.06 dia. and an activated resin flux such as part number 1544 of the Kester Solder Company, 4201 Wrightwood Avenue, Chicago, Ill. 60639, Federal Supply Code No. 75297 or equivalent. Place parts in an induction coil or on a hot plate and heat to effect a proper soldered bond. Add additional solder if required, but do not permit excess solder to remain on rear surface of front ring or on outer circumference of the case. Allow the assembly to cool undisturbed. Perform leak test outlined in step I of Section 31-00-4, Inspection to determine if proper sealing has been achieved.

B. If the end cover assembly (5) was disassembled, proceed as follows. Place the end cover (7) on a flat surface, rear side (as shown in exploded view) up. Center evacuation hole in twelve o'clock or zero degree position. Insert receptacle (6) into end cover with polarizing key at 62 ± 3 degree position. Maintain these relative positions and use an induction coil, hot plate, or torch to solder parts together. Use solder conforming to Specification QQ-S-571, comp Sn50, Form W, 0.06 dia. and the flux specified in step A. Allow assembly to cool undisturbed. Perform leak test outlined in step I of Section 31-00-4, Inspection, to assure that proper sealing has been achieved.

C. Secure dial plate (18) on synchro assembly (19). Make certain pilot on synchro housing is seated squarely in recess in dial plate; secure with screws (17).

D. Secure dial (16) on dial plate (18) with dial screws (15).

E. Assemble a piece of tubing (4) over each synchro assembly lead. Pass leads back through compression ring (8) and solder leads to terminal pins of receptacle (6) in compliance with Table II, Wiring Data. Make certain there is no excess solder on connections and that there are no cold solder joints. Thoroughly clean away all flux. Fit tubing down over receptacle pins.

F. Calibrate unit as follows. Connect the mechanism assembly to the synchro servoed test transmitter 13695-2-A and impose electrical zero. Tap the synchro assembly lightly to overcome the effects of friction so rotor will assume the true EZ position. With the rotor held in this position, press on the pointer assembly (14) with tip centered on EZ reference mark. (Refer to Table III, Calibration Data.)

G. Perform the following tests outlined in Section 31-00-7, Testing.

Step	Test
B (2)	Electrical Zero Test
B (3)	Scale Error and Friction Error Test
B (4)	Position Error Test

In the event of failure of any of these tests, check for probable cause and correct as required in accordance with following tabulation.

Test Failed	Probable Cause	Corrective Procedure
Electrical Zero	Improper placement of pointer on shaft.	Refer to Step D
	Faulty synchro.	Replace synchro.
Scale Error	Pointer not tight on shaft.	Affix pointer on shaft.
	Improper E-Z adjustment.	Refer to Step D.
	Dial not in proper position.	Reposition dial as required.
	Faulty synchro	Replace synchro.
Friction Error	Pointer drag against dial or glass.	Reposition pointer on shaft.
	Excessive end play or other fault in synchro.	Replace synchro.

H. Final Assembly. When each test of step G has been concluded with the mechanism within tolerance, proceed as follows. Use a vacuum hose as necessary to remove any lint and dust from the mechanism and from inside of the case and glass assembly (9). Perform a final inspection to insure that there are no finger marks or other imperfections on inside of cover glass (11). Make certain there are no imperfections in the paint on spacer (13), pointer assembly (14), dial screws (15), or dial (16). Insert spacer and mechanism into the case assembly. Insert end cover assembly (5) against the compression ring (8) in such position that polarizing key of receptacle is within 5 degrees of vertical centerline of the dial. Maintain this relative position and apply an axial force of from 8 to 12 pounds to end cover to press it into proper position.

Maintain this force and solder outer edge of end cover to inner circumference of case all around using solder conforming to Specification QQ-S-571, Comp Sn63, Form W, 0.06 dia. and the flux specified in step A.

I. Perform sealing test outlined in step B (5) of Section 31-00-7, Testing, to assure that a proper hermetic seal has been achieved. Connect instrument to the vacuum pump, Hyper-Vac Model 25A, and evacuate the unit to a pressure of 500 or less microns. With vacuum maintained, bake unit at 160°F for two hours. Then backfill the unit to a pressure of approximately one atmosphere with dry helium. Helium used for backfill shall be at least 98 percent pure, dust free, and shall contain not more than 0.006 milligrams of water vapor per liter (dew point -65°C) at the filling pressure. Seal unit by soldering in eyelet (3) using solder conforming to Specification QQ-S-571, Comp Sn63, Form W, 0.03 dia. and flux specified in step A.

J. Touch up any unpainted portions of case (12) using black epoxy paint such as that manufactured by the Desoto Chemical Coatings Co., Inc., 8600 River Road, Pennsauken, J.J. 08110 (Federal Supply Code 70947).

TESTING

A. Test Conditions. Unless otherwise specified, perform the tests outlined in step B under the following conditions.

(1) Standard atmospheric conditions. Perform tests at atmospheric pressure, approximately 29.92 inches Hg. and at room temperature, approximately 77°F or 25°C.

(2) Attitude. Test indicator in the normal upright operating position with the plane of the dial vertical.

(3) Power Supply. Perform tests using 26 ± 1 volt, single phase, 400 ± 5 cps ac power.

(4) Electrical Zero. If the synchro servoed test transmitter 13695-2-A is not available, determine electrical zero in accordance with the procedures of Specification MIL-I-7057, paragraph 4.5.3.

(5) Vibration. Prior to taking a test reading, vibrate the indicator lightly by hand.

B. Tests. Perform the following tests.

(1) Dielectric Strength. Use the insulation breakdown test set 13700-1-C, to apply a potential of 200 volts (rms) at a commercial frequency for a minimum period of five seconds between any pin of receptacle (6) and ground (indicator case (12)). There shall be no breakdown of insulation. In the event of failure, make certain there are no trailing wire ends or deposits of foreign matter causing shorting at the receptacle. Replace a defective synchro assembly (19) if that is the cause of failure.

(2) Electric Zero. Connect the indicator to the synchro servoed test transmitter 13695-2-A and impose electrical zero. The tip of pointer assembly (14) shall be within 0.010 inch of the electrical zero reference mark on the dial (16). (Refer to Table III, Calibration Data.) If the synchro servoed test transmitter 13695-2-A is not available, refer to paragraph (4) of step A for method of determining electrical zero. In event of failure of test, refer to step G of Section 31-00-6, Reassembly.

(3) Scale Error and Friction Error. Connect indicator to synchro servoed test transmitter 13695-2-A. Adjust test transmitter to bring its pointer assembly (14) successively to each test point specified in Table III, Calibration Data. At each test point, take two readings: the first before and the second after the indicator is lightly tapped. The difference between the two readings represents friction error which shall not exceed the friction error tolerance specified in Table III. The second

reading shall not differ from the specified test point reading by an amount greater than the scale error tolerance of Table III. In event of failure of either test, refer to step G of Section 31-00-6, Reassembly. The following position error test can be performed concurrently with this test.

(4) Position Error Test. With the indicator connected to the synchro servoed test transmitter 13695-2-A. Adjust the test transmitter to center the pointer assembly (14) on the electrical zero reference mark. Now, hold the indicator in any position. The change in indication caused by changing the position of the indicator, shall not exceed the position error tolerance as specified in Table III, Calibration Data. In the event of failure of test, refer to step G of Section 31-00-6, Reassembly.

(5) Sealing Test. Use the helium leak detector, Model 24-120A, to measure the rate of helium leakage from the indicator case. At a pressure differential of one atmosphere, leak rate shall not exceed 1.0 micron-cubic-foot per hour. If leak rate is excessive, correct by either replacing the defective component or reworking the faulty soldered joint.

TABLE III

CALIBRATION DATA

SYNCHRO SERVOED TEST TRANSMITTER SETTING (DEGREES)	DESIRED INDICATOR READING (PPH)	SCALE ERROR TOLERANCE (DEGREES)
61.2	60	1.6
75.9	100	1.6
125.6	200	1.6

INTRODUCTION

1. General. This manual contains descriptive data, overhaul instructions, test procedures and illustrated parts breakdown for the Fuel Flow Transmitter, Bendix Type 9133-54-B1. See Figure 1. This equipment is manufactured by the Instruments and Life Support Division of The Bendix Corporation, Davenport, Iowa.

2. Additional Models. Models very similar, or identical except for minor modifications, will be included in Difference Data Sheets. Overhaul procedures for these additional models are the same as those recommended in this basic manual except for the specific differences noted by the applicable Difference Data Sheets. Difference Data Sheets will be issued as available and should be attached to and filed with this basic manual.

INTRODUCTION

1. General. This manual contains descriptive data, overhaul instructions, test procedures and illustrated parts breakdown for the Fuel Flow Transmitter, Bendix Type 9133-54-B1. See Figure 1. This equipment is manufactured by the Instruments and Life Support Division of The Bendix Corporation, Davenport, Iowa.

2. Additional Models. Models very similar, or identical except for minor modifications, will be included in Difference Data Sheets. Overhaul procedures for these additional models are the same as those recommended in this basic manual except for the specific differences noted by the applicable Difference Data Sheets. Difference Data Sheets will be issued as available and should be attached to and filed with this basic manual.

DESCRIPTION AND OPERATION

1. General.

   A. This equipment is manufactured by the Instruments & Life Support Division of Bendix Aviation Corporation, Davenport, Iowa.

2. Description.

   A. The Fuel Flow Transmitter, Bendix Type 9133-54-B1, measures the rate of fuel flow and transmits an electrical signal to an indicator.

3. Operation.

   A. The Fuel Flow Transmitter is inserted in the line through which fuel flows. The fuel is routed through the chamber in the body of the transmitter and deflects a pivoted vane. This deflection increases with the rate of fuel flow. The vane deflection is transmitted through a magnetic coupling to a synchro transmitter which rotates in accordance. The degree of the synchro transmitter rotation is converted to an electrical signal which is transmitted to an indicator.

4. Leading Particulars.

   A. The leading particulars of the equipment are given in Table I.

TABLE I
TABLE OF LEADING PARTICULARS

Instrument Weight	2.0 lbs
Range-lbs/hr	50-350
Operating Temperature Range.	Satisfactory Operation Within Temp. Range of +70°C to -55°C (+158°F to -65°F)
Power Requirements	26 volts, 400 cycles ±10%, single phase
Power Rating	3.25 VA at 0.18 power factor
Working Pressure	200 psi maximum
Accuracy	Within 5 pounds per hour over entire range

DISASSEMBLY

1. Separation of Connection Housing from Mechanism. See Figure 3.

   A. Remove sealing decals (2). Remove the plugs (3) from the fuel flow ports. Remove the lockwire (10) and four screws (11) and lift off the connection housing (9). Remove the pin (13) from the housing (53). Remove the packing (12) from the connection housing.

2. Removal of the Relief Valve. See Figure 3.

   A. Remove the retaining ring (4) which holds the relief valve plug (5), spring (7) and relief valve (8). Remove the packing (6) from the relief valve plug.

3. Removal of Cover and Receptacle Assembly. See Figure 3.

   A. Remove the cap (14) from the receptacle. Remove the four screws (16) and lockwashers (17) and lift out the cover and receptacle assembly (15).

   B. Remove the packing (18) from the cover, but do not separate the cover and receptacle, which are cemented together.

   C. Do not unsolder the leads of the synchro transmitter (19) from the receptacle unless the synchro transmitter and/or cover and receptacle assembly (15) are being replaced.

4. Removal of Synchro Transmitter and Bar Magnet Assembly. See Figure 3.

   A. Remove three screws (21) which secure the clamp (20) to the housing (53). Carefully withdraw the synchro transmitter (19) with the bar magnet assembly (22) and clamp (20) affixed to it.

   B. Loosen the two setscrews (23) and ease the bar magnet assembly (22) off the synchro transmitter shaft. Remove the clamp (20) from the synchro transmitter.

      CAUTION: WHEN REMOVING THE BAR MAGNET ASSEMBLY FROM THE SYNCHRO TRANSMITTER SHAFT, PUSH SHAFT OUT OF THE BAR MAGNET TO PREVENT DAMAGE TO SYNCHRO BEARINGS DUE TO EXCESSIVE AXIAL FORCE.

      CAUTION: DO NOT DISASSEMBLE THE SYNCHRO TRANSMITTER (19). IF INDICATOR READINGS ARE UNSATISFACTORY AND THE DIFFICULTY IS TRACED TO THE SYNCHRO TRANSMITTER, REPLACE IT AS A UNIT.

5. Disassembly of the Mechanism. See Figure 3.

   A. Remove the lockwire (25) and four screws (26) and lift off the cover retainer (24). Remove the housing cover (27) from the housing (53) using Cover Puller 31TF10538. Remove the packing (28) from the housing cover.

   B. Loosen setscrew (31) and slide the spring and hub assembly (30) and spring adjusting plate assembly (32) from the vane shaft (49).

C. Remove screw (33), lockwasher (34) and washer (35) which secure the outer end of spring and hub assembly (30) to the spring adjusting plate assembly (32) and separate the two assemblies.

6. Disassembly of Vane and Drive Assembly. See Figure 3.

A. Loosen setscrew (46) and slide the ring magnet assembly (45) off the vane shaft (49).

NOTE: Do not disassemble the ring magnet assembly (45).

B. Remove three screws (38) and lift off the housing cover (37).

NOTE: The housing cover (37) is part of the matched housing assembly (36), which also includes the vane housing barrier (40) and vane housing (43). If any of these three components are being replaced, it is necessary to replace the entire matched housing assembly (36).

C. Carefully slide the vane (47) and the vane shaft (49) out of the vane housing (43). Loosen two setscrews (48) and slide the vane shaft (49) out of the vane (47).

NOTE: The vane, shaft and magnet assembly (44) is a matched assembly, consisting of the ring magnet assembly (45), vane (47) and vane shaft (49). If any of these three components are being replaced, it is necessary to replace the entire matched vane, shaft and magnet assembly (44).

D. Remove two screws (41) and remove the vane housing barrier (40) from the vane housing (43), if necessary.

E. Remove ball bearing (50) and screw (52) from the vane housing (43).

CLEANING

CAUTION: AFTER DISASSEMBLY, IT IS ESSENTIAL TO KEEP ALL PARTS ABSOLUTELY CLEAN AND FREE OF DIRT OR MOISTURE. USE PROTECTIVE COVERS.

1. General.

A. Moving parts, or parts in contact with moving action in normal operation, should be cleaned with an approved cleaning solution such as trichlorethylene, Stock No. 8500-950500, or naptha aliphatic, Federal Specification No. TT-N-95. After cleaning, dry with warm air.

B. Brush castings with cleaning solution.

C. Remove all traces of oil or grease from electrical parts with cleaning solution.

D. Clean pivot holes with orangewood stick.

E. Clean small parts sonically with Bendix SEC1420-A system or spray with cleaning solution called out in paragraph 1A and dry with warm air.

F. Clean ball bearing using Ball Bearing Cleaning Kit QB70606-3 and Bearing Cleaning Solution QB14634-1.

CAUTION: IMMEDIATELY AFTER CLEANING, OIL BEARING LIGHTLY TO PREVENT CORROSION. KEEP BEARING CLEAN.

2. Vent Holes. See Figure 3.

A. Examine the vent holes in the housing cover (37) and the vane housing (43) to be sure there is no obstruction.

INSPECTION

1. General.

A. After cleaning, inspect all parts for damage, wear, or other defects. Check components for tightness in assemblies that have not been disassembled. Inspect screws and washers for damage and wear. Check the electrical connector receptacle for broken pins, stripped or burred threads or corrosion.

B. Inspect ball bearing for flat spots, roughness and excessive wobble between inner and outer races.

REPAIR

1. Relief Valve.

A. If any part included in the assembly of the relief valve is corroded or damaged, replace it. The face of the relief valve must be smooth to prevent leakage and the spring must be in good condition providing proper tension. Check the relief valve spring for compression by applying a compression load of 4 ounces ±0.10 ounce. The length of the compressed spring must be 0.664 ±0.005 inches. If the spring does not measure within tolerance, replace it with a new spring.

2. Synchro Transmitter.

A. Before reassembly, check the resistance of the synchro transmitter as described in TESTING, Paragraph 3A.

3. Demagnetizing Magnets.

   A. Demagnetize the magnets with a suitable Demagnetizer, such as Bendix No. 13290-1-A. To demagnetize, first hold the bar magnet assembly between the two arms of the demagnetizer. Revolve the assembly in at least two planes with respect to the demagnetizing poles, and then withdraw the assembly slowly, along a straight line and at right angles to the demagnetizer field. Repeat this procedure with the ring magnet. This precaution is necessary since it is comparatively difficult to determine accurately the actual polarity of such small objects. The line of magnetism between poles must be at right angles to the demagnetizing flux to insure fullest effect.

4. Remagnetizing Bar Magnet.

   A. Remagnetize the bar magnet assembly to full strength using Magnet Charger Model 107A, manufactured by the Radio Frequency Laboratories, Inc., Boonton, N. J., together with Magnetizing Jig, QB71063-1, and Magnetizing Adapter, QB71063-10. For proper concentration of the lines of force, be sure that the center lines of the magnetizer poles line up with the center lines of the magnet. After remagnetizing, place the magnet in Magnet Keeper QB70735-4.

5. Remagnetizing Ring Magnet.

   A. Use the magnet charger mentioned in paragraph 5A together with Magnetizing Jig QB71063-1 and repeat the procedure of the preceding paragraph to remagnetize the ring magnet. After remagnetizing, place the ring magnet in Magnet Keeper QB2674-1.

ASSEMBLY

1. Reassembly of Vane and Drive Assembly. See Figure 3.

   CAUTION: BEFORE REASSEMBLY, CAREFULLY EXAMINE ALL CONTACT SURFACES OF MOVING PARTS FOR BURRS OR CHIPS. THESE SURFACES MUST BE CLEAN AND SMOOTH TO INSURE CORRECT OPERATION OF THE TRANSMITTER.

   A. Carefully insert ball bearing (50) into vane housing (43) and make sure that the bearing flange is seated against the vane housing.

   B. Apply castor oil to the threads of screws (11, 16, 21, 26, 33, 38 and 41). If vane housing barrier (40) has been removed, place it in position in the vane housing (43) as determined by the two dowel pins (42). Use Alignment Gage 31TF10644 to align the barrier in the vane housing before tightening two screws (41).

NOTE: See "NOTE" following paragraphs 6B and 6C in DISASSEMBLY.

C. To check end play of vane shaft (49) in housing assembly (36), set vane shaft only (minus vane) against bearing with 0.0015 shim between bearing and shaft shoulder. Assemble and tighten housing cover (37) with screws (38). This adjustment should position the vane shaft for an end play of 0.001 to 0.002 inch.

D. Carefully insert the vane shaft (49) in the vane (47) and position it so that the edge of the vane towards the larger end of the shaft is 0.022 ±0.005 inch from the shoulder on the shaft, and that the two setscrews (48) are aligned with the flat on the vane shaft. Tighten the two setscrews to secure the vane in position. When looking at the larger end of the vane shaft, the vane blade should be to the right of the setscrews.

CAUTION: IT IS IMPERATIVE NOT TO BEND OR SCORE THE VANE SHAFT OR DAMAGE THE VANE, IN ORDER TO MAINTAIN A PROPER FIT WITH THE INSIDE CIRCULAR WALL OF THE HOUSING AND THE MATING SURFACE OF THE VANE HOUSING BARRIER.

E. Carefully insert the larger end of the vane shaft (49) through the ball bearing (50) in the vane housing (43).

F. Slide the housing cover (37) over the smaller end of the vane shaft (49) and into position against the vane housing (43) as determined by the two dowel pins (39). It may be tapped lightly with a fiber mallet to seat it on the dowel pins. Secure the housing cover to the vane housing with three screws (41). Vane shaft end play is 0.001 to 0.002 inch.

NOTE: Examine that clearance around vane is equalized.

G. Rotate the vane (47) and vane shaft (49) and test for friction. If there is stickiness or unevenness, first examine the housing assembly and make certain that the housing cover (37) is lying flat. If the cover is satisfactorily positioned, remove it and examine ball bearing (50) for wear or damage or for incorrect reassembly if it were replaced. Examine the vane shaft (49) for wear, damage or misalignment. Check to make sure bearing is not cocked.

H. Position the ring magnet assembly (45) on the larger end of the vane shaft (49) with the setscrew (46) aligned with the flat on the shaft and the ring magnet assembly hub flush against the shoulder on the shaft. Apply American Sealants Co. "Locktite" Grade AAV to setscrew (46). Tighten the setscrew to secure the ring magnet assembly in position.

I. Apply American Sealants Co. "Locktite" Grade A to threads of screw (52) before assembling into housing (43).

2. Reassembly of the Mechanism. See Figure 3.

A. Ease the vane and drive assembly (29) into the housing (53) until its leading edge butts against the shoulder in the housing.

B. Align the slot in the vane housing barrier with the dowel pin hole in the bottom of the housing (53). Carefully tap the dowel pin (13) into place with a fiber mallet so that it projects approximately 1/4 inch.

C. Insert outer end of spring of spring hub assembly (30) into spring clamp of spring adjusting plate assembly (32) to the adjustment scribe mark on the spring. Secure the spring in the clamp with screw (33), lockwasher (34) and washer (35).

D. Place the hub of the spring and hub assembly (30) on the extended end of the vane shaft (49) with the end of the hub flush with the end of the vane shaft and the back of the spring adjusting plate assembly (32) flush against the housing cover (37).

E. Rotate the spring hub until the setscrew (31) aligns with the flat on the vane shaft (47) and tighten the setscrew.

F. Carefully insert the housing cover (27) with packing (28) in the housing (53) so that the slot in the face of the cover aligns with the mating boss on the spring adjusting plate assembly (32).

NOTE: Use Dow Corning DC7 silicone grease on "O" ring prior to assembly.

G. Place cover retainer (24) in position on the end of housing (53) and secure with four screws (26).

NOTE: Do not lockwire screws (26) until unit has been calibrated and tested.

3. Reassembly of Synchro Transmitter and Bar Magnet Assembly. See Figure 3.

A. Replace clamp (20) in retaining groove on synchro transmitter (19).

B. Slide the bar magnet assembly (22) on the end of the synchro transmitter shaft until the end of the hub is flush with the end of the shaft and tighten two setscrews (21) to secure it.

C. Carefully insert the synchro transmitter (19) and bar magnet assembly (22) into the housing (53) and secure in place by attaching the clamp (20) to the housing with three screws (21).

CAUTION: BACKUP PRESSURE ON OTHER END OF SHAFT TO PREVENT DAMAGE TO BEARINGS OF SYNCHRO.

4. Reassembly of the Cover and Receptacle Assembly. See Figure 3.

A. If the synchro transmitter (19) and/or cover and receptacle assembly (15) were replaced, solder synchro lead wires to the receptacle pins as shown in Figure 2.

B. Solder electrical connections with Eclipsaloy No. 9, Grade 10 solder. This rosin-core solder consists of 63 percent tin and 37 percent lead and has a melting temperature of 181°C. Solder conforming to Federal Specification QQ-S-571, having a similar composition and melting range, may be used.

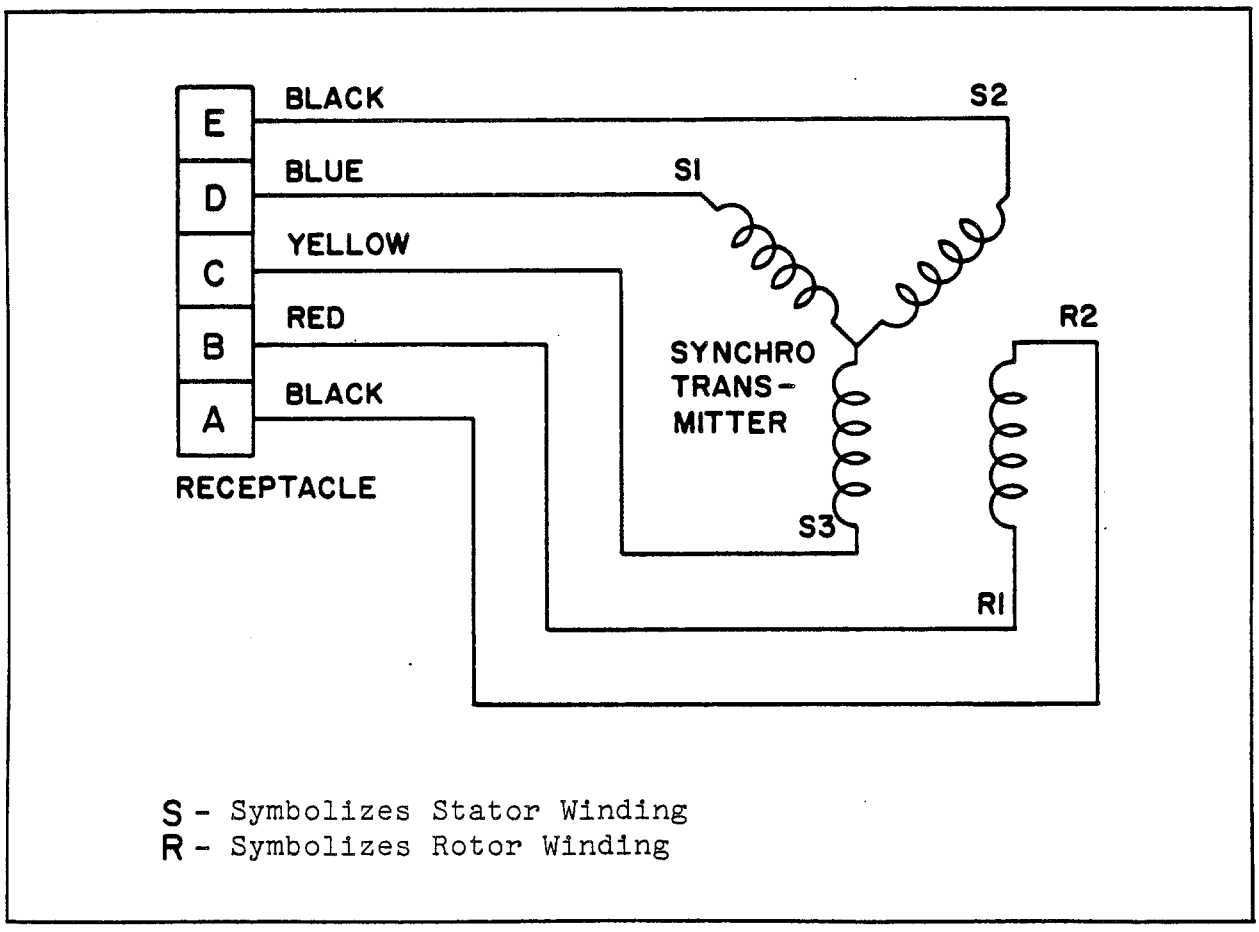

FIGURE 2. SCHEMATIC WIRING DIAGRAM

C. Insert the cover and receptacle assembly (15) with packing (18) in end of housing (53) with the polarizing key of the receptacle at the top and secure in place with four screws (16) and lockwashers (17).

NOTE: Use Dow Corning DC7 silicone grease on "O" ring before assembly.

5. Reassembly of Relief Valve. See Figure 3.

A. Insert the relief valve (8) in the connection housing (9) with the central raised portion of the valve toward the spring.

B. Insert relief valve spring (7) and relief valve plug (5) with packing (6) in the connection housing. Make sure that the spring coils fit on the plug extension and that the spring is not cocked.

C. Depress the relief valve plug (5) using Compression Tool 31TF10540 and insert the retaining ring (4) in the groove in the connection housing (9) to hold the relief valve assembly in place.

6. Reassembly of Connection Housing. See Figure 3.

A. Place the packing (12) in the groove in the connection housing (9).

NOTE: Use Dow Corning DC7 silicone grease sparingly on "O" ring before assembly.

B. Place the connection housing (9) on the housing (53), aligning it with the dowel pin (13) and attach it with four screws (10).

NOTE: Do not replace cap (14), plugs (3), lockwires (10 and 25) and sealing decals (2) until all tests have been completed.

FITS AND CLEARANCES

No fits and clearances are required other than those already mentioned.

TESTING

1. General.

A. Whenever the pressure and temperature conditions for the test are not definitely specified, it is understood that the test is to be made at atmospheric pressure of 29.92 ±2 inches of Hg. and room temperature of +25°C ±5°C.

When pressure and temperature differ from these values, proper allowances shall be made for the differences.

B. The fuel flow transmitter shall be mounted with its longitudinal axis vertical and the inlet in the lower position.

C. The indicator and transmitter shall be connected to a 26 volt, 400 cycle single-phase power supply.

D. Unless otherwise specified during all tests the transmitter shall be vibrated at a frequency of 1500 to 2000 CPM and an amplitude of 0.002 to 0.005 inch total excursion from positive maximum to negative maximum.

E. The fuel used for conducting tests shall be aviation gasoline, grade 115/145, Federal Specification MIL-F-5572. The specific gravity of the fuel shall be 0.715 ±0.003 at a temperature of 20°C ±2°C.

NOTE: For conversion purposes, one gallon of gasoline at specific gravity of 0.72 weighs six pounds.

F. Measurements requiring the use of a Vacuum Tube Volt Meter shall be made with a precision VTVM calibrated to 1% of actual value.

2. Tests.

A. Electrical Breakdown.

WARNING: THE ELECTRICAL BREAKDOWN TEST SHALL NOT BE PERFORMED IN A ROOM WHERE FLAMMABLE VAPORS ARE PRESENT.

(1) Use Insulating Tester 31TJ2179-2 to apply 200 volts, 60Hz between each pin of the receptacle and housing. Increase the voltage at a uniform rate to the test value and maintain for 5 seconds, then reduce to zero. This test shall cause no insulation breakdown.

(2) Use the Insulating Tester 31TJ2179-2 to apply 500 VDC between all pins of the receptacle and housing for a period of 5 seconds. The insulation resistance shall be not less than 10 megohms.

B. Excitation.

(1) The current drawn by the transmitter shall be 105 ±20 milliamperes.

C. Scale Error and Friction Test.

(1) Connect the instrument to the Fuel Flow Test Stand 31TF2237-1 and test for scale errors at the flow rate

tabulated in Table II. The test shall be made by subjecting the transmitter to the flows specified, first with rates of flow increasing, then with rates of flow decreasing. With the rate of flow increasing, the rate shall be brought up to, but shall not exceed the rate specified and with the rate of flow decreasing, the rate shall be brought down to, but shall not fall below the rate specified. The errors at the test points shall not exceed 5 pounds per hour or 3.83 indicator degrees, and the difference between the reading on the increasing rate of flow and the reading on the decreasing rate of flow at each test point shall not exceed 3.5 pounds per hour or 2.68 indicator degrees.

TABLE II

Flow Rate PPH	Dial Calibration DEG
50	64.97
100	103.31
150	141.66
200	180.00
250	218.34
300	256.69
350	295.03

D. Leak Test.

(1) The transmitter shall be tested for leaks with Flowmeter Leak Tester 31TF2227-1 immediately after the scale error test while the flow chamber is still moist from fuel, but with all the free fuel drained out. The flow chamber shall be subjected to a pressure of 200 psi. With the air supply disconnected, there shall be no more than 0.125 psi change in pressure over a period of five minutes. The piping from the air supply and to the gauge shall be as short as practicable and have an inside diameter not exceeding 1/4 inch.

E. Position Error.

(1) Readings of the standard indicator shall be taken with the transmitter in any position but the normal testing position as specified in paragraph 1B. These position readings shall not differ from the normal position readings by more than 5 pounds per hour or 3.83 indicator degrees.

NOTE: This test may be combined with the Scale Error Test.

3. Synchro Transmitter.

A. Check the resistance of the synchro transmitter, using a standard ohmmeter. The resistance across any two leads of the stator should be 6.7 ohms ±10% for the 1610122-1 and 3.8 ohms ±20% for the 1610122-2. The resistance of the rotor shall be 16 ohms ±10% for the 1610122-1 and 9.3 ohms ±20% for the 1610122-2. If the synchro transmitter does not meet these requirements, it must be replaced with a new assembly.

4. Calibration.

A. To calibrate the transmitter, proceed as follows:

(1) Set transmitter at full flow (vane against stop), loosen clamp screws (21) and rotate the synchro using Adjusting Tool 31TF10539 to obtain a reading of 300° on calibration dial.

(2) Set flow rate at 50 lbs and adjust pre-tension of spring by rotating housing cover (27) using Calibrating Tool 31TF10537 to obtain a reading of 65° on calibration dial.

(3) Tighten all screws and run a Scale Error Test.

(4) If error at high end of flow rate is too low, loosen screw (33) and set spring clamp toward end of spring.

(5) If error at high end of flow rate is too high, set spring clamp further away from end of spring to stiffen spring.

(6) Repeat the Scale Error Test and centralize the error curve by rotating the synchro housing.

(7) If error curve is out of tolerance in mid portion of flow rate repeat steps (1) through (6) with full flow set above or below 300°.

NOTE: If error curve droops at the high end of the error curve, a lower full flow indicator angle will pick it up.

5. Test Equipment.

A. The Fuel Flow Test Stand, type 31TF2237-1 is supplied with factory calibrated master transmitter equipment for testing purposes.

TROUBLE SHOOTING

1. See Table III, Trouble Shooting Chart.

TABLE III

TROUBLE SHOOTING CHART

TROUBLE	PROBABLE CAUSE	REMEDY
Out of calibration.	Rate spring (30) out of calibration. Spring torque to be 147 ±3 gram-centimeters at scribe mark when deflected through 270°.	Calibrate rate spring (30) as required, using Torsion Spring Tester Model 7358 and Spring Adapter 31TF10541.
Failure of Electrical Breakdown Test.	Shorted or grounded synchro transmitter (19). Faulty wiring.	Replace the synchro transmitter. Repair wiring.
Extreme calibration error.	Relief valve (8) not seated properly.	Check and reassemble the relief valve.
Inoperative	A. Friction B. Locked Vane (47).	A. Check for friction and end play. B. Check for burrs on the vane and housing.

STORAGE INSTRUCTIONS

1. Oven dry the flowmeter, at a moderate temperature, to remove all moisture.
2. Cap the inlet and outlet ports of the transmitter.
3. Clean the unit with a clean cloth.
4. Place the unit in a polyethylene bag.
5. Cushion the bottom of a suitable corrugated carton with hair cushioning.
6. Place the unit contained in a polyethylene bag in carton and surround with hair cushioning.
7. Close and tape seal the carton. Label the carton as to content and date of packing.

NOTE: Units which remain in storage or are inoperative beyond 12 months must be tested, inspected and lubricated where applicable prior to operation. To prevent expiration of the shelf life during the interval between shipment and factory installation, it is recommended that the customer schedule orders for equipment so as not to exceed 6 months storage time. Only this type of control will assure operators of satisfactory service life. In the event that shelf life is exceeded, such units must be returned to Instruments & Life Support Division for rework, at the customer's expense, to renew warranty of the equipment.

DIFFERENCE DATA SHEET FOR FUEL FLOW TRANSMITTER, TYPE 9133-25-B1

NOTE: Descriptive data and instructions covered in this section are the same as those for Type 9133-54-B1, covered in the previous sections, except for the specific differences noted.

DESCRIPTION AND OPERATION

1. In general the description and operation is the same as for Type 9133-54-B1. The major difference is in the vane and drive assembly components.

DISASSEMBLY

1. Same as for Type 9133-54-B1.

CLEANING

1. Same as for Type 9133-54-B1.

INSPECTION

1. Same as for Type 9133-54-B1.

REPAIR

1. Same as for Type 9133-54-B1.

ASSEMBLY

1. Same as for Type 9133-54-B1.

FITS AND CLEARANCES

1. Same as for Type 9133-54-B1.

TESTING

1. Testing is, in general, the same as for Type 9133-54-B1 except for the following:

   A. General - paragraph E. The fuel JP-4 per MIL-F-5624 used for conducting tests shall have a specific gravity of 0.775 ±0.005 at a temperature of $20^{\circ} \pm 2^{\circ}$C.

B. Tests - paragraph A. Electrical Breakdown.

(1) Use the Insulating Tester 31TF2179-2 to apply 550 volts 60 Hz at all pins of the electrical receptacle connected together and the housing for 5 seconds. This test shall cause no insulation breakdown.

C. Scale Error and Friction Test - paragraph C.

(1) The instrument shall be tested at the flow rates tabulated in Table V. The test shall be made by subjecting the transmitter to the flows specified, first with rates of flow increasing, then with rates of flow decreasing. With the rate of flow increasing, the rate shall be brought up to, but shall not exceed the rate specified and with the rate of flow decreasing, the rate shall be brought down to, but shall not fall below the rate specified. The errors at the test points shall not exceed the tolerances listed in Table V, and the difference between reading on the increasing rate of flow and reading on the decreasing rate of flow at each test point shall not exceed 2.5 indicator degrees.

TABLE V.

Flow Rate (PPH)	Dial Calibration (Degrees)	Room Temp Tolerances		High-Low Temp Tolerances	
		Flow Rate ±(PPH)	Indicator (Degrees)	Flow Rate ±(PPH)	Indicator ±(Degrees)
50	58.5	10	±2.7	15	4.2
100	75.9	6	±2.8	13	5.9
150	99.9	5	±2.5	11	5.5
200	125.6	4	±2.1	10	5.3
250	152.8	4	±2.2	12	6.6
300	180.0	5	±2.8	15	8.5
350	208.5	6	+2.1,-3.4	17	9.7
400	237.0	7	+3.6,-4.1	20	11.8
450	267.9	8	+4.5,-5.0	20	12.5
500	299.2	10	+5.8,-6.3	20	12.5

D. Position Error Test - paragraph E.

(1) Readings of the standard indicator shall be taken with the transmitter in any position but the normal testing position as specified in paragraph 1B. These position readings shall not differ from the normal position readings by more than 3.5 indicator degrees.

NOTE: This test may be combined with the Scale Error Test.

E. Calibration - paragraph A, step (2).

(1) Set flow rate at 50 lbs and adjust pre-tension of spring by rotating housing cover (27) using calibrating tool 31TF10537 to obtain a reading of 58.5° on calibration dial.

TROUBLE SHOOTING

1. Same as for Type 9133-54-B1.

STORAGE INSTRUCTIONS

1. Same as for Type 9133-54-B1.

SPECIAL TOOLS, FIXTURES AND EQUIPMENT

1. Same as for Type 9133-54-B1.

ILLUSTRATED PARTS LIST

1. Figure 3 illustrates the Fuel Flow Transmitter. The associated parts list, through the Usable On Code, depicts the part differences between the units covered.

INFORMATION SUBJECT TO EXPORT CONTROL LAWS

THIS DOCUMENT CONTAINS INFORMATION SUBJECT TO THE INTERNATIONAL TRAFFIC IN ARMS REGULATION (ITAR) AND/OR THE EXPORT ADMINISTRATION REGULATION (EAR) WHICH MAY NOT BE EXPORTED, RELEASED, OR DISCLOSED TO FOREIGN NATIONALS INSIDE OR OUTSIDE THE UNITED STATES WITHOUT FIRST OBTAINING REQUIRED U.S. GOVERNMENT APPROVAL OR A VALIDATED EXPORT LICENSE. A VIOLATION OF THE ITAR OR EAR MAY BE SUBJECT TO A PENALTY OF UP TO 10 YEARS IMPRISONMENT AND A FINE OF $100,000 UNDER 22 U.S.C. 2778 OR SECTION 2410 OF THE EXPORT ADMINISTRATION ACT. INCLUDE THIS NOTICE WITH ANY REPRODUCED PORTION OF THIS DOCUMENT.

NOTICE

- REPAIRS AND MAINTENANCE OF EQUIPMENT COVERED IN THIS MANUAL MUST BE PERFORMED AS SPECIFIED IN THIS MANUAL
- REPAIRS AND MAINTENANCE MUST BE PERFORMED BY TECHNICALLY COMPETENT PERSONNEL UTILIZING TOOLING AND TEST EQUIPMENT SPECIFIED IN THIS MANUAL.
- REPAIRS AND MAINTENANCE MUST BE PERFORMED IN A REPAIR FACILITY APPROVED BY THE APPROPRIATE GOVERNING AIRWORTHINESS AUTHORITY USING ONLY PARTS AUTHORIZED IN THIS MANUAL.
- FAILURE TO COMPLY WITH THE ABOVE STANDARDS AND REQUIREMENTS MAY POSE A SAFETY HAZARD, ADVERSELY AFFECT OPERATION OF THE EQUIPMENT, AND JEOPARDIZE WARRANTIES.

SUNDSTRAND CORPORATION
ROCKFORD, ILLINOIS

ORIGINAL ISSUE MAR 1/73
REVISION 8 MAR 1/95

TO: Holders of Overhaul Manual with Illustrated Parts List, 73–10–04 (P&WC Manual P/N 3020549) for Sundstrand Power Driven Rotary Pump (P/N 025323–402 Series) Issued March 1, 1973.

Revision 8, dated March 1, 1995

HIGHLIGHTS

Shown below are highlights of the significant changes and the affected pages contained in this revision. Remove the used affected pages and put the new affected pages into the manual as shown on the List of Effective Pages.

We recommend that you put this revision into your manual without delay. Mark the Record of Revisions sheet with the new revision number and date, and write your initials on the Record of Revisions sheet in the appropriate spaces after you have put the revised pages in your manual.

Please call Shirley A. Tooze, (815) 226-6000, TWX: 910-631-3458, TELEX: 25-7496, FAX: (815) 966–8525, or write to Sundstrand Aerospace, Technical Publications Department 768–1, 4747 Harrison Avenue, P.O. Box 7002, Rockford, IL 61125-7002, if you have any questions about this revision.

Page Number(s)	Description of Change
Disassembly, 101	Added the disposition requirements for the seal at overhaul and repair.
Repair, 403 and 405; Fits and Clearances, 602	Expanded check requirements for the gearset to include inspection for erosion.
Assembly, 501; Special Tools, Fixtures, and Equipment, 1001 and 1002	Deleted pin driver T–013242T1 from the list of special tools and fixtures. This particular pin driver is not required for maintenance of the pump.
Assembly, 502	Added a requirement to clean the seal surfaces before assembly with lubrication fluid.
Testing, 702; Special Tools, Fixtures, and Equipment, 1001	Correctly identified the inlet adapter to correspond with test fixture requirements.
Testing, 703 and 705	Updated the testing procedures to meet the latest engineering requirements.
Trouble-shooting, 801	Deleted troubleshooting procedures for bypass pressure requirements to correspond with the latest testing requirements. Expanded correction criteria for pump leaks. The seals are not 100% replaceable items. They may be lapped if leakage is evident during testing. If lapping does not correct the leakage problem, then the seals may be replaced.

Light Overhaul, 1301	Reidentified the grade of aloxite resinoid stone used to dress the carbon seal to correspond with that used in the repair procedures.

DISASSEMBLY

1. General

   A. Disassembly of the pump is generally in the order of sequence numbers assigned to the exploded view, Ref. IPL Fig. 1, in the ILLUSTRATED PARTS LIST section. The stationary bearings and gears are a matched set. These parts should be retained in sets for reinstallation in the position from which they were removed if they are found to be serviceable. The filter bypass valve sleeve and piston and regulating valve sleeve and piston are not matched pairs; however, they should be kept together to maintain the seating pattern developed through operation of the valve on the seat.

   B. Locating pins, studs, and thread inserts need not be removed at overhaul unless inspection reveals the part must be replaced.

   C. All preformed packings and retaining rings are 100 percent replacement items.

2. Disassembly Procedures

   WARNING: WEAR GOGGLES WHEN REMOVING LOCKWIRE.

   CAUTION: DO NOT MIX PARTS BETWEEN PUMPS.

   A. Pumping Element and Seals

      CAUTION: DO NOT REUSE RETAINING RING (3).

      (1) Pull pump drive coupling (2A, IPL Fig. 1) off drive gear spline. Remove and discard retaining ring (3). Do not remove spring pin (2J) from coupling (2) unless necessary for replacement as applicable.

      (2) Remove bolts (5A and 6A) and washers (7) and lift off front cover (4A).

      (3) Remove internal retaining ring (8) and press seal (9) out of front cover (4A) from the back side. Remove and discard preformed packings (10, 11, and 12). At overhaul, discard seal (9). At repair (for pumps returned for fuel leaks), lap seal (9) (refer to REPAIR) and test for leaks. If a leak is evident, replace the seal (refer to TROUBLESHOOTING).

         CAUTION: BEARINGS MUST BE REMOVED SIMULTANEOUSLY IN PAIRS TO PREVENT DAMAGE BY SPRING PINS (14). DURING DISASSEMBLY, ACCOUNT FOR THE TWELVE BEARING SPRINGS (18) TO BE SURE NONE HAVE BECOME LODGED IN AN INTERNAL PASSAGE WITHIN THE PUMP HOUSING.

      (4) Place the pump housing on end; matched bearing set (13A) and matched gearset (15A) should slide out easily. If not, gently tap the body face with a soft head mallet to dislodge parts. Continue tapping face to dislodge drive and driven bearings (16A and 17A), permitting removal of bearing springs (18). Remove and discard preformed packings (19).

(5) Identify driven gear of matched gearset (15A) for reference at reassembly to be sure gear is installed with same face of gear towards matched bearing set (13A).

(6) Do not remove spring pins (14) from matched bearing set (13A) or drive and driven bearings (16A or 17A) unless replacement is necessary.

(7) Pull drive coupling (22J) from drive gear of matched gear set (15A). Remove and discard retaining ring (22M) from internal spline of drive gear of matched gearset (15A).

B. Discharge Filter

WARNING: WEAR GOGGLES WHEN REMOVING SAFETY WIRE.

Cut lockwire and remove discharge filter cover (23A), preformed packing (24), discharge filter (26), and preformed packing (27). Discard preformed packings (24 and 27).

C. Inlet Adapter

(1) Remove inlet adapter (27J) by removing bolts (27P) and washers (27T). Remove and discard performed packing (27V).

(2) Do not remove stepped studs (27M) from inlet adapter (27J) unless replacement is necessary. Refer to REPAIR for replacement instructions.

D. Inlet Filter

(1) The inlet filter will come out as an assembly. Remove inlet filter cover assembly (28). Remove and discard preformed packings (31 and 32).

(2) Remove bolt (33), spring (34), washer (35), seal washer (36), and inlet filter (37).

(3) Do not remove insert (30) from inlet filter cover assembly (28) or spring pin (38) from inlet filter (37) unless replacement is necessary. Refer to REPAIR for replacement of insert (30) and for replacement of spring pin (38).

E. Bypass Pressure Regulating Valve

Remove valve cap (39), preformed packing (40), regulating valve spring (41), valve piston (42), valve sleeve (43), and preformed packing (44). Discard preformed packings (40 and 44).

NOTE: Valve piston and valve sleeve are not a matched set; however, they should be kept together to retain any wear pattern that may have developed during operation.

this fiche to include the above.

REPAIR

CAUTION: ENSURE PARTS ARE THOROUGHLY CLEANED AFTER DEBURRING, LAPPING, OR POLISHING.

1. Valve Pistons and Valve Sleeves

Minor damage to the valve pistons (42 and 48, IPL Fig. 1) or valve sleeves (43 and 49) may be removed with a hard stone or fine abrasive paper. Remove only enough material to restore surface to its original contour.

2. DELETED

3. Bearings

Dress faces (gear contact surfaces) lightly to remove scoring on drive and driven bearings (16A and 17A, IPL Fig. 1) and matched bearing set (13A). Use an Aloxite Resinoid Stone, Part Number A–800–FB (obtainable from Sticks and Stones Unlimited Incorporated, 1800 E. Northwest Parkway, Southlake, TX 76092).

Proceed as follows:

A. Be sure stone is true and flat.

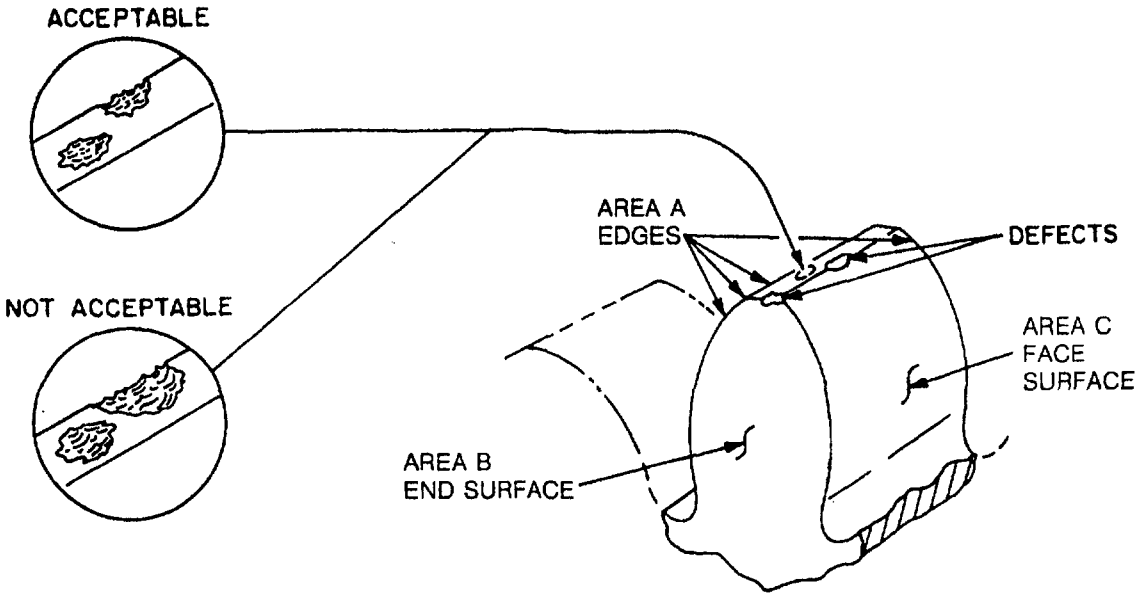
B. Move bearing through a figure 8 motion while pressing lightly against stone.

C. Periodically rotate bearing through an arc while dressing.

D. Flatness, squareness, length, and parallelism must be as specified in Fig. 601.

NOTE: Drive and driven bearings (16A and 17A, IPL Fig. 1) do not have length and parallelism requirements.

4. Gears



Repair gears as follows, maintaining the requirements shown in Fig. 601.

NOTE: Normal burnishing and circumferential scoring of gear end surfaces (Ref Fig. 401, Area B or Fig. 404, Area D) is acceptable, if gearset is maintained with original bearings.

A. Lightly dress journals with crocus cloth while rotating gear in a lathe.

B. Refinish end surfaces with an Aloxite Resinoid Stone, Part Number A–800–FB (obtainable from Sticks and Stones Unlimited Incorporated, 1800E. Northwest Parkway, Southlake, TX 76092). If defects cannot be removed, replace the gearset.

NOTE: End surfaces of reused matched gearset must be refinished to 4 microinches root mean square if bearings (16A and 17A, IPL Fig. 1) or bearing set (13A) is replaced.

A–67853

Gear Tooth Damage Limits
Figure 401

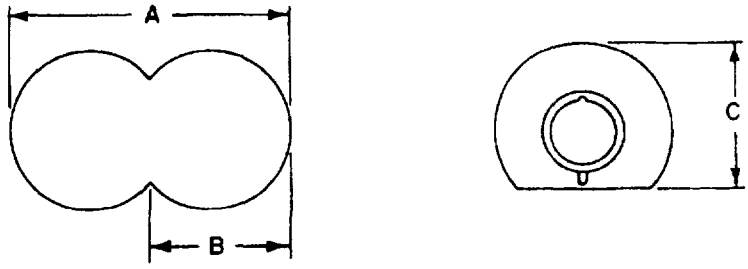
C. Blend chips or nicks in tooth edges (Ref Fig. 401, Area A or Fig. 404, Area A) with a hard stone. Remove rough edges or high spots that could damage mating gear tooth surfaces.

NOTE: This repair should not exceed 50 percent of any one tooth edge. Such repair on consecutive teeth within the same circumferential area is not permissible. No repair is allowed on the face surfaces (Ref Fig. 401, Area C or Fig. 404, Areas B and C).

D. Lap seal surfaces on the ends of the gear journals to restore the 4 micro-inch root mean square, 2 light band finish. A maximum of 0.0003 inch may be removed.

5. Inserts

Remove and replace inserts (30, 56 and 57, IPL Fig. 1) if damaged. Install new inserts 1/4 to 1 full turn below the countersink using standard helicoil installation kit. Remove tang.



6. Pins

A. If damaged, remove and install spring pin (28) in inlet filter (37). Make sure pin bottoms in inlet filter.

B. If damaged, remove and install headless pins (55) in pump housing (58A). Install pins to protrude from pump housing surface 0.340 ± 0.030 inch.

7. Bearing Installation

Fit new drive and driven bearings (16A and 17A) and bearing set (13A) to bores in pump housing (58A) according to Figure 402. Lap bearing flats if necessary, to obtain correct bearing-to-bore fit according to Fig. 402.

A–16600–3

NOTES

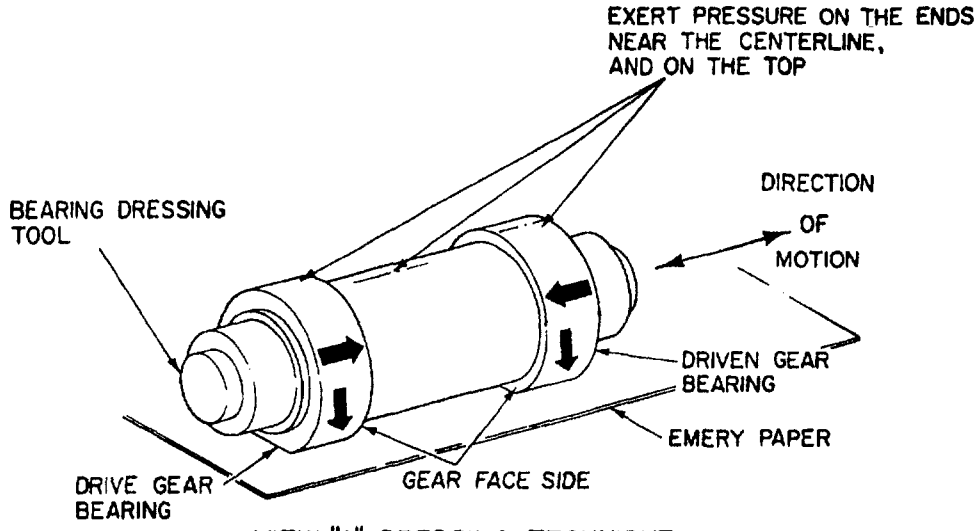
A Housing bore dimension.
B Bearing cavity dimension.
C Bearing width dimension.

PROCEDURES

Bearings must fit housing bore with 0.0002 inch to 0.0006 inch clearance between bearing flats. Fit bearings to housing bore as follows:

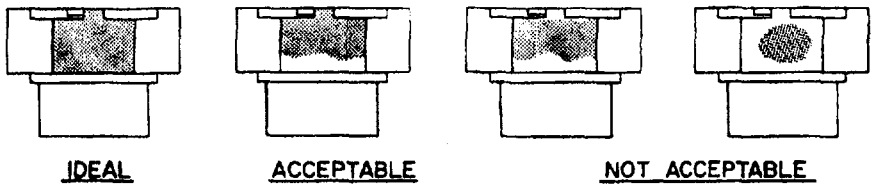
A. Measure housing bore and record as dimension A.

B. Divide dimension A by two to obtain dimension B.



C. To obtain dimension C, select new drive and driven bearings (16 and 17, IPL Fig. 1) or matched bearing set (13) at a width of 0.0001 inch to 0.0003 inch less than dimension B. If necessary, touch-lap bearing flats according to Fig. 403 to obtain correct bearing-to-bore fit.

Fitting Bearings to Housing Bore
Figure 402



8. Stud Installation

A. If necessary, remove stepped studs (27M) from inlet adapter (27J). Turn in new studs to 0.460 to 0.480 inch height.

B. If necessary, remove and replace locked-in studs (54A) in pump housing (58A) according to Fig. 405.

VIEW "A" DRESSING TECHNIQUE

VIEW "B" INSPECTION LIMITS

A–28413

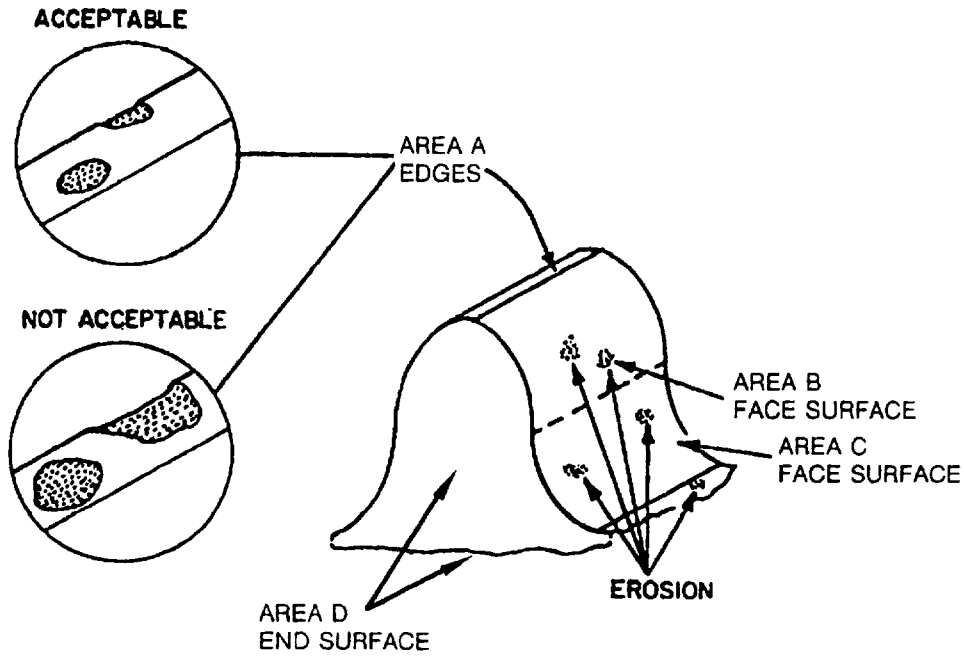
PROCEDURES

After determining correct bearing width (Fig. 402, dimension B), if necessary, touch-lap bearings to obtain a bearing width within limits stated in Fig. 402 as follows:

A. Place both bearings of a pair or set on small diameter of bearing dressing tool SF97–1019.

NOTE: If bearing dressing tool SF97–1019 is not available, a suitable dressing tool can be obtained by grinding or machining down the gear teeth of a drive or driven gear of matched gear set (15A, IPL Fig. 1) to gain clearance for dressing bearing flats.

B. Dress bearing flats a maximum of four strokes on 320 or 400 grit abrasive paper (View "A"). Half the strokes are to be performed with horizontal movement force against driven gear bearing, and half the strokes with force against drive gear bearing.



Dressing and Polishing Bearing Flats
Figure 403 (Sheet 1 of 2)

C. Polish bearing flats on flat Aloxite stone a maximum of four strokes until bearing flats are polished to acceptable limits of View "B". Half the polishing strokes are to be performed with horizontal movement force against driven gear bearing, and half the strokes with force against drive gear bearing.

D. Clean bearings according to CLEANING.

E. Inspect bearings. Each bearing must meet acceptance criteria (View "B") and must be within limits stated in Fig. 402.

Dressing and Polishing Bearing Flats
Figure 403 (Sheet 2 of 2)

A-67854

Gear Tooth Erosion Limits
Figure 404

9. Insert Ring

A. If necessary, remove and replace insert ring (59) in pump housing (58A) as follows:

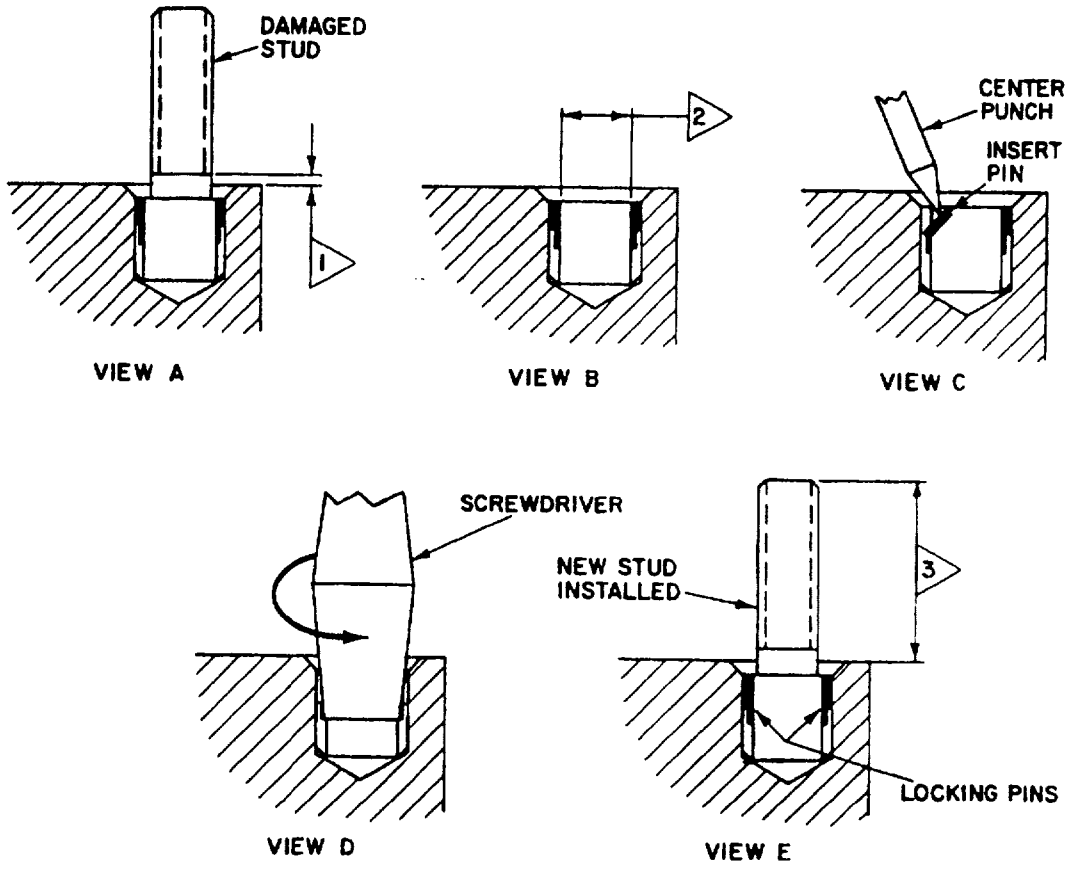
WARNING: USE CARE WHEN HANDLING HEATED PARTS. WEAR GLOVES AND OTHER PROTECTIVE CLOTHING.

(1) Heat pump housing (58A) to 227° to 232°C (440° to 450°F).

(2) Using standard bearing puller, remove insert ring (59).

(3) Remove scoring from housing bore with 400 grit lapping paper.

WARNING: LOCTITE SEALANT AND PRIMER ARE TOXIC. USE IN WELL VENTILATED AREA. PREVENT EYE AND SKIN CONTACT AND DO NOT BREATHE VAPORS. IN CASE OF EYE CONTACT, FLUSH WITH WATER AND SEEK MEDICAL ATTENTION. IN CASE OF SKIN CONTACT, WASH WITH SOAP AND WATER.



(4) Apply a thin coat of Locquic primer, grade "N" (available from Loctite Corp., 115 North Mountain Rd., Newington, CT 06111) to the housing bore and OD of new insert ring (59). Allow to air dry for 15 minutes.

(5) Apply Loctite retaining compound, 262 (available from Loctite Corp., 115 North Mountain Rd., Newington, CT 06111) in a smooth, thin coat to the OD of insert ring (59).

(6) Press insert ring (59) into pump housing (58A) bore until bottomed.

10. Seals

If required, touch-lap seal (9, IPL Fig. 1) before assembly according to Fig. 406.

A–60051

NOTES AND DIMENSIONS

1 Noted dimension, 0.030 to 0.060 inch above surface of housing.

2 Noted dimension, 0.266 inch diameter hole through stud.

3 Noted dimension, 0.745 to 0.775 inch above housing surface.

PROCEDURE

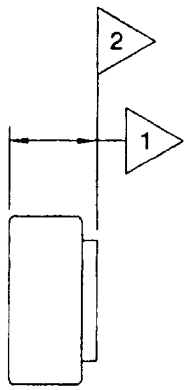
CAUTION: DO NOT DAMAGE MACHINED SURFACES OF HOUSING WHEN REMOVING LOCKED-IN STUDS.

A. Cut off damaged stud (View A) above surface of housing according to 1 .

B. Using staking fixture (Ref SPECIAL TOOLS, FIXTURES, AND EQUIPMENT, Fig. 1001) in position on studs, drill through center of remaining part of stud (View B) according to 2 .

Stud Removal and Installation
Figure 405 (Sheet 1 of 2)

C. Use a suitable size punch to bend locking pins inward (View C) and break off.



WARNING: WHEN USING COMPRESSED AIR FOR CLEANING OR DRYING, REGULATE PRESSURE TO 29 POUNDS PER SQUARE INCH OR LESS. WEAR GOGGLES OR FACE SHIELD TO PROTECT EYES.

D. Remove remaining shell of stud out from cover with a screwdriver (View D). Airblow to remove chips. Inspect threads for damage; if necessary, chase threads with a 0.375–16UNC–3A tap.

E. Clean according to CLEANING.

F. Using staking driver (Ref SPECIAL TOOLS, FIXTURES, AND EQUIPMENT, Fig. 1001), install new locked-in studs (54A, IPL Fig. 1) according to MS51835 and 3 .

Stud Removal and Installation
Figure 405 (Sheet 2 of 2)

A-27960-1

NOTES AND DIMENSIONS

1 Minimum dimension after lapping, 0.360 inch.

2 Noted surface to be flat within 0.000035 inch (3 light bands).

PROCEDURES

A. Lap face of seals (9, IPL Fig. 1) according to the following:

(1) Touch-lap Aloxite Resinoid stone on 4/0 polishing paper on a surface plate to clean.

(2) Hand lap carbon seal face (dry) on a flat Aloxite Resinoid stone. Lightly polish in a figure 8 motion.

(3) Clean carbon seal face by wiping with a clean soft cloth.

(4) Inspect seal according to 1 and 2 .

Touch-Lapping of Seals
Figure 406

ASSEMBLY

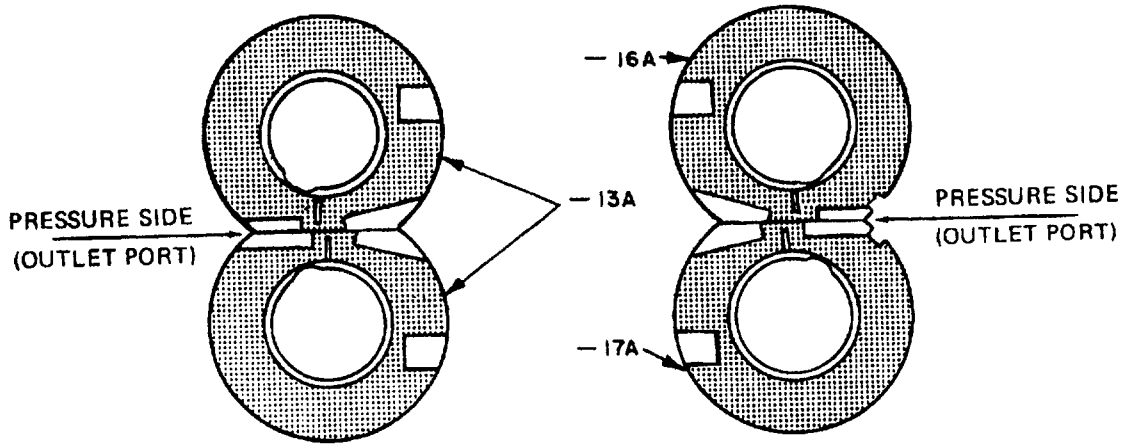
1. Consumable Materials

The following is a list of consumable materials required during overhaul:

Cloth, Crocus	Specification No. P-C-458
Fluid, Lubrication	Specification No. MIL-H-5606
Fluid, Calibrating	Specification No. MIL-C-7024, Type II
Paper, Fine Abrasive	Grade 4/0 Minnesota Mining and Manufacturing Company, St. Paul, MN 55144-1000
Petrolatum, Technical	Specification No. VV-P-236
Solvent, Dry-Cleaning	Specification No. P-D-680, Type II
Stone, Aloxite Resinoid	Part Number A-800-FB Sticks and Stones Unlimited Incorporated 1800 E. Northwest Parkway Southlake, TX 76092
Stone, Hard Arkansas	Specification SS-S-736, Type I

2. Assembly Procedures

A. Pumping Element and Seals



(1) If removed, press spring pin (14, IPL Fig. 1) into driven bearing (16A) and into drive bearing of matched bearing set (13A) as follows:

(a) Position drive bearing (16A) or driven bearing of matched bearing set (13A) into fixture (Ref SPECIAL TOOLS, FIXTURES, AND EQUIPMENT, Fig. 1001).

(b) Using a pin driver, press spring pin (14, IPL Fig. 1) into drive bearing (16A) or driven bearing of matched bearing set (13A) until bottomed.

(2) Install preformed packings (19) onto drive and driven bearings (16A and 17A) and bearing springs (18) into holes in bearings and position bearings in pump housing assembly (53A). (Ref Fig. 501 for proper bearing installation.)

NOTE: To ease installation of drive and driven bearings (16A and 17A, IPL Fig. 1) into pump housing assembly (53A), retain bearing springs (18) in holes with a small amount of petrolatum. To prevent damaging preformed packings, lubricate with petrolatum before installation.

A-20960-1

Bearing Installation
Figure 501

(3) Install matched gearset (15A) and matched bearing set (13A) into the pump housing (53A). (Ref Fig. 501 for proper bearing installation.)

NOTE: When installing driven gear of matched gearset (15A, IPL Fig. 1) be sure identified face of gear (Ref DISASSEMBLY) is towards matched bearing set (13A). Lubricate gears with lubrication fluid (MIL-H-5606).

(4) Install preformed packings (11 and 12) into pump housing assembly (53A). Install front cover (4A) and secure with washers (7) and bolts (5A and 6A). Torque bolts (Ref FITS AND CLEARANCES, Fig. 603).

(5) Install preformed packing (Ref 10, IPL Fig. 1) in recess in pump cover (4).

CAUTION: USE CARE WHEN INSTALLING SEAL AS CARBON INSERT CHIPS EASILY. TOUCH LAP SEAL ACCORDING TO REPAIR, FIGURE 406 BEFORE ASSEMBLY.

(6) Clean seal (9) face by wiping with a clean, soft cloth made wet with Military Specification MIL-H-5606 lubrication fluid. Using seal driver (Ref SPECIAL TOOLS, FIXTURES, AND EQUIPMENT, Fig. 1001), press seal (9) into cover bore. Install retaining ring (8) into cover bore.

NOTE: Internal retaining ring is installed with the sharp edge towards the outside.

CAUTION: RETAINING RING (3) IS INSTALLED CLOSED END FIRST TO PREVENT DISTORTION AND LOSS OF RETENTION ABILITY.

CAUTION: DO NOT APPLY GREASE OR ANTIFRETTING COMPOUND TO THE COUPLING AND DRIVE GEAR SPLINES. THE SPLINES ARE LUBRICATED WITH OIL SUPPLIED BY THE ENGINE DURING ACTUAL OPERATION. APPLYING GREASE OR ANTIFRETTING COMPOUND WILL RESTRICT OIL SUPPLY AND ACCELERATE SPLINE WEAR.

(7) Install a new retaining ring (3) in coupling). If removed, install new spring pin (2J) into coupling (2B). Lubricate splines of coupling and drive gear of matched gearset (15A) with lubrication fluid (MIL-H-5606). Install coupling over drive gear of matched gear set, ensuring that retaining ring is firmly seated in retaining ring groove of drive gear spline.

B. Bypass Pressure Regulating Valve

(1) Install preformed packing (44) on valve sleeve (43). Install the valve sleeve (43), valve piston (42), and spring (41) in the bypass valve port in the pump housing assembly (53A).

(2) Install preformed packing (40) on valve cap (39). Install valve cap in pump housing assembly (53) and torque valve cap (Ref FITS AND CLEARANCES, Fig. 603).

C. Discharge Filter Bypass Valve

(1) Install preformed packing (50, IPL Fig. 1) on valve sleeve (49). Install the valve sleeve (49), valve piston (48), and bypass valve spring (47) in the discharge filter bypass port in the pump housing assembly (53A).

NOTE: Bypass valve spring (47) is coated with green dye for identification.

(2) Install preformed packing (46) on valve cap (45). Using special socket wrench (Ref SPECIAL TOOLS, FIXTURES, AND EQUIPMENT, Fig. 1001), install cap in pump housing assembly (53A, IPL Fig. 1). Torque valve cap (Ref FITS AND CLEARANCES, Fig. 603).

(3) Install preformed packing (50M, IPL Fig. 1) on plug (50J). Install plug in pump housing assembly (53A) and torque plug (Ref FITS AND CLEARANCES, Fig. 603).

D. Discharge Filter

(1) Install preformed packing (27, IPL Fig. 1) in discharge filter (26) and install in pump housing assembly (53A).

(2) Install preformed packing (24) on discharge filter cover (23A). Install in pump housing assembly (53A) and torque discharge filter cover (Ref FITS AND CLEARANCES, Fig. 603).

E. Inlet Filter

(1A) Position inlet filter (37, IPL Fig. 1) into holding fixture (Ref SPECIAL TOOLS, FIXTURES, AND EQUIPMENT, Fig. 1001).

(1B) Using a pin driver (Ref SPECIAL TOOLS, FIXTURES, AND EQUIPMENT, Fig. 1001), press new spring pin (38, IPL Fig 1) into inlet filter (37) until bottomed.

(2) Install inlet filter (37), seal washer (36), washer (35), spring (34), and bolt (33) onto inlet filter cover assembly (28). Torque bolt (33) (Ref FITS AND CLEARANCES Fig. 603).

(3) Install preformed packings (31 and 32, IPL Fig. 1) on inlet filter cover assembly (28) and install assembled inlet filter into pump housing assembly (53A). Torque inlet filter cover assembly (28) (Ref FITS AND CLEARANCES, Fig. 603).

F. Inlet Adapter

Install preformed packings (27V, IPL Fig. 1) onto inlet adapter (27J). Install inlet adapter (27J) into pump housing assembly (53A) and secure using washers (27T) and bolts (27P). Torque bolts (Ref FITS AND CLEARANCES, Fig. 603)

G. Drive Coupling

Install retaining ring (22M, IPL Fig. 1) into drive gear of matched gearset (15A) (closed end first). Install drive coupling (22J) into drive gear of matched gearset (15A).

H. Identification Plate

If removed, secure identification plate (51, IPL Fig. 1) to pump housing with drive screws (52).

FITS AND CLEARNCES

1. General

Fits and clearances and acceptable wear limits for the pump are given in Fig. 601. Wear location is shown in Fig. 602 with reference to Fig. 601. Assembly torque values are given in Fig. 603. Spring specifications are given in Fig. 604.

ITEM	DIMENSION, CLEARANCE, OR TOLERANCE
Pump drive coupling (2A, IPL Fig. 1)	
Internal spline	*0.005 inch max.
External spline	Measure over two 0.0959 to 0.0961 inch diameter pins. Minimum dimension, 0.7328 inch.
Bearing surfaces of matched bearing set (13A, IPL Fig 1), drive bearing (16A), and driven bearing (17A)	Pits within 3/64 of an inch of the outer edge must not exceed 0.0070 inch in depth and 0.0625 inch in diameter, or equivalent area. Pits having a depth between 0.005 inch to 0.010 inch must not exceed 1/8 of an inch in diameter, or equivalent area. Pits having a depth between 0.010 to 0.015 inch must not exceed 1/16 of an inch in diameter, or equivalent area. Surface pitting less than 0.005 inch in depth is acceptable in any amount, if it does not create a bypass passage from the high pressure to the low pressure area.
Flat surfaces (contacting gears only)	Flat within 0.0003 inch (max) and square with bore within 0.0003 inch (max).
Bore ID	0.5645 inch (max). (Ref A, Fig. 602).
	* Difference between worn and unworn surface.

Fits and Clearances
Figure 601 (Sheet 1 of 2)

ITEM	DIMENSION, CLEARANCE, OR TOLERANCE
Matched Bearing set (13A, IPL Fig. 1) lengths	Equal within 0.0002 inch (max) (Ref B, Fig. 602).
Face surfaces	Parallel within 0.0002 inch.
Matched Gear set (15A, IPL Fig. 1)	
Internal spline	*0.004 inch max.
External spline (drive gear)	Measure over two 0.0599 to 0.0601 inch diameter pins. Minimum dimension, 0.3896 inch.
Gear width	Equal within 0.0002 inch (max). Minimum width, 0.3526 inch (Ref C, Fig. 602.)
Gear OD	OD of gear teeth shall not be less than 1.1649 inches.
Gear teeth (Ref Fig. 401)	Area A - Chips or nicks on tooth edges must not exceed an area 0.030 in. by 0.007 in. by 0.007 in. deep and should not extend more than halfway (circumferentially) across tip. Area B - Gears having chips or nicks on one or both end surfaces are acceptable, if the defects can be removed by lapping, and dimensions and surface finish can be maintained. Area C - Gears having scuff marks on tooth faces in excess of 125 micro-inches RMS shall be rejected.
Gear Teeth (Ref Fig. 404)	Area A - Erosion not to extend more than halway (circumferentially) across the width of the tooth tip. Area B (Tooth Face Surface) - Erosion not to exceed 0.010 inch (0.254 millimeter) depth. Area C - Erosion not to exceed 0.020 inch (0.508 millimeter) depth. NOTE: If there is evidence of cavitation erosion which undermines any surface, the gears must be replaced. Area D - Evidence of overheating. (Discoloration that cannot be removed with light polishing.)
Gear journals	Minimum diameter, 0.5602 inch (Ref D, Fig. 602.) *Difference between an unworn and worn surface.

Fits and Clearances

TESTING

1. Test Requirements

Test Equipment Required.

WARNING: CALIBRATING FLUID IS TOXIC AND FLAMMABLE. DO NOT BREATHE VAPORS. USE IN WELL VENTILATED AREA FREE FROM SPARKS, FLAME, OR HOT SURFACES. WEAR SPLASH GOGGLES, SOLVENT-RESISTANT GLOVES, AND OTHER PROTECTIVE GEAR. IN CASE OF EYE CONTACT, FLUSH WITH WATER AND SEEK MEDICAL ATTENTION. IN CASE OF SKIN CONTACT, WASH WITH SOAP AND WATER.

A. A test stand, equipped with a motor with a minimum rating of 5 horsepower, capable of driving the pump at speeds up to 6500 revolutions per minute, supplying test fluid filtered to 10 microns, at controlled pressures and temperatures, and as follows, is required:

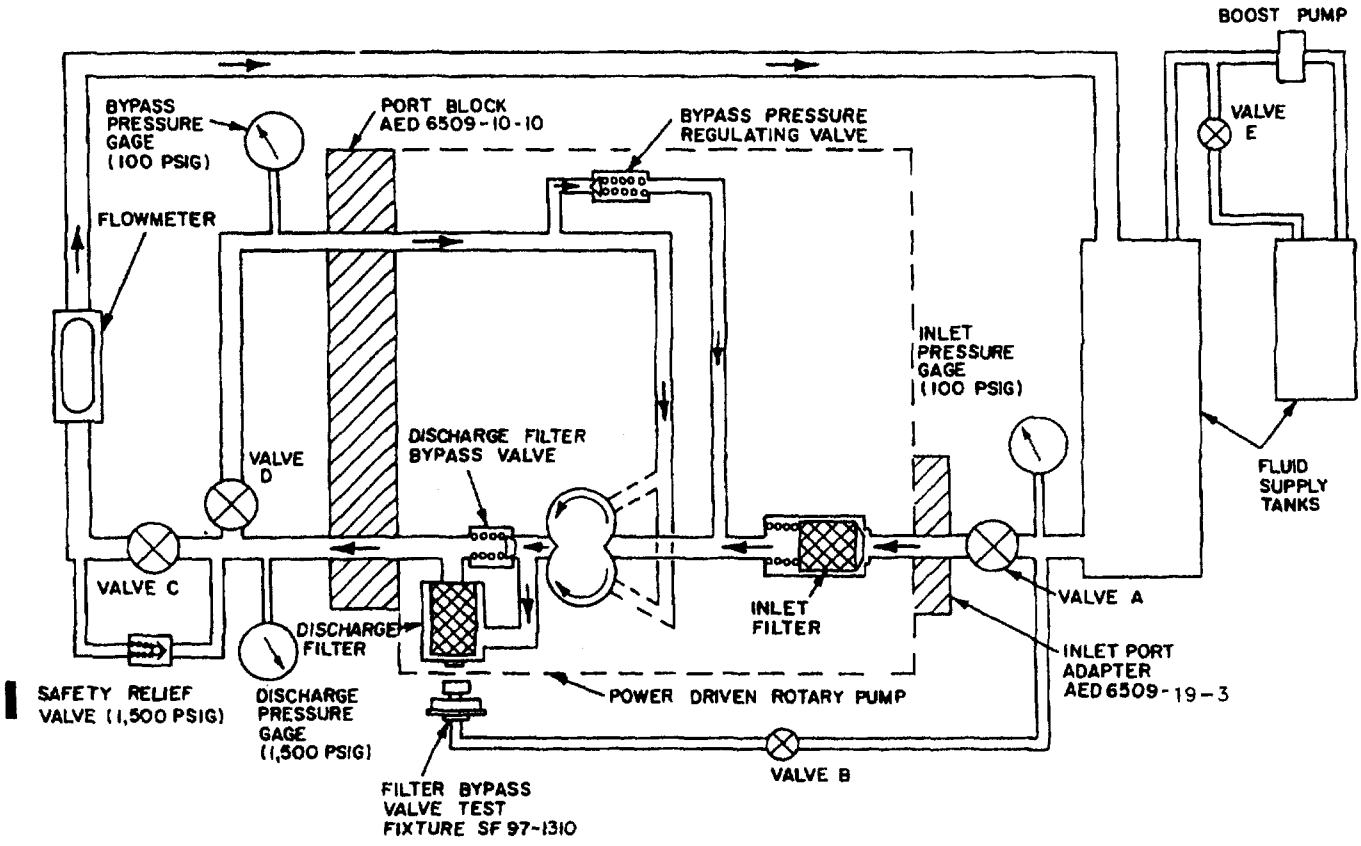
Rotation:	Clockwise viewing pump drive end
Fluid:	Military Specification MIL-C-7024, Type II
Inlet Pressure:	0 to 100 pounds per square inch gage
Discharge Pressure:	0 to 1,500 pounds per square inch gage
Bypass Pressure:	0 to 100 pounds per square inch gage
Accuracy of Measurements:	
*Pressure	2 percent or 0.5 pounds per square inch, whichever is greater
*Flow	2 percent, using rotometer or turbine flowmeter
*Speed	1 percent
Fuel Temperature (measured before inlet to pump):	
Break-in	16° to 32°C (60° to 90°F)
Performance Test	24° to 29°C (75° to 85°F)

* At the point of operation

B. A port block to provide a connection for the bypass return line during testing (Ref SPECIAL TOOLS, FIXTURES, AND EQUIPMENT).

C. A filter bypass valve fixture for testing the filter bypass valve (Ref SPECIAL TOOLS, FIXTURES, AND EQUIPMENT).

D. An inlet port adapter to provide a connection for the inlet line during testing of the power driven rotary pump (Ref SPECIAL TOOLS, FIXTURES, AND EQUIPMENT).



2. Test Procedures

A. Break-in

(1) Remove the discharge filter cover (23A) and discharge filter (26) from the pump. Reinstall only the discharge filter cover (23A) and preformed packing (24) in the pump.

(2) Install port block (Ref 2, Fig. 1002) on the governor end of the pump using four 1/4–inch flat washers and four 1/4–inch –28UNF–3A nuts.

(3) Install inlet adapter (Ref 4, Fig. 1002) on the inlet port using two 1/4-20UNC bolts 1/2 inch long. Install the pump on the test stand in a position resembling its engine-mounted position as nearly as possible (discharge filter cover down). Connect fuel lines to ports as shown in Fig. 701. Refer to Fig. 4, DESCRIPTION AND OPERATION for identification of ports and mounting dimensions.

A–27969–1

Typical Test Schematic
Figure 701

WARNING: CALIBRATING FLUID IS TOXIC AND FLAMMABLE. DO NOT BREATHE VAPORS. USE IN WELL VENTILATED AREA FREE FROM SPARKS, FLAME, OR HOT SURFACES. WEAR SPLASH GOGGLES, SOLVENT-RESISTANT GLOVES, OR OTHER PROTECTIVE GEAR. IN CASE OF EYE CONTACT, FLUSH WITH WATER AND SEEK MEDICAL ATTENTION. IN CASE OF SKIN CONTACT, WASH WITH SOAP AND WATER.

(4) Start boost pump; then operate pump to purge air from the system to be sure all parts of the pump are immersed in calibrating fluid.

(5) Operate the pump according to either method in Fig. 702, as follows:

(a) Open valve A, close valves B and D, and adjust valve C for the required discharge pressure.

(b) With the boost pump operating, adjust valve E to maintain the inlet pressure at 10 to 20 pounds per square inch gage and inlet temperature at 16° to 32°C (60° to 90°F) for break-in.

(c) Bearing temperature may be measured during break-in using a thermometer or thermocouple temporarily attached to the side of the pump housing. "Hot spots" can also be determined by feeling the pump housing by hand. If the bearing temperature rises 5.5°C (10°F) above the fuel inlet temperature or if the torque or outlet pressure is unsteady, reduce the pump speed and pressure until the bearing temperature falls within the specified limit and the pressure and torque can be held steady. If only rubber parts were replaced, no break-in run is required. If metal parts were replaced (body, gears, or bearings), the complete run-in is required.

METHOD I

PUMP SPEED (± 10 rpm)	DISCHARGE PRESSURE (± 10 psig)	TIME (MINUTES)
2,000	200	2
2,000	350	2
2,000	500	2
6,350	500	2
6,350	700	2
6,350	900	2

METHOD II

NOTE: Open valve C (Ref Fig. 701) fully at start and at each increase in speed.

PUMP SPEED (rpm)	DISCHARGE PRESSURE (psig)	TIME (MINUTES)
1,725	200	2
	350	2
	500	2
3,450	500	2
	700	2
	900	2

NOTE: The transition rate between conditions shall be as follows:
Speed: 150 rpm sec max
Pressure: 50 psi sec max

Break-in Schedule
Figure 702

(6) Perform surge test as follows:

(a) Set pump speed at 6,350 revolutions per minute and inlet pressure at 5 to 10 pounds per square inch gage.

(b) Adjust valve C to surge discharge pressure from 800 to 1,200 pounds per square inch gage (three times).

B. Discharge Filter Bypass Valve Check

(1) Shut off boost pump and pump under test. Remove discharge filter cover (23A, IPL Fig. 1), and install the Filter Bypass Valve Test Fixture (Ref 3, Fig. 1002) in place of the filter and cover. Connect line between valve B and the fixture. Disconnect the line from the pump discharge port.

(2) Start boost pump; then operate pump to purge air from the system to be sure all parts of the pump are immersed in calibrating fluid.

(3) With valve A closed and valve B open, increase the inlet pressure by opening valve E until a steady flow is noted from the discharge port.

(4) Reduce inlet pressure to 0 pounds per square inch gage. Increase pressure slowly to 10 pounds per square inch gage. Leakage from the discharge port shall not exceed 50 cubic centimeters per minute.

(5) Adjust valve E to increase the inlet pressure slowly until the valve cracks as indicated by an increase in flow from the discharge port. Cracking pressure shall be 15.0 to 25.0 pounds per square inch gage.

(6) Shut off boost pump and pump under test. Disconnect line between valve B and the test fixture. Remove fixture from pump. Disconnect line between valve B and the test fixture. Remove the fixture from the pump. Reconnect discharge port line. Reinstall the discharge filter (26, IPL Fig. 1). Torque discharge filter cover (Ref FITS AND CLEARANCES, Fig. 603).

C. Pump Performance

WARNING: CALIBRATING FLUID IS TOXIC AND FLAMMABLE. DO NOT BREATHE VAPORS. USE IN WELL VENTILATED AREA FREE FROM SPARKS, FLAME, OR HOT SURFACES. WEAR SPLASH GOGGLES, SOLVENT-RESISTANT GLOVES, AND OTHER PROTECTIVE GEAR. IN CASE OF EYE CONTACT, FLUSH WITH WATER AND SEEK MEDICAL ATTENTION. IN CASE OF SKIN CONTACT, WASH WITH SOAP AND WATER.

(1) Start boost pump; then operate pump to purge air from the system to be sure all parts of the pump are immersed in calibrating fluid.

(2) Operate the pump according to Fig. 703, as follows:

(a) Open valve A, close valve B, and adjust valve C for the required discharge pressure.

(b) Maintain the inlet pressure at 0 to 1 pound per square inch gage and inlet temperature at 24° to 29°C (75° to 85°F).

(c) Pump flow rate must exceed the requirements given in Fig. 703.

PUMP SPEED (rpm)	DISCHARGE PRESSURE (psig)	FLOW RATE (pph)
810 6,350	75 ± 5 850	213 1,605

Pump Performance
Figure 703

D. DELETED.

E. Seal Leakage

(1) Install a new discharge filter assembly (Ref 25, IPL Fig. 1) (Ref ASSEMBLY).

(2) With valve A (Fig. 701) open and valves B and D closed, operate the pump at 6,350 revolutions per minute and adjust valve C for 850 pounds per square inch gage discharge pressure.

(3) Adjust valve E to increase the inlet pressure to 50 pounds per square inch gage for 3 minutes.

(4) Leakage from the seal drain port shall not exceed 5 drops per minute, and there shall be no leakage from the casting or parting line.

TROUBLESHOOTING

1. General

The troubles covered in this section are those which can be located using overhaul shop test equipment. They do not include those troubles which might develop in related equipment and may appear to be the fault of the pump. They include troubles apt to be found in after-overhaul test and in equipment prematurely removed from service.

2. Troubleshooting Chart

Troubles most likely to occur in the pump are listed in Fig. 801 along with their possible cause, isolation procedure, and correction.

PUMP FLOW RATE OR OUTLET PRESSURE BELOW MINIMUM REQUIREMENT

POSSIBLE CAUSE	ISOLATION PROCEDURE	CORRECTION
Gear set defective	Disassemble and inspect parts	Replace the gear set.
Bearings or bearing set defective	Disassemble and inspect parts	Replace defective bearings.

PUMP LEAKS

POSSIBLE CAUSE	ISOLATION PROCEDURE	CORRECTION
Seals defective	Disassemble and inspect parts	Touch-lap seals (Ref Fig. 406, REPAIR). Replace seals if lapping does not eliminate leakage.
Preformed packings defective	Disassemble and inspect parts	Replace preformed packings.
Castings defective	Disassemble and inspect parts	Replace housing or cover.

Troubleshooting Chart
Figure 801 (Sheet 1 of 2)

DISCHARGE FILTER BYPASS VALVE PRESSURE EXCEEDS REQUIRMENTS

POSSIBLE CAUSE	ISOLATION PROCEDURE	CORRECTION
Wrong spring	Disassemble and inspect to be sure spring is green in color.	Install correct (green) spring.
Piston binding in sleeve	Disassemble and inspect parts	Clean, repair, or replace parts.

DISCHARGE FILTER BYPASS VALVE LEAKAGE EXCESSIVE

POSSIBLE CAUSE	ISOLATION PROCEDURE	CORRECTION
Piston binding in sleeve	Disassemble and inspect parts	Clean, repair, or replace parts.
Bad seat	Disassemble and inspect parts	Lap or replace defective parts.

Troubleshooting Chart

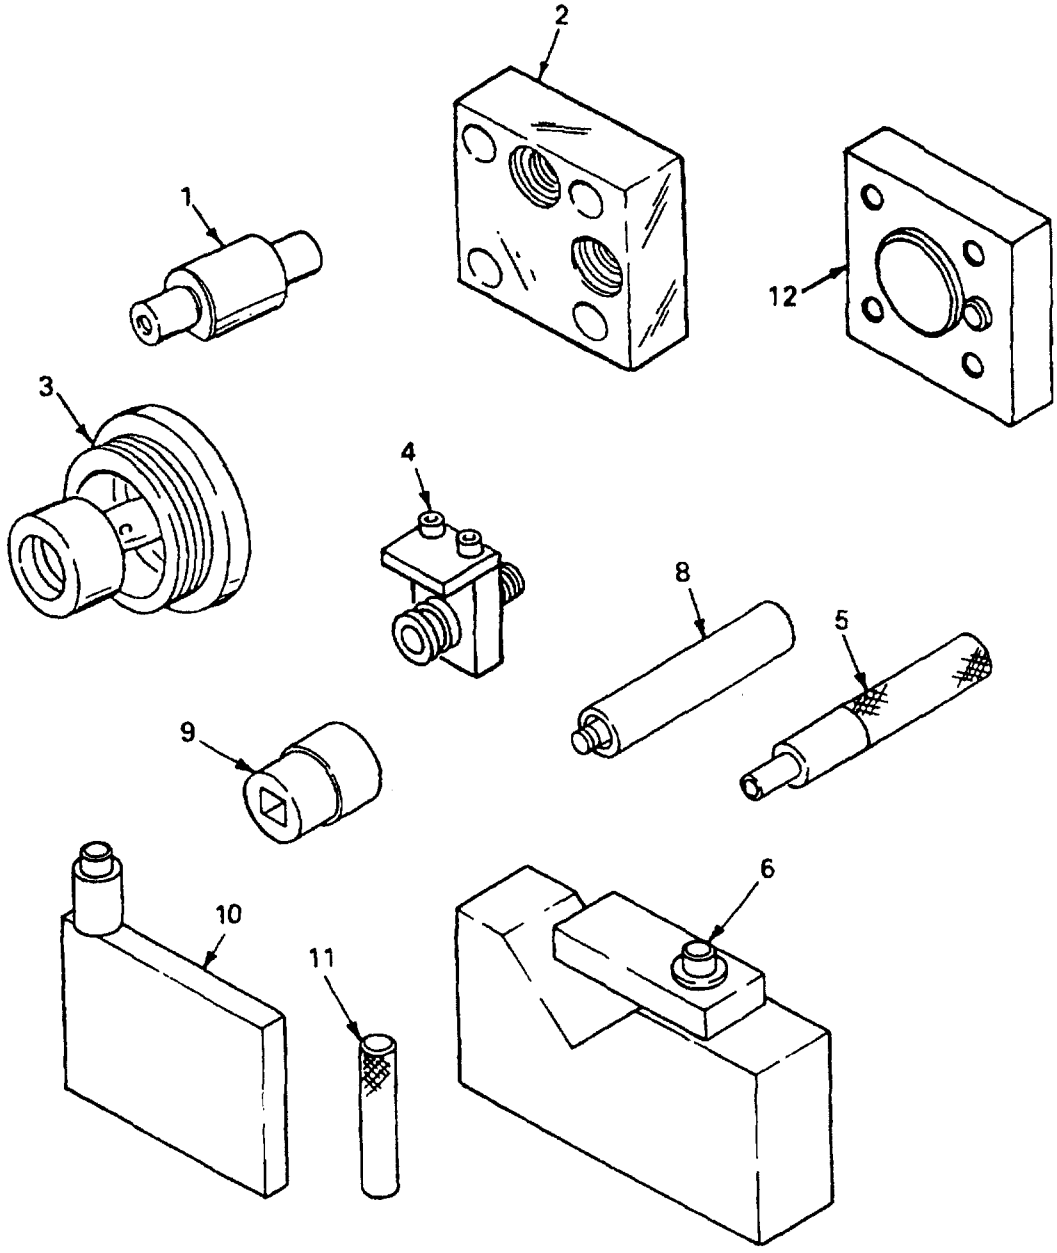
this fiche to include the above.



SPECIAL TOOLS, FIXTURES, AND EQUIPMENT

1. General

Special tools and fixtures required for overhaul and test of the pump are listed in Fig. 1001 and illustrated in Fig. 1002.

FIG. 1002 INDEX NO.	PART NO.	NOMENCLATURE	USE
1	SF97–1019	Tool, Bearing Dressing	Dress bearing flats during repair and assembly.
2	AED6509–10–10	Block, Port	Provide connection for bypass return during testing.
3	SF97–1310 or 97–1372	Fixture, Filter Bypass Valve Test	Replaces filter during test of filter bypass valve.
4	AED6509–19–3	Adapter, Inlet	Provide connection for inlet line during test.
5	DJS–23609	Driver, Staking	Used to install studs in pump housing.
6	FDS–22868	Fixture, Assembly	Used to hold bearings during pin installation.
7	T-013242–T1	DELETED (Driver, Pin)	
8	AKS–24288	Driver, Seal	Used to install seal into cover and pump housing assembly.
9	WAS–37524	Wrench, Special Socket	Used to remove and install valve cap.
10	024922–100–M2	Fixture, Holding	Used to hold inlet filter during pin installation.
11	025028–100–M2	Driver, Pin	Used to install pin in inlet filter.
12	FTS–23608	Fixture, Staking	Used as a guide for drilling during stud removal.

LIGHT OVERHAUL

1. General

Pumps which are prematurely removed from service due to a minor malfunction within the following categories may be repaired, tested, and returned to service.

2. Procedures

A. Seal(s) Leak

(1) Remove seal from pump as described in DISASSEMBLY.

(2) Lightly dress the carbon seal face on an Aloxite Resinoid stone, grade A-800-F-B, using a figure 8 motion.

(3) Clean seal as described in CLEANING.

(4) Reinstall seal and retainer as described in ASSEMBLY.

B. Discharge Filter Bypass Valve and/or Bypass Pressure Regulating Valve Leakage

(1) Disassemble valve as described in DISASSEMBLY.

(2) Inspect piston and sleeve for contamination, burrs, or scoring that would cause piston to hang-up.

(3) Repair as described in REPAIR.

(4) Inspect piston for complete contact wear pattern with seat in sleeve.

(5) If complete wear pattern is not evident, lightly lap the piston and sleeve together until complete contact is obtained.

(6) Clean parts as described in CLEANING.

(7) Reassemble valve as described in ASSEMBLY.

C. High/Low Filter Bypass Pressure

(1) Disassemble valve as described in DISASSEMBLY.

(2) Install new filter bypass valve spring and reassemble parts as described in ASSEMBLY.

D. High/Low Bypass Pressure Regulating Valve Pressure

(1) Disassemble valve as described in DISASSEMBLY.

(2) Install new regulating valve spring and reassemble parts as described in ASSEMBLY.

ATP-15410, Rev. A (3 sheets)		

1.0 Scope

This procedure delineates the necessary steps to identify the cause of failure and to correct the failure in an orderly fashion. This procedure is broken into four sections:

Disassembly

Inspection/Replacement

Assembly and

Test

2.0 Disassembly

CAUTION: Under no circumstances shall the solenoid be unscrewed from the body without the solenoid being energized at 18 to 24 VDC.

2.1 Lockwire Removal

The lockwire shall be cut from both the solenoid assembly and the body assembly. The lockwire shall be removed and discarded assuring that no lockwire is allowed into the outlet or inlet port.

2.2 The solenoid shall be energized by applying a voltage of 18 to 24 VDC to pins A and B of the electrical connector. The appropriate mating connector shall be used.

2.3 While the solenoid is energized, the solenoid assembly shall be unscrewed from the body assembly using a strap wrench. Care shall be exercised in assuring that the strap wrench does not apply pressure to the lockwire loop which is on the solenoid assembly.

2.4 After the solenoid has been removed from the body, the

solenoid assembly shall be deenergized. When the solenoid is deenergized, the operator shall assure that the solenoid plunger assembly *does not fall onto a hard surface.*

3.0 Inspection/Replacement

All critical surfaces which include the O-rings, valve seats and plunger assemblies, shall be inspected under at least 5X magnification.

3.1 Inspection of Plunger Assembly

The plunger assembly shall be inspected for nicks and cuts of the O-ring at its seating surface. The plunger shall be inspected for evidence of scratches, nicks and burrs on its outside diameter and in the spring cavity. If there is any evidence of any scratches, nicks and burrs on the plunger assembly or cuts and nicks on the O-ring sealing surface, the plunger assembly shall be replaced.

3.2 Body Assembly

The body assembly shall be inspected for nicks, cuts or burrs at the seat edge. Also, the O-ring sealing surface shall be inspected for evidence of nicks, burrs or scratches. Both the inlet and outlet bosses shall be inspected to assure that there are no nicks, cuts or burrs at the O-ring seal area. If there is any evidence of nicks, cuts or burrs at these sealing surfaces, the body assembly shall be replaced. Also, the .400/.401" dimension, as shown per Figure 1 of this procedure, shall be inspected. If this dimension is not met, the body assembly shall be replaced.

3.3 Spring

The spring shall be visually inspected for breaks and for loss of load. The spring should yield a load of 2.0 lbs. at .350 ±.003". If these criteria are not met, the spring shall be replaced.

3.4 Solenoid Assembly

The solenoid assembly shall be inspected for evidence of burrs or scratches in the solenoid bore. Also, the O-ring seal lands of the solenoid assembly shall be visually inspected for scratches, nicks or burrs. If cleaning bore is required to allow visual inspection, the bore shall be cleaned with a lint-free wiper using Freon TF, butyl or ethyl alcohol or water. If there is any evidence of nicks, scratches or burrs, the solenoid assembly shall be replaced. The connector shall be inspected for evidence of dirt and pin misalignment. The pins may be straightened to a small extent as a repair. The resistance of the solenoid shall be measured and shall be between 35 to 40 ohms at 76°F. If the solenoid is warm, this resistance may be slightly higher. If this is the case, the solenoid shall be allowed to cool and the resistance measured at room temperature. If the solenoid resistance exceeds 40 ohms at 76°F, it shall be replaced.

3.5 O-ring

The O-ring shall be removed from the solenoid assembly and replaced. Care shall be exercised in replacing this O-ring

to assure that it is not nicked or scratched as it is placed over the threads. The O-ring shall be well lubricated with silicone grease or equivalent. After placement on the solenoid assembly, the O-ring shall be visually inspected to assure that it is not twisted or has any nicks or cuts.

4.0 Assembly

Prior to assembly, all parts shall be thoroughly cleaned using butyl alcohol, ethyl alcohol, Freon TF or water. Isopropyl alcohol, Dowclean, Trichlorethylene, MEK, Zylol or acetone shall not be used for cleaning. The O-ring shall be well lubricated along with the threads on the body assembly and on the solenoid assembly. Silicone grease or equivalent may be used.

4.1 The solenoid shall be energized at 18 to 24 VDC and the plunger assembly and spring shall be installed into the solenoid and pushed into the bore until the solenoid retains the parts.

4.2 The solenoid shall be screwed into the body assembly. Care shall be exercised in assuring that the O-ring is not pinched or cut during assembly. This can be accomplished by screwing in the solenoid assembly a half a turn and backing the solenoid out a quarter of a turn. This procedure shall be followed until the solenoid assembly is fully assembled to the body assembly. There shall be no evidence of a gap between the solenoid assembly and the body assembly at their faying surface. The solenoid assembly may be tightened using a strap wrench at a torque not to exceed 50 in.-lbs.

4.3 The solenoid assembly shall be relockwired to the body assembly.

4.4 The solenoid shall be deenergized.

5.0 Test

The assembled solenoid valve shall be tested to the requirements of ATP-15410.

RSP/100 valves is the recommended Spare Parts Quantity for 100 valves in use. If the quantity is any part of 100 units, the quantities listed pertain.

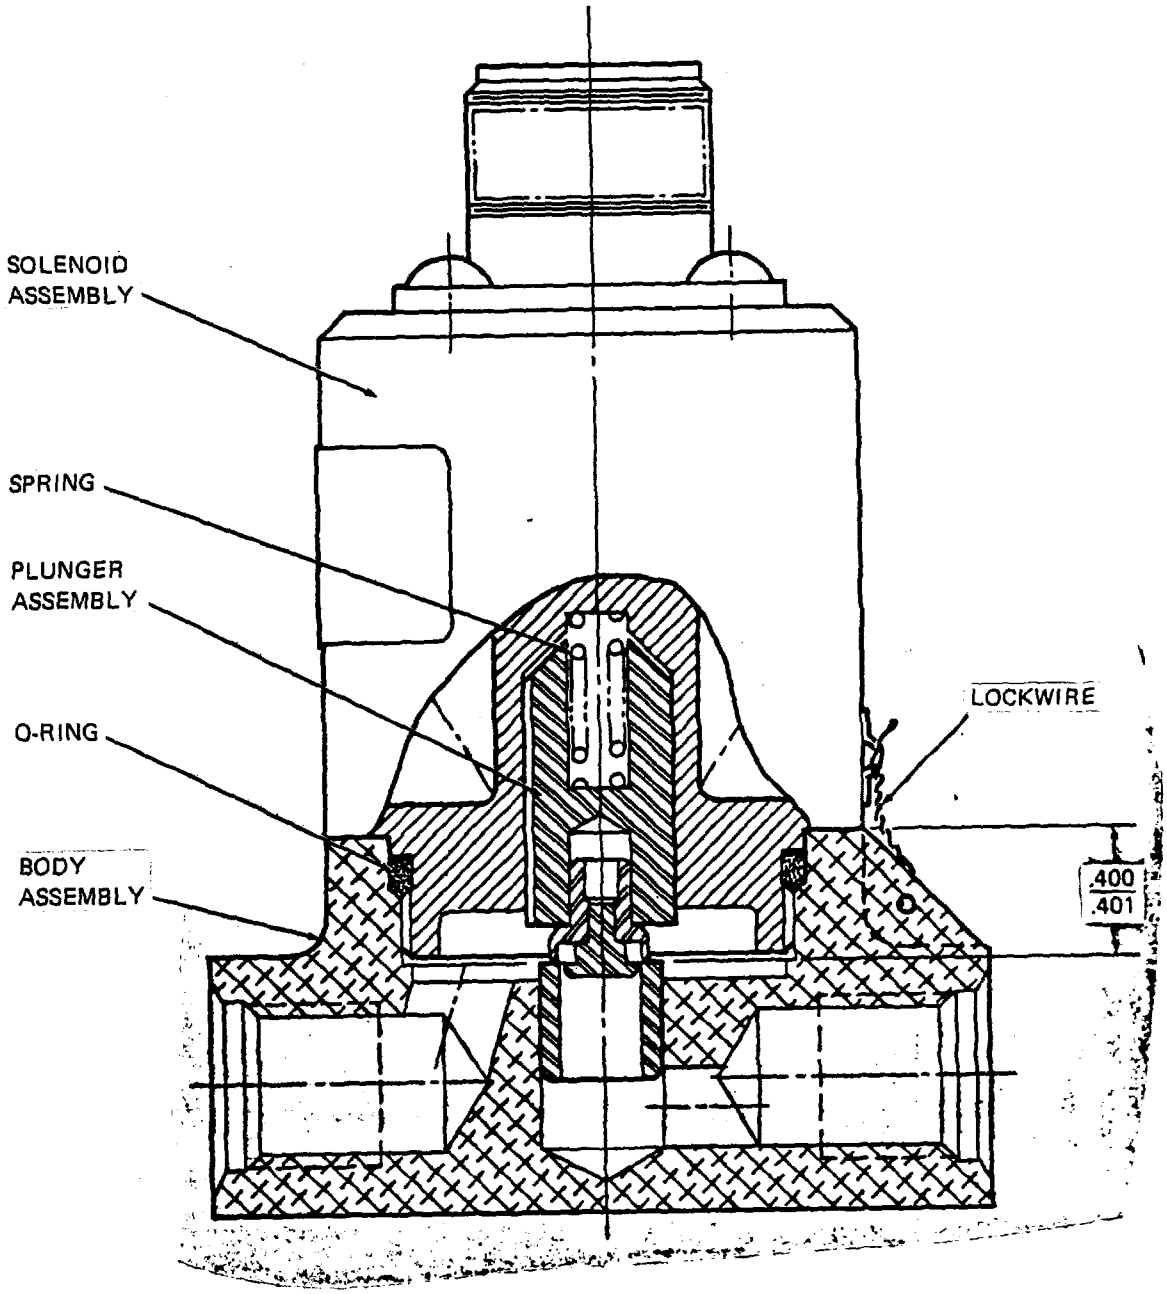

FIGURE 1

Repair Procedure
P/N 15410

ATP-15410

ACCEPTANCE TEST PROCEDURE for WCI P/N 15410

1.0 Scope

This Acceptance Test Procedure defines the test criteria to which each valve must be subjected and passed prior to shipment.

2.0 Test Conditions

Fluid: MIL-F-7024, (Calibration Fluid)
Fluid Temperature: 80°F ±20°F
Ambient Temperature: 75°F ±15°F

3.0 Tests

The following are the tests to be performed and the requirements thereof.

3.1 Examination of Product

The test valve shall be examined against WCI drawing 15410. The valve shall also be examined for defects, flaws and workmanship.

Requirements

The test valve shall meet all of the drawing requirements of 15410. The valve shall have no physical defects or flaws and shall exhibit good workmanship.

3.2 Proof Pressure

With the outlet port capped, and the solenoid energized at 18 VDC ±2 VDC, the inlet pressure shall be set to 77 ±2 psig. This pressure shall be held for a time period of not less than 1 minute while the valve is observed for evidence of external leakage or physical deformation.

Requirements

There shall be no external leakage during this test. Successful completion of the proof pressure test herein shall be constituted by the subsequent successful completion of the performance tests.

3.3 Actuation Voltage

With the test setup in accordance to Figure 1 of this procedure

and the inlet pressure at 50 psig, and the flow set to 380 PPH (60 GPH), the voltage to the solenoid shall be slowly increased from 0 VDC until the valve opens. The voltage at which the valve opens shall be measured and recorded.

Requirements

The opening voltage shall not exceed 15 VDC.

3.4 Pressure Drop

The pressure drop across the opened test valve shall be measured and recorded at a flow of 380 PPH (60 GPH). The pressure drop shall be measured as the gross pressure drop minus the tare pressure drop. Tare pressure drop shall be measured as the pressure drop incurred when the valve is replaced in the same test setup by the equivalent length of .172" dia. (I.D.) tubing.

Requirements

The pressure drop shall not exceed 6.4 psid at 380 PPH.

3.5 Internal Leakage

With the valve closed and the supply pressure set at 50 ±5 psig, the internal leakage shall be measured and recorded after a one minute wait for a period of one minute.

Requirements

The internal leakage as measured over the second minute shall be less than 1 drop in that minute.

3.6 Coil Resistance

The coil resistance shall be measured and recorded at room temperature.

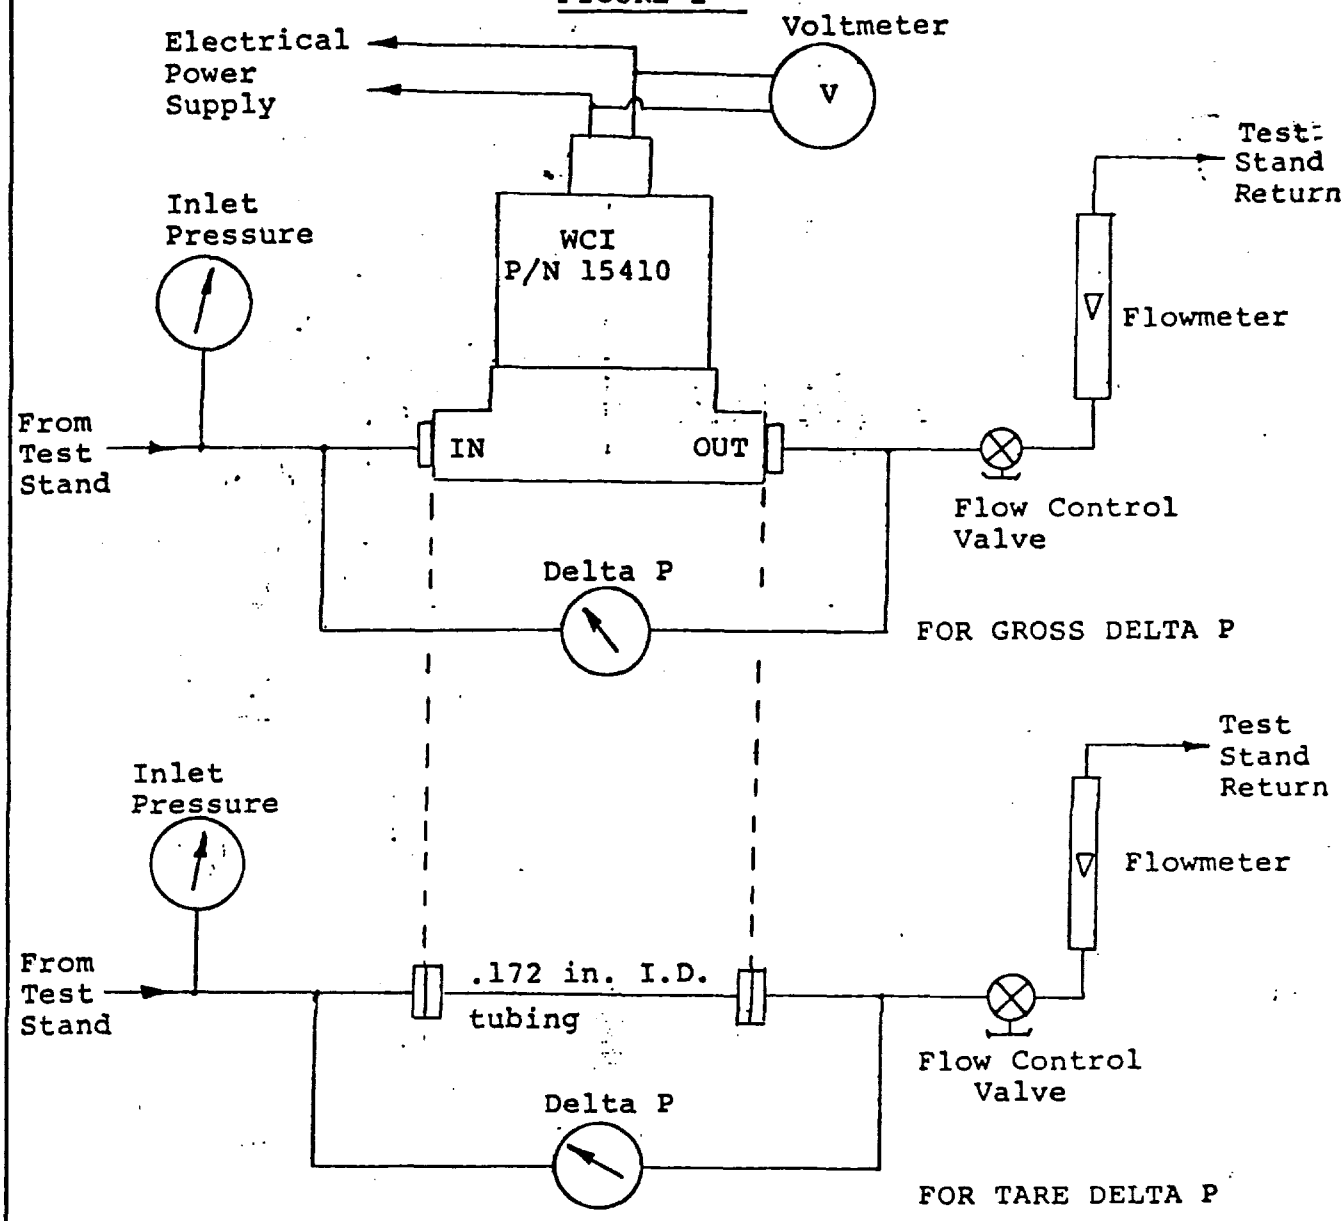
Requirements

The coil resistance shall not be less than 35 ohms at 76°F.

3.7 Insulation Resistance

The insulation resistance of the current carrying pins of the connector and case ground shall be measured and recorded at 500 VDC ±50 VDC. The insulation resistance shall be measured as the current leakage at that voltage.

Requirements



The current leakage at 500 VDC ±50 VDC shall not exceed

500 microamps. (100 megohms max.)

4.0 Preparation for Delivery

The test fluid shall be shaken from the valve fittings and clean plastic port plugs shall be placed on both the inlet and outlet fittings. The valve shall be then placed into a clean plastic bag which shall be appropriately sealed. Each valve shall be placed into a Jiffy-bag and boxed for shipment.

OVERHAUL INSTRUCTIONS WITH PARTS BREAKDOWN

TACHOMETER GENERATOR MODEL 32005-005

ISi® CANADA

AIRCRAFT APPLIANCES & EQUIPMENT LTD.

585 Dixon Road *Rexdale, Ontario, Canada*

DIVISION OF LEAR SIEGLER, INC., POWER EQUIPMENT DIVISION.

PRICE $2.00 PER COPY

INTRODUCTION

This publication contains overhaul instructions and a Group Assembly Parts List for the Tachometer Generator, Model 32005-005. Included are disassembly, inspection, reassembly, lubrication, repair and test instructions. This manual is intended for use by experienced maintenance personnel; therefore, coverage is limited to essentials. All information contained herein is of a general nature. Common shop practices, known and used every day by experienced technicians, have been omitted.

Table 1. Leading Particulars

DISASSEMBLY

Special Tools: The special tools for overhaul of the tachometer generator are listed below. The proper application of each tool is given in the text.

Part Number	Nomenclature
70571-1	Magnet Keeper
70572-1	End Play Checking Fixture
70573-1	Retaining Ring Installation Tool

General: Disassembly procedures should follow the sequence of index numbers on the exploded view illustration. Special instructions are given to procedures which are not apparent in the exploded view.

a. (Figure 1) Remove pins (2) and unsolder ground lead from retaining ring (3). Remove retaining ring (3) by prying up outer edge being careful not to damage ground lead. Remove the paint from the end bell (1) edge and inner surface of the stator housing assembly (12). Press the complete rotor and shaft assembly out of the stator by pressing on the drive end bearing. Disassemble individual parts as indicated except the stator housing assembly (12).

NOTE

The rotor should be placed where it will not pick up metal chips, filings, or other foreign material.

CLEANING PROCEDURE

General: Clean all metal parts except the stator housing assembly with cleaning solvent, Federal Specification P-S-661. Use a bristle brush to aid in cleaning if necessary. Dry parts with filtered compressed air. Do not immerse stator housing assembly in solvent. Blow dust and other foreign particles out of the stator, then wipe with a cloth moistened in the solvent. Scrape loctite from the bearing area.

INSPECTION AND REPAIR

Stator.

a. The stator windings of the generator shall be checked for resistance between phases A, B and C. The resistance measured between phases shall measure 28.0 ohms maximum at 77°F (25°C). The maximum phase resistance variation shall not differ by more than one ohm. Should the stator be defective, replace the stator housing assembly (12).

b. Visually inspect connector insert (13). If defective, replace along with insulation sleeves (15). Visually inspect connector retaining ring (14). If the connector insert (13) is damaged and must be replaced, remove the retaining ring (14) and cut the stator leads close to the connector insert. Place new insulation sleeves (15) over the lead wires, then solder stator leads to terminal pins with high temperature solder (99.8% tin). Slide sleeving over soldered connections and heat shrink the sleeving to size. Place connector insert (13) in the housing and secure with retaining ring (14). Dress the stator leads between stator end turns and housing, secure with RTV 732 adhesive.

NOTE

The leads are identified: "A" - red; "B" - Yellow; "C" - Blue. Solder "A" and "B" to respective connector insert terminal pins.

Rotor: Inspect rotor (11) for damage. Bearing journals and OD of rotor should be concentric with each other within 0.001 total indicator reading. Replace if not within these tolerances.

Bearings: Replace bearings (10) at each overhaul.

Drive Shaft Pin: Replace pin (9) at each overhaul.

Drive Shaft: Replace if damaged.

Retaining Ring: Replace Ring (3) at each overhaul.

Roll Pins: Replace pins (2) at each overhaul.

REASSEMBLY

Procedure: Refer to figure 1 for relative position of component parts. Special notes are as follows:

a. When installing the bearings (10), make sure that the grooves are facing away from the rotor magnet. Insert 1/8" length of Super Mil ASU M100 grease as a plug in the drive end hole of the rotor shaft. Insert the drive shaft into the rotor shaft. Install the drive shaft pin (9) making sure that the open side of the roll pin is facing the rotor magnet and that the ends of the roll pin protrude an equal amount on each side of the rotor shaft.

b. Clean and lightly prime bearing outer race (drive end) and the portion of the housing where the bearing seats with Locquic grade N primer. Do not handle primed surfaces.

c. Fully magnetize the rotor with the poles of the rotor and magnetizer aligned, then slide the rotor into the magnet keeper P/N 70571-1 and install in unit making sure not to take the

rotor through air. The magnet keeper is designed to fit on the end of the stator housing assembly with the protruding barrel down inside the stator windings. Any suitable commercial magnetizer can be used.

NOTE

To insure minimum harmonic output of the generator, the rotor must be correctly aligned when being magnetized. Use a compass or other suitable means to locate the polarity and the centre of the rotor poles for proper alignment.

d. Place end-play checking fixture P/N 70572-1 on the end of the stator housing assembly to determine the number of shims required. See table below.

End Play Fixture Reading	No. of Shims Required
.0000 - .0050	0
.0051 - .0150	1
.0151 - .0250	2
.0251 - .0350	3
Over .0351	4

e. Using Super Mil ASU M100 grease, attach the bearing lock (6) to exposed bearing making sure that the dogs enter the slots in the bearing. Dress blue lead "C" up through the hole in the end bell. Use the same type of grease to hold the shim(s) (4) and then wavy washer (5) in place in the end bell (1) while installing the end bell. Be sure that the key on the bearing lock (6) enters the slot in the end bell (1) and that it does not slip out of the slots in the bearing. Install the end bell.

f. Push the rotor assembly (7) along with the end bell partially out of position (1/8" approx.) Place 3 small drops of loctite, Hot Strength 306 adhesive on the bearing surface of the housing. Push the rotor assembly and the end bell into their proper position. Clean excess adhesive off of the bearing and housing with a clean, dry cloth. Be sure no loctite is permitted to enter the bearing.

g. Press in retaining ring (3) with retaining ring installation tool P/N 70573-1. Be careful not to damage the ground lead.

h. Prior to grounding the "C" lead, make an insulation breakdown test. Apply a potential of 250 volts AC, 60 cycle for five seconds between the individual electrical pins and the metal parts of the stator housing. There shall be no breakdown of insulation during this test.

i. Solder the ground lead "C" to the retaining ring (3) with high temperature solder (99.8% tin).

j. Press the roll pins (2) in the housing.

k. Paint all exterior surfaces except the mounting pad and the connector threads with 1 coat of Sherwin Williams primer E42AP7 with V66KP15 converter, and 1 coat of Enamel, black F55BP12 with V66KP11 converter.

TEST PROCEDURE

Standard Test Conditions: Unless otherwise specified, standard test conditions shall be 77°F (25°C). Voltages shall be measured with rms indicating instruments which draw no appreciable current (1000 ohm per volt min.) and which are free from frequency errors.

Phase Rotation: Connect the tachometer generator to a suitable phase rotation indicator and check the phase rotation. Correct phase sequence shall be B-A-C when the generator drive shaft is rotated in a counter-clockwise direction (viewed from the drive shaft end).

Performance Tests.

a. Connect the tachometer generator to a load of three resistances as directed in Table II. While operating the generator at 4200 rpm, short circuit the generator output 5 times for 1 second on and 4 seconds off. Drive the generator at the speed given and check to see that the output voltage is within limits per Table II.

b. If output voltage is below the minimum limits, the rotor must be removed from the stator housing assembly and remagnetized per paragraph "c" under REASSEMBLY.

c. If the output voltage exceeds the maximum limit, use the following procedure to calibrate the generator output voltage.

Use a variable 0-50 volt 60Hz 50 VA power supply that is isolated from the ground. Connect the supply to leads A and B of the tachometer generator through a momentary push button switch which will also disconnect the load bank and voltmeter when depressed.

Adjust the supply to zero and operate the generator at 4200 rpm. Keep pulsing the 60Hz power into the generator while slowly increasing the supply voltage until the generator output voltage is seen to drop. Recheck the generator rated output and if still too high, repeat the discharge procedure.

Table II. Performance Test Data

GENERATOR RPM (Drive Shaft Speed)	LOAD RESISTORS	LOAD (OHMS) EACH RESISTOR	CONNECTION LOAD	EACH TERMINAL VOLTAGE (VOLTS) Measured At Generator Terminals
4,200	3	40	Y	21 ± 0.5
1,000	3	20	Y	3.5V Min.

DATA DIFFERENCE SHEET 22

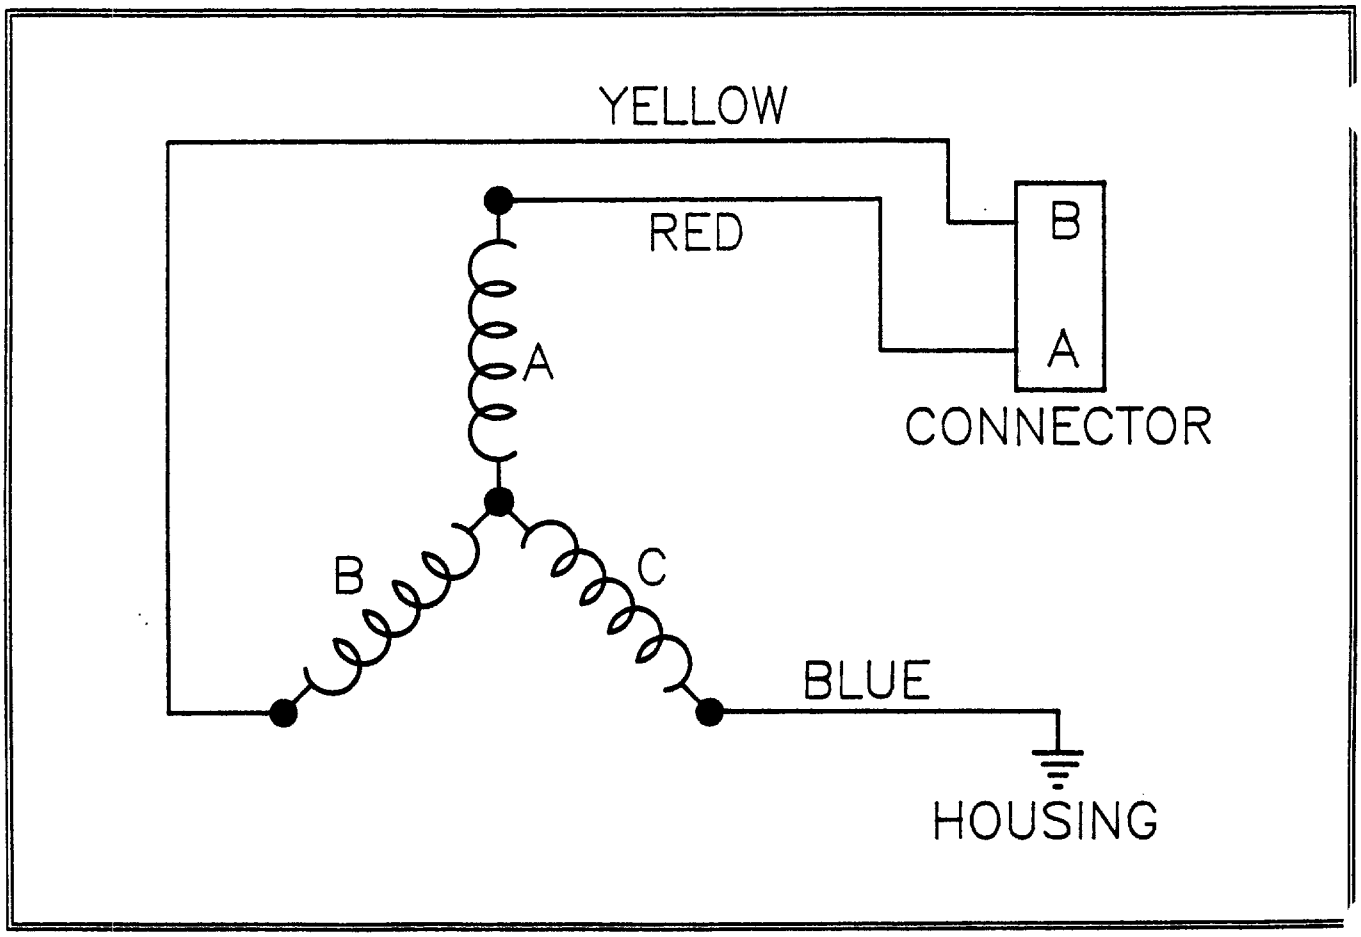
PART 1

DESCRIPTION AND OPERATION

GENERAL

1. This publication contains overhaul instructions and a Group Assembly Parts List for Aircraft Appliances & Equipment Limited Tachometer Generator Models 32005-007, -008, -023,-025, -026, -030, -034 and -037. The manual describes the overhaul instructions for the model 32005-007. The differences in overhaul instructions between this model and the other models are described in Part 9 - DATA DIFFERENCE SHEETS.

THEORY OF OPERATION



2. Tachometer generators are used in aircraft for the purpose of providing an indication of engine speeds. The tachometer generator is mounted on the accessory pad of each engine and is connected electrically with one or two associated synchronous motor indicators (not supplied with the generator). The indicators are located on the aircraft instrument panels.

3. As the rotor of the tachometer generator is turned by the engine, the magnetic field created by the rotor's permanent magnet rotates in the stator and induces an electromotive force or voltage in the three-phase stator windings. The frequency of the output voltage is directly proportional to drive speed. Since the indicators used with the tachometer generators are frequency sensitive, an accurate means of determining engine speeds is thereby provided. The generated voltage at any speed need only be above the minimum value necessary to actuate the indicator. Table 1-1 shows the Leading Particulars for the tachometer generator. The schematic diagram of the tachometer generator can be seen in Figure 1-1.

TABLE 1-1 LEADING PARTICULARS

Weight, (approx. pounds)	.97
Rotation (viewed from drive end)	CCW or CW
Phase	3
Phase Rotation CCW	B-A-C
CW	A-B-C

FIGURE -1-1 SCHEMATIC DIAGRAM

PART 2

DISASSEMBLY

PROCEDURE

1. Remove three roll pins (Figure 8-1, Item 2) from endbell (1) using a drive pin punch (see Table 7-1, Item 1), discard roll pins.

2. Press rotor assembly (5) and endbell (1) out of stator housing assembly (11) by pressing on the driveshaft end.

3. Remove the endbell (1) from the rotor assembly (5). Remove shims (3) and spring washer (4) from the endbell. Discard shims (3) and spring washer (4).

4. Remove the bearings (8) from the rotor assembly using a suitable bearing puller, discard bearings (8).

5. Remove sleeving (9) from the rotor shaft. Using a drive pin punch (Table 7-1, Item 1) remove drive shaft pin (7) discard pin (7) and sleeve (9). Remove drive shaft.

6. Do not disassemble stator housing assembly (11) unless a defect is detected. If necessary disassemble and repair the stator housing assembly as per Part 4.

PART 3

CLEANING PROCEDURE

GENERAL.

1. Clean all metal parts except the stator assembly with cleaning solvent, Federal Specification P-D-680. Use a bristle brush to aid in cleaning if necessary. Dry parts with filtered compressed air. Do not immerse stator assembly in solvent. Blow dust and other foreign particles out of the stator, then wipe with a cloth moistened in the solvent.

2. Remove any metal particles attracted to the rotor by the permanent magnet.

PART 4

INSPECTION AND REPAIR

INDIVIDUAL COMPONENT INSPECTION

1. Perform inspection of individual components in accordance with Table 4-1

TABLE 4-1

Part List Item Figure 8-1	Description	Inspection
11	Stator, Housing Assembly	The stator windings of the generator shall be checked for resistance between Phases A, B and C. The resistance measured between phases shall measure 28.0 ohms maximum at 77°F(25°C). The maximum phase resistance variation shall not differ by more than one ohm from each other. Perform dielectric test in accordance with paragraph 2. Inpsect bearing bore of housing for wear. Diameter must be within 0.7502/+0.0004/-0.0000 inches. Replace if defective.
1	Endbell	Inspect bearing bore of endbell for wear. Diameter must be within 0.7502/+0.0004/ -0.0000 inches. Replace if defective.
10	Rotor	Check pin hole in shaft for evidence of excessive wear. Bearing journals and O.D. of rotor should be concentric with each other within 0.001 total indicator reading. Inspect bearing journal diameter for wear. Diameters must be within 0.2502 /+0.0000/ -0.0002 inches. Replace if defective.
6	Shaft, Drive	Inspect drive shaft surface for cracks, excessive wear on square drive section or pin hole. Replace if defective.
13	Connector, Insert	Visually inspect the receptacle. Replace if defective in accordance with instructions below.
-	Miscellaneous Parts	Visually inspect remaining parts. Replace if defective.

NOTE

Item 10 will have surface imperfections from the casting process. These should not be mistaken for defects. The rotor magnet casting should be inspected visually for cracks, chips or looseness to the shaft.

STATOR DIELECTRIC TEST

2. In order to perform a dielectric test, the ground ring (12) must not be in contact with the housing. To remove the ground ring first remove any RTV732 adhesive which is on the ground ring.

NOTE

Phase C (blue leadwire) leadwire is soldered to the ground ring. Do not damage the soldered joint when removing the RTV732 adhesive.

3. - Pull the ground ring out of the housing.

4. Once removed support the ground ring on a non-conductive surface so that it is not in contact with the housing.

5. Apply a potential of 250 volts AC, 60 Hz for five seconds between the individual electrical pins and the metal parts of the stator housing. There shall be no evidence of insultation breakdown during this test.

NOTE

If the dielectric tester has an adjustable trip setting, set the trip at 5 mA.

6. Reinstall the ground ring in the housing. Press the stator leadwires between the end turns and the housing. Secure the leadwires with RTV732 adhesive.

NOTE

Ensure that the RTV732 adhesive does not extend above the ground ring and prevent improper seating of the endbell against the ground ring.

REPAIR

7. Repair is limited to replacement of the stator housing assembly (11) connector insert (13). The stator winding is permanently fixed to the housing and is not repairable.

8. If the connector insert (13) is damaged and must be replaced remove the retaining ring (14) and pull the connector insert up and out of the housing. Cut the stator leads close to the connector insert. Place new insulation sleeves (15) over the leadwires, then solder the stator leads to the terminal pins with high temperature solder, Sn95Sb05, Kester P/N 24-0001-0027 or equivalent.

NOTE

The leadwires are identified "A" - red; "B" - yellow; "C" - blue; solder "A" and "B" to respective connector insert terminal pins.

9. Slide sleeving over soldered connections and head shrink the sleeving to size. Place connector insert in the housing and secure with retaining ring (14).

10. Perform dielectric test in acordance with the procedure above.

PART 5

REASSEMBLY

ROTOR REASSEMBLY

1. Slide sleeve (Figure 8-1, Item 9) over rotor shaft drive end. Roll sleeve back on itself so as not to cover drive shaft pin hole. Press bearings (8) onto rotor shaft (10). Insert a 1/8" length of grease P/N 13CF (MIL-G-25013E), manufactured by Royal Lubricants, as a plug in drive end hole of rotor shaft. Insert the drive shaft (6) into the rotor shaft. Install the drive shaft pin (7) making sure that the open side of the roll pin is facing the rotor magnet and that the ends of the roll pin protrude an equal amount on each side of the rotor shaft. Grease the rotor shaft pin hole until the grease purges out between drive shaft and rotor shaft. Roll sleeve (9) over drive pin and position 1/32 inch from the bearing.

NOTE

Check the flexability of the drive shaft (6) of Rotor assembly (5) per paragraphs 2 and 3. If out of limits, replace the defective parts.

2. The face of the shaft shall be free to move 0.016 inch in any direction about the centre line of the rotor. The free axial play shall not exceed 0.021 inch.

3. The shaft rotational backlash about its longtudinal axis shall not exceed 10 angular degrees.

4. Fully magnetize the rotor with the poles of the rotor and magnetizer (Table 7-1, Item 3) aligned, then slide the rotor into the magnet keeper (Table 7-1, Item 2) and install in stator housing assembly making sure not to take the rotor through air. The magnet keeper is designed to fit on the end of the stator housing assembly with the protruding barrel down inside the stator windings.

NOTE

To ensure minimum harmonic output of the generator, the rotor must be correctly aligned when being magentized. Use a compass or other suitable means to locate the polarity and the centre of the rotor poles for proper alignment.

5. Determine the proper number of shims (3) required using the SHIMMING PROCEDURE, paragraphs 8 to 13.

6. Using grease, P/N 13CF, to hold shims (3) and spring washer (4) in place, install end bell (1). Rotate end bell 15° approximately so as to misalign existing pin holes and drill three new holes (.078/.081 dia.) using existing holes in housing as pilots. Install three roll pins (2).

NOTE

Make sure that the end bell is properly seated before drilling. Do not enlarge existing holes in housing.

7. Paint all exterior surfaces except the mounting pad and the connector threads with 1 coat of a good commercial black enamel.

SHIMMING PROCEDURE

8. Shims (3) are used so that the spring washer (4) will always be compressed the same amount and therefore always provide a fixed axial preload on the bearings.

9. The number of shims required can be determined using one of the two methods below.

METHOD A

10. Push shimming fixture (Table 7-1, item 4) into the back of the housing until it firmly seats against the ground ring, see Figure 5-1. The fixture will center the bearing and rotor.

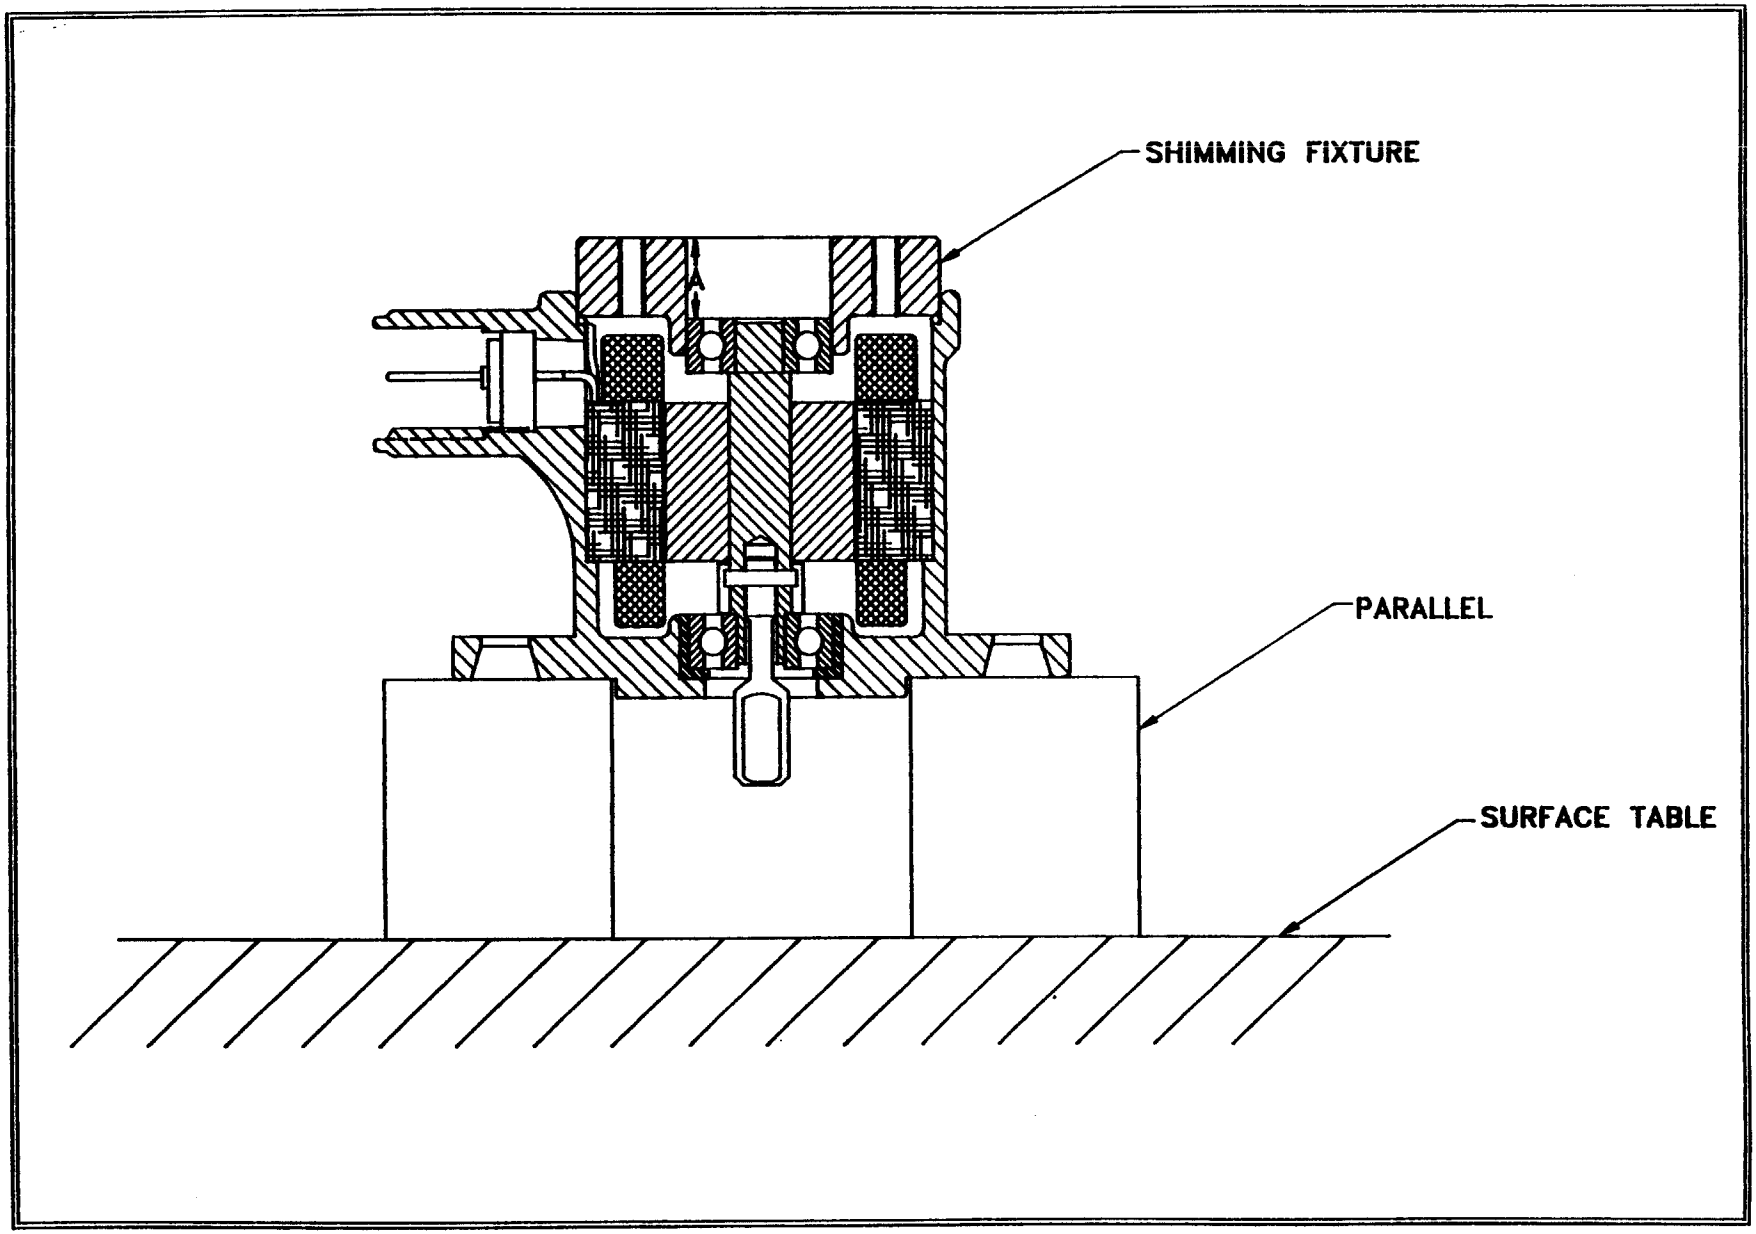

FIGURE 5-1

11. Using a depth micrometer, measure dimension A at four equally spaced postions around the outside of the bearing. Calculate the average of the four measurements and use Table 5-1 to determine the number of shims (3) required.

12. Two #4-40 screws can be installed in the shimming fixture to facilitate removal from the housing.

METHOD B

13. Place end play checking fixture (Table 7-1, item 5) on the end of the stator housing assembly, ensure that the fixture is seated against the ground ring (12). Apply the reading on the end play checking fixture to Table 5-2 to determine the number of shims (3) required.

NOTE

The end plug checking fixture (Table 7-1, item 5) should be zeroed each time prior to use. Place the end play checking fixture on the zeroing fixture (Table 7-1, item 6) and adjust the indicator dial to zero.

TABLE 5-1

DIMENSION A (INCHES)	NUMBER OF SHIMS REQUIRED
0.4300 - 0.4350	0
0.4351 - 0.4450	1
0.4451 - 0.4550	2
0.4551 - 0.4650	3
OVER 0.4651	4

TABLE 5-2

END PLAY FIXTURE READING	NUMBER OF SHIMS REQUIRED
0.0000 - 0.0050	0
0.0051 - 0.0150	1
0.0151 - 0.0250	2
0.0251 - 0.0350	3
OVER 0.0351	4

PART 6

TEST PROCEDURE

STANDARD TEST CONDITIONS

1. Unless otherwise specified, standard test conditions shall be 77°F (25°C). Voltages shall be measured with rms indicating instruments which draw no appreciable current (1000 ohm per volt min.) and which are free from frequency errors.

PHASE ROTATION TEST

2. Connect the tachometer generator to a suitable phase rotation indicator and check the phase rotation. Correct phase sequence shall be B-A-C when the generator drive shaft is rotated in a counter clockwise direction (viewed from the drive shaft end).

PERFORMANCE TEST

3. Connect the tachometer generator to a load comprised of three resistors as directed in Table 6-1. While operating the generator at 4200 rpm, short circuit the generator output 5 times for 1 second and 4 seconds off. Drive the generator at the speed given and check to see that the output voltage is within limits of Table 6-1.

4. If the output voltage is below the minimum limits, the rotor must be removed from the stator housing assembly and remagentized per paragraph 4 under REASSEMBLY.

5. If the output voltage exceeds the maximum limit, use the following procedure to calibrate the genrator output voltage.

CALIBRATION PROCEDURE

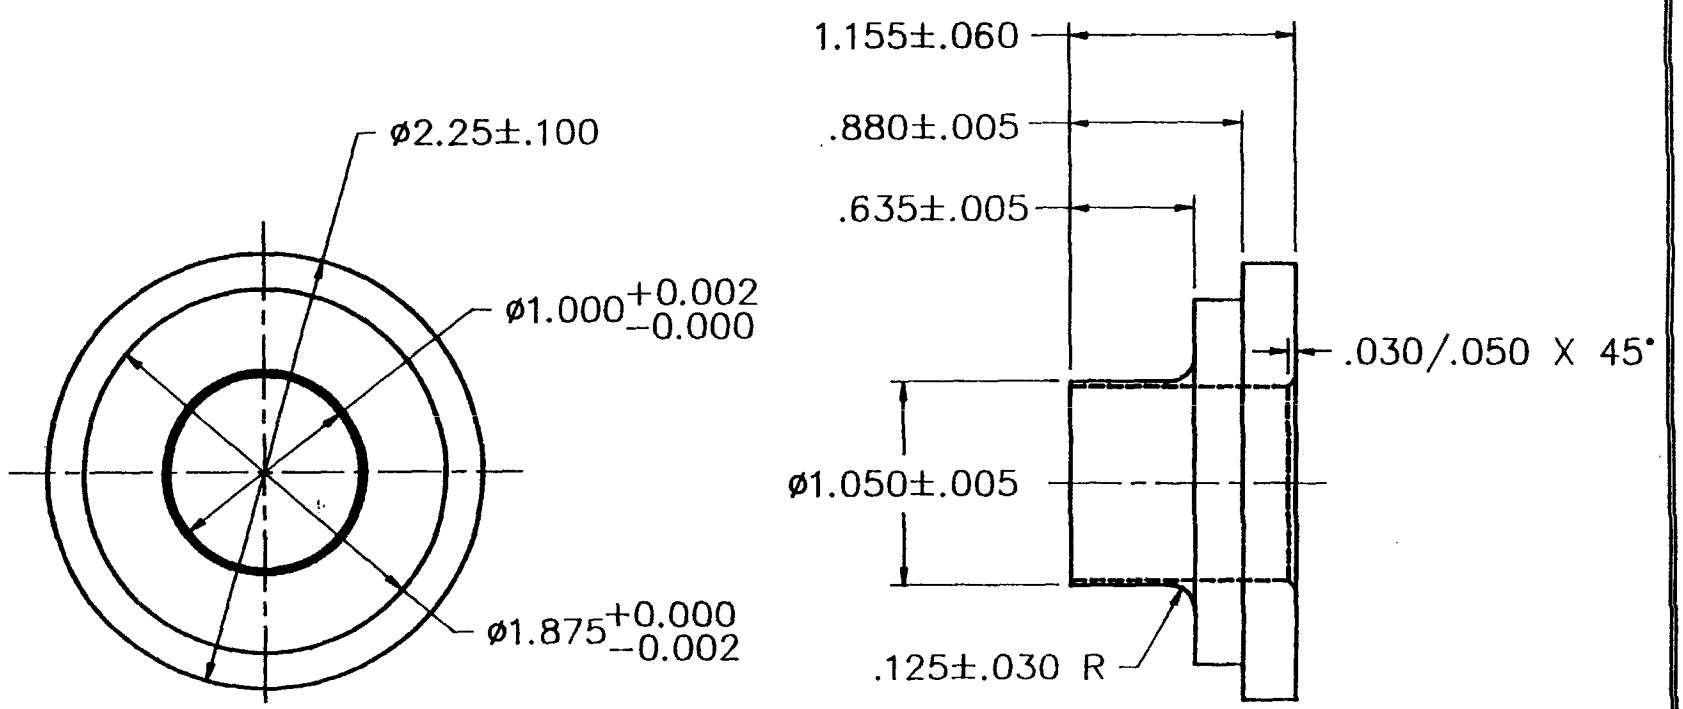
6. Use a variable 0-50 volt, 60 Hz, 50 VA minimum power supply that is isolated from the ground. Connect the supply to leads A and B of the tachometer generator through a momentary push button switch which will also disconnect the load bank and voltmeter when depressed.

7. Adjust the supply to zero and operate the generator at 4200 rpm. Keep pulsing the 60 Hz power into the generator while slowly increasing the supply voltage until the generator output voltage is seen to drop. Recheck the generator rated output and if still too high, repeat the discharge procedure.

TABLE 6-1 PERFORMANCE TEST DATA

GENERATOR RPM (Drive Shaft Speed)	LOAD RESISTORS	LOAD (OHMS) EACH RESISTOR	LOAD CONNECTION	EACH TERMINAL VOLTAGE (VOLTS) Measured at Generator Terminals
4,200	3	40	Y	21 ± 0.5
1,000	3	20	Y	3.5V Min.

PART 7



SPECIAL TOOLS

GENERAL

1. Table 7-1 lists the special tools required for repair/overhaul of the tachometer generator.

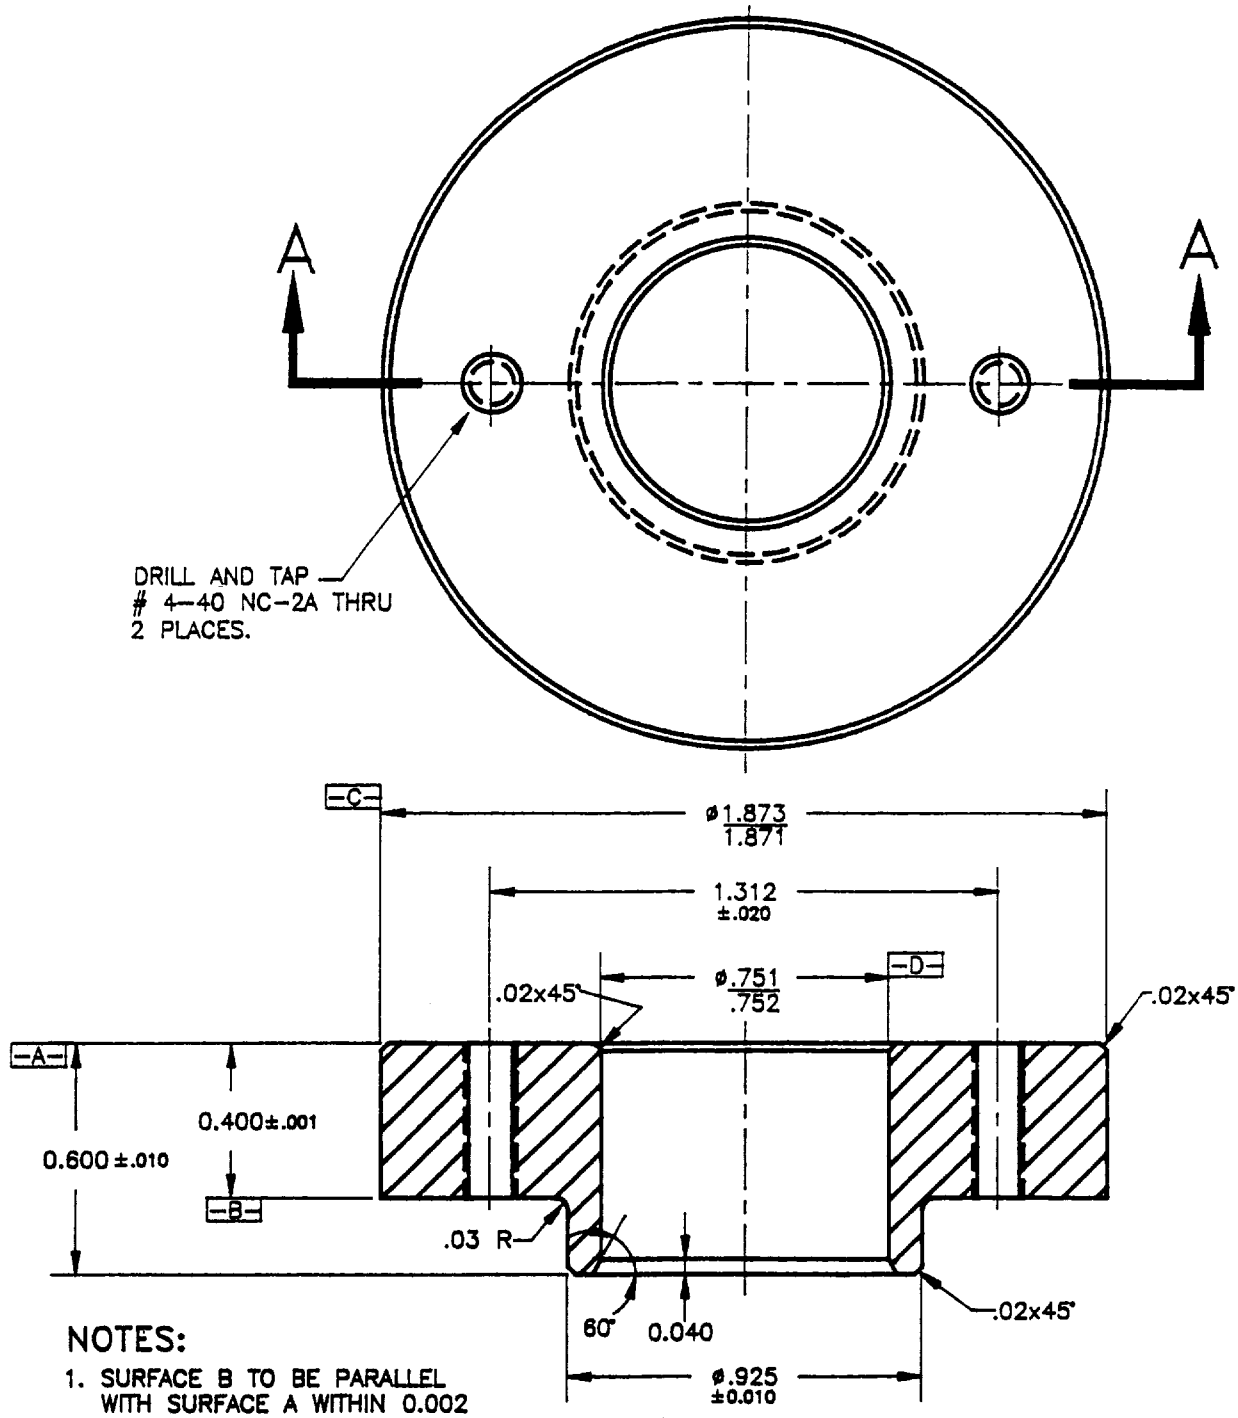


TABLE 7-1

ITEM	TOOL PART NUMBER	DESCRIPTION	SOURCE OF SUPPLY	FIGURE NUMBER

PART 9

DATA DIFFERENCE SHEET

GENERAL

1. The following Data Difference Sheets describe the difference in repair/overhaul instructions for the models 32005-008, -023, -025, -026, -030, -034, and -037.

TACHOMETER GENERATOR 32005 SERIES	
DATA DIFFERENCE SHEET	MODEL 32005-008

DESCRIPTION AND OPERATION

1. Same as for Model 32005-007 except the connector is located at the back of the generator and overall length is 3.82 inches.

DISASSEMBLY

2. Same as for Model 32005-007 except after removing the three roll pins (2) remove the receptacle mounting bracket (14) and the RTV insulation from the rear of the endbell (13) before removing the endbell.

CLEANING

3. Same as for Model 32005-007.

INSPECTION AND REPAIR

4. - Same as for Model 32005-007 except generators with Serial Number 95292 or less have not been modified with the new ground ring (12); therefore if the stator housing assembly is defective, and replaced with a new housing, install a new ground ring (12). Leave the ground lug (18) in place but do not connect the stator lead to the lug.

5. If the stator housing assembly is not damaged, caution must be used to prevent the end bell from touching the stator housing when performing the dielectric test. Also, generators with Serial No. 95292 or less without the letter "R" stamped after the serial number must be modified per Service Bulletin #165 Rev. A.

6. Visually inspect receptacle mounting bracket assembly (1). If defective, replace along with insulation sleeves (20). Cut the stator leads close to the receptacle terminal pins.

TACHOMETER GENERATOR 32005 SERIES	
DATA DIFFERENCE SHEET	MODEL 32005-008

REASSEMBLY

7. Same as for Model 32005-007 except after rotating end bell assembly and drilling 3 new pin holes, remove receptacle mounting bracket (14), deburr holes and blow out loose metal chips.

TEST PROCEDURE

8. Same as for Model 32005-007.

SPECIAL TOOLS

9. Same as for Model 32005-007.

TACHOMETER GENERATOR 32005 SERIES	
DATA DIFFERENCE SHEET	MODEL 32005-023

DESCRIPTION AND OPERATION

1. Same as the model 32005-008 except overall length is 3.97 inches.

DISASSEMBLY

2. Same as the model 32005-008.

CLEANING

3. Same as the model 32005-008.

INSPECTION AND REPAIR

4. Same as the model 32005-008.

REASSEMBLY

5. Same as the model 32005-008.

TEST PROCEDURE

6. Same as the model 32005-008.

SPECIAL TOOLS

7. Same as the model 32005-008.

TACHOMETER GENERATOR 32005 SERIES	
DATA DIFFERENCE SHEET	MODEL 32005-025

DESCRIPTION AND OPERATION

1. The 32005-025 tachometer genrator is the same as the 32005-007 except that the tach generator uses a special drive shaft that has a nylon square driving surface This nylon bushing can be removed and replaced with a new piece when worn or cracked without disassembling the tach generator.

DISASSEMBLY

2. Same as the model 32005-007.

CLEANING

3. Same as the model 32005-007.

INSPECTION AND REPAIR

4. Same as the model 32005-007 except use the following procedure to replace damaged nylon Bushings:

a) Remove the old nylon square material. Clean any adhesive or bonding agent which may be adhered to the stainless steel drive, using any chlorothene or a cleaner which will not leave a residue when dry.

b) Apply Loctite Activator No. 7075 to the drive shaft, wait five minutes. Apply Loctite Adhesive No. 325 to the nylon bushing.

c) Slide new nylon bushing quill onto shaft.

d) Allow 48 hours for full cure.

THE BENDIX CORPORATION – FLIGHT AND ENGINE INSTRUMENTS DIVISION

OVERHAUL INSTRUCTIONS WITH PARTS BREAKDOWN

7749-121A5-1 and 7749-122A5-1

NEW PART NO. 3567749 - 7103

1. Description and Operation.

The 7749-121A5-1 and 7749-122A5-1 transmitters are hermetically sealed, bellows type instruments. They are used in conjunction with remotely located indicators to provide a visual indication of engine oil pressure. The instruments are designed to be mounted directly on the engine.

The shaft of the Autosyn in the transmitter is linked, by means of a rocker arm and a sector assembly, to the bellows assembly in such a manner that a rotary displacement of the shaft will be produced when pressure variations cause the bellows to deflect.

The Autosyns of the transmitters are electrically connected to remotely located indicators which translate the bellows deflection into visual indications of the pressure at the point of measurement.

Table 1. Leading Particulars

Pressure Range	
7749-121A5-1	0 to 65 psi
7749-122A5-1	0 to 125 psi
Temperature Range	-54°C to +165°C (operating) -54°C to +232°C (exposure)
Power Requirements	26VAC 400 Hz
Accuracy	Approx. 1% of full scale
Vibration	20g to 2000 Hz

2. Disassembly

A. Disassemble the transmitter according to the following procedure: (Refer to figure 1.)

(1) Remove screw (1) and identification plate (2).

(2) Cut off evacuation tube in end cover assembly (6) just below point where it is pinched off. With electrical receptacle end of transmitter held down, apply just enough air pressure to evacuation tube to force silicon fluid from transmitter when pressure is released.

(3) Mount transmitter in a lathe and machine away weld on both ends of case. Place transmitter, receptacle end down, in a suitable container to allow remaining fluid to drain from case.

(4) Remove mechanism from transmitter case (5).

(5) Disconnect leads from receptacle in end cover assembly (6).

(6) Capillary tubing from vent bellows assembly (45) is connected to

capillary tubing from end cover assembly (6) by a silver brazed joint. Shield from mechanism as necessary and, using a torch, melt silver braze to separate ends of tubing.

(7) Separate capillary tubing from pressure bellows assembly (48) in the same manner as described in step (6).

(8) Remove slotted head screw (3) and eccentric bushing (4) from end cover assembly (6).

(9) Remove spacer posts (8) and lock washers (9).

(10) Remove screws (10), lock washers (11) and special washers (12) to free mechanism assembly (7).

(11) Remove screws (13), lock washers (14), washers (15), spring clamps (16) and washers (17).

(12) Loosen screws (19 and 21) and slide bearings (18 and 20) away from pivots of sector assembly (22).

(13) Remove screws (25) and lock washers (26) and remove synchro retainer (24).

(14) Remove screws (28), lock washers (29) and flat washers (30).

NOTE: Do not remove nut (32) and spur pinion (33) unless necessary to replace a damaged or worn part.

(15) Remove tubing (35) from leads of synchro (34).

(16) Remove support posts (36).

(17) Remove screws (38) and lock washers (39) from torsion bar clamps (37).

(18) Remove bearing holder (40), bearings (41) and bearing spacer (42) from rocker arm assembly (49).

(19) Remove hex nut (43) and overpressure screw (44) from pressure bellows (48).

(20) Remove screws (46) and lock washers (47) to free vent bellows assembly (45) and pressure bellows assembly (48).

3. Cleaning

A. Cleaning parts of transmitter according to the following instructions:

WARNING: USE SOLVENT IN A WELL VENTILATED AREA. DO NOT INHALE SOLVENT

VAPORS OR ALLOW SOLVENT TO COME IN CONTACT WITH THE SKIN. KEEP SOLVENT AWAY FROM OPEN FLAME.

CAUTION: DO NOT IMMERSE SYNCHRO ASSEMBLY (34) IN SOLVENT OR ALLOW SOLVENT TO ENTER INTERIOR OF SYNCHRO.

(1) Clean all metal parts with naptha or an approved solvent.

(2) Clean exterior of synchro assembly (34) with a cloth moistened in naptha. Make certain that leads are clean.

(3) Clean teeth of sector assembly (22) and intermeshing teeth of spur pinion (33) with a stiff hair brush or glass fiber brush. Make certain that teeth are free from burrs and foreign matter.

4. Inspection/Check.

A. Inspect transmitter assembly according to the following instructions:

(1) Inspect all parts for visible wear, damage or defects.

(2) Inspect washers for scratches, scoring or damage.

(3) Inspect threads for stripping or burrs.

(4) Inspect end cover assembly (6) for broken, bent or loose terminal pins, damaged or loose insulation and defective threads.

(5) Inspect synchro assembly (34) for crimped, broken or worn leads at point of entry into synchro housing.

(6) Inspect bellows assemblies (45 and 48) for dents, cracks or deformed bellows.

5. Repair.

No repair of parts is recommended. Replace any parts that inspection discloses to be defective.

6. Assembly.

A. Assemble the transmitter according to the following instructions:

(1) Braze tubing from pressure bellows assembly (48) to mounting base (50). Wash to remove flux.

(2) Assemble bellows assemblies (45 and 48) to rocker arm assembly (49) using screws (46) and lock washers (47).

(3) Bend capillary tubing to align torsion bar of rocker arm assembly (49) with "V" grooves in mounting base (50).

(4) Place bearings (41) and bearing spacer (42) in bearing holder (40) and position on end of torsion bar.

(5) Fasten torsion bar in place using torsion bear clamps (37), lock washers (39) and screws (38). Do not tighten screws. Pull clamps down evenly.

(6) Install four support posts (36).

CAUTION: DO NOT ROTATE SYNCHRO (34) IN COUNTERCLOCKWISE DIRECTION, NOR IN CLOCKWISE DIRECTION MORE THAN 1¼ TURNS FROM REST POSITION. SYNCHRO SPRING MAY BE DAMAGED.

(7) If spur pinion (33) and nut (32) were removed, reassemble using a sealant, MS22473, Grade E, to lock nut in place.

(8) Assemble synchro (34) eccentric ring (27) and synchro retainer (24) using screws (25) and lock washers (24).

(9) Clamp assembled synchro and eccentric ring to supporting plate (31) with screws (28), lock washers (29) and flat washers (30).

(10) Position sector assembly (22) in null adjust arm (23). Tighten socket head screw (19) to hold bearing (19) in place. Adjust bearing (20) for end play of 0.002 to 0.004 inch. Tighten socket head screw (21).

(11) Fasten null adjust arm assembly to supporting plate (31) using screws (13), lock washers (14), washers (15), spring clamps (16) and block clamps (17). Adjust mesh for minimum friction. Backlash must be less than 2.5^{o} maximum synchro rotation.

(12) Bake assembly completed to this point at 450^{o} for 2 hours.

(13) Position mechanism assembly (7) on supporting posts (36) and assemble spacer posts (8) and lock washers (9). Pin on end of rocker arm assembly (49) must be positioned between pins of sector assembly (22).

(14) Hold transmitter assembly so that it is viewed from receptacle end. Position pin of rocker arm assembly (49) at left side of slot in supporting plate (31). With rocker arm assembly in this position securely tighten screws (38) to secure torsion bar clamps (37).

(15) Silver braze tube from vent bellows assembly (45) to tube in end cover assembly (6).

(16) Adjust pin assembly on rocker arm assembly (49) for minimum possible clearance that will not cause excess friction. Clearance is to be 0.002 inch maximum.

(17) Connect mechanism to synchro servoed test indicator 13647-3-A with test cable QB72260-1. Attach pressure fitting to dead weight tester type 460.

(18) Set and lock range adjustment at an initial setting.

(19) Rotate the synchro to a point where low end of range is 20^{o}.

(20) Apply rated pressure to pressure fitting and check indicator reading. (See table 2. Calibration data) If adjustment is required, move range pin out to increase range and in to decrease range.

(21) Return pressure to zero psi and check. Synchro and/or range adjustment may require slight additional adjustment to obtain the 20^{o} to 340^{o} range.

(22) Check all points of calibration indicated in table 2. If necessary, reposition rocker arm slightly to obtain a linear calibration. For a small amount of movement use shim (12) or for larger amount move torsion bar of rocker arm assembly (49). Move rocker arm assembly "downscale" to raise midscale readings and "upscale" to lower midscale readings.

(23) Set overpressure stop (screw 44) at 360^{o} with 10% to 20% overpressure applied and lock in place with hex nut (43).

(24) Bake unit at 450^{o} for 4 hours. At end of period apply rated pressure to unit and check for proper operation.

(25) Assemble tubing (35) over synchro wires and solder synchro wires to receptacle terminals as shown in table 4. wiring data.

(26) Slide case (5) carefully over mechanism from mounting base (50) end.

NOTE: Be sure that null adjust mechanism is engaged and wiring is clear of moving components.

(27) Tack weld case (5) to end cover (6) in 3 or 4 spots and adjust mechanism so that zero travel of 20^{o} in both directions can be obtained.

(28) Tack weld mounting base (50) to cover in 3 or 4 spots.

(29) Check calibration of transmitter for proper function.

(30) If all functions are normal, complete welding operations using a Heliarc Welder or equivalent.

(31) After welding recheck zero travel for $+7^{o}$ minimum travel.

(32) Evacuate transmitter to 500 microns pressure or less and backfill.

with silicone fluid until transmitter weighs 658 grams. This is an addition of approximately 73 grams of silicone fluid.

NOTE: Silicone fluid consist of a mixture of equal parts of Dow Corning type 330 fluid with a viscosity of 50 centistokes at 25°C and Dow Corning type 510 fluid with a viscosity of 1000 centistokes at 25°C. This mixture has a viscosity of approximately 200 centistokes at 25°C and will withstand temperature extremes to which transmitter may be exposed.

(33) Leak check transmitter using Helium Leak Detector Model 24-120A. Leak rate shall not exceed 0.1 micron cubic foot per hour.

(34) Clean transmitter to remove oil, welding scale and any foreign matter.

(35) Attach identification plate (1) using screws (2).

7. Fits and Clearances.

All applicable fits and clearances are called out in assembly procedures.

8. Testing.

A. Unless otherwise specified for an individual test testing is to be done at atmospheric conditions (approximately 29.92 inches Hg.) and room temperature (approximately 25°C (77°F)).

B. Transmitter with long axis horizontal and letters VENT in upright position, shall be tested using Synchro Servoed Test Indicator 13647-3-A or an equivalent.

C. The indicator and transmitter shall be connected to a 26 volt 400 Hz source and shall be vibrated during all tests unless otherwise specified.

D. Observing preceding conditions perform following tests on transmitter.

(1) Dielectric Strength. Apply 250 volts at a commercial frequency between any pin of the receptacle and ground. There shall be no breakdown of insulation.

(2) Scale Error. Test transmitter for scale errors at test points specified in table 2. calibration data; first with pressure increasing then with pressure decreasing. With pressure increasing, pressure shall be brought up to, but shall not exceed, pressure specified to given desired reading and with pressure decreasing, pressure shall be brought down to, but shall not fall below, pressure specified to give desired reading. Errors at test points shall not exceed tolerance specified.

(3) Friction. Test Transmitter for friction at every test point spec-

ified in table 2. calibration data. Increase pressure to bring pointer approximately to desired reading. Take two readings, first before transmitter is vibrated or tapped and second after. Difference between two readings shall not exceed tolerance given.

(4) Position Error. Subject transmitter to pressure specified in table 2. Reading of indicator, taken while transmitter is held at any desired position, shall not differ from readings taken while transmitter is held in any other position by more than tolerance given in table 2.

(5) Leak Test. Test transmitter for leakage using helium leak detector model 24-120A. Leak rate shall not exceed 0.1 micron-cubic foot per hour at a pressure differential of approximately one atmosphere.

Table 2. Calibration Data

7749-121A5-1			7749-122A5-1		
Test Pressure PSI	Indicator Degrees	Tolerance Degrees ±	Test Pressure PSI	Indicator Degrees	Tolerance Degrees ±
0	20.0	8.3	0	20.0	8.3
10	69.2	8.3	20	71.2	8.3

50	266.2	1.4	100	276.0	1.4
60	315.4	3.4	120	327.2	3.4
65	340.0	4.4	125	340.0	4.4
OP Stop	360.0	10.0			
Friction Error		1.6°	Friction Error		1.6°
Position Error	At 30 PSI	1.6°	Position Error	At 50 PSI	1.6°

9. Trouble Shooting.

Table 3 contains a list of possible defects that may become evident in the indicator. It lists possible causes and steps to correct them.

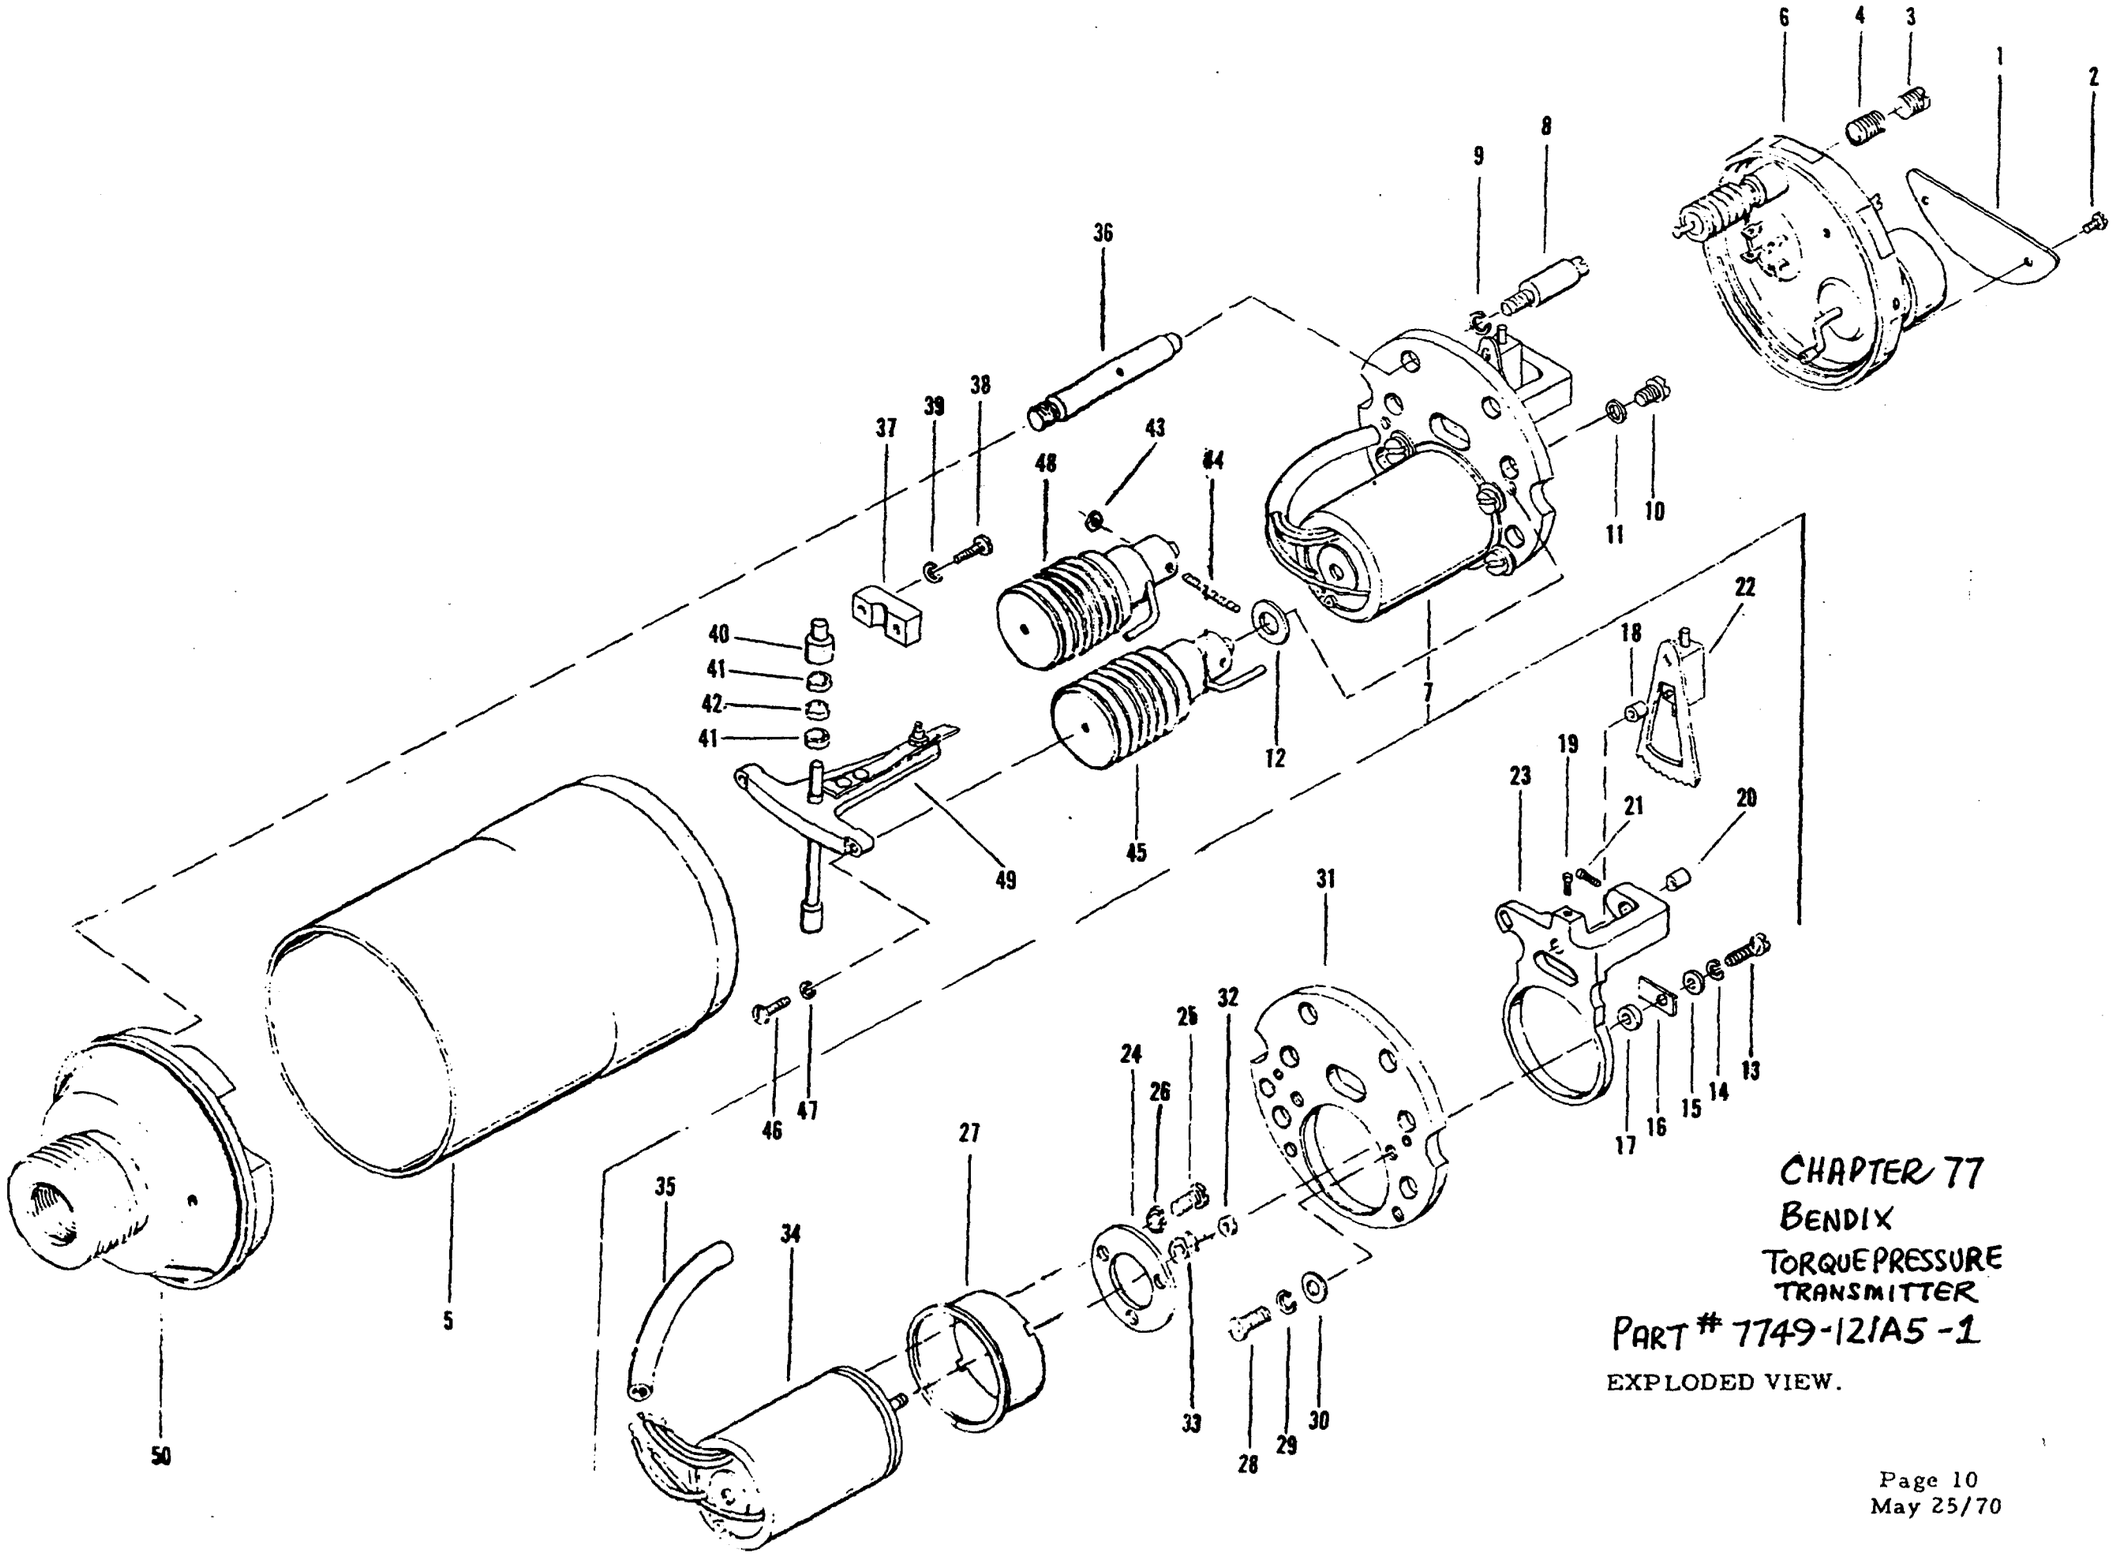
Table 3. Trouble Shooting

Trouble	Probabe Cause	Remedial Steps
No indication on indicator when current is applied.	Open circuit.	Check for loose connection at solder joints or broken wire.
Readings are out of tolerance.	Gear friction.	Check mesh of pinion and sector teeth.
	Improper zero setting.	Repeat calibration procedure.
Transmitter fails dielectric strength test.	Faulty synchro or connector pins shorted.	Check connector for shorts. Test synchro windings at 500 volts with test set 13700-1-C.

Table 4. Wiring Data

Wire Color		Receptacle Pin
Stator	Black	A
	Yellow	C
	Blue	D
Rotor	Black/White	A
	Red/White	B

10. Storage Instructions.



The transmitter should be stored in a suitable cardboard box of an appropriate size. Cushion the transmitter in the box with a commercial dunnage such as Kimpack.

11. Special Tools, Fixtures and Equipment.

The following listing contains the special test equipment necessary to overhaul and test the transmitter. If the listed equipment is not available a suitable equivalent may be used. The tools listed are manufactured by The Bendix Corporation unless otherwise indicated.

Table 5. Test Equipment

Part No.	Nomenclature	Application
QB72260-1	Test Cable	Used to connect transmittor to test indicator 13647-3-A.
13647-3-A	Synchro Servoed Test Indicator	Used in assembly to set mechanism calibration. Used to test calibration.
13700-1-C	Insulation Breakdown Test Set	Used to test for insulation failure and shorted wires.
Model 24-12A	Helium Leak Detector Consolidated Engineering Pasadena, Calif.	Used to test transmitter for case leakage.
Model 25 Hyper Vac	Vacuum Pump Central Scientific Co. Chicago, Ill.	Used to evacuate transmitter.
Type 460	Dead Weight Tester Amthor Testing Instrument Co. Brooklyn, N.Y.	Used with 13647-3-A to test calibration.

SINGLE SYNCHRO INDICATORS

25122- SERIES TYPE NUMBERS

DESCRIPTION AND OPERATION

Bendix indicators identified by type numbers in the 25122- series are precision instruments designed to provide visual readings of any function that can be monitored by a mating synchro type of transmitter.

The indicators are of simplified construction to provide units capable of extended periods of maintenance free service. They can be readily disassembled, however, whenever maintenance is required.

The indicator incorporates a dial mounted on the forward end of an Autosyn synchro assembly.

Dial readings are indicated by a pointer that transverses the dial. The hub of the pointer extends through the dial and is affixed on the synchro shaft; this constitutes to sole moving component.

These components and their mounting hardware are hermetically sealed in a two-inch clamp-on case.

LEADING PARTICULARS

The function indicated, the range and the dial spread of the model of indicators covered by this manual are listed in Table I. The following data applies to all units covered by the manual.

Operating Voltage	26 volts ac
Rated Frequency	400 cps
Case Size	2-inch dia.
Temperature Range	-54 to +71°C

TABLE I

LEADING PARTICULARS

Indicator Type Number	Function Indicated	Range	Dial Spread (Degrees)

DISASSEMBLY

NOTE

Two basic types of construction are encountered in the 25122- series indicators. They can be readily distinguished by the dial. Early model indicators incorporate a flat metal dial secured in position by two dial screws. Refer to figure 1. Later model units incorporate a preformed nylon dial secured in position with locking cement and requiring no dial screws. Refer to figure 2. Determine the type of unit under work, refer to the corresponding exploded view, and observe the applicable procedures.

A. Remove shipping cap (1), retaining ring (2), and identification plate (3).

B. Attach a mating connector (MS3106-14S-2S or MS3108-14S-2S) to electrical receptacle (6).

C. Use a torch to heat the soldered bond that secures the end cover assembly (5) in the rear end of the case assembly (10). When the solder has melted sufficiently that the plating will not be stripped from the end cover (7) or the case (13), use the connector to pull the end cover free.

D. Unsolder and remove the closed end eyelet (4), but do not disassemble the end cover or case assemblies unless necessary to replace a defective part.

E. If it is necessary to separate the components of the case assembly (10), place it on a hot plate or in an induction coil and heat until the solder flows sufficiently that the case (13) can be detached from the bezel (11). Remove excess solder from the components. If necessary, separate the receptacle assembly (6) from the end cover (7) in a similar manner or use a torch to melt the solder bond.

F. Carefully withdraw the mechanism assembly straight out from the case assembly (10).

G. Unsolder and disconnect the leads from the terminal pins of the receptacle (6). Remove excess solder from pins. Remove rear spacer (8).

H. Remove the dial spacer (9) from the case assembly (10).

I. Use the pointer remover 310A to lift the pointer (14) straight away from the dial

NOTE

Steps J and K apply to units with flat metal dials and dial screws. (Refer to figure 1.)

J. Dial screws (15) are secured with locking cement. Break the seal to remove the screws. Remove dial (16).

NOTE

Step L refers to units having preformed nylon dials requiring no dial screws. (Refer to figure 2.)

L. Do not remove dial (15) from synchro (16) unless it is necessary to replace a defective part. Dial is secured to synchro with Pliobond cement. Break the seal to separate the components.

CLEANING

A. Clean all parts except as mentioned in cleaning solvent. Use a soft brush; dry parts thoroughly. Keep parts free from dust particles until reassembled.

WARNING

Use solvent in a well ventilated area. Do not inhale solvent vapors or allow solvent to come in contact with the skin. Keep solvent away from open flame. Do not conduct insulation breakdown test in the immediate vicinity of open solvent.

CAUTION

Do not immerse synchro assembly in solvent or allow solvent to enter interior of synchro.

B. Clean exterior portions of synchro including leads with a lint free cloth dampened with solvent.

C. Be certain that any deposits of grease and other foreign matter are removed from the terminal pins, insulation, and threads of the receptacle assembly.

D. Clean pointer assembly with a soft eraser such as art gum.

C. Wash glass with pure soap and water. Rinse, dry, and keep free from finger marks until reassembled.

E. Carefully clean dial with a lint free cloth dampened in soap and water; avoid damage to dial markings. Rinse, dry, and keep free from finger marks until reassembled.

INSPECTION

A. Visually inspect all metallic parts, as applicable, for breaks, cracks, nicks, scratches, scoring, stripped or crossed threads, corrosion, distortion, worn plating, pitting, gouging, or other obvious defects.

B. Inspect receptacle for bent, broken, or loosened terminal pins, for cracked or loosened insulation and for damaged threads.

C. Inspect glass for chips, cracks, and discoloration.

D. Inspect dial and pointer for damaged or discolored paint.

E. Inspect leads of synchro assembly, especially at points of entry into synchro, for crimps, breaks, and damaged insulation.

TESTING OF SUB-ASSEMBLIES

A. Perform following tests.

B. Synchro assembly - insulation breakdown test. Using insulation breakdown test set 13700-1-C, apply a potential of 500 volts rms at a commercial frequency for a minimum period of five seconds across a rotor lead and ground (shaft) and then across a stator lead and ground (housing). There must be no electrical breakdown of insulation. Failure of the test requires replacement of the defective synchro.

C. Leak test - case assembly and end cover assembly. Use helium leak detector, Model 24-120A, to test these assemblies for leaks. Evacuate interior of each assembly to approximately 50 microns absolute pressure. Leak rate must not exceed 0.1 micron-cubic-foot per hour. If the leak rate is excessive, repair by reworking the faulty soldered joint or by replacing the defective component. If a helium leak detector is not available, perform the following immersion test of these assemblies. Install the assembly in the clamping fixture of hermetic sealing stand 13693-1-B or other suitable device so openings are sealed. Connect the outlet of the clamping fixture to a source of air. Apply a pressure of 15 psi and immerse the part in water. Any bubbles emanating from the interior of the assembly are evidence of leakage. Correct as required.

REPAIR OR REPLACEMENT

A. Repair of parts is not recommended. Replace any component disclosed by inspection or testing to be defective.

LUBRICATION

A. None required.

ASSEMBLY

A. If the components of the case assembly (10) were separated, install the case (13) and glass (12) in position in the bezel (11). Place a ring of solder having a melting range of 375 to 416°F (180 to 213°C) under the glass. Place the assembled components on a hot plate or in an induction coil and heat to effect a proper solder bond. If necessary, add additional solder. Do not permit excess solder to remain on rear surface of bezel or outer circumference of case. Allow the assembly to cool undisturbed. Perform leak test of step C - Testing of Sub-Assemblies.

B. If the components of the end cover assembly (5) were separated, solder the receptacle into the end cover in a manner similar to that described in step A. (It is not necessary to maintain any specified angular relationship between the polarizing key of the receptacle and the opening for the closed end eyelet in the end cover.) Perform leak test of step C - Testing of Sub-Assemblies.

NOTE

The procedures of steps C, D, and E apply to units with a flat metal dial and dial screws. (Refer to figure 1.)

C. Secure dial plate (18) to synchro assembly (19) with two attaching screws (17).

D. Pass synchro leads back through rear spacer (8); attach and solder leads to terminal pins of connector (6) in accord with Table II, Wiring Data. Clean joints to remove flux.

E. Secure dial (16) to dial plate with two dial screws (15).

NOTE

The procedure of steps F and G applies to units with a preformed nylon dial with no dial screws. (Refer to figure 2.)

F. Sparingly apply a coat of Pliobond 20 or equivalent cement around inside of rear extension of dial (15). Insert synchro assembly (16). Pliobond cement is manufactured by the Goodyear Rubber Products Company, 144 Mulberry Street, Newark, New Jersey.

G. Pass synchro leads back through rear spacer (8); attach and solder leads to terminal pins of connector (6) in conformance with the Wiring Data of Table II. Clean joints to remove flux.

CALIBRATION

A. Attach the mechanism to the precision transmitter 13695-2-A with test cable QB72260-1. Refer to the calibration tables and locate the applicable tabulation. Impose electrical zero. Tap the synchro to overcome the effects of friction so the rotor will assume the true EZ position. Press the pointer on the synchro shaft so that the tip is centered on the electrical zero (EZ) reference mark on the dial.

B. Perform the scale error, friction error, and position error tests outlined in steps D and E of the section - Test Procedures. Minor changes in the calibration of units with a flat dial can be made by slightly shifting the dial. When proper calibration is obtained, back out the dial screws, one at a time, and sparingly apply clear glyptol to the threads, then reinsert the screws. Cure the glyptol by baking at 120°F for two hours or air dry at room temperature for four hours.

FINAL ASSEMBLY

A. When the tests of step B of Calibration have been concluded within tolerance, insert the dial spacer (9) into the case assembly (10). Check the dial and dial screws (if used) to be sure that the paint is not marred. Install the mechanism into the case assembly.

B. Align the polarizing key of the receptacle with the top center line of the dial. Maintain these relative positions and insert the end cover assembly into the case.

C. Apply an axial force of 8 to 12 pounds to end cover to press it into proper position. Maintain the pressure and solder the end cover to the case to effect a hermetic seal.

D. Perform the leak test of step C of Test Procedures to ascertain if proper sealing has been achieved.

E. When proper sealing has been achieved, attach the unit to the vacuum pump Hyper Vac Model 25. Evacuate case to a pressure of 100 microns or less. With vacuum maintained, bake unit at 160°F for two hours. Backfill the case to a pressure of approximately one atmosphere of dry helium. The helium must be at least 98 percent pure, dust free, and it must not contain more than 0.006 milligrams of water vapor per liter (dew point -65 degrees C) at the filling pressure. Solder in the closed end eyelet (4) to seal the case. Touch up unpainted portions of the case with dull black enamel. Air dry only, do not bake the paint.

TABLE II

WIRING DATA

Synchro Lead	Terminal Pin
Rotor	
Black and White	A
Red and White	B
Stator	
Black	A
Yellow	C
Blue	D

TEST PROCEDURE

A. Perform the following tests at atmospheric pressure, approximately 29.92 in.Hg., and at room temperature, approximately 77°F (25°C).

B. Insulation Breakdown Test. Using insulation breakdown test set 13700-1-C, apply a potential of 200 volts rms at a commercial frequency for a minimum period of five seconds across any terminal pin of the electrical receptacle and ground (the indicator case). There shall be no electrical breakdown of insulation. In event of failure of this test, check to make certain that there are no trailing wire ends or deposits of foreign material to cause shorting at the receptacle. Check synchro leads for damaged insulation. Replace a defective synchro if that is cause of failure.

C. Sealing Test. Use helium leak detector, Model 24-120A, to check indicator case for leaks. At a pressure differential of approximately one atmosphere, leak rate must not exceed 1.0 micron-cubic-foot per hour. If leak rate is excessive, correct either by reworking the faulty soldered joint or by replacing the defective component. If a helium leak detector is not available, perform the following immersion test. Treat de-aerated distilled water by adding approximately 0.1 percent by weight of a wetting agent of the alkyl-aryl-sodium-sulfonate type (40 percent active ingredient). Place the treated water within the aquarium of the hermetic sealing stand 13693-1-B or in a similar enclosed chamber. Immerse the indicator in the water and reduce the absolute pressure of the air above the water to approximately 2 1/2 in.Hg. Any bubbles resulting from air entrapped on various exterior portions of the indicator do not constitute evidence of leakage; however, any bubbles emanating from the interior of the indicator case are evidence of leakage. Repair as required.

D. Electrical Zero Tests.

NOTE

Two types of electrical zero (EZ) test apply to the 25122- series indicators. Both are outlined in the following paratraphs. The first described requires a single indicator with the cover glass removed and applies to the following indicators:

25122-A2C-1-A1	25122-A37B-1-A1
25122-A10B-1-A1	25122-A73A-2-A1
25122-A17F-2-A3	25122-B4A-1-A1
25122-A27C-1-A1	25122-B7A-1-A1
25122-A27E-1-A3	25122-B16A-1-A1
25122-A30E-1-A1	25122-B22C-1-A1

Electrical Zero Test - First Type. Obtain a single indicator with the cover glass removed - this unit will be used as the EZ-test-indicator. (The precision transmitter 13695-2-A is not used for this test to prevent possible damage to that instrument.) Connect the indicator under test to the EZ-test-indicator. With power disconnected, displace the pointer of the EZ-test-indicator 180 degrees from the position of the pointer of the indicator under test. Hold the pointer in this position and apply power. Repeat the procedure a minimum of three times; then impose electrical zero on the indicator under test. The tip of the pointer shall be within 0.010 inch of the EZ reference mark on the dial.

Electrical Zero Test - Second Type. Attach the indicator under test to the precision transmitter 13695-2-A with test cable QB72260-1. Impose electrical zero. The tip of the indicator pointer must be within 0.010 inch of the EZ reference mark. The EZ reference mark when coinciding with a calibration mark is specified in the applicable calibration table.

In the event of failure of the electrical zero test, check the position of the pointer on the shaft as outlined in step A of the section - Calibration. Be certain the dial is properly positioned. Replace a defective synchro if that is cause of failure.

E. Scale Error and Friction Error Tests. Connect the indicator to the precision transmitter 13695-2-A. Adjust the controls of the transmitter to bring the transmitter pointer to each of the test points specified in the applicable calibration table. At each test point take two readings: the first before and the second after the indicator is tapped. The difference between the two readings represents friction error which must not exceed the specified friction error tolerance. The second reading must not differ from the specified test point value by an amount greater than the specified scale error tolerance. If any readings are out of tolerance, check the EZ setting as outlined in the previous test, step C. Be certain pointer does not drag on dial or touch glass. Replace a defective synchro if that is cause of failure.

F. Position Error Tests.

NOTE

Two slightly differing position error tests are applicable to the 25122- series indicators. The first test described applies to those units listed in the former part of step C. The second test applies to all other units covered by the manual. Determine the unit under test; perform the proper test.

Position Error Test - First Type. Adjust the controls of the precision transmitter to position the pointer of the indicator at midscale. The indicator reading taken with the indicator in the normal upright operating position must not differ from the reading taken with the indicator in other position by an amount greater than the position error tolerance specified in the applicable calibration table.

Position Error Test - Second Type. Adjust the controls of the precision transmitter 13695-2-A to position the indicator pointer at any value. Observe the exact reading on the indicator dial. Now hold the indicator in any other position. The change in the indicator reading caused by the change in the indicator's position shall not exceed the position error tolerance specified in the applicable calibration table.

If the indicator fails the position error test, check for pointer drag against either the dial or glass. Make certain that the dial is properly positioned. Replace a defective synchro if it has introduced the excessive position error.

SPECIAL TOOLS, FIXTURES AND EQUIPMENT

Part Number	Nomenclature	Application
QB72260-1	Test Cable	Connects indicator to synchro precision transmitter 13695-2-A.
13693-1-B	Hermetic Sealing Stand	Used to hermetically seal the case.
13695-2-A	Synchro Precision Transmitter	Used to calibrate and test indicator.
13700-1-C	Insulation Breakdown Test Set	Used to check insulation for breakdown.
Model 24-120A	Helium Leak Detector Consolidated Engineering Pasadena, Calif.	Used to test sealing of indicator case.
Model 25 Hyper Vac	Vacuum Pump Central Scientific Co. Chicago, Ill.	Used to evacuate case preparatory to backfill with helium.
Model 310A	Pointer Remover Hammel Riglander and Co. New York, N. Y.	Used to withdraw pointer from shaft of synchro.

PARTS BREAKDOWN

NOTE

This parts breakdown lists the components for those indicators incorporating a flat metal dial secured in position with two dial screws. (Refer to figure 1.)

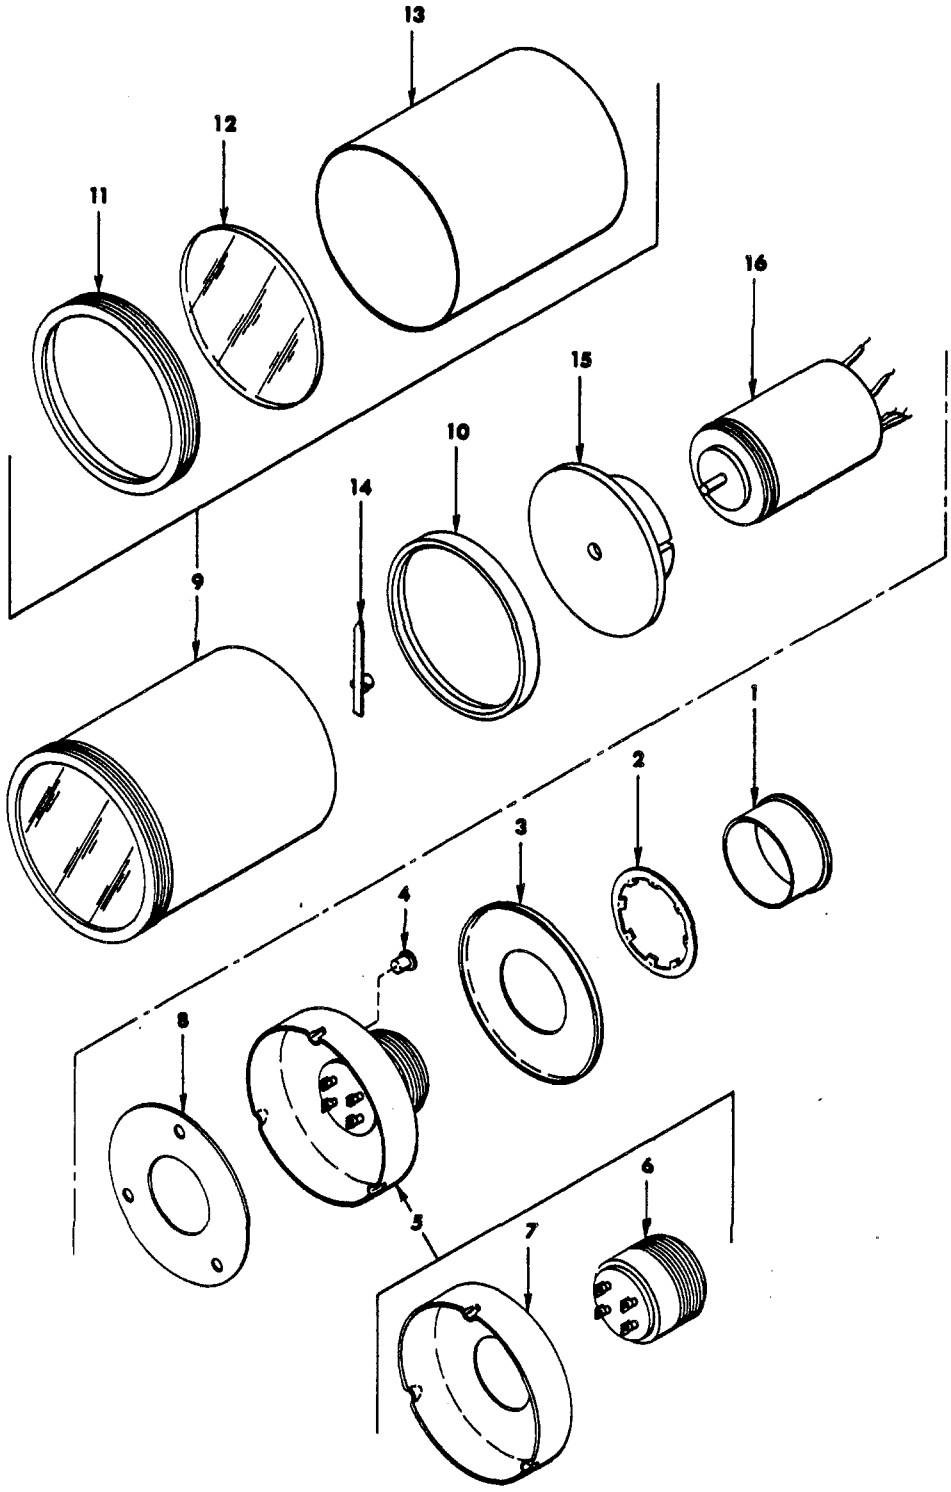

Figure 2. 25122- Series Indicator
With Formed Type of Dial

TROUBLE SHOOTING

Fault	Probable Cause	Remedy
No rotation of pointer.	No power to indicator.	Turn on power. Check for an open in rotor leads.
	Inoperative transmitter.	Remove and replace transmitter.
	Defective indicator.	Remove and replace indicator.
Reversed rotation of pointer of indicator.	Leads reversed.	Reconnect wires.
Erratic movement of pointer.	Pulsating pressure at transmitter.	Install a suitable damping device.
	Open lead.	Repair defect in wiring.
	Loose electrical connector.	Provide proper connection.
	Internal defect of indicator.	Remove and replace the indicator.

MAINTENANCE

Since the 25122- series indicators are hermetically sealed units, no internal inspection is possible; neither is it necessary. Periodic inspection of the system of which the indicator is a component is normally sufficient to insure continued accurate operation of the indicator. Suggested inspection procedures are tabulated in the following chart. Inspection times, as applicable to airframe utilization of the indicator, are indicated.

System Component	Procedure	Time of Inspection
Indicator	Inspect cover glass for loosening, cracks, and discoloration.	Preflight and post flight.
	Turn on power to the indicator. Check for proper normal indicated values before and after activation of the monitored function. Check for apparent lag or sticky operation.	Preflight and post flight.
Indicator and Transmitter	Inspect mountings to be sure instruments are securely fastened in position.	After 300 flying hours.
Pressure Line or other Mechanical Connections to the Transmitter.	Examine to assure that pressure lines and fittings are in good condition; free from leaks and securely attached. Check for proper condition of other mechanical devices.	After 300 flying hours.
Electrical Connectors and Interconnecting Cables	Inspect to be certain connectors are secure and that there is no damage to cables.	After 300 flying hours.

OVERHAUL INSTRUCTIONS WITH PARTS BREAKDOWN

34107C1AG13-1A3

1. Description and Operation.

The 34107C1AG13-1A3 tachometer indicator is a hermetically sealed, unlighted instrument. It consists of a synchronous motor, a gear train assembly, a drag cup, two pointers and a graduated dial mounted in a 2 inch diameter case.

The indicator is normally connected electrically to a remotely located tachometer generator to form a complete system. Any change in the frequency of the generator (caused by the function being measured) will cause the synchronous motor to change speed. The pointers are mounted on shafts driven by the gear train assembly and the drag cup, which acts as a slipping clutch. In moving over the dial range, the pointers provide a visual indication of the function being measured.

The sub-dial facilitates reading indications between the main dial divisions.

The clamp-on mounting feature used allows the indicator to be rotated in order that all pointers on the instrument panel will be aligned under normal operating conditions with all pointers horizontal to the left. Any deviation from normal (indicated by a pointer dropping out of alignment) will be readily apparent.

The indicator will withstand vibration up to 2 g's.

Table 1. Leading Particulars

Operating Temperature . . .	-54°C to +71°C
Power Requirements	Generator to MIL-G-26611 or MIL-G-9398
Weight	0.9 lbs.
Accuracy	.5%

2. Disassembly.

A. Disassemble the indicator according to the following procedure: (refer to figure 2)

(1) Remove retaining ring (2) using a screwdriver or other suitable instrument to pry off ring.

(2) Lift identification plate (1) over connector (5).

(3) Unsolder eyelet (3) and remove from end cover (4).

(4) Heat edge of case and glass assembly (7) around end cover (4) to melt solder holding end cover in place, and with a wire hook or other suitable tool inserted into eyelet hole, pull cover from case and glass assembly.

NOTE: Do not disassemble connector (5) from end cover unless necessary to replace a damaged part.

(5) Unsolder wires from connector (5).

(6) Remove compression ring (6).

(7) Clean excess solder from inner diameter of case and glass assembly (7) and withdraw indicator mechanism from assembly.

NOTE: Do not disassemble case and glass assembly (7) unless necessary to replace a damaged part.

(8) Remove dial spacer (11) from case and glass assembly (7).

(9) Remove pointer and hub assembly (12) by turning pointer against stop and gently continuing rotation and pulling pointer and hub assembly away from dial (14).

CAUTION: USE CARE TO AVOID BENDING POINTER STOP WHEN REMOVING POINTER AND HUB ASSEMBLY (12).

(10) Remove two dial screws (15).

(11) Insert a strip of thin, flat steel beneath dial (14) directly under pointer assembly (13) and carefully pry pointer assembly loose.

(12) Remove two screws (17) and washers (18) to separate gear train assembly (16) from motor housing (39).

CAUTION: USE CARE IN REMOVING GEAR TRAIN ASSEMBLY (16) TO AVOID DAMAGE TO THE PROTRUDING ENDS OF SHAFTS.

(13) Loosen screw (20) to remove return path assembly (25).

NOTE: Magnet assembly (26) should not be exposed to an open circuit. To avoid such exposure during disassembly, slide the magnet assembly directly from the indicator into magnet keeper 1489036-1. Place magnet and keeper in a non-magnetic container or on a non-magnetic surface.

(14) Remove screw (27) and disc (28) and slide magnet assembly (26) off starter and shaft assembly (34).

NOTE: Do not disassemble magnet assembly (26) unless it is necessary to replace a damaged part.

(15) Slide spacer (35), motor rotor assembly (36), and ball bearings (38) from shaft of starter and shaft assembly (34).

NOTE: Stator assembly (37) is secured in housing by shrink fit. If removal is necessary the housing must be heated.

B. Disassemble the gear train assembly (16) according to the following procedure: (refer to figure 3)

(1) Remove three screws (2) and lockwashers (3) and loosen rear plate assembly (1).

(2) Unsolder outer end of hairspring (10) from hairspring plate (6).

(3) Remove screw (7) and washer (8) to release hairspring plate (6).

NOTE: Do not disassemble jewel (4) from rear plate (5) unless necessary to replace a damaged part.

(4) Slide hub, gear and shaft assembly (9) out of front plate assembly (14).

CAUTION: USE CARE IN DISASSEMBLING GEAR TRAIN ASSEMBLY TO AVOID DAMAGE TO SHAFT PIVOTS, JEWELS, AND TEETH OF GEAR AND PINION.

(5) Remove hairspring (10) from shaft (13).

(6) Balance spring (11) need not be removed.

(7) Remove roll pin (15) and bushing and shaft assembly (17).

NOTE: Do not disassemble jewel (16) from plate assembly (22) unless necessary to replace a damaged part.

Do not disassemble bushing and shaft assembly (17) unless necessary to replace a damaged part.

3. Cleaning.

A. Clean main assembly of indicator according to the following instructions:

WARNING: USE SOLVENT IN A WELL VENTILATED AREA. DO NOT INHALE SOLVENT VAPORS OR ALLOW SOLVENT TO COME IN CONTACT WITH THE SKIN. KEEP SOLVENT AWAY FROM OPEN FLAME.

(1) Clean all metal parts with an approved solvent or use Naptha.

(2) Wash the dial (14) and cover glass (9) with a pure soap and water using care not to damage dial markings. Rinse and dry.

(3) Clean ball bearings (38) with Naptha or an approved solvent. Dry thoroughly. Do not handle ball bearings with bare fingers.

(4) Keep parts clean and free from dust particles.

B. Clean gear train assembly according to the following instructions:

(1) Clean pivots of shafts by inserting them into a piece of pithwood.

(2) Clean jewels (7 and 16) with a piece of soft pegwood freshly tapered for each jewel.

(3) Clean the teeth of pinion (18) and gear and cup assembly (12) with a stiff hair brush or glass fiber brush.

(4) Clean metal parts with Naptha or an approved solvent. Dry in accordance with standard shop practice.

(5) Keep parts clean and free from dust particles until reassembled.

4. Inspection/Check.

A. Inspect main assembly of indicator according to following steps:

(1) Inspect all parts for visible wear, damage, or defects.

(2) Inspect washers for scratches, scoring or damage.

(3) Inspect threads for stripping or burrs.

(4) Inspect lead wires for breaks.

(5) Inspect insulation for damage, breakdown or frayed material.

(6) Inspect pins of connector (5) for bending, breaks or loosening.

(7) Inspect case and glass assembly (7) for leaks, corrosion, dents or damage to case.

(8) Inspect glass (9) for chips or cracks.

(9) Inspect dial (14) and pointers (12 and 13) for chipped paint.

(10) Inspect bearings (38) for damage, wear or foreign material.

B. Inspect gear train assembly according to the following steps:

(1) Inspect jewels (7 and 16) under magnification for cracks or wear.

(2) Inspect teeth of pinion (18) for breaks, stripping, burrs or foreign material.

(3) Inspect teeth of gear and cup assembly (12) for breaks, stripping, burrs or foreign material.

(4) Inspect hairspring (10) for twisting or distortion, or improperly wound convolutions.

5. Repair.

No repair of any parts is recommended. Replace any parts found in inspection to be defective.

6. Assembly.

A. Assemble the gear train assembly according to the following instructions: (refer to figure 3)

CAUTION: USE CARE IN HANDLING AND ASSEMBLING GEAR TRAIN ASSEMBLY. TEETH OF PINION (18), TEETH OF GEAR AND CUP ASSEMBLY (12), PIVOTS OF SHAFTS (13 and 20), AND JEWELS (4 and 16) ARE DELICATE AND CAN BE EASILY DAMAGED.

(1) Assemble jewels (19) with high surface toward bottom jewel housings in bushing (21). Assemble pinion (18) on end of bushing with tapered end. Adjust opposite jewel for end play of shaft of 0.003 to 0.005 inch. Press on pinion (18) to allow clearance of 0.025 inch between inner face of pinion and opposing face of bushing (21). Hand taper ream hub of pinion if necessary.

(2) Press in bushing and shaft assembly (17) flush to 0.002 inch below rear surface of front plate (22).

(3) Press shaft (13) into gear and cup assembly (12) with 0.215 inch length pivot extending from gear on the side on which balance wheel is staked. Press in shaft (13) until shoulder of large diameter of shaft at front extends 0.401 inch beyond front surface of washer on front of hub of gear and cup assembly (12).

(4) Position hairspring (10) into gear and cup assembly (12) with 0.215 inch length pivot extending from gear on side on which balance wheel is staked (toward rear in exploded view illustration). Press in shaft (13) until shoulder of large diameter of shaft at front extends 0.401 inch beyond front surface of washer on front of hub of gear and cup assembly (12).

(5) Position hairspring (10) on shaft (13) as follows:

(a) View cup and gear assembly (12) from rear with the center of hole, which has been pressed into one of three gear spokes in a vertical position. Place hairspring (10) on shaft (13) so that free end of hairspring points clockwise from vertical.

(b) Maintain this position and press hub of hairspring (10) against hub of gear and cup assembly (12). Hairspring must be parallel to main gear; in free condition hairspring must be centered with shaft.

(c) Locate outer end of hairspring so that coils are equally spaced when the spring is wound up approximately 150 degrees. This adjustment is made by bending outer end of spring while free and after soldered to hairspring plate (6).

(6) Press in pin (15) so that they extend 0.130 inch from rear surface of plate assembly (22).

(7) Press in bushing and shaft assembly (17) flush to 0.002 inch below rear surface of front plate assembly (14).

(8) If jewel (16) was removed, press in place with high point of jewel toward rear of front plate assembly (14).

(9) If jewel (4) was removed press in with high point of jewel toward front of rear plate (5).

(10) Assemble front plate assembly (14), hub, gear and shaft assembly (9), and rear plate assembly (1).

(11) Adjust jewel (16) for 0.0013 to 0.0020 inch end play of shaft (13).

(12) Solder end of hairspring (10) to hairspring plate (6). Bend and readjust as necessary to insure that coils are equally spaced when hairspring is wound up approximately 150 degrees.

B. Assemble the main indicator assembly according to the following instructions: (refer to figure 2)

(1) If stator assembly (37) was removed from housing (39), reassemble as follows:

(a) Place housing in oven at 200°F (±20°F) for a period of two hours.

(b) Immerse stator assembly in dry ice for a period of two hours.

(c) Within five minutes after removal of parts from oven and dry ice, insert stator into housing.

(2) Completely demagnetize motor rotor assembly (36) with magnetreater model 990. Using magnet charger 107A with fixture 1489486, fully remagnetize motor rotor assembly. Fixture 1449486 must be used in order to obtain desired magnetic path to assure proper motor starting characteristics. Demagnetize to a field strength of 380 to 420 gauss. Insert motor rotor assembly into magnet keeper 1489071 or install it immediately into motor assembly.

(3) Install spacers (35) and motor rotor assembly (36) on shaft of starter and shaft assembly (34).

(4) Place one bearing (38) on shaft of starter and shaft assembly (34) with flanged edge of bearing against spacer (35).

(5) Insert bearing mounted on shaft into seat at rear of motor housing (39).

(6) Place second bearing (38) on shaft on front side of motor housing (39) with flanged edge of bearing toward front of indicator.

(7) If magnet assembly (26) has been exposed to an open magnet circuit, it must be remagnetized. First demagnetize magnet assembly completely using model 990 magnetreater. Then place magnet assembly in magnet charger model 107A with fixture 1489041-1 and charge to full strength. Discharge maximum dc current through magnet charger winding. Remove magnet assembly from magnet charger directly into magnet keeper 1489036-1. Take care to avoid exposure to an open magnetic circuit. Do not remove magnet assembly from magnet keeper until ready to place in return path (25) in indicator.

NOTE: In order to stabilize magnet assembly (26), immerse magnet assembly (in its keeper) in dry ice for two hours, then immerse in boiling water for ten minutes. Repeat cycle a minimum of four times.

NOTE: If compensating discs (30 and 31) are replaced, they must be replaced with equal diameter discs to those removed.

(8) Assemble magnet assembly (26) on shaft extending through housing (39). To avoid demagnetization, place magnet assembly directly on to shaft from magnet keeper.

(9) Adjust end play of motor 0.0013 to 0.0020 inch with 8 oz. reversing gage load and tighten setscrew (27) against disc (28).

(10) Fit drag cup assembly (19) on shaft of gear train assembly (16). A replacement drag cup assembly may require reaming.

(11) Fasten gear train assembly (16) to motor housing (39) using screws (17) and washers (18).

(12) Install dial (14) on gear train assembly using dial screws (15).

NOTE: Apply purple glyptal lacquer to dial screw holes in gear train assembly by placing a drop of glyptal lacquer to end of a wire and placing it in screw hole. Spread glyptal in hole with wire. Add a second drop of glyptal to hole in same manner.

(13) Press pointers (12 and 13) in place on their respective shafts. If new pointers are used they may require reaming with a 3 degree, 3 flute standard taper reamer to achieve a positive fit on shaft.

(14) Connect leads of stator to connector (5) according to wiring diagram (see figure 1)

NOTE: If drag cup magnet has been remagnetized and thermocycled, before recalibrating, the return path should be positioned forward against the rear plate, connected to a generator and operated at 4200 RPM. In this condition, demagnetize the drag cup magnet until the pointer indicates 92 to 93% RPM. Recalibrate.

(15) Connect indicator to tachometer generator TT3 or equivalent. Adjust smoothness of motor when running at low (75 to 100 rpm) speeds. This is accomplished by adjusting screw (23). Lock screw in place after adjustment with locking nut (24).

(16) Place entire mechanism into case and glass assembly (7). Position rear cover in place and tape securely together.

(17) Conduct tests outlined under section 8, Testing, for room temperature starting, scale error, friction error and position error.

(18) If indicator meets all test requirements, remove tape, clean case and cover of any tape residue. If connector (5) was removed solder in place in end cover (4).

(19) Line up end cover so that polarizing key of connector (5) is within 2 degrees of top centerline of dial (14).

(20) Solder end cover (4) in place in case (10).

(21) Connect indicator to dual valve manifold that is connected to both a vacuum pump and a source of helium. Evacuate indicator to a pressure of 50 microns. With vacuum maintained, bake indicator at 71° to 79°C (160° to 175°F) for twelve hours.

(22) Switch valve to dry helium source, backfill and seal indicator by soldering eyelet (3) in place.

NOTE: Helium used shall be at least 98 percent pure, dust free and shall contain not more than 0.006 milligrams of water vapor per liter (dew point -65°C (-85°F) at filling pressure.

7. Fits and Clearances.

All applicable fits and clearances are called out in assembly procedures.

8. Testing.

A. Unless otherwise specified for an individual test following conditions shall be observed for testing:

(1) All tests shall be conducted at atmospheric pressure (approximately 29.9" Hg.) and at room temperature (approximately +25°C).

(2) Indicator shall be tested in its normal operating position (dial surface shall be held in a vertical plane).

(3) All voltages noted herein are alternating current root-mean-square values. Voltmeter used to measure voltages shall be of a type which is free from frequency error.

(4) Indicator shall be gently tapped or vibrated before a test reading is taken.

B. The indicator shall be subjected to the following tests:

(1) Room temperature starting.

Connect indicator to TT3 generator or an equivalent variable frequency power supply. Supply voltage shall be a maximum of 0.0035 times frequency in cycles per minute. Frequency of supply shall be increased from 0 cycles per minute to a maximum of 150 cycles per minute. Reading shall not be less than 2.5 percent RPM at 150 cycles per minute input.

(2) Scale error.

Connect indicator to TT3 generator and test at points of scale listed in table 2. Test shall be made by setting generator at

speed shown and reading error from indicator, or by setting the indicator at desired reading and reading error in generator speed whichever is more convenient. Errors at test points shall not exceed tolerances specified in table 2. When speed is held constant at any point of scale (above 5.0 percent RPM) pointer shall not oscillate over a range greater than 0.5 percent RPM from 3.5 to 15 percent RPM and 0.3 percent RPM from over 15 to 100 percent RPM as shown on indicator.

(3) Friction error.

Indicator shall be set at 5, 20, 40, 85, and 100 percent RPM graduations. After each setting indicator shall be gently tapped and change in indication noted. Change shall not exceed 1.5 percent RPM at 5 percent RPM graduation, and 0.5 percent RPM at 40, 70, 85 and 100 percent graduations. This test may be combined with scale error test.

(4) Position error.

Indicator shall be operated at 100 percent RPM while indicator is in normal operating position. Indicator reading shall be noted. Maximum deviation from normal position reading, when tested in the following positions, shall not exceed 0.3 percent RPM.

(a) Rotated from normal position through 45 degrees to rear (dial tilted 45° back from vertical position).

(b) Rotated from normal position through 45 degrees to front (dial tilted 45° forward from vertical position).

(c) Rotated from normal position through 45 degrees to right (dial vertical).

(d) Rotated from normal position through 45 degrees to left (dial vertical).

(5) Pointer alignment.

Indicator shall be operated so main pointer will indicate 90 and 96 percent RPM respectively. Sub-dial pointer shall then correspondingly indicate 0 and 6 respectively, within 0.2 percent RPM.

(6) Sealing.

Indicator shall be tested for leaks by means of a mass spectrometer type of helium leak detector. Total leak rate shall not exceed 0.1 micron-cubic foot per hour.

(7) Fogging.

Indicator shall be placed in a controlled ambient temperature of 85°C +5°C for minimum period of two hours. Within ten seconds after removal from oven, immerse indicator to depth of ¾ inch (cover glass down) in ice water bath maintained at 0° to 5°C. After 5 minutes remove indicator and quickly wipe dry. Inspect cover glass and dial immediately for evidence of fog. Evidence of fog is cause for rejection.

As an alternate method, indicator may be placed in a controlled oven with temperature maintained at 71°C ±2°C for a minimum of one hour. Remove indicator and while still at this temperature, rub an ice cube on indicator glass for a period of one to two minutes. Wipe glass dry and inspect indicator for evidence of water or oil fog. Evidence of fog is cause for rejection.

Table 2. Calibration Data

Generator Speed RPM	Current Indication Percent RPM	Scale Error Percent RPM ± Indicated	Tolerance Generator RPM Limits
0	0	0.5	
210	5	0.5	189 - 231
420	10	0.5	339 - 441
630	15	0.5	609 - 651
840	20	0.5	819 - 861
1260	30	0.6	1235 - 1285
1680	40	0.8	1647 - 1713
2100	50	0.8	2067 - 2133
2520	60	0.8	2487 - 2553
2940	70	0.8	2907 - 2973
3150	75	0.5	3129 - 3171
3360	80	0.5	3339 - 3381
3570	85	0.5	3549 - 3591
3780	90	0.5	3759 - 3801
3990	95	0.5	3969 - 4011
4200	100	0.5	4179 - 4221
4263	101.5	0.5	4242 - 4284
4410	105	0.5	4389 - 4431
4620	110	0.5	4599 - 4641

9. Trouble Shooting.

Table 3 contains a list of possible defects that may become evident in the indicator. It lists possible causes and steps to correct them.

Table 3. Trouble Shooting

Trouble	Probable Cause	Remedial Steps
Indicator fails position error test. Right or left.	Hairspring out of position.	Reposition hairspring.
Indicator does not meet minimum starting speed requirement.	Screw (23) out of position in return path (25).	Adjust screw (23) until proper speed is obtained.
	Motor rotor assembly (36) demagnetized.	Remagnetize as called out in paragraph.
Indicator fails scale error test.	Incorrect balance, hairspring out of position.	Reposition hairspring.
Indicator fails friction error test.	Dirt on shaft or pivots.	Clean properly.
Indicator fails fogging test.	Moisture or excessive oil.	Open indicator, bake in oven at 71°C to 79°C (160°F to 175°F) for 12 hours.

DIRECTION OF ROTATION OF MAGNET FOR PHASE SEQUENCE B - A - C WHEN VIEWED FROM REAR END OF MOTOR

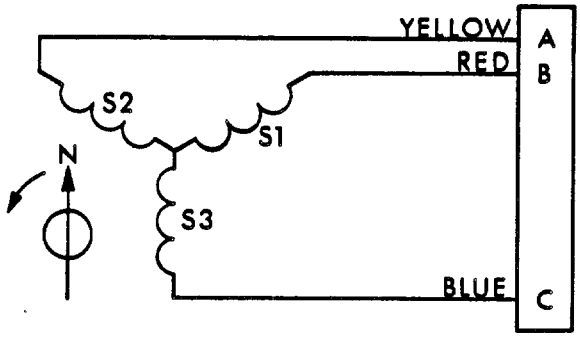

Figure 1. Wiring Diagram

10. Storage Instructions.

Prepare indicator for storage or shipment by placing protective cap, part no. 1489206-12 over connector (5). Using a cardboard box of suitable size, cushion indicator with a sufficient amount of dunnage to prevent any damage during shipment. Make certain that glass (9) is well protected. Seal box with a standard cloth or paper tape.

11. Special Tools, Fixtures and Equipment.

The following listing contains special tools required to overhaul and test indicator. If listed tools are not available, a suitable equivalent may be used. Unless otherwise indicated tools listed are manufactured by The Bendix Corporation.

Table 4. Special Tools and Test Equipment

Part No.	Nomenclature	Application
1489036-1	Magnet Keeper	To hold magnet assembly (26) at disassembly.
1489041-1	Magnetizing Fixture	To hold magnet assembly (26) in magnet charger model 107A.
1489071	Magnet Keeper	To hold motor rotor assembly (36) at disassembly.
1489486	Magnetizing Fixture	To hold motor rotor assembly (36) in magnet charger.
Model 107A	Magnet Charger Radio Frequency Lab. Boonton, N.J.	To remagnetize magnet assembly (26) and motor rotor assembly (36).
Model 990	Magnetreater Radio Frequency Lab. Boonton, N.J.	To demagnetize magnet assembly (26) and motor rotor assembly (36).
MIL-G-26611 MIL-G-9398	Generator	To supply power for indicator tests.

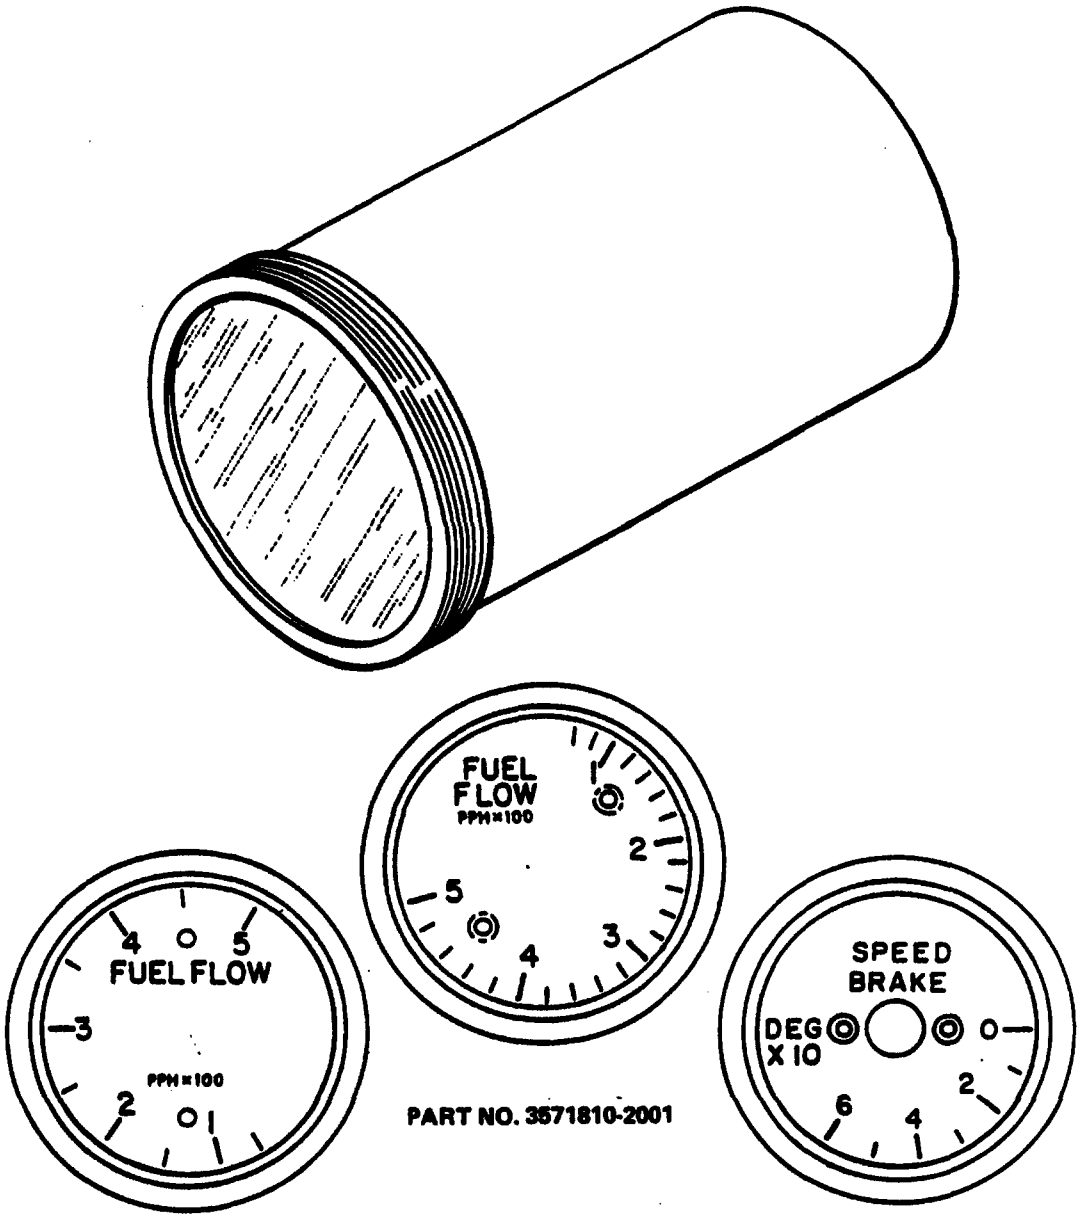
Fuel Flow Indicators, Part Nos. 3571810-0003 (25510B25B8A3), 3571810-2001 (25514B25A3A3), and Speed Brake Indicator, Part No. 3571810-8001 (25516C96A14A3).

1. Description and Operation

A. General



This manual contains descriptive information, maintenance, test instructions, and an illustrated parts list for Fuel Flow Indicators, part Nos. 3571810-0003 (25510B25B8A3), 3571810-2001 (25514B25A3A3), and Speed Brake Indicator, part No. 3571810-8001 (25516C9A14A3), hereinafter referred to as indicator. These indicators are manufactured by the Allied Corporation, Bendix Flight Systems Division, Teterboro, New Jersey 07608. Refer to Figure 1.

B. Description

The indicator is a hermetically sealed unit, with a single synchro. The indicator has a single pointer mounted on the shaft of a receiver synchro that provides visual indication.

C. Operation

In the indicator, the receiver synchro is remotely connected to a mating synchro transmitter. This synchro transmitter produces voltages representative of the angular position of the rotor in relation to the stator. With an ac excitation applied to the rotor, a magnetic field is set up about the rotor, and a voltage is induced in the stator windings. The magnitude and polarity of the output voltage of the stator of the transmitter is dependent at any instant on the angular position of the rotor with respect to the stator. The rotor of the synchro receiver in the indicator is free to turn and assume a position with respect to its stator corresponding to the rotor position of the transmitter synchro to which it is electrically connected. When the rotor of the receiver synchro turns, it moves the pointer connected on its shaft. This pointer moves in front of a dial, thus indicating the required information. The dial of the Speed Break Indicator is translucent permitting filtered light from two lamps to illuminate the dial face.

D. Leading Particulars

Leading particulars for the indicator are given in in Table 1.

Table 1. Leading Particulars

	FUEL FLOW INDICATOR 3571810-0003, 3571810-2001	SPEED BRAKE INDICATOR 3571810-8001
Operating Voltage:	26 Volts, 400 Hz	26 Volts, 400 Hz
Lighting Voltage:		5 Volts
Temperature Range:	-54°C to +71°C (-65°F to +159.8°F)	-54°C to +71°C (-65°F to +159.8°F)
Length:	3.25 inches	3.00 inches
Diameter:	2.000 inches	1.563 inches
Dial Spread:	240°	180°
Range:	50 to 500 pph (3571810-0003 only) 60 to 500 pph (3571810-2001 only)	0-60 Degrees
Autosyn* Synchro:		
Primary:	Rotor	Rotor
Voltage & Frequency:	26 Volts, 400 Hz	26 Volts, 400 Hz
Current:	120 milliamps, max.	120 milliamps, max.
Rotor Resistance:	18.0 ohms ± 10%	18.0 ohms ± 10%
Stator Resistance:	10.0 ohms ± 10%	18.0 ohms ± 10%

* Registered in U.S. Patent Office.

2. Disassembly

NOTE: Test the indicator in accordance with paragraph 8 (Testing) to establish the condition of the unit or the most probable cause of malfunction.

A. Disassemble the indicator only to the extent necessary to effect required repairs.

B. Indicator (Ref. IPL Fig. 1)

(1) Remove shipping cap (2).

(2) Remove retaining ring (3).

(3) Remove identification plate (4).

(4) Remove closed-end eyelet (evacuation plug) (5) by heating with a soldering iron and lifting out with needlenose pliers or screwdriver. Remove tubing (6), as necessary.

(5) Apply heat with a soldering iron around edge of end cover assembly (7) where solder holds end cover assembly in place and separate.

(6) Unsolder leads from connector (8); tag wires to facilitate reassembly.

(7) Do not disassemble end cover assembly (7) unless necessary to replace a damaged part. If it is necessary to separate items, use a torch to melt solder in order to separate connector (8) from rear cover (9).

NOTE: Compression ring (10) is used as a spacer, and is position 180° (the two cups facing) in relation to rear cover (9).

(8) Remove compression ring (10).

(9) Carefully withdraw synchro assembly (11) with attached components straight out from case and glass assembly (37).

(10) Remove dial spacer (12).

(11) Using pointer removal tool, remove pointer assembly (13) or (19) by pulling straight away from dial (14) or (22).

(12) Remove dial (14) or (22) by loosening and removing two dial screws (15) or (25).

(13) For Fuel Flow Indicator, Part Nos. 3571810-0003, and 3571810-2001, remove dial plate (16) by removing the two plate screws (17).

(14) For Speed Break Indicator, Part No. 3571810-8001, proceed as follows:

a) Remove filter (26).

b) Remove diffuser assembly (27) by removing two diffuser screws (28) and two washers (29).

c) Remove two screws (31 and 33) and remove terminal lug (30) and wire and contact spring (32).

d) Remove two lamps (34) and two contact rings (35).

NOTE: Do not disassemble case, bezel and glass assembly (37) unless necessary to replace damaged parts. If necessary to disassemble case, bezel and glass assembly (37) for all units, perform the following step.

(15) To disassemble case, bezel and glass assembly (37), place assembly on a hot plate or in an induction coil. Apply heat to bezel indicator (38) until solder melts. Separate into individual parts: bezel indicator (38), glass (39) and case (40).

3. Cleaning

A. Clean all metal parts, except as noted, with solvent, Federal Specification P-S-661. Use a soft brush; dry parts thoroughly. Keep parts clean and free from dust particles until reassembled.

WARNING: USE SOLVENT IN A WELL-VENTILATED AREA. DO NOT INHALE SOLVENT VAPORS OR ALLOW SOLVENT TO COME IN CONTACT WITH THE SKIN. KEEP SOLVENT AWAY FROM OPEN FLAME.

CAUTION: DO NOT IMMERSE AUTOSYN SYNCHRO (11, IPL Fig. 1) IN SOLVENT OR ALLOW SOLVENT TO ENTER INTERIOR OF SYNCHRO SINCE DAMAGE TO COMPONENTS MAY RESULT.

B. Remove residue resin from solder joints with alphatic naphtha, Federal Specification TT-N-95, or equivalent.

C. Clean pointer assembly (13 or 19, IPL Fig. 1) with a soft eraser, such as art gum.

D. Wash glass (39, IPL Fig. 1) with pure soap and water. Rinse, dry and keep glass free from finger marks.

E. Carefully clean dial (14 or 22, IPL Fig. 1) with a lint-free cloth dampened in soap and water, and avoid damage to dial markings. Rinse, dry, and keep dial free from finger marks.

4. Inspection/Check

A. Visually inspect all metallic parts, as applicable, for breaks, cracks, nicks, scratches, scoring, stripped or crossed threads, corrosion, distortion, worn plating, pitting, gouging, or other obvious defects.

B. Perform nondestructive inspection of parts in accordance with Table 301.

Table 301. Nondestructive Inspection Data

Part Name	Type of Inspection	Procedure	Acceptable Defects
Connector (8, IPL Fig. 1)	Visual	Inspect for bent, broken, and loose terminals. Examine insulation for cracks and loosening. Make sure threads are in good condition.	None
Glass (39) (IPL Fig. 1)	Visual	Inspect for chips, cracks, scratches and discoloration. Check that anti-glare coating has not been damaged.	None
Dial (14 or 22, IPL Fig. 1)	Visual	Inspect for damage to dial markings.	None
Pointer Assembly (13 or 19, IPL Fig. 1)	Visual	Inspect for bent or distorted condition and chipped paint.	None
Case, bezel and Glass Assembly (37, IPL Fig. 1)	Visual	Check condition of solder seal between bezel (38, IPL Fig. 1) and case (40, IPL Fig. 1).	None
Case (40, IPL (Fig. 1)	Visual	Inspect condition of paint.	None

5. Repair

A. No repair of parts is recommended.

B. Replace any part disclosed by inspection or testing to be defective.

C. If any component of the matched part assemblies (19,20 21, 22, 23, or 24) needs replacement, all components should be replaced with another matched parts assembly.

6. Assembly

A. Refer to indicator wiring diagram, figure 501, for wiring information.

B. Indicator (Ref. IPL Fig. 1)

(1) If required, reassemble case, bezel and glass assembly (37) with a ring of soft solder, Federal Specification QQ-S-571, Comp. Sn63, Form W, 0.06 inch diameter, placed under glass (39).

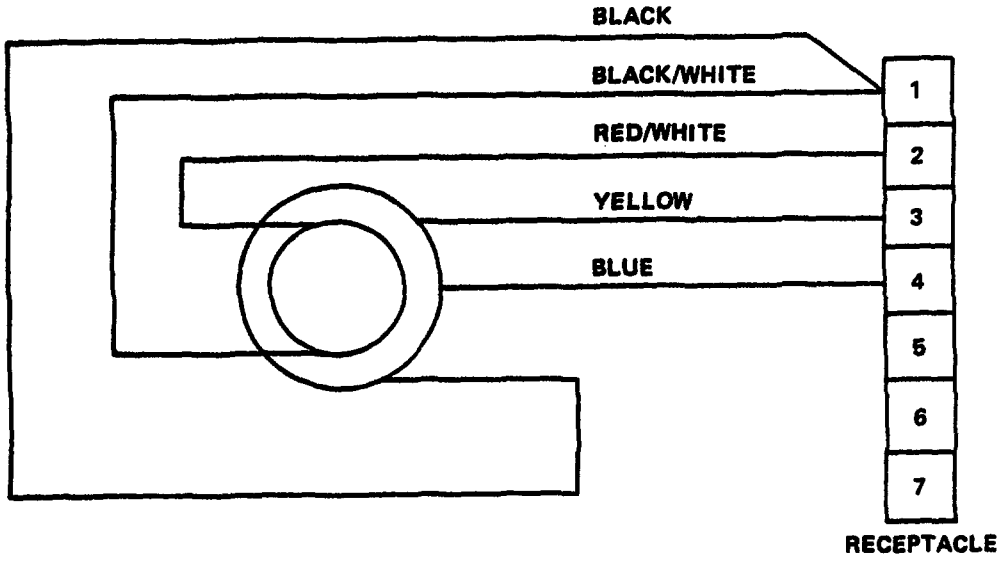
CAUTION: AVOID DAMAGE TO ANTI-GLARE COATING ON SURFACE OF GLASS WHEN APPLYING HEAT TO CASE AND GLASS ASSEMBLY.

(2) With bezel indicator (38), glass (39), and case (40) in proper position, place case, bezel and glass assembly (37) in an induction coil or on a hot plate to effect a proper solder bind. Allow parts to cool undisturbed.

(3) Check seal of case, bezel and glass assembly (37) for leaks with a helium leak detector. With interior of case assembly evacuated to approximately 500 microns absolute pressure, any detected leak should not exceed 0.01 micron per cubic foot per hour.

(4) For Fuel Flow Indicator, part numbers 3571810-0003 and 3571810-2001 install dial plate (16) on synchro assembly (11) with two plate screws (17).

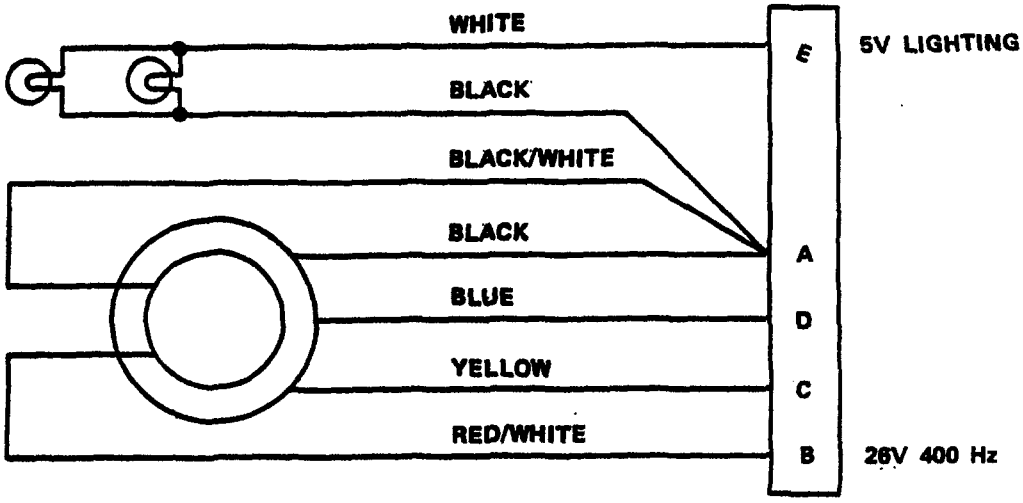
(5) For Speed Break Indicator, part number 3571810-8001, proceed as follows:



(a) Install two lamps (34) and two contact rings (35) in diffuser block (36).

b) Install contact spring (32) and lug (30) covering lamps (34) and secure with screws (31 and 33).

c) Install diffuser assembly (27) and secure with screws (28) and washers (29).



d) Install filter (26).

e) Install retaining ring (21A) on pointer -20.

FUEL FLOW INDICATORS 3571810-0003 AND 3571810-2001

2853-2-2

SPEED BREAK INDICATOR 3571810-8001

Indicator Wiring Diagram
Figure 501

CAUTION: ITEMS 19, -20, -21, 22, -23 AND -24 ARE PARTS OF A MATCHED SET AND MUST NOT BE INTERCHANGED.

(6) Install dial (14) with two dial screws (15). For Fuel Flow Indicators only.

(7) Press pointer assembly (13) or (19) through center of dial (14) or (22) till pointer assembly (13) or (19) clicks into place on shaft of synchro assembly (11).

(8) Pass wires of synchro assembly (11) through compression ring (used as a spacer) (10).

(9) If disassembled, assemble connector (8) and rear cover (9) to make end cover assembly (7).

(10) Connect and solder wires of synchro assembly (11) to connector (8) as tagged during disassembly.

(11) Connect synchro assembly (11) through the connector (8) to precision Autosyn Transmitter Test Set, part No. 13695-2-A. Actuate the electrical zero to position the synchro at its electrical zero prosition.

(12) Readjust pointer assembly (13) or (19) on shaft of synchro assembly (11) so that tip of pointer is at the 300 pounds per hour mark on dial (14) for the indicator, part numbers 3571810-0003 and 3571810-2001, and 0 RPM mark on dial (22), for Speed Break Indicator, part number 3571810-8001. Tip of pointer should be 0.015 inch away from face of dial.

(13) Test uncased indicator in accordance with procedures in Section 8, paragraphs A through H.

(14) Place dial spacer (12) into case, bezel and glass assembly (37).

(15) Insert uncased indicator into case, bezel and glass assembly (37). The key of the connector (8) must line up with the top centerline of the dial (14) or (22).

NOTE: In the procedures to follow, use hermetic sealing stand, part No. 13693-1-B, as necessary.

(16) Assemble identification plate (4) and retaining ring (3) in place, if applicable.

(17) Solder connector (8) to end cover assembly (7).

(18) Solder end cover assembly (7) in place, using solder QQ-S-571, Composition Sn63, Form W, Type S, 0.06-inch diameter and flux part No. 1493835-0000. While soldering, apply an axial force of 8 to 12 pounds to rear cover (9), part of end cover assembly (7), to keep it in its proper position.

(19) Pressurize indicator to 20 p.s.i.g.

WARNING: USE ALCOHOL ONLY IN A WELL-VENTILATED AREA AWAY FROM FIRE, SPARKS, OR OTHER SOURCE THAT MAY CAUSE IGNITION.

(20) Immerse indicator in clean, clear alcohol. Any bubbles coming from within indicate a leak which must be repaired. Mark leaks for repair.

(21) Remove indicator from alcohol container.

(22) Place indicator under bell jar supplied with hermetic sealing stand, part No. 13693-1-B, and connected to vacuum pump, Hyper-Vac Model 25.

(23) Evacuate the bell jar to a pressure of 500 microns or less.

(24) With vacuum maintained, bake indicator in an oven at 71°C (160°F) for 2 hours.

NOTE: Helium-nitrogen mixture should be 88 to 92% nitrogen and the remainder helium. Helium used should be at least 98% pure and dust-free and shall contain not more that 0.006 milligram of water vapor (dew point of 65°C (149°F) at filling pressure.

(25) Backfill indicator with one atmosphere of dry helium-nitrogen mixture and seal.

(26) Replace tubing (6), as necessary. Seal by inserting closed end eyelet (5) into end cover assembly (7) and soldering in place.

(27) Using helium leak detector, model 24-120B, and test port and roughing station, model 24-038 or equivalent, check that maximum allowable total leak rate is 0.01 micron per cubic foot per hour.

(28) If leak rate is over maximum allowable rate, repeat steps (19) through (27) to locate and repair leak.

8. Testing

A. Perform tests at atmospheric pressure of approximately 29.92 inches Hg, at a temperature of approximately 25°C (77°F) and at a relative humidity of 90 percent or less. Unless otherwise specified, test indicator in the normal upright operating position, with the plane of the dial vertical. Prior to taking a test reading, vibrate the indicator lightly by hand.

B. Test Procedures

Connect the indicator to Precision Autosyn Synchro Transmitter Test Set, part No. 13695-2-A, and perform tests listed in paragraphs C, D, E, and J for Fuel Flow indicator and paragraphs F, G, H, I and J for Speed Brake Indicator.

C. Electrical Zero Test

Impose electrical zero (EZ) on indicator. Check that pointer assembly (13), IPL Figure 1 is installed so that the tip of the pointer lies within 0.10 inch of the electrical zero reference mark. This mark is 300 pounds per hour for the Fuel Flow Indicator.

D. Scale Error and Friction Error

Rotate knob of transmitter to bring its pointer to each of the test points indicated in Table 701, Calibration. Two readings shall be taken; the first before the indicator is vibrated and tapped, and the second after the indicator is vibrated and tapped. The difference between the first and second readings shall not exceed 1.4 degrees. The test shall be performed in both up-scale and down-scale directions.

E. Position Error

Set transmitter at any reading and lock. Reading of the Fuel Flow Indicator, while held in any of the following positions, shall not vary by more than 1.4 degrees.

(1) Rotated from normal position through 45 degrees to the rear (dial tilted 45 degrees back from vertical position).

(2) Rotated from normal position through 45 degrees to the front (dial tilted 45 degrees forward from vertical position).

(3) Rotated form normal position through 90 degrees to the right (dial vertical).

(4) Rotated from normal position through 90 degrees to the left (dial vertical).

F. Scale Error and Friction Error

Rotate knob of transmitter to bring pointer of indicator up to but not exceeding the desired test points specified in Table 701. Record reading on transmitter; tap or vibrate indicator and readjust transmitter knob to bring pointer of indicator to initial test point, again record reading on transmitter. The difference between the first and second readings is friction error and shall not exceed the tolerance specified in Table 701. The second reading is scale error and shall be within the "min" and "max" values specified in Table 701. This test shall be accomplished by starting with the lowest test point and progressing to the highest and returning through each test point to the lowest.

G. Position Error

Rotate knob of transmitter to bring pointer of indicator at the 30 graduation mark and record reading on transmitter. Rotate the indicator 90 degrees right, 90 degrees left, face up and face down. At each position if indicator pointer is not at the 30 graduation mark, rotate transmitter knob until 30 graduation mark is obtained and record each transmitter reading. The difference between the two readings at each position shall not exceed ± 1.6 degrees.

H. Lighting

The lighting system shall be excited with 4.5 ± 0.05 volts. Check that all lamps are lit. Perform lighting test using photometric readings per MIL-I-23479.

I. Fogging

The indicator shall be energized and placed in a +71°C ± 2°C controlled ambient temperature for a minimum perid of one (1) hour. After this period and while still at this specified temperature, an ice cube shall be rubbed on the cover glass for a period of 1 to 2 minutes. The glass shall be wiped dry (do not use compressed air) and the indicator inspected for evidence of water or oil fog inside the cover glass. Evidence of fogging shall be cause for rejection.

J. Sealing

A leak rate of 0.01 micron-cubic foot per hour at a pressure differential of approximately one atmosphere must not be exceeded when tested on the helium leak detector.

Table 701. Calibration Data

Test Points (Pounds Per Hour)	Transmitter Reading (Degrees)	Scale Error and Friction Error Tolerance (± Degrees)
50 (3571810-0003 only)	58.5	1.4
60 (3571810-2001 only)	61.2	1.4
100	75.9	1.4
200	125.6	1.4
300 (E-Z REF)	180.0	1.4
400	237.0	1.4
500	299.2	1.4

Indicator Test Points	Transmitter (Degrees)	Transmitter Reading in Degrees		Error Tolerance (± Degrees)
		Min.	Max.	
(3571810-8001 only)				
0(EZ)	180	178.4	181.6	1.6
10	200	198.4	201.6	1.6
20	220	218.4	221.6	1.6
30	240	238.4	241.6	1.6
40	260	258.4	261.6	1.6
50	280	278.4	281.6	1.6
60	300	298.4	301.6	1.6

9. Troubleshooting

Refer to Table 801 for indicator troubleshooting data.

Table 801. Troubleshooting

Trouble	Possible Cause	Remedy
Electrical zero cannot be obtained.	Defective Autosyn synchro (11, IPL Fig. 1)	Replace synchro.
Friction error and/or position error exceeds tolerance.	a. Pointer assembly (13 or 19, IPL Fig. 1) not secure on Autosyn synchro shaft.	a. Check pointer for security. Correct as necessary.
	b. Defective Autosyn synchro (11, IPL Fig. 1)	b. Replace synchro.
Pointer assembly (13 or 19, IPL Fig. 1) not at EZ mark when EZ is applied.	Pointer assembly (13 or 19, IPL Fig. 1) loose on shaft.	Press pointer assembly on shaft securely.
Indicator will not operate.	Improper wiring connection.	Check electrical connections. Check indicator for loose or broken wires.
Indicator fails sealing test	Leaky solder joint on indicator cap, eyelet, or front glass seal.	Locate leak, open indicator, repair leak, and reseal.

10. Storage Instructions

NOTE: Unit in storage (or inoperative in aircraft) beyond specified time limits must be inspected, lubricated, and tested prior to installation or use.

A. The indicator may be stored for 12 months (maximum) provided the following conditions prevail.

CAUTION: IF THESE CONDITIONS ARE NOT OBSERVED, SHELF LIFE WILL BE CONSIDERABLY SHORTENED.

(1) Storage area must be dry.

(2) Unit must not be subjected to extremely high temperatures.

(3) Unit must be effectively protected from dust.

(4) Unit must be handled with care at all times.

(5) Unit should be stored in shipping container.

11. Special Tools, Fixtures and Equipment

Table 1001 lists the special tools and Table 1002 lists the equipment needed to perform the procedures in this manual. If the listed equipment is not available, equivalent substitutes may be used.

Table 1001. Special Tools

PART/MODEL NO.	NOMENCLATURE	APPLICATION

12. Illustrated Parts List

A. Introduction

(1) Purpose

This parts list is intended for use in requisitioning, storing, and issuing the replaceable parts of the Fuel Flow Indicator, part number 3571810-0003 (old type No. 25510B25B8A3) Fuel Flow Indicator, part number 3571810-2001 (old type No. 25514B25A3A3), and Speed Break Indicator, part number 3571810-8001 (old type No. 25516C96A14A3).

(2) Effectivity Code Symbols

Since more than one part number is covered in one or more of the parts lists, an effectivity code is included to identify each specific part with its corresponding assembly. If no effectivity code letter is used, the part is common in all units.

(3) How To Use This Parts List

(a) When the part number is not known, locate the part on the illustration and note its item number. Use this item number to locate the part number in the Detailed Parts List, Paragraph 12C.

(b) When the part number is known, but the location on the illustration is not known, find the part number in the Numerical Index, Paragraph 12B, and note the figure and item number. Use this figure and item number to locate the part in the Detailed Parts List, Paragraph 12C. If the Detailed Parts List indicates that the part is illustrated, locate the part on the illustration by its item number.

(4) Bendix Flight Systems Division Part Numbering System

The part number consists of a basic number and a dash number. The dash number indicates variations of the basic part.

(5) Vendor's Code

Parts obtainable from vendors other than the Allied Corporation are listed (by the vendor's part number) in the part number column. The vendor's code number is listed in the nomenclature column, and the Bendix part number is listed for reference purposes following the vendor's code.

NOTE: Inclusion of vendor part numbers and vendor codes in the nomenclature column for Bendix Flight Systems Division controlled parts is for information purposes only and does not authorize direct procurement from those sources.

Code	Name and Address
V55972	Allied Corp. Bendix Flight Systems Division Teterboro, NJ 07608
V57771	Edwin B. Stimpson Co., Inc. 900 Sylvan Ave. Bayport, NY 11705

ENGINE INDICATING - MILLIVOLTMETER TEMPERATURE INDICATORS (GRADED SCALE) TO IMPROVE TEMPERATURE COMPENSATION OF THE MOVING COIL MOD. 02

1. PLANNING INFORMATION

A. Effectivity

Unit affected:- Millivoltmeter Temperature Indicator (Graded Scale).

Code:- */727 MV/BU/* series (except */727 MV/BU/42/690), */762 MV/BU/* series.

B. Reason
The present combination of the thermistor and shunt of the moving coil could cause the unit to indicate maximum specification tolerances over the operating ambient temperatures.

C. Description
The value of the thermistor is changed, which improves temperature compensation of the moving coil and prevents the unit indicating maximum specification tolerances over operating ambient temperatures.

D. Compliance
Optional.

E. Approval
This modification is issued under A.R.B. Authority Reference No. AD/1017/39.

F. Manpower
Not applicable.

G. Material
Not applicable.

H. Tooling
No special tools are required.

I. Weight
Unit weight change ..... None.

ENGINE INDICATING - GRADED LONG SCALE MOVING COIL INDICATOR

INTRODUCTION OF COLD JUNCTION WITHIN THE INSTRUMENT CASE

MOD. 01

1. PLANNING INFORMATION

A. Effectivity

Unit affected:- Graded Long Scale Moving Coil Indicator.

Code:- */727 MV/BU/* series, */762 MV/BU/* series.

B. Reason

To reduce time lag between a change in ambient temperature and the correct temperature being indicated.

C. Description

The Cold Junction, which was formally externally fitted, is now incorporated within the case of the instrument.

D. Compliance

Optional.

E. Approval

This modification is issued under A.R.B. Authority Reference No. AD/1017/39.

F. Manpower

This modification will take no extra man hours if undertaken during overhaul.

G. Material

The following parts will be required for this modification and can be supplied as a modification kit:-

727 MV/BU/30 only

Part No.	Description	Qty.
MV 6204	Terminal Block Assy.	1

2. ACCOMPLISHMENT INSTRUCTIONS

A. Embodiment Instructions

(1) Disassemble the unit in accordance with instructions in the Overhaul Manual 77-20-205/5 . Discard the old case back and terminal block assembly.
(2) Proceed with Assembly using the new case back assembly.
(3) Fit the sleeving (supplied in the Mod. Kit) over each of the Chromel and Alumel wires (Red for Chromel and Black for Alumel - see FIG.1).
(4) Using the new terminal block, feed the two sleeved wires through the two 'A' holes in the terminal block and solder to the inserts (see FIG.2). The Chromel wire is connected to the +ve terminal.
NOTE: The length of these wires is important and they must not be shortened.
(5) Complete Assembly and test the unit as instructed in the Overhaul Manual 77-20-205/5.

B. Method of Identification

Mark the modification label to show that Mod. 01 has been incorporated.

GENERAL INFORMATION

1. Introduction

This manual contains instructions for the overhaul of EDISON Aircraft Torque Pressure Indicator, part No. 217-03221.

It is prepared in accordance with ATA Specification No. 100 including the Uniform Chapterization and Numbering System designated therein so that the pages may be inserted into their proper locations in the basic aircraft overhaul manual if desired.

All of the material in this manual falls within the classification "Engine Indicating - Chapter 77".

TORQUE PRESSURE INDICATOR NO. 217-03221

OVERHAUL INSTRUCTIONS

1. Description and Operation

The pressure indicator covered by these overhaul instructions is part of the EDISON variable reluctance type Torque Pressure Indicating System. (Ref. Fig. 1)

The Indicator
Figure 1

Table of Leading Particulars
Power Supply .. 26 V single phase 400 Hz
Pressure Range ..... 0 to 60 psi

It is an hermetically sealed instrument designed to be secured to an instrument panel by means of a standard mounting clamp. An electrical connector on the rear provides for connection to the transmitter and power supply.

The function of the indicator is to translate into torque pressure the voltage applied to its moving coil by the pressure transmitter. This is accomplished through the use of several simple principles as follows:

A. When the current flows in the same direction through two coils, their magnetic flux is in the same direction. Thus their opposite magnetic poles are next to each other, so the coils are attracted to each other. (Ref. Fig. 2A)

B. When alternating current flows through a coil, the resulting flux cutting across a second coil induces a current within it if its circuit is complete. At any given instant the induced current flows in the direction opposite to the applied current. (Ref. Fig. 2B) Thus the induced fluxes are opposed and the coils repel each other.

C. In the indicator a constant 26 volt 400 hertz current flows through the stationary field coil making a flux pattern through the core and across

TORQUE PRESSURE INDICATOR NO. 217-03221

OVERHAUL INSTRUCTIONS

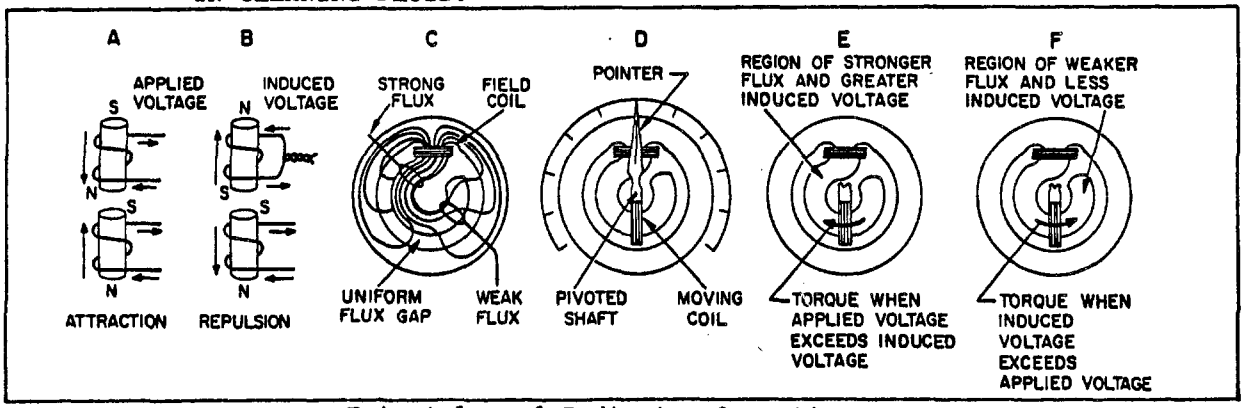
the air gap. (Ref. Fig. 2C) The flux is strongest near the base of the hook-shaped part of the core and decreases uniformly along its length.

D. The moving coil with attached pointer is pivoted to rotate with the core hook at its center. (Ref. Fig. 2D) Two hairsprings transmit applied voltage to coil and furnish torque to swing pointer off low end of scale when no voltage is applied.

E. When the transmitter applies voltage to the moving coil it causes a current at any given instant to be in the same direction as that in the field coil (in phase).

F. At the same time, since the coils are energized with alternating current, the transformer effect is inducing an opposing voltage (180° out of phase) in the moving coil.

G. If the moving coil is at a position where applied voltage is greater than induced voltage, current will flow in the same direction as that of the field coil and the resulting torque will move the coil toward the base of the hook where the field coil flux is greater. (Ref. Fig. 1E) As it moves the induced voltage increases, the current and resulting torque decrease until the coil comes to rest at the point where applied voltage is just enough greater than induced voltage to overcome hairspring torque.



H. If applied voltage decreases below induced voltage, the resulting torque will cause the coil to swing toward the end of the hook until it reaches a point where equilibrium is again achieved. (Ref. Fig. 2F)

I. Because the voltage applied to the moving coil is obtained from two similar inductive, resistive voltage dividers, any variations in power supply voltage cause proportional changes in all voltages involved, hence do not affect the position assumed by the moving coil. (Ref. Fig. 3)

J. In order to compensate for resistance changes in the copper field coils, thermistors are connected in series with them.

2. Disassembly (Ref. Fig. 9)

CAUTION: USE EXTREME CARE TO KEEP DUST, FIBERS AND OTHER FOREIGN MATTER OUT OF SILICONE FLUID IMPREGNATED BEARINGS. DO NOT IMMERSE MECHANISM IN CLEANING FLUID.

Principles of Indicator Operation
Figure 2

TORQUE PRESSURE INDICATOR NO. 217-03221

OVERHAUL INSTRUCTIONS

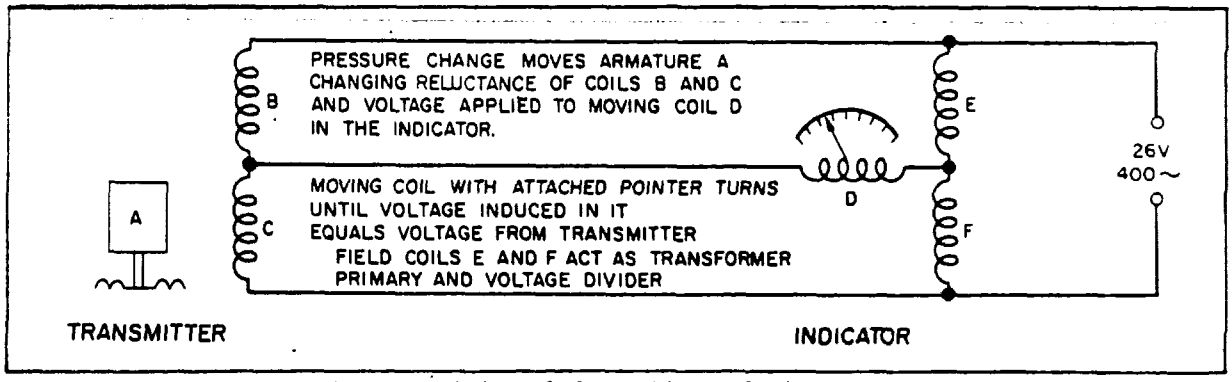
A. Remove case and mask assembly (6).
   (1) Use induction heater (Ref. Section 11) to unsolder case and mask assembly (6) from base and receptacle assembly (48) of complete movement assembly after stripping paint.

   NOTE: *No further disassembly of case and mask assembly is recommended.*

B. Remove evacuation hole rivet (5).
   (1) Remove the two screws (2) and washers (3, 4) and nameplate (1).
   (2) Unsolder and remove rivet (5) from hole in base and receptacle assembly (48).

   NOTE: No further disassembly of the movement assembly is required to permit cleaning, inspection and check of detail parts. If parts are found to be defective, continue disassembly as required.

C. Remove dial (11)
   (1) Remove dial nut (12), screw (14), washers (13, 15, 16) and bushing (17).
   (2) Tip dial (11) and carefully slide it out from under pointer of rotor and hairspring assembly (24).



D. Remove rotor balance weights (18, 19).
   (1) Grasp weight (18, 19) with tweezers in manner to straighten the slight bend of the weight so that it may be slipped off of the balance cross of the rotor.

E. Remove front housing and bearing assembly.

   NOTE: If rotor and hairspring assembly (24) is to be removed, delay this step until top plate (22) has been removed.

   (1) Loosen front bearing nut (20).
   (2) Unscrew and remove housing and bearing assembly (21) and nut (20).

F. Remove rotor and hairspring assembly (24).
   (1) Bend cut wire (29), which forms upper snubber, away from rotor shaft to clear outer turn of hairspring (25).
   (2) Unsolder hairsprings (25) from terminal of plate and terminal assembly (28) and board and adjuster assembly (47).

Basic Principle of Operation of the System
Figure 3

TORQUE PRESSURE INDICATOR NO. 217-03221

OVERHAUL INSTRUCTIONS

(3) Remove self-locking nuts (23) and lift off top plate (22) using care not to damage pointer.
(4) Turn and lift out rotor and hairspring assembly (24).

NOTE: Removal of pivots (26) from rotor body assembly (27) is not recommended.

G. Remove hairsprings (25) from rotor and hairspring assembly (24).

H. Remove stator assembly (29-41 assembled) and board and bearing assembly (43-47 assembled).
(1) Lift off top bushings (28).
(2) Unsolder leads from base and receptacle assembly (48).
(3) Lift off stator assembly with board and bearing assembly attached.
(4) Take out bottom bushings (42).
(5) Unsolder fixed coil leads from board and adjuster assembly (44), thus separating stator assembly and board and bearing assembly.

I. Remove fixed coil (40).
(1) Unsolder fixed coil lead from terminal of plate and terminal assy (30).
(2) Unsolder and remove cut wire (29) only if replacement is required.
(3) Remove rivet (32).
(4) Remove plate and terminal assembly (30) and bottom plate (31).
(5) Push out inside core (33).
(6) Remove screws (34, 35), lock washer (36), and shunt nut (37).
(7) Slide shunt (38) and coil bracket (39) from under fixed coil (40).
(8) Slide fixed coil (40) from outside lamination assembly (41).

J. Disassemble board and bearing assembly (43-47 assembled).
(1) Unscrew and remove rear housing and bearing assembly (43).
(2) Unsolder and remove thermistors (45).
(3) Unsolder and remove snubber (46).

3. Cleaning (Ref. Fig. 9)

A. Carefully clean solder from case and mask assembly (6) and base and receptacle assembly (48) so they will be ready for resealing case after assembly.

B. If microscopic inspection of bearings shows hairlike fibers in the bearing cavity, remove with tweezers. Use no other cleaning method on bearings since they are factory impregnated with a special silicone fluid.

C. Vapor degrease all parts made solely of metal, using trichlorethylene.

WARNING: AVOID BREATHING FUMES OR PERMITTING TRICHLORETHYLENE TO CONTACT SKIN.

4. Inspection/Check (Ref. Fig.9)

A. Visual
(1) Check cover glass (9) for cracks or chips.
(2) Check dial (11) for scratches or stains.
(3) Check hairsprings (25) for distortion.
(4) Check pointer of rotor and hairspring assembly (24) for distortion or chipped paint.

TORQUE PRESSURE INDICATOR NO. 217-03221

OVERHAUL INSTRUCTIONS

B. Microscope (30X)
(1) Check pivots (26) for pits, grooves or distortion.
(2) Check housing and bearing assemblies (21, 43) for dents in bearing cap, foreign matter, and loss of clear fluidity of silicone fluid.

C. Ohmmeter
(1) Check moving coil with ohmmeter across adjuster and upper hairspring terminal of assembled indicator, or directly across coil of rotor body assembly (27). Acceptable resistance: 25 ± 8 ohms.
(2) Check fixed coil (40) with ohmmeter across lower terminals. Acceptable resistance: 46 ± 15 ohms.
(3) Check thermistors (45) with ohmmeter across leads. Acceptable resistance at 25°C (77°F): 5.6 ± 0.1 ohm.

5. Repair

Replace all defective or damaged parts.

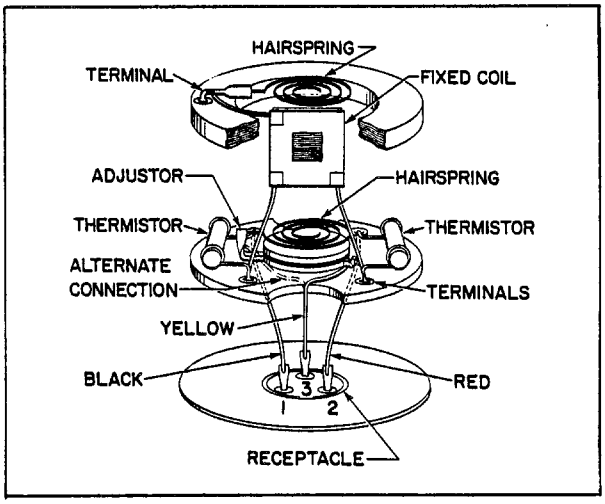
6. Assembly (Ref. Fig.9)

A. Assemble board and bearing assembly.
(1) Slide snubber (46) to bottom of higher prong of hairspring adjuster of board and adjuster (47). Position the snubber so its projecting wire is over the outer edge of the adjuster, then solder its coil to the adjuster prong.
(2) Place thermistors (45) on lower face of board and adjuster (47) and solder one lead of each together with red or black base connection lead wire (Ref. Fig. 4) in eyelet terminal.
(3) Screw and tighten rear housing and bearing assembly (43) into rear of board and adjuster (47).

B. Assemble stator assembly.
(1) Place fixed coil (40) on hook of outside lamination assembly (41) in position shown. (Ref. Fig. 4)
(2) Slip end of coil bracket (39) between upper face of outside lamination assembly (41) and fixed coil (40).
(3) Slip end of shunt (38) between lower face of outside lamination assembly (41) and fixed coil (40).
(4) Pass screw (35) through lock washer (36), coil bracket (39), outside lamination assembly (41) and shunt (38) and tighten in shunt nut (37).
(5) Pass screw (34) through outer end of shunt and turn it a few turns into shunt nut (37).
(6) Press inside core (33) into outside lamination assembly (41).
(7) Position bottom plate (31) and plate and terminal assembly (30) on previous assembly and secure. Check to be sure holes through plates and inside core are aligned to permit later assembly onto studs of base and receptacle assembly (48).
(8) Make a hook in the end of cut wire (29) as shown and solder it and the center top lead of fixed coil (40) to the neck of the hairspring terminal of plate and terminal assembly (30).

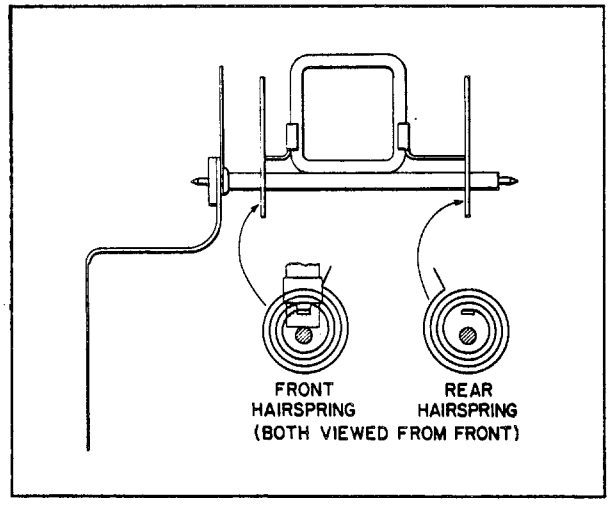
C. Assemble board and bearing assembly and stator assembly on base and receptacle assembly.
(1) Slide board and bearing assembly onto studs.
(2) Slide stator assembly onto studs in position that permits fixed coil leads to run directly down into eyelet terminals with thermistor leads not already soldered in. (Ref. Fig.4)

TORQUE PRESSURE INDICATOR NO. 217-03221



OVERHAUL INSTRUCTIONS

(3) Solder thermistor and fixed coil leads to terminals.
(4) Solder black lead to "1" terminal of receptacle and red lead to "2" terminal.



D. Assemble rotor and hairspring assembly.
(1) Solder hairspring (25) to terminals of moving coil on rotor body assembly (27). Ref. Fig. 5)
(2) If necessary, reshape hairspring slightly so that turns are equally spaced and lie in a plane at right angles to rotor shaft.

E. Install rotor and hairspring assembly.
(1) Place rotor and hairspring assembly (24) in stator assembly with hook of outside lamination assembly (41) passing through its moving coil.
(2) Slide top bushing (28) on studs of base and receptacle assembly (48).
(3) Carefully slide tipped top plate (22) over pointer of rotor and hairspring assembly (24) and seat it on studs of base and receptacle assembly (48).
(4) Install and tighten self-locking nuts (23) on studs.
(5) Place front bearing nut (20) on housing and bearing assembly (21).
(6) Screw housing and bearing assembly (21) into top plate (22) and seat pivots (26) of rotor and hairspring assembly (24) in both upper and lower bearings. Be careful pivot is in bearing and not resting against cap of housing.
(7) Adjust housing and bearing assembly (21) to provide 0.001 to 0.002 inch rotor end play, then lock in position by tightening front bearing nut (20). Be careful not to change end play when tightening nut.
(8) Solder hairsprings to their respective terminals. (Ref. Fig. 4)

F. Install dial and adjust movement.
(1) Carefully slide tipped dial (11) over pointer and attach to top plate (22) by means of dial nut (12) and dial screw (14) which passes through dial bushing (17) between dial and top plate. Use washers (13, 15, 16).
(2) Bend upper snubber made from cut wire (29) and lower snubber (46) to position. (Ref. sub-section 7A)

Internal Wiring
Figure 4

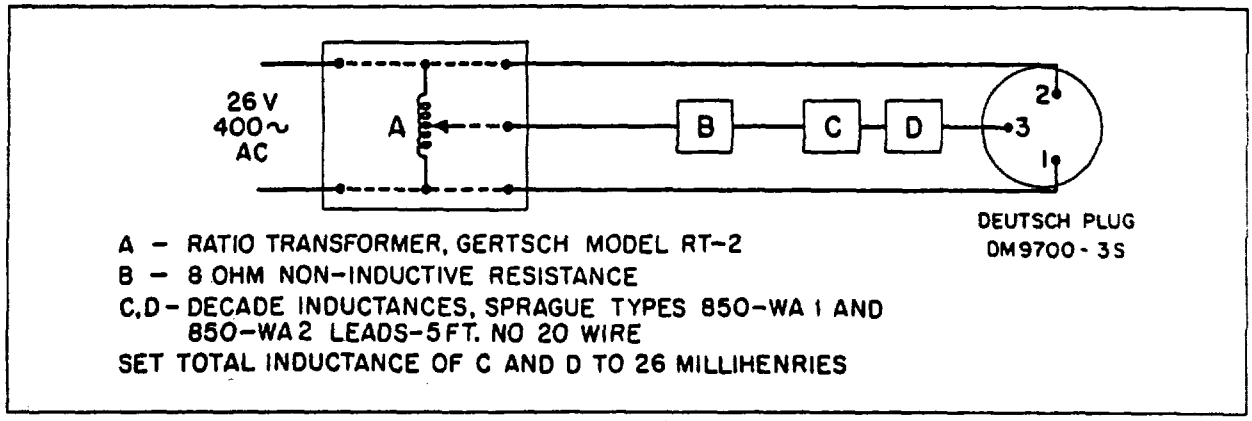
Detail of Hairspring Position
Figure 5

TORQUE PRESSURE INDICATOR NO. 217-03221

OVERHAUL INSTRUCTIONS

(3) Bend pointer to position. (Ref. sub-section 7B)
(4) Adjust lower hairspring to proper torque. (Ref. sub-section 7C)
(5) Solder yellow lead to most accessible end of hairspring adjuster.

G. Calibrate the indicator. (Ref. Section 8)



H. Install case and mask assembly and seal indicator.
(1) Install case assembly with mask (7) in proper position over dial (11).
(2) Solder case assembly (8) to base and receptacle assembly (48) with 63-37 resin core solder using induction heater. (Ref. Section 11)
(3) Check to be sure rivet (5) fits hole in base and receptacle assembly (48) but leave out of hole.
(4) Head indicator to 75 ± 5°C (167 ± 9°F) for 30 minutes.
(5) Place indicator in autoclave and evacuate to 200 microns and hold for five minutes.
(6) Admit dry helium, dew point below -55°C (-67°F), to autoclave to pressure of one atmosphere (760 mm mercury).
(7) Re-evacuate to 200 microns then refill with dry helium to one atmosphere of pressure.
(8) Remove indicator from autoclave and immediately place rivet (5) in hole in base and receptacle assembly (48) and seal in place with a minimum of solder.
(9) Touch up case with dull black paint or lacquer.
(10) Using screw (2) and washers (3,4), install nameplate (1).

7. Fits and Clearances

A. Bend snubbers to lie parallel to base, approximately 1/16 inch from hairspring, and approximately 1/32 inch from rotor shaft.

B. Bend pointer so it is parallel with and 0.02 to 0.04 inch from dial, covers half of the length of a minor graduation line and is over offscale reference mark when against low-end stop.

C. With the dial horizontal, rotate the hairspring adjuster to swing the pointer against the low-end stop. Continue turning the adjuster in the down-scale direction an additional 90 to 100 degrees.

Test Circuit
Figure 6

TORQUE PRESSURE INDICATOR NO. 217-03221

OVERHAUL INSTRUCTIONS

8. Testing

A. Calibration Procedures - uncased indicator. (Ref. Fig. 9)

(1) Connect indicator to test circuit. (Ref. Fig.6)
(2) Check to be sure power applied to ratio transformer is 26 ± 0.5 volts, 400 ± 2 hertz.
(3) Set ratio transformer to ".5980".
(4) Holding indicator with dial horizontal, use a screwdriver to avoid moving the housing and bearing assembly (21), loosen dial nut (12).
(5) Loosen dial screw (14).
(6) Rotate dial (11) until pointer indicates 0 psi.
(7) Tighten dial screw (14).
(8) Reduce voltage applied to ratio transformer to 15 volts.
(9) Set ratio transformer to move pointer to exact middle of scale. Since indicator has not yet been calibrated, this will not necessarily be specified mid-scale value.
(10) Install balance weights (18, 19) as required to make pointer position remain unchanged when dial is moved from horizontal to normal vertical operating position, then rotated 90, 180 and 270 degrees.
(11) Increase applied voltage to 26 ± 0.5 volts.
(12) Set ratio transformer to ".5980".
(13) With indicator in normal operating position, if necessary, loosen dial screw (14) and rotate dial until pointer indicates 0 psi, then tighten dial screw (14).
(14) Set ratio transformer to ".4020".
(15) Turn shunt adjusting screw (34) to open or close the shunt (38) until the pointer indicates 60 psi. If necessary, remove and discard screw (34) and bend shunt (38) to obtain correct pointer position.
(16) Set ratio transformer to "5600", then turn power off. If pointer fails to swing off low end of scale without tapping, increase lower hairspring tension as required. Test the indicator in all four dial vertical positions and with dial horizontal.
(17) Check indications at all test values. (Ref. Fig. 7)
(18) Repeat steps 13 and 15 as required to bring all indications within tolerance.
(19) Holding housing and bearing assembly (21) with screwdriver, tighten dial nut (12).
(20) Place a drop of glyptal on shunt screw (34), if used, to seal it in place.

Transformer Setting	Indicated PSI	Tolerance ± PSI	Transformer Setting	Indicated PSI	Tolerance ± PSI
.5980	0	0.9	.4666	40	0.2
.5648	10	0.6	.4344	50	0.3
.5312	20	0.6	.4020	60	0.6
.4989	30	0.3			
Friction Test Tolerance: ± 0.35 psi			Position Error Tolerance: ± 0.30 psi		

Test Values
Figure 7

TORQUE PRESSURE INDICATOR NO. 217-03221

OVERHAUL INSTRUCTIONS

B. Test Procedure - sealed indicator.

(1) Connect the indicator to test circuit. (Ref. Fig. 6)
(2) Check to be sure power supply to ratio transformer is 26 ± 0.5 volts, 400 ± 2 hertz.
(3) With indicator at room temperature and with dial in normal operating position, successively set ratio transformer at each test value shown in Figure 7. Notice indication before and after lightly tapping the indicator. The difference caused by tapping shall not exceed specified Friction Test Tolerance, nor shall the indication after tapping be out of tolerance for the test value involved.
(4) Set ratio transformer to mid-scale value and note pointer position after tapping. Rotate indicator 90, 180 and 270 degrees, then to position with dial horizontal. The difference between the indication in normal position and any other position shall not exceed specified Position Error Tolerance. (Ref. Fig. 7)
(5) Turn off power supply. Pointer shall swing off scale without tapping.

9. Trouble Shooting

The only troubles which occur in an indicator, other than external physical damage, cause failure to pass test specified in sub-section 8B. When it has been determined in which test the trouble occurs, the indicator must be opened (Ref. sub-section 2A) after which possible causes as listed in Figure 8 may readily be checked to isolate the trouble.

TROUBLE	PROBABLE CAUSE	REMEDY
SCALE ERROR TEST		
POINTER OFF SCALE AT ALL VALUES	Open lead or leads	Connect or replace lead
	Open hairspring	Connect or replace hairspring
	Open moving coil	Replace rotor assembly
POINTER SLAMS LOW	Shorted moving coil	Replace rotor assembly
POINTER SLAMS HIGH OR LOW	Open fixed coil	Replace coil
	Open lead	Connect or replace lead
	Open thermistor	Replace thermistor
ERROR AT LOW VALUES	Incorrect zero and span adjustment	Readjust
ERROR AT HIGH VALUES	Incorrect span adjustment	Readjust
ALL READINGS EQUALLY HIGH OR LOW	Incorrect zero adjustment	Readjust
ERROR AT INTERMEDIATE VALUES	Irregular air gap in lamination	Replace inside core, outside lamination assy, or both
POWER FAILS TO RETURN OFF SCALE	Rotor assembly unbalanced	Rebalance rotor assembly
	Incorrect hairspring adjustment	Increase hairspring tension
	Incorrectly shaped pointer	Bend to proper shape
FRICTION TEST EXCESSIVE ERROR	Pivot out of bearing	Adjust position
	No end play	Adjust end play
	Defective pivots	Replace pivots
	Defective or dirty bearings	Replace housing and bearing assembly
	Lint in air gap	Clean
POSITION ERROR TEST EXCESSIVE ERROR	Rotor assembly unbalanced	Rebalance rotor assembly
POINTER FAILS TO RETURN OFF SCALE IN SOME POSITIONS	Rotor assembly unbalanced	Rebalance rotor assembly
	Incorrectly shaped pointer	Bend to proper shape

Trouble Shooting Chart

TORQUE PRESSURE INDICATOR NO. 217-09261

GENERAL INFORMATION

1. Introduction

This Manual contains instructions for the overhaul of EDISON Aircraft Torque Pressure Indicator, part No. 217-09261.

It is prepared in accordance with ATA Specification No. 100 including the Uniform Chapterization and Numbering System designated therein so that the pages may be inserted into their proper locations in the basic aircraft overhaul manual if desired.

All of the material in this manual falls within the classification "Engine Indicating - Chapter 77".

2. List of Effective Pages

Overhaul Manual 1085-5W

TORQUE PRESSURE INDICATOR NO. 217-09261

OVERHAUL INSTRUCTIONS

1. Description and Operation

The pressure indicator covered by these overhaul instructions is part of the EDISON variable reluctance type Torque Pressure Indicating System. (Ref. Fig. 1)

The Indicator
Figure 1

Table of Leading Particulars
Power Supply .. 26 V single phase 400 Hz
Pressure Range .....0 to 75 psi

It is an hermetically sealed instrument designed to be secured to an instrument panel by means of a standard mounting clamp. An electrical connector on the rear provides for connection to the transmitter and power supply.

The function of the indicator is to translate into pressure units the voltage applied to its moving coil by the pressure transmitter. This is accomplished through the use of several simple principles as follows:

A. When the current flows in the same direction through two coils, their magnetic flux is in the same direction. Thus their opposite magnetic poles are next to each other, so the coils are attracted to each other. (Ref. Fig. 2A)

B. When alternating current flows through a coil, the resulting flux cutting across a second coil induces a current within it if its circuit is complete. At any given instant the induced current flows in the direction opposite to the applied current. (Ref. Fig. 2B) Thus the induced fluxes are opposed and the coils repel each other.

C. In the indicator a constant 26 volt 400 hertz current flows through the stationary field coil making a flux pattern through the core and across

TORQUE PRESSURE INDICATOR NO. 217-09261

OVERHAUL INSTRUCTIONS

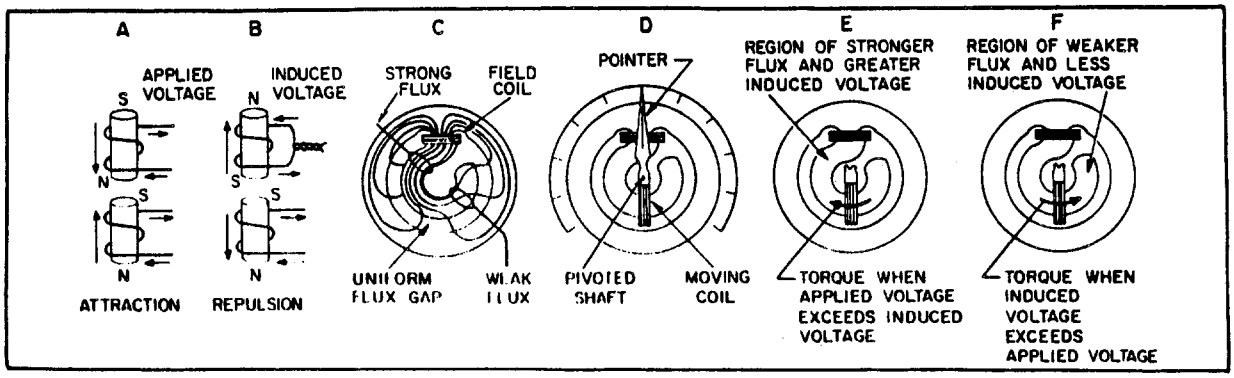
the air gap. (Ref. Fig. 2C) The flux is strongest near the base of the hook-shaped part of the core and decreases uniformly along its length.

D. The moving coil with attached pointer is pivoted to rotate with the core hook at its center. (Ref. Fig. 2D) Two hairsprings transmit applied voltage to coil and furnish torque to swing pointer off low end of scale when no voltage is applied.

E. When the transmitter applies voltage to the moving coil it causes a current at any given instant to be in the same direction as that in the field coil (in phase).

F. At the same time, since the coils are energized with alternating current, the transformer effect is inducing an opposing voltage (180° out of phase) in the moving coil.

G. If the moving coil is at a position where applied voltage is greater than induced voltage, current will flow in the same direction as that of the field coil and the resulting torque will move the coil toward the base of the hook where the field coil flux is greater. (Ref. Fig. 1E) As it moves the induced voltage increases, the current and resulting torque decrease until the coil comes to rest at the point where applied voltage is just enough greater than induced voltage to overcome hairspring torque.



H. If applied voltage decreases below induced voltage, the resulting torque will cause the coil to swing toward the end of the hook until it reaches a point where equilibrium is again achieved. (Ref. Fig. 2F)

I. Because the voltage applied to the moving coil is obtained from two similar inductive, resistive voltage dividers, any variations in power supply voltage cause proportional changes in all voltages involved, hence do not affect the position assumed by the moving coil. (Ref. Fig. 3)

J. In order to compensate for resistance changes in the copper field coils, thermistors are connected in series with them.

2. Disassembly (Ref. Fig. 9)

CAUTION: USE EXTREME CARE TO KEEP DUST, FIBERS AND OTHER FOREIGN MATTER OUT OF SILICONE FLUID IMPREGNATED BEARINGS. DO NOT IMMERSE MECHANISM IN CLEANING FLUID.

Principles of Indicator Operation
Figure 2

TORQUE PRESSURE INDICATOR NO. 217-09261

OVERHAUL INSTRUCTIONS

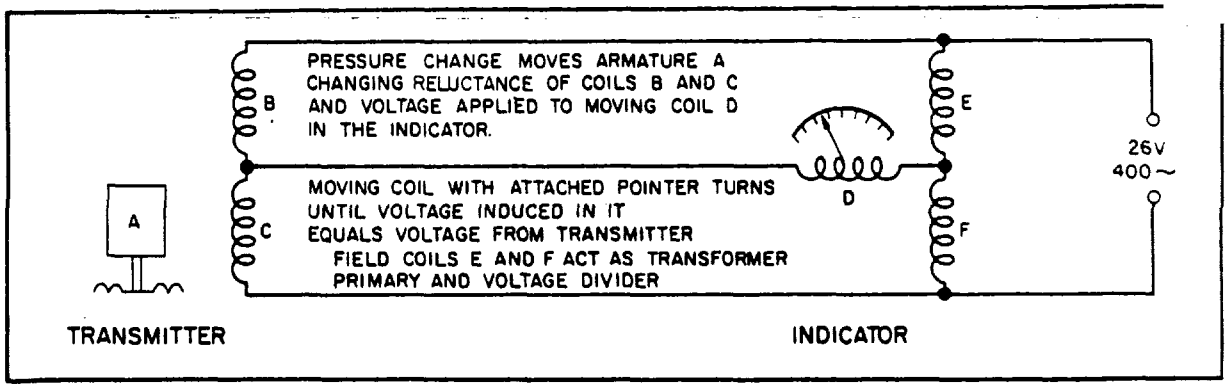
A. Remove case and mask assembly (6).
   (1) Use induction heater (Ref. Section 11) to unsolder case and mask assembly (6) from base and receptacle assembly (48) of complete movement assembly after stripping paint.

   NOTE: No further disassembly of case and mask assembly is recommended.

B. Remove evacuation hole rivet (5).
   (1) Remove the two screws (2) and washers (3, 4) and nameplate (1).
   (2) Unsolder and remove rivet (5) from hole in base and receptacle assembly (48).

   NOTE: No further disassembly of the movement assembly is required to permit cleaning, inspection and check of detail parts. If parts are found to be defective, continue disassembly as required.

C. Remove dial (11).
   (1) Remove dial nut (12), screw (14), washers (13, 15, 16) and bushing (17).
   (2) Tip dial (11) and carefully slide it out from under pointer of rotor and hairspring assembly (24).



D. Remove rotor balance weights (18, 19).
   (1) Grasp weight (18, 19) with tweezers in manner to straighten the slight bend of the weight so that it may be slipped off of the balance cross of the rotor.

E. Remove front housing and bearing assembly.

   NOTE: If rotor and hairspring assemble (24) is to be removed, delay this step until top plate (22) and snubber (29) have been removed.

   (1) Loosen front bearing nut (20).
   (2) Unscrew and remove housing and bearing assembly (21) and nut (20).

F. Remove rotor and hairspring assembly (24).
   (1) Cut off upper snubber (29).
   (2) Unsolder hairsprings (25) from terminal of plate and terminal assembly (28) and board and adjuster assembly (47).

Basic Principle of Operation of the System
Figure 3

TORQUE PRESSURE INDICATOR NO. 217-09261

OVERHAUL INSTRUCTIONS

(3) Remove self-locking nuts (23) and lift off top plate (22) using care not to damage pointer.
(4) Turn and lift out rotor and hairspring assembly (24).

NOTE: Removal of pivots (26, from rotor body assembly (27) is not recommended.

G. Remove hairsprings (25) from rotor and hairspring assembly (24).

H. Remove stator assembly (29-41 assembled) and board and bearing assembly (43-47 assembled).
(1) Lift off top bushings (28).
(2) Unsolder leads from base and receptacle assembly (48).
(3) Lift off stator assembly with board and bearing assembly attached.
(4) Take out bottom bushings (42).
(5) Unsolder fixed coil leads from board and adjuster assembly (44), thus separating stator assembly and board and bearing assembly.

I. Remove fixed coil (40).
(1) Unsolder fixed coil lead from terminal of plate and terminal assy (30).
(2) Unsolder and remove cut wire (29) only if replacement is required.
(3) Remove rivet (32).
(4) Remove plate and terminal assembly (30) and bottom plate (31).
(5) Push out inside core (33).
(6) Remove screws (34, 35), lock washer (36), and shunt nut (37).
(7) Slide shunt (38) and coil bracket (39) from under fixed coil (40).
(8) Slide fixed coil (40) from outside lamination assembly (41).

J. Disassemble board and bearing assembly (43-47 assembled).
(1) Unscrew and remove rear housing and bearing assembly (43).
(2) Unsolder and remove thermistors (45).
(3) Unsolder and remove snubber (46).

3. Cleaning (Ref. Fig. 9)

A. Carefully clean solder from case and mask assembly (6) and base and receptacle assembly (48) so they will be ready for resealing case after assembly.

B. If microscopic inspection of bearings shows hairlike fibers in the bearing cavity, remove with tweezers. Use no other cleaning method on bearings since they are factory impregnated with a special silicone fluid.

C. Vapor degrease all parts made solely of metal, using trichlorethylene.

WARNING: AVOID BREATHING FUMES OR PERMITTING TRICHLORETHYLENE TO CONTACT SKIN.

4. Inspection/Check (Ref. Fig. 9)

A. Visual
(1) Check cover glass (9) for cracks or chips.
(2) Check dial (11) for scratches or stains.
(3) Check hairsprings (25) for distortion.
(4) Check pointer of rotor and hairspring assembly (24) for distortion or chipped paints.

TORQUE PRESSURE INDICATOR NO. 217-09261

OVERHAUL INSTRUCTIONS

4. B. Microscope (30X)
   (1) Check pivots (26) for pits, grooves or distortion.
   (2) Check housing and bearing assemblies (21, 43) for dents in bearing cap, foreign matter, and loss of clear fluidity of silicone fluid.

   C. Ohmmeter
   (1) Check moving coil with ohmmeter across adjuster and upper hairspring terminal of assembled indicator, or directly across coil of rotor body assembly (27). Acceptable resistance: 25 ± 8 ohms.
   (2) Check fixed coil (40) with ohmmeter across lower terminals. Acceptable resistance: 46 ± 15 ohms.
   (3) Check thermistors (45) with ohmmeter across leads. Acceptable resistance at 25°C (77°F): 5.6 ± 0.1 ohm.

5. Repair

   Replace all defective or damaged parts.

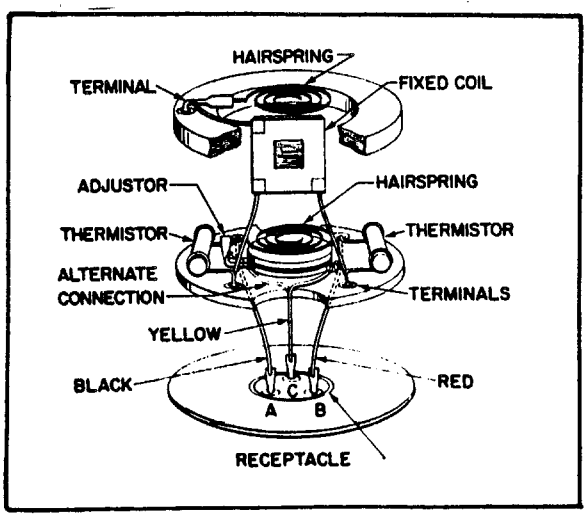
6. Assembly (Ref. Fig. 9)

   A. Assemble board and bearing assembly.
   (1) Slide snubber (46) to bottom of higher prong of hairspring adjuster of board and adjuster (47). Position the snubber so its projecting wire is over the outer edge of the adjuster, then solder its coil to the adjuster prong.
   (2) Place thermistors (45) on lower face of board and adjuster (47) and solder one lead of each together with red or black base connection lead wire (Ref. Fig. 4) in eyelet terminal.
   (3) Screw and tighten rear housing and bearing assembly (43) into rear of board and adjuster (47).

   B. Assemble stator assembly.
   (1) Place fixed coil (40) on hook of outside lamination assembly (41) in position shown. (Ref. Fig. 4).
   (2) Slip end of coil bracket (39) between upper face of outside lamination assembly (41) and fixed coil (40).
   (3) Slip end of shunt (38) between lower face of outside lamination assembly (41) and fixed coil (40).
   (4) Pass screw (35) through lock washer (36), coil bracket (39), outside lamination assembly (41) and shunt (38) and tighten in shunt nut (37).
   (5) Pass screw (34) through outer end of shunt and turn it a few turns into shunt nut (37).
   (6) Press inside core (33) into outside lamination assembly (41).
   (7) Position bottom plate (31) and plate and terminal assembly (30) on previous assembly and secure. Check to be sure holes through plates and inside core are aligned to permit later assembly onto studs of base and receptacle assembly (48).
   (8) Make a hook in the end of cut wire (29) as shown and solder it and the center top lead of fixed coil (40) to the neck of the hairspring terminal of plate and terminal assembly (30).

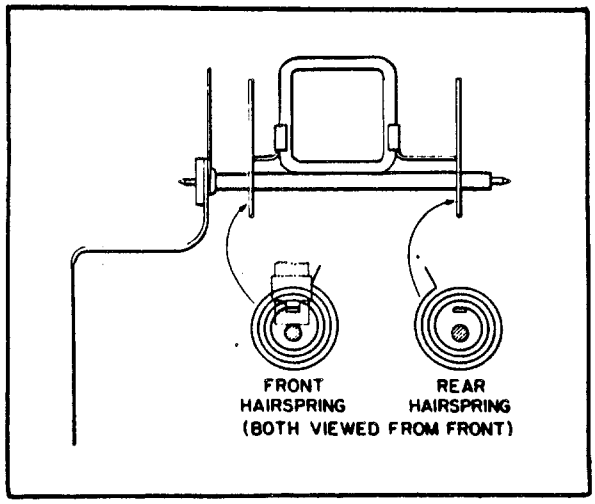
   C. Assemble board and bearing assembly and stator assembly on base and receptacle assembly.
   (1) Slide board and bearing assembly onto studs.
   (2) Slide stator assembly onto studs in position that permits fixed coil leads to run directly down into eyelet terminals with thermistor leads not already soldered in. (Ref. Fig. 4).

TORQUE PRESSURE INDICATOR NO. 217-09261



OVERHAUL INSTRUCTIONS

(3) Solder thermistor and fixed coil leads to terminals.
(4) Solder black lead to "A" terminal of receptacle and red lead to "B" terminal.



D. Assemble rotor and hairspring assembly.
(1) Solder hairspring (25) to terminals of moving coil on rotor body assembly (27). (Ref. Fig. 5).
(2) If necessary, reshape hairspring slightly so that turns are equally spaced and lie in a plane at right angles to rotor shaft.

E. Install rotor and hairspring assembly.
(1) Place rotor and hairspring assembly (24) in stator assembly with hook of outside lamination assembly (41) passing through its moving coil.
(2) Slide top bushing (28) on studs of base and receptacle assembly (48).
(3) Carefully slide tipped top plate (22) over pointer of rotor and hairspring assembly (24) and seat it on studs of base and receptacle assembly (48).
(4) Install and tighten self-locking nuts (23) on studs.
(5) Place front bearing nut (20) on housing and bearing assembly (21).
(6) Screw housing and bearing assembly (21) into top plate (22) and seat pivots (26) of rotor and hairspring assembly (24) in both upper and lower bearings. Be careful pivot is in bearing and not resting against cap of housing.
(7) Adjust housing and bearing assembly (21) to provide 0.001 to 0.002 inch rotor end play, then lock in position by tightening front bearing nut (20). Be careful not to change end play when tightening nut.
(8) Solder hairsprings to their respective terminals. (Ref. Fig. 4)

F. Install dial and adjust movement.
(1) Carefully slide tipped dial (11) over pointer and attach to top plate (22) by means of dial nut (12) and dial screw (14) which passes through dial bushing (17) between dial and top plate. Use washers (13, 15, 16).
(2) Bend and cement upper snubber (29) using epoxy cement and lower snubber (46) to position. (Ref. sub-section 7A).

Internal Wiring
Figure 4

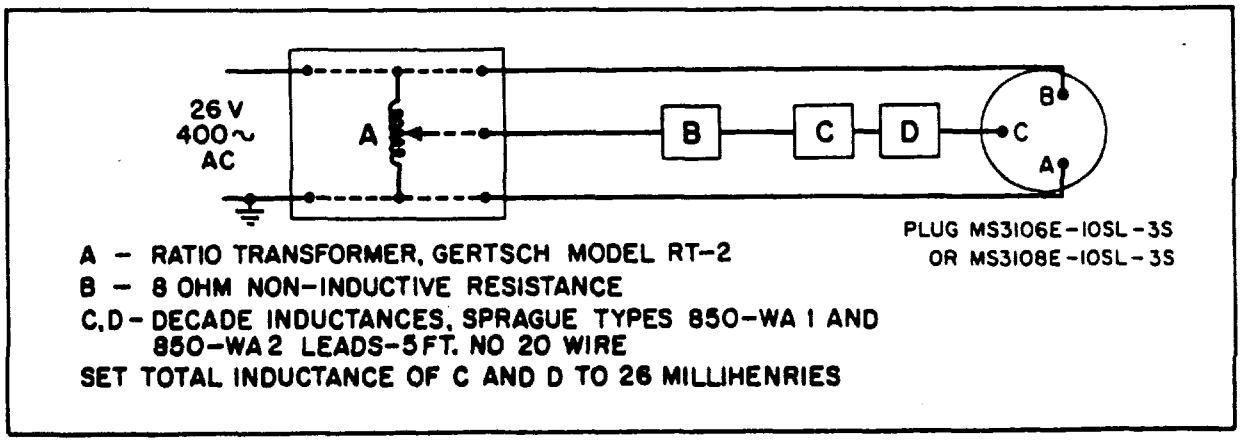
Detail of Hairspring Position
Figure 5

TORQUE PRESSURE INDICATOR NO. 217-09261

OVERHAUL INSTRUCTIONS

(3) Bend pointer to position. (Ref. sub-section 7B)
(4) Adjust lower hairspring to proper torque. (Ref. sub-section 7C)
(5) Solder yellow lead to most accessible end of hairspring adjuster.

G. Calibrate the indicator. (Ref. Section 8)



H. Install case and mask assembly and seal indicator.
(1) Install case assembly with mask (7) in proper position over dial (11).
(2) Solder case assembly (8) to base and receptacle assembly (48) with 63-37 resin core solder using induction heater. (Ref. Section 11)
(3) Check to be sure rivet (5) fits hole in base and receptacle assembly (48) but leave out of hole.
(4) Heat indicator to 75 ± 5°C (167 ± 9°F) for 30 minutes.
(5) Place indicator in autoclave and evacuate to 200 microns and hold for five minutes.
(6) Admit a dry mixture of 10% Helium and 90% Nitrogen, dew point below -55°C (-67°F), to autoclave to pressure of one atmosphere (760 mm mercury).
(7) Re-evacuate to 200 microns then refill with a dry mixture of 10% Helium and 90% Nitrogen to one atmosphere of pressure.
(8) Remove indicator from autoclave and immediately place rivet (5) in hole in base and receptacle assembly (48) and seal in place with a minimum of solder.
(9) Touch up case with dull black paint or lacquer.
(10) Using screw (2) and washers (3,4), install nameplate (1).

7. Fits and Clearances

A. Bend snubbers to lie parallel to base, approximately 1/16 inch from hairspring, and approximately 1/32 inch from rotor shaft.

B. Bend pointer so it is parallel with and 0.02 to 0.04 inch from dial, covers half of the length of a minor graduation line and is over offscale reference mark when against low-end stop.

C. With the dial horizontal, rotate the hairspring adjuster to swing the pointer against the low-end stop. Continue turning the adjuster in the down-scale direction an additional 90 to 100 degrees.

Test Circuit
Figure 6

TORQUE PRESSURE INDICATOR NO. 217-09261

OVERHAUL INSTRUCTIONS

8. Testing

A. Calibration Procedures - uncased indicator. (Ref. Fig. 9)

(1) Connect indicator to test circuit. (Ref. Fig. 6)
(2) Check to be sure power applied to ratio transformer is 26 ± 0.5 volts, 400 ± 2 hertz.
(3) Set ratio transformer to ".5980".
(4) Holding indicator with dial horizontal, use a screwdriver to avoid moving the housing and bearing assembly (21), loosen dial nut (12).
(5) Loosen dial screw (14).
(6) Rotate dial (11) until pointer indicates 0 psi.
(7) Tighten dial screw (14).
(8) Reduce voltage applied to ratio transformer to 15 volts.
(9) Set ratio transformer to move pointer to exact middle of scale. Since indicator has not yet been calibrated, this will not necessarily be specified mid-scale value.
(10) Install balance weights (18, 19) as required to make pointer position remain unchanged when dial is moved from horizontal to normal vertical operating position, then rotated 90, 180 and 270 degrees.
(11) Increase applied voltage to 26 ± 0.5 volts.
(12) Set ratio transformer to ".5980"
(13) With indicator in normal operating position, if necessary, loosen dial screw (14) and rotate dial until pointer indicates 0 psi, then tighten dial screw (14).
(14) Set ratio transformer to ".4020".
(15) Turn shunt adjusting screw (34) to open or close the shunt (38) until the pointer indicates 75 psi. If necessary, remove and discard screw (34) and bend shunt (38) to obtain correct pointer position.
(16) Set ratio transformer to "5600", then turn power off. If pointer fails to swing off low end of scale without tapping, increase lower hairspring tension as required, test the indicator in all four dial vertical positions and with dial horizontal.
(17) Check indications at all test values. (Ref. Fig. 7) Vary transformer setting between low and high values to obtain exact reading.
(18) Repeat steps 13 and 15 as required to bring all indications within tolerance. If impossible to obtain acceptable calibration, use alternate dial.
(19) Holding housing and bearing assembly (21) with screwdriver, tighten dial nut (12).
(20) Place a drop of glyptal on shunt screw (34), if used, to seal it in place.

Transformer Setting			Indicated	Tol.	Transformer Setting			Indicated	Tol.
Low	Nominal	High	PSI	± PSI	Low	Nominal	High	PSI	±PSI
.6012	.5980	.5948	0	1.20	.4672	.4664	.4656	50	.30

.5198	.5185	.5172	30	.50	.4046	.4020	.3994	75	1.00
.4926	.4918	.4910	40	.30					
Friction Test Tolerance: ±.75 psi					Position Error Tolerance: ±.75 psi				

Test Values
Figure 7

TORQUE PRESSURE INDICATOR NO. 217-09261

OVERHAUL INSTRUCTIONS

B. Test Procedure - sealed indicator.

(1) Connect the indicator to test circuit. (Ref. Fig. 6).

(2) Check to be sure power supply to ratio transformer is 26 ± 0.5 volts, 400 ± 2 hertz.

(3) With indicator at room temperature and with dial in normal operating position, successively set ratio transformer at each nominal test value shown in Figure 7. Notice indication before and after lightly tapping the indicator. The difference caused by tapping shall not exceed specified Friction Test Tolerance. If indication is not correct, change transformer setting to obtain correct reading, Necessary change shall not be beyond low or high value in figure 7.

(4) Set ratio transformer to mid-scale value and not pointer position after tapping. Rotate indicator 90, 180 and 270 degrees, then to position with dial horizontal. The difference between the indication in normal position and any other position shall not exceed specified Position Error Tolerance. (Ref. Fig. 7).

(5) Turn off power supply. Pointer shall swing off scale without tapping.

9. Trouble Shooting

The only troubles which occur in an indicator, other than external physical damage, cause failure to pass test specified in sub-section 8B. When it has been determined in which test the trouble occurs, the indicator must be opened (Ref. sub-section 2A) after which possible causes as listed in Figure 8 may readily be checked to isolate the trouble.

10. Storage Instructions

No special storage requirements apply to this indicator. It is an hermetically sealed unit subject only to damage from rough handling.

11. Special Tools, Fixture, and Equipment

Autoclave (4 qt. home pressure cooker - modified, add connector and valve) ("Mirror-Matic" or equivalent)
Vacuum Pump (Central Sci. Co., Chicago, Ill. "Cenco-Magnavac" or equivalent)
Induction Heater, 3 KW, RF (McDowell Electronics Inc., Metuchen, N.J., Model 3KW-2 or equivalent)
Ratio Transformer (Singer Metrics Inc., Los Angeles, Calif. Gertsch Model RT-2)
Resistor - 8 ohm non-inductive (General Radio Co., West Concord, Mass., Type 510B)
Decade Inductances (Sprague Elec. Co., North Adams, Mass., Types 850-WA1 and 850-WA2- one of each required.)

TORQUE PRESSURE TRANSMITTER NO. 318-02020

GENERAL INFORMATION

1. Introduction

This Manual contains instructions for the overhaul of EDISON Aircraft Torque Pressure Transmitters, part No. 318-02020.

It is prepared in accordance with ATA Specification No. 100 including the Uniform Chapterization and Numbering System designated therein so that the pages may be inserted into their proper locations in the basic aircraft overhaul manual if desired.

All of the material in this Manual falls within the classification "Engine Indicating - Chapter 77".

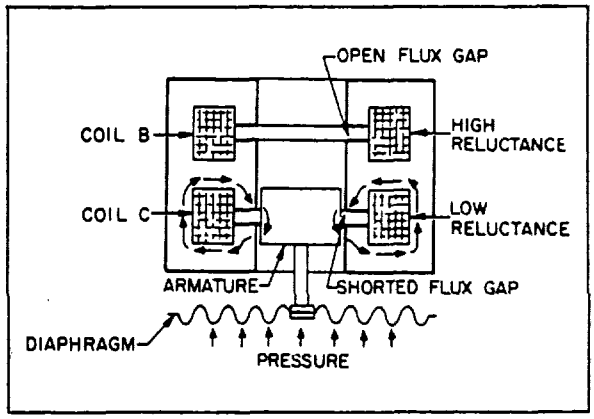
TORQUE PRESSURE TRANSMITTER NO. 318-02020

OVERHAUL INSTRUCTIONS



1. Description and Operation

The pressure transmitter covered by these overhaul instructions is the sensing unit of the EDISON variable reluctance type Torque Pressure Indicating System. (Ref. Fig. 1)

It is a factory sealed unit, the lower end of which is provided with both external and internal threads for pressure connection. It can be installed directly on a pressure boss on the engine by means of the external thread. It may also be mounted on a bracket by means of these threads, pressure connection being made to the internal threads by means of fittings and tubing. A pressure boss at the top of the transmitter permits connection of a vent pressure line if differential pressure is to be measured. A removable plug cap at the top of the transmitter gives access for calibration adjustment. An electrical connector receptacle is also on the top of the transmitter.

OVERHAUL INSTRUCTIONS

The function of the transmitter is to furnish to the indicator an electrical potential which varies according to the applied pressure. In the transmitter a diaphragm moves a magnetic armature inside of two stationary coils whenever there is a change in applied pressure. (Ref. Fig. 2) These coils are connected in series with a 26 volt 400 hertz power source and act as a variable reluctance voltage divider. The armature position determines the effective flux gaps in the magnetic housing of the coils, hence the reluctance of the coils. As connected to the indicator, which contains a similar but fixed voltage divider, a voltage regulated by the transmitter is applied to the moving coil of the indicator. (Ref. Fig. 3)

2. Disassembly (Ref. Fig. 6)

A. Remove plug cap to permit calibration adjustment.
   (1) Remove lockwire.
   (2) Remove screws (2) and lock washers (3).
   (3) Remove plug cap (1) with "O" ring (5) attached.
   (4) Remove nameplate (4).
   (5) Remove "O" ring (5) from plug cap (1).

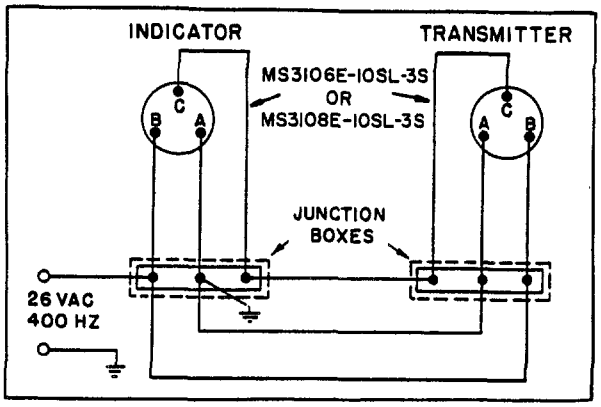
B. Attempt no other disassembly.

3. Cleaning

A. Wash outside with trichlorethylene and blow dry.

WARNING: AVOID BREATHING FUMES OR PERMITTING TRICHLORETHYLENE TO CONTACT SKIN.

4. Inspection/Check



None required.

5. Repair

Non-repairable.

6. Assembly (Ref. Fig. 6)

A. Install plug cap following calibration adjustment.
   (1) Install new "O" ring (5) on plug cap (1).
   (2) Place nameplate (4) on transmitter.
   (3) Install plug cap and "O" ring assembly on transmitter.
   (4) Secure with screws (2) and lock washers (3).
   (5) Install new lockwire.

Test Connections

TORQUE PRESSURE TRANSMITTER NO. 318-02020
OVERHAUL INSTRUCTIONS

7. Fits and Clearances

None applicable.

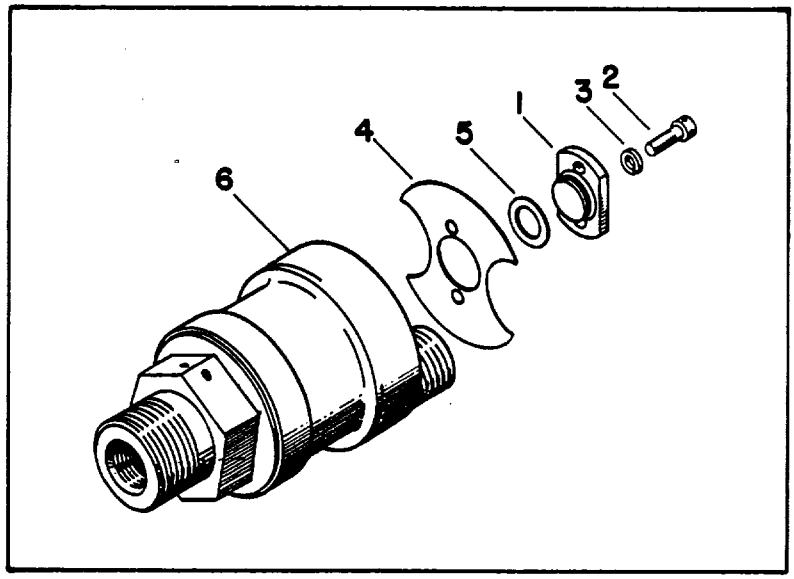
8. Testing

A. For equipment required, refer to sub-heading 11.
B. Test calibration:
(1) Mount the transmitter in vertical position on a dead weight or other type of pressure tester capable of supplying accurate pressure of dry air in the range involved.
(2) Connect the transmitter to EDISON Transmitter Test Indicator, part No. 389-1, or 389-00340, which has been checked for accuracy.(Ref.Fig.4)
(3) Energize the circuit with 26 ± 0.5 volts, 400 ± 5 hertz.
(4) Apply pressure, testing transmitter at each applicable value marked on indicator dial. Before reading indicator, lightly tap both transmitter and indicator. All readings shall be within tolerances as marked on dial.
C. Adjust calibration if necessary.
(1) Leave transmitter connected to indicator and power on.
(2) Set pressure to zero psi value.
(3) Remove plug cap (Ref. sub-heading 2).
(4) Using zero adjusting tool, part No. 41486, turn armature assembly inside transmitter until indicator reads approximately correctly.
(5) Apply maximum pressure for range.
(6) Using both zero adjusting tool, part No. 41486,and scale span adjusting tool, part No. 42015, hold zero adjusting tool stationary while turning scale span adjusting tool to give indicator reading within tolerance after tapping.
(7) Reduce pressure to zero psi value.
(8) Hold span adjusting tool stationary while turning zero adjusting tool to give indicator reading within tolerance after tapping.
(9) Repeat steps (5) through (8) until both readings are within tolerance with tools removed before reading indicator.
(10)Check readings at all test values.
(11)Replace plug cap (Ref. sub-heading 6).
(12)Replace lock wire using No. 20 corrosion resistance steel wire.
D. Test for leakage:
(1) Disconnect wiring and pressure connection.
(2) Connect "VENT" boss to pressure tester by means of flexible tubing.
(3) With transmitter in vertical position, immerse it in alcohol until only the upper half of the electrical connector receptacle projects above the alcohol.
(4) Apply 15 psi air pressure to the "VENT". No evidence of leakage shall be visible.
(5) Remove from alcohol, blow dry, release pressure, and disconnect pressure tube.

9. Trouble Shooting

None required. If transmitter leaks, or can not be calibrated within tolerance, it must be scrapped since no repairs are possible.

10. Storage Instructions



Cover pressure and vent ports and electrical connector to keep out foreign matter during storage. Use shipping caps such as Edison No. 14234, 14235, and 14236, or other suitable means.

TORQUE PRESSURE TRANSMITTER NO. 418-01064

GENERAL INFORMATION

1. Introduction

This manual contains instructions for the overhaul of EDISON Aircraft Torque Pressure Transmitter, part No. 418-01064.

It is prepared in accordance with ATA Specification No. 100 including the Uniform Chapterization and Numbering System designated therein so that the pages may be inserted into their proper locations in the basic aircraft overhaul manual if desired.

All of the material in this manual falls within the classification "Engine Indicating - Chapter 77".

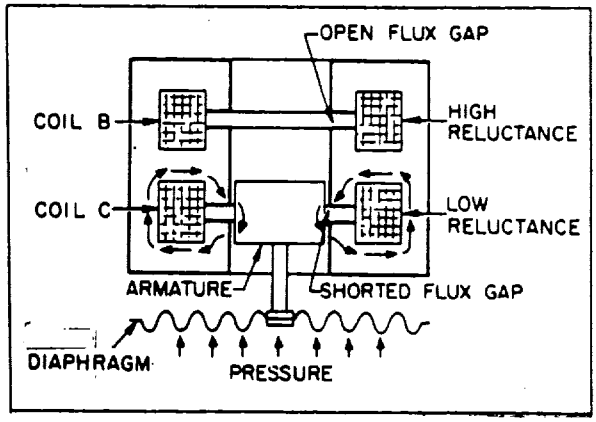
TORQUE PRESSURE TRANSMITTER NO. 418-01064

OVERHAUL INSTRUCTIONS



1. Description and Operation

The pressure transmitter covered by these overhaul instructions is the sensing unit of the EDISON variable reluctance type Torque Pressure Indicating System. (Ref. Fig. 1).

It is a factory sealed unit, the lower end of which is provided with both external and internal threads for pressure connection. It can be installed directly on a pressure boss on the engine by means of the external thread. It may also be mounted on a bracket by means of these threads, pressure connection being made to the internal threads by means of fittings and tubing. A pressure boss at the top of the transmitter permits connection of a vent pressure line if differential pressure is to be measured. A removable plug cap at the top of the transmitter gives access for calibration adjustment. An electrical connector receptacle is also on the top of the transmitter.

OVERHAUL INSTRUCTIONS

The function of the transmitter is to furnish to the indicator an electrical potential which varies according to the applied pressure. In the transmitter a diaphragm moves a magnetic armature inside of two stationary coils whenever there is a change in applied pressure. (Ref. Fig. 2) These coils are connected in series with a 26 volt 400 hertz power source and act as a variable reluctance voltage divider. The armature position determines the effective flux gaps in the magnetic housing of the coils, hence the reluctance of the coils. As connected to the indicator, which contains a similar but fixed voltage divider, a voltage regulated by the transmitter is applied to the moving coil of the indicator. (Ref. Fig. 3).

2. Disassembly (Ref. Fig. 7)

   A. Remove plug cap to permit calibration adjustment.
      (1) Remove lockwire.
      (2) Remove screws (2) and lock washers (3).
      (3) Remove plug cap (1) with "O" ring (5) attached.
      (4) Remove nameplate (4).
      (5) Remove "O" ring (5) from plug cap (1).
   B. Attempt no other disassembly.

3. Cleaning

   A. Wash outside with trichlorethylene and blow dry.

      WARNING: AVOID BREATHING FUMES OR PERMITTING TRICHLORETHYLENE TO CONTACT SKIN.

4. Inspection/Check

   None required.

5. Repair

   Non-repairable.

6. Assembly (Ref. Fig. 7)

   A. Install plug cap following calibration adjustment.
      (1) Install new "O" ring (5) on plug cap (1).
      (2) Place nameplate (4) on transmitter.
      (3) Install plug cap and "O" ring assembly on transmitter.
      (4) Secure with screws (2) and lock washers (3).
      (5) Install new lockwire.

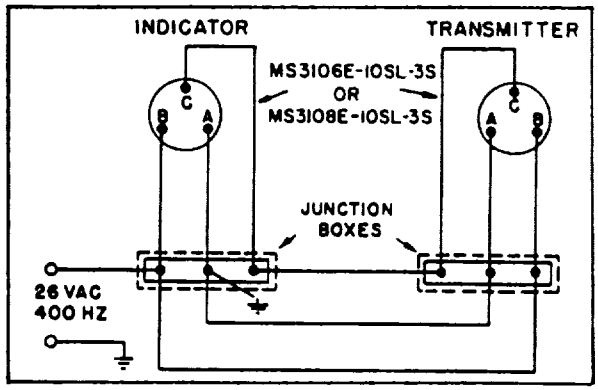
Indicator Test Circuit

Figure 4

TORQUE PRESSURE TRANSMITTER NO. 418-01064

OVERHAUL INSTRUCTIONS

7. Fits and Clearances



None applicable.

8. Testing

A. For equipment required, refer to sub-heading 11.
B. Test calibration:
(1) Connect test indicator, part No. 289-100A or 289-00341, to test circuit. (Ref. Fig. 4)
(2) Check to be sure power applied to ratio transformer is 26 ± 0.5 volts, 400 ± 10 hertz.
(3) Successively set the ratio transformer to the two values for each test pressure in Fig. 5 and record the readings either as a table or as range marks on a paper pasted on the indicator cover glass. Lightly tap the indicator before each reading.
(4) Mount the transmitter in a vertical position on a dead weight tester or other type of pressure tester capable of supplying accurate pressure of dry air at each test value specified in Fig. 5.
(5) Connect the transmitter to the test indicator. (Ref. Fig. 6)
(6) Energize the circuit with 26 ± 0.5 volts, 400 ± 10 hertz.
(7) Apply exact pressure, testing transmitter at each test value in Fig.5. Before reading, lightly tap both transmitter and indicator. All indicator readings shall be between tolerance values as determined in step (3) for pressure involved.
C. Adjust calibration if necessary.
(1) Leave transmitter connected to indicator and power on.
(2) Set pressure to zero psi value.
(3) Remove plug cap (Ref. sub-heading 2).
(4) Using zero adjusting tool, part No. 41486, turn armature assembly inside transmitter until indicator reads approximately correctly.
(5) Apply 75 psi pressure.
(6) Using both zero adjusting tool, part No.41486, and scale span adjusting tool, part No.42015, hold zero adjusting tool stationary while turning scale span adjusting tool to give indicator reading within tolerance after tapping.
(7) Reduce pressure to zero psi value.
(8) Hold span adjusting tool stationary while turning zero adjusting tool to give indicator reading within tolerance after tapping.
(9) Repeat steps (5) through (8) until both readings are within tolerance with tools removed before reading indicator.

Test Pressure PSI	Indicator Reading To Be Between Readings Caused By Transformer Settings of		Equivalent PSI Tolerance
0	.6015	.5945	± 1.30
10	.5741	.5683	± 1.10
20	.5473	.5425	± 0.90
30	.5203	.5167	± 0.70
40	.4931	.4905	± 0.50
45	.4801	.4781	± 0.40
50	.4671	.4657	± 0.30
60	.4423	.4393	± 0.60
70	.4172	.4126	± 0.90
75	.4048	.3992	± 1.10

Test Values
Figure 5

Transmitter Test Connections
Figure 6

TORQUE PRESSURE TRANSMITTER NO. 418-01064

OVERHAUL INSTRUCTIONS

(10) Check readings at all test values, using method in "B. Test Calibration".
(11) Replace plug cap (Ref. sub-heading 6).
(12) Replace lockwire using No. 20 corrosion resistant steel wire.

D. Test for leakage:
(1) Disconnect wiring and pressure connection.
(2) Connect "VENT" boss to pressure tester by means of flexible tubing.
(3) With transmitter in vertical position, immerse it in alcohol until only the upper half of the electrical connector receptacle projects above the alcohol.
(4) Apply 15 psi air pressure to the "VENT". No evidence of leakage shall be visible.
(5) Remove from alcohol, blow dry, release pressure, and disconnect pressure tube.

9. Trouble Shooting

None required. If transmitter leaks, or can not be calibrated within tolerance, it must be scrapped since no repairs are possible.

10. Storage Instructions

Cover pressure and vent ports and electrical connector to keep out foreign matter during storage. Use shipping caps such as Edison No. 14234, 14235 and 14236, or other suitable means.

11. Special Tools, Fixtures and Equipment

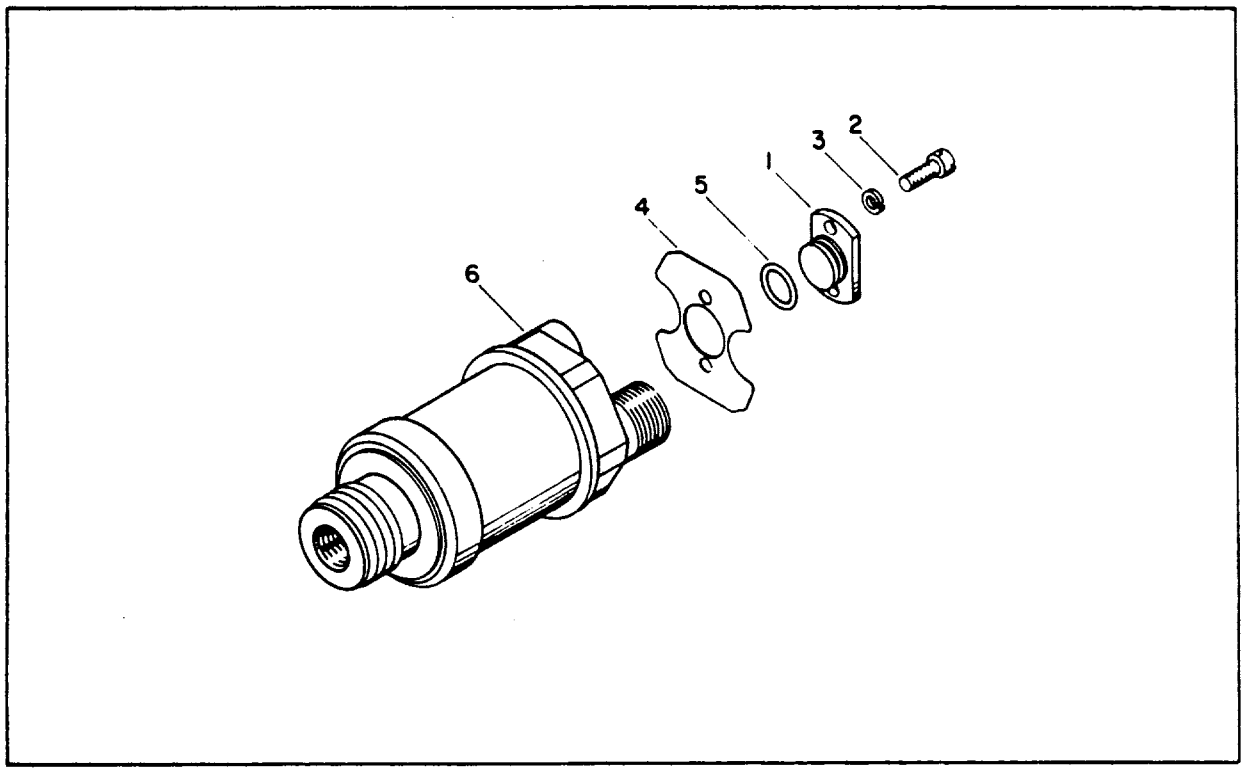
Dead Weight or other Pressure Tester

Transmitter Test Indicator - Edison Part No. 289-100A or 289-00341

Zero Adjusting Tool - Edison Part No. 41486

Scale Span Adjusting Tool - Edison Part No. 42015

Ratio Transformer - Singer Metrics Div., Los Angeles, Calif. (Gertsch Model RT-2)



Resistor - 8 ohm non-inductive (General Radio Co., West Concord, Mass., Type 510B Decade Resistor, or equivalent.)

Decade Inductances - Sprague Elec. Co., North Adams, Mass. (Types 850-WA1 and 850-WA2 - one each required)

NOTE: If the last three items are unavailable, the table referred to in paragraph 8.B.3. can be made and supplied by the Edison Instrument Division for any individual test indicator.

GENERAL ELECTRIC

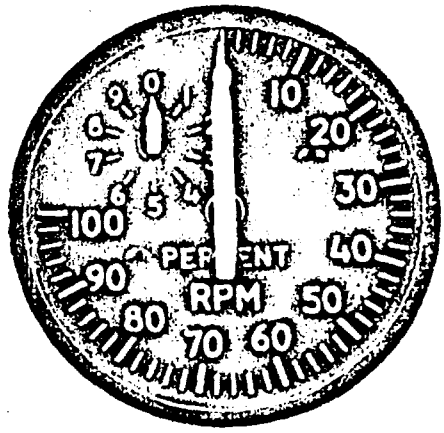
OVERHAUL MANUAL
TACHOMETER INDICATOR
TYPE DJ-81



GEI-73341A

1. DESCRIPTION AND OPERATION.

A. GENERAL. This manual provides overhaul instructions and a parts list for Type DJ-81 tachometer indicators, manufactured by the General Electric Company, Instrument Department, West Lynn, Massachusetts. These indicators (see figure 1) are designed for use in aircraft at panel locations to provide visual indication of the speed of rotation of remotely-located shafts. They are provided with and without integral lighting. These overhaul instructions apply to the following models:

MODEL	RANGE
8DJ81CAE1	0-110%
8DJ81CAE2	0-110%
8DJ81LAA1 (Integrally lighted)	0-110%
8DJ81LAA2 (Integrally lighted)	0-110%

Overhaul and Test instructions for additional models are provided in Section 13 by the use of Difference Data Sheets. See Contents page A-1/A-2 for a list of the Difference Data Sheets.

Type DJ-81 Aircraft Panel Instrument
Figure 1

B. DESCRIPTION. The Type DJ-81 tachometer indicator is a hermetically-sealed unit consisting of a synchronous motor, with magnetic coupling to an indicating mechanism. The synchronous motor is driven by the three-phase supply of a tachometer generator whose frequency is a function of the speed at which it is driven. A torque proportional to the motor speed is applied to the indicating mechanism through magnetic coupling. Integral lighting of the indicator scale and pointer is provided in lighted models by three lamps mounted internally and operated on a 5-volt supply (a-c or d-c).

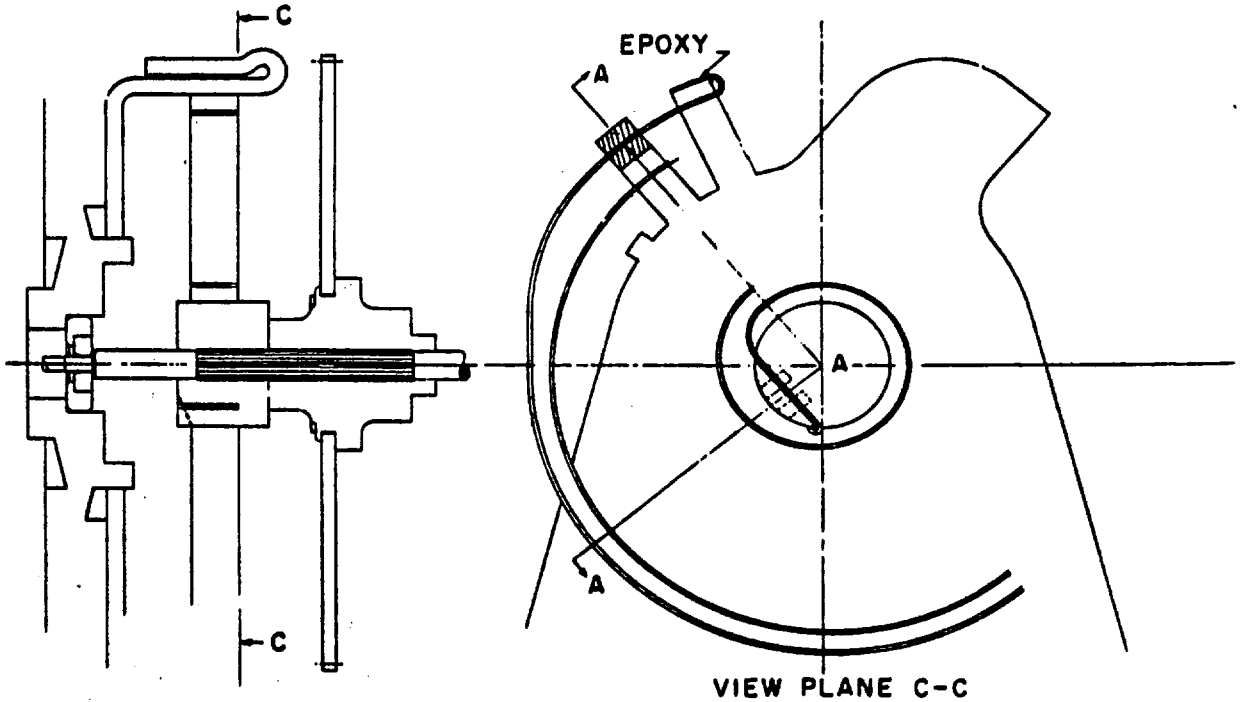
C. PRINCIPLES OF OPERATION. The Type DJ-81 tachometer indicator contains a self-starting, permanent magnet, synchronous motor. The synchronous motor is driven by a tachometer generator coupled to a shaft whose speed

is being measured. Hence, the motor speed is directly proportional to the generator frequency and shaft speed. The indicating mechanism is coupled to the synchronous motor through magnetic coupling, which permits slippage between the drive and the indicating mechanism, but transmits a torque proportional to the motor speed. The indicating mechanism is spring loaded against this torque and deflects through an angle which is proportional to the speed of the shaft being monitored.

D. MODIFICATIONS OF SUB 1 MODELS. In order to improve tachometer indicator performance, a modification to existing design has been initiated to reduce calibration drift noted in some indicators. Hence, all models not converted to the sub 2 configuration should be modified as described below. The modification consists of replacing the existing control spring and method of attachment of the spring to provide a more positive clamping action and more stable calibration.

(1) To perform the modification described herein, proceed as follows:

(a) Disassemble the instrument per instructions in section 2 of this manual. Disassemble only to the point necessary to replace the modified components.



(b) When existing shaft and hub assembly and adjusting arm have been removed, replace as follows:

(1) Slip outer turn of spring into bent-over tab and hook the end of the spring onto the straight tab of the adjusting arm. Pull the hooked portion of the spring tight against the straight tab. (See figure 2.)

(2) Continue assembly per section 2 of this manual. When the instrument is assembled, less the can, level the spring and apply a small amount of epoxy (Armstrong Adhesive A-12) to the straight tab at the point of attachment of the control spring.

NOTE: When properly mixed (i.e. one to one ratio, resin to activator) Armstrong Adhesive A-12 should be quick cured by heating in an 125°C oven for 15 or 20 minutes. Quick curing will eliminate the possibility of movement of the spring under extended cure at room temperature, and guarantees proper flowing of the epoxy. Removal of the epoxy may be facilitated by using a soldering iron to break the bond of the epoxy and allow it to be chipped away. The epoxy stripper should be used for cleaning only and similar to No. 688 Cold Stripper, manufactured by the Fidelity Chemical Products Corp., Newark, New Jersey.

(3) Continue assembly and perform all test of section 8 of this manual.

Layout of Spring Clamping Method
Figure 2

(2) When assembly and test of the instrument is complete, restamp the case nameplate to indicate a sub 2 instead of sub 1. This allows identification that the change has been accomplished.

(3) Modification kits are available to perform the above modification. Table I lists the components of the modification kits.

TABLE I
MODIFICATION KITS

New Part No.	Quantity	Nomenclature	Old Part No.	Disposition
9850494G1	1	Modification Kit*		
5468506G12	1	Shaft and Hub Assembly	5468506G9	Scrap
5468500P6	1	Adjusting Arm	5468500P5	Scrap
9850495G1	1	Modification Kit**		
5468506G13	1	Shaft and Hub Assembly	5468506G2	Scrap
5468500P7	1	Adjusting Arm	5468500P4	Scrap

*For all Type DJ-81 unlighted models.
**For all Type DJ-81 lighted models.

E. LEADING PARTICULARS. Leading particulars of the indicator are listed in Table II.

TABLE II
LEADING PARTICULARS

Stator resistance	Approx. 75 ohms, lead-to-lead
Number of elements	One
Number of poles (motor rotor)	Four
Receptacle	
8DJ81CAE1, CAE2	Hermetically Sealed 10SL-3P
Mating Plug	
8DJ81CAE1, CAE2	MS3106-10SL-3S or MS3108-10SL-3S
Receptacle	
8DJ81LAA1, LAA2	Hermetically Sealed 14S-5P
Mating Plug	
8DJ81LAA1, LAA2	MS3106-14S-5S or MS3108-14S-5S
Scale	
8DJ81CAE1, CAE2	0-110% RPM
8DJ81LAA1, LAA2	0-110% RPM
Weight	
8DJ81CAE1, CAE2	0.7 pounds
8DJ81LAA1, LAA2	0.9 pounds
Length (less receptacle)	
8DJ81CAE1, CAE2	4-1/4 inch (max)
8DJ81LAA1, LAA2	4-1/2 inch (max)
Diameter	2.0 inches
Ambient Temperature Range	-54°C (-67°F) to +70°C (+158°F)

2. DISASSEMBLY.

A. GENERAL. Before disassembly, study the exploded views given in figures 3 and 4 and become familiar with the parts and assemblies, and their relationships. Special overhaul tools available are listed in Table X.

B. REMOVAL OF MOTOR AND HEAD ASSEMBLY.

(1) Disengage retaining ring (2, figure 3) and remove nameplate (1) from motor and head assembly (6).

(2) Unseal the instrument by heating soldered rivet (3) in the sealing hole with the tip of a hot soldering iron for about 15 seconds. The combination of the solder melting and the helium gas expanding will permit the rivet to pop out. Attach a mating plug to the receptacle and fasten the mating plug assembly in a vise. Wrap a damp cloth around the front of the instrument and, with the instrument vertical (dial up), apply a small gas flame to the solder seal on the outer

edge of cup support assembly (16) while pulling and twisting case assembly slightly until it is free. Immediately wipe off any excess solder.

(3) Remove bezel (5) from can assembly (4).

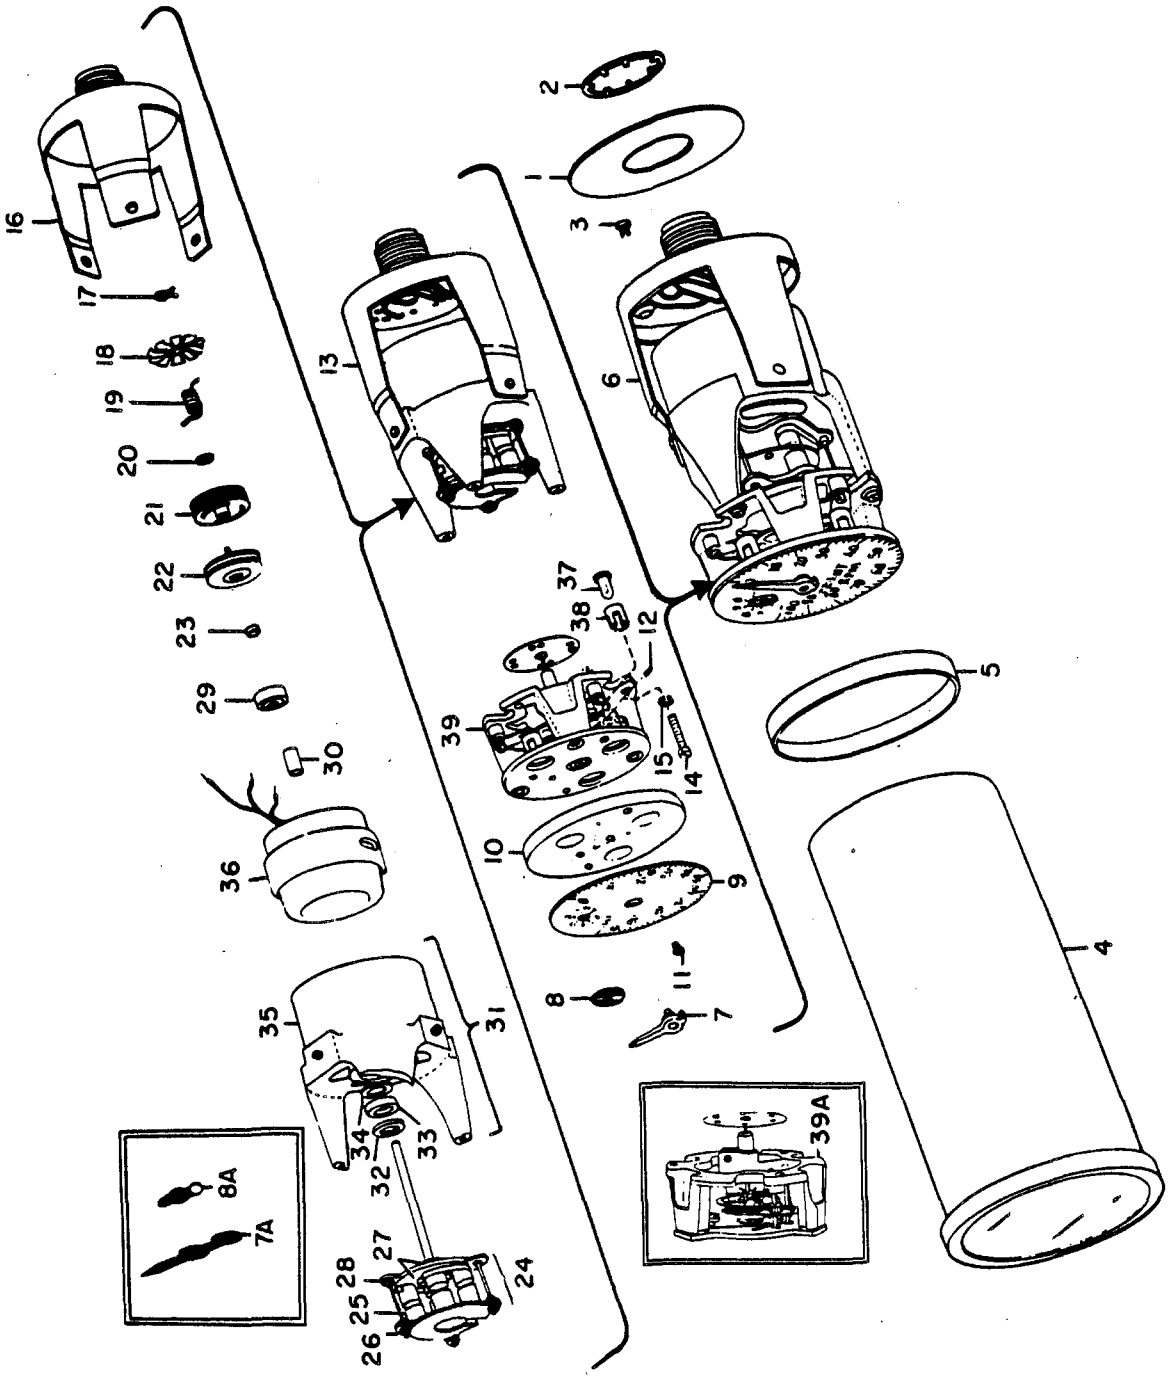
C. DISASSEMBLY OF HEAD ASSEMBLY.

(1) Remove pointers (7 or 7A and 8 or 8A) from their respective shafts.

(2) Remove two screws (11) and remove scale plate (9). On lighted models remove diffuser plate (10).

(3) Separate head assembly (39 or 39A) from motor assembly (13) by removing three screws (14) and lockwashers (15). Remove head assembly (39 or 39A) by sliding it radially outward so that the disk and hub assembly (1 or 1A, figure 4), and the center shaft and hub assembly (7 or 7A) pass through the slot in the shaft and magnet assembly (24, figure 3).

CAUTION: HOLD HEAD ASSEMBLY (39 OR 39A) FIRMLY AGAINST MOTOR ASSEMBLY (13) WHILE REMOVING SCREWS (14) TO PREVENT DAMAGE TO THE DISK AND HUB ASSEMBLY (1 OR 1A, FIGURE 4) AND CENTER SHAFT AND HUB ASSEMBLY (7 OR 7A).



(4) Using a soldering iron, apply heat at the hub of disk and hub assembly (1 or 1A, figure 4) and remove from center shaft and hub assembly (7 or 7A).

NOTE: Clean all solder from the shaft while the solder is still molten, to facilitate reassembly.

(5) To release the outer turn of control spring from the tab on adjusting arm, proceed with the following:

(a) On CAE1 and LAA1 models, unsolder the control spring (8 or 8A) from the adjusting arm (4 or 4A).

NOTE: Bent over tab on spring must be straightened to remove. This whole procedure is not recommended for normal dissembly and repair. Instead, let adjusting arm stay with the spring and center shaft and hub assembly. Center shaft and hub assembly is normally furnished with spring attached. The only time the spring needs to be removed from the adjusting arm is to replace either the arm or center shaft and hub assembly.

(b) On CAE2 and LAA2 models, apply heat with a soldering iron to break the bond of the epoxy and chip away the rest to release the control spring (8A) from the adjusting arm (4 or 4A). Straighten the bent tab on spring and slip the outer turn of the control spring out of the bent over tab and pull end of spring away from the straight tab on the adjusting arm (4 or 4A).

NOTE: Clean epoxy from adjusting arm (4 or 4A) with cold stripper (Cold Stripper No. 688, see Table III).

(6) Remove plate and jewel assembly (2 or 2A) and adjusting arm (4 or 4A) by removing three screws (3).

(7) Separate plate and jewel assembly and adjusting arm by removing screw (5) and washer (6).

(8) Remove center shaft and hub assembly (7 or 7A) with control spring (8 or 8A), small pointer shaft assembly (9 or 9A), and idler shaft and gear assembly (10) from head and jewel assembly (18), being careful not to damage the gears.

Figure 4

(9) To remove control spring from center shaft and hub assembly, proceed as follows:

(a) On models CAE1 and LAA1, unsolder the control spring (8 or 8A) from the anchor hub of the center shaft and hub assembly (7 or 7A).

NOTE: Bent over tab on spring must be straightened to remove. This whole procedure is not recommended for normal disassembly and repair. Instead, let adjusting arm stay with the spring and center shaft and hub assembly. Center shaft and hub assembly is normally furnished with spring attached. The only time the spring needs to be removed from the adjusting arm is to replace either the arm or center shaft and hub assembly.

(b) On models CAE2 and LAA2 apply heat using a soldering iron to break the bond of epoxy and chip away the rest to release the control spring (8A) from the anchor hub of the center shaft and hub assembly (7 or 7A).

NOTE: Clean anchor hub and control spring (8A) with cold stripper (Cold Stripper No. 688, see Table III).

(10) Loosen screw (17) and slide jewel holder assembly (16) out of head and jewel assembly (18).

D. DISASSEMBLY OF THE MOTOR ASSEMBLY (13, Figure 3).

(1) Remove the cup support assembly (16) from the motor housing (35) by carefully springing the three arms outward so that they are free of the bosses on the casting. Unsolder the leads from the receptacle, taking care not to put a strain on the leads at the soldering points and label the leads.

(2) Remove pin spring (17) and slide balance wheel (18) from the shaft of shaft and magnet assembly (24).

NOTE: Mark top of balance wheel so that it can be replaced in the same position at reassembly. (Same side facing outward.)

(3) Remove spring (19) by grasping the tab and turning it counterclockwise.

(4) Remove spacer (20), hysteresis rotor assembly (21), rotor assembly (22) and spacer (23) from shaft of shaft and magnet assembly (24).

(5) Remove shaft and magnet assembly (24) from motor housing assembly (31) being careful not to damage bearing (33).

(6) Disassemble shaft and magnet assembly (24, figure 3) as follows:

(a) Remove upper magnet assembly (25) attached by three nuts (26).

(b) Remove temperature compensators (27) from upper magnet assembly (25) and lower magnet and post assembly (28).

NOTE: Do not remove or reposition temperature compensators (27) unless components of shaft and magnet assembly (24) are to be replaced. This will likely avoid readjusting of the compensators at reassembly, providing the disk and hub assembly (1 or 1A, figure 4) and/or the control spring (8 or 8A) are not replaced.

(c) Remove three adjusting nuts (26, figure 3) from lower magnet and post assembly (28).

(7) Remove bearing (29) and spacer (30) from motor housing assembly (31).

(8) Unstake and remove stator frame and coil assembly (36).

(9) To disassemble the motor housing assembly (31), unstake washer (32) and remove ball bearing (33) and washer (34) from motor housing (35).

3. CLEANING.

A. Clean metal parts by washing in a suitable solvent. Dry with clean, moisture-free air.

B. Clean bearings (29 and 33, figure 3) and the bearing in rotor assembly (22) and then dry with clean, moisture-free air. Lubricate the bearings immediately after cleaning.

NOTE: Before assembly, lubricate each ball bearing (29 and 33) and the bearing in the rotor assembly (22) with three drops of silicone fluid (D50W97). The fluid must be applied with a No. 25 hypodermic needle (or equivalent), directly into the bearings, avoiding any contact between the needle and the bearings. Spin the bearings so that the fluid will completely cover the balls and races.

C. CLEANING MATERIALS. Table III is a list of approved cleaning materials recommended for use during cleaning and assembly procedures.

The note on page 10A applies only to indicators assembled in accordance with the alternate method (units not sealed).

NOTE: Before assembly, lubricate each bearing in the rotor assembly (22) with two drops of oil, Pioneer P-10 (MIL-L-6085A). The fluid must be applied with a No. 25 hypodermic needle (or equivalent) directly into the bearing avoiding contact between the needle and the bearings. Spin the bearings so that the fluid will completely cover the balls and rails.

This note applied to all indicators sealed and unsealed.

CAUTION: All previous lubrication must be removed in accordance with section 3B.

C. CLEANING MATERIALS. Table III is a list of approved cleaning materials recommended for use during cleaning and assembly procedures.

TABLE III
CLEANING MATERIALS

Materials	Vendor
Petroleum Spirits (G-E Spec D5B8) (for cleaning connectors)	General Electric Company, Instrument Dept., 40 Federal Street West Lynn, Massachusetts
Toluene (G-E Spec D51311) (for cleaning metal parts)	General Electric Company, Instrument Dept., 40 Federal Street West Lynn, Massachusetts
Chlorethane (for removing petroleum base materials)	Dow Chemical Company 200 Main Street Midland, Michigan
Acetone (for rinsing parts cleaned with petroleum spirits or toluene)	Available commercially
Naphtha (for removing anti-rust preservative)	Available commercially
Benzine (for cleaning metal parts)	Available commercially
No. 688 Cold Stripper (epoxy stripper to clean the adjusting arm tab and control spring)	Fidelity Chemical Products Corp. Newark, New Jersey

4. INSPECTION.

A. GENERAL. Tachometer indicator components should be inspected as follows before assembly is undertaken. The components should also be scrutinized carefully during the assembly procedure.

(1) Examine bearings, bearing surfaces, pivots and gears for wear and broken parts. Replace as required.

(2) Measure the resistance of the stator windings. The resistance of the three phases should match within ±1 ohm. Phase resistance is approximately 75 ohms. Replace faulty stators.

(3) Measure the stator winding insulating value by applying 800 volts a-c between the windings and the frame for five seconds. Replace faulty stators.

5. REPAIR.

A. GENERAL. Repair of the indicators is limited to the replacement of worn or broken parts, magnetizing knocked-down or new magnets, and stabilizing the subassemblies.

B. REPLACEMENT OF SHAFTS. When replacing shaft to which disk is attached, tin end of shaft to be soldered using Ruby stainless flux (G-E specification A10B18) and 50-50 solder.

C. MAGNETIZING THE SHAFT AND MAGNET ASSEMBLY (24, Figure 3).

NOTE: Elimination of air gap will facilitate magnetizing.

(1) Magnetizing is accomplished by means of a Magnetizer (R.F.L. Cat. No. 107A) or equivalent and associated fixture (see Table X).

(2) Insert the magnetizing fixture through the long narrow opening formed by the drag magnets and the top and bottom plates of the shaft and magnet assembly. Pass sufficient current through the Magnetizer to produce a minimum magnetizing force of 3000 oersteds in the magnets.

D. TEMPERATURE STABILIZING THE SHAFT AND MAGNET ASSEMBLY.

NOTE: Required only after magnetizing the shaft and magnet assembly.

(1) Temperature stabilization is accomplished by completing four distinct steps as follows:

(a) Soak one hour minimum (in air) at -70°C (-94°F) to -80°C (-112°F).

(b) Soak one hour minimum (in air) at 100°C (212°C) to 125°C (257°F).

(c) Soak one hour minimum (in air) at -70°C (-94°F) to -80°C (-112°F).

(d) Soak one hour minimum (in air) at 100°C (212°F) to 125°C (257°F).

NOTE: The time of one hour for each step may be reduced to 15 minutes if the magnets are submerged alternately in a -70°C (-84°F) alcohol-dry ice bath and a boiling water bath. Transport the magnet assembly rapidly between the low and high temperatures so as to avoid condensation. Care should be taken to avoid having the magnets contact any magnetic material.

E. REFINISH EXTERIOR CAN ASSEMBLY. If the exterior can assembly requires painting, refinish it using Raffi and Swanson (Wilmington, Massachusetts) No. 4851 black paint or equivalent. (See Table IV.) The surface to be painted must be thoroughly clean.

6. ASSEMBLY.

A. GENERAL. During reassembly it is necessary to make certain adjustments and checks. These are described at the appropriate points in the instructions that follow. Table IV lists materials required during assembly.

TABLE IV
BULK MATERIALS

Material	Vendor
Tape (G-E Spec A23C4A2)	General Electric Company, Instrument Dept., 40 Federal Street West Lynn, Massachusetts
Silicone Fluid (G-E Spec D50W97)	General Electric Company, Instrument Dept., 40 Federal Street West Lynn, Massachusetts
Silicone Fluid, G-E Spec SF81 (50)	General Electric Company, Silicone Products Dept., Mechanicville Rd. Waterford, New York
SAF-T-FLUX (number 2213)	Available commercially
Ruby Stainless Flux (G-E Spec A10B18)	Ruby Chemical Company Box 1108 Columbus, Ohio
Epoxy Adhesive A-12 (G-E Spec A50W298-S1)	Armstrong Products Company Argonne Road Warsaw, Indiana
Cold Stripper (No. 688)	Fidelity Chemical Products Corp. Newark, New Jersey
Black Paint (No. 4851)	Raffi and Swanson Wilmington, Massachusetts

B. ASSEMBLY OF MOTOR ASSEMBLY (13, Figure 3).

(1) Assemble Motor Housing Assembly (31) as outlined below:

(a) Install washer (34, Figure 3), ball bearing (33) and washer (32) in motor housing (35). Before staking washer (32), check the thickness of ball bearing (33) and washer (34). Combined thickness must be 0.165 ± 0.002 inch for the disk (1 or 1A, figure 4) to lie in the approximate center of the air gap of the assembled instrument. If the dimension is not within tolerance, replace washer (34, figure 3) with one of the correct thickness. Measure the bearing thickness from one edge of the inner race to the

opposite edge of the outer race and subtract one-half of the total bearing end play, as measured with the bearing under a one-half pound axial load. Table V gives the recommended pairing of bearing and washer.

TABLE V

BEARING THICKNESS (IN.)	WASHER THICKNESS (IN.)
0.158	0.008
0.156	0.008
0.156	0.010
0.154	0.010
0.154	0.012
0.152	0.012
0.152	0.014
0.150	0.014

(2) Assemble shaft and magnet assembly (24, figure 3) as outlined below:

(a) Install three adjusting nuts (26) on lower magnet and post assembly (28).

(b) Install temperature compensator (27) on upper magnet assembly (25) and lower magnet and post assembly (28).

(c) The temperature compensator (27) provides an adjustment for the effect of temperature on the shaft and magnet assembly (24), the disk and hub assembly (1 or 1A, figure 4), and the control spring (8 or 8A). If any of these parts have been replaced, it will be necessary to readjust the position of the temperature compensator. In addition, if the disk and hub assembly (1 or 1A) has been replaced, a different number of compensators may be required. Table VI gives the recommended initial number and location of compensators according to the temperature coefficient of the disk being used. The coefficient number is marked on the disk.

TABLE VI
LOCATION OF TEMPERATURE COMPENSATOR

DISK RES. TEMP. COEFF.	CODE STAMP	NUMBER OF COMPENSATORS		DISTANCE FROM COMPENSATOR TO AIR GAP
		LOWER MAGNET	UPPER MAGNET	
0.00075 0.00076 0.00077	1	2	0	0.070
0.00078 0.00079 0.00080	2	2	1	0.120
0.00081 0.00082 0.00083	3	2	1	0.095
0.00084 0.00085 0.00086	4	2	1	0.070
0.00087 0.00088 0.00089 0.00090	5	2	2	0.120

NOTE: When only one compensator is required, a "dummy" compensator must be added to the diametrically opposite set of magnets for balance purposes. As the dummy compensator will not affect compensation, it can be located at any convenient distance from the air gap.

(d) Assemble upper magnet assembly (25, figure 3) to lower magnet and post assembly (28) and secure with nuts (26), adjusting the air gap between the magnets to 0.045 to 0.050 inch by positioning nuts.

(e) Magnetize the magnets as outlined in Section 5, Paragraph C.

(f) After magnetizing, temperature stabilize the shaft and magnet assembly (24), making sure the compensators are in place, as outlined in Section 5, Paragraph D.

(3) Assemble shaft and magnet assembly to the motor housing assembly (31) as follows:

(a) Insert shaft and magnet assembly carefully through the bearing (33) in the motor housing assembly.

(b) Slide spacer (30), ball bearing (29), and spacer (23) on the shaft of the shaft and magnet assembly.

(c) Slide rotor assembly (22) on the shaft with the arm facing to the rear of the indicator.

(d) Install hysteresis rotor assembly (21) on the shaft, carefully engaging the arm of rotor assembly (22) with the slot in hysteresis rotor assembly (21).

(e) Slide spacer (20) onto the shaft, then install spring (19) with three open turns toward rotor of motor.

(f) Slide balance wheel (18) onto the shaft and lock in place with pin spring (17).

(g) Balancing of the rotors (21 and 22) and shaft and magnet assembly (24) must be performed as follows:

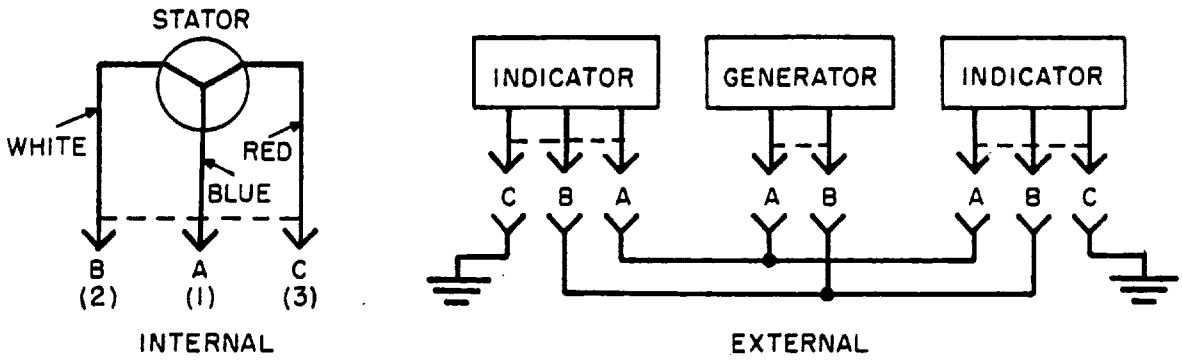
CAUTION: DO NOT PERFORM FOLLOWING BALANCING OPERATION WITH STATOR FRAME AND COIL ASSEMBLY IN PLACE SINCE THE MAGNETIC ATTRACTION BETWEEN THIS ITEM AND THE ROTORS WILL CAUSE ERRONEOUS RESULTS.

(1) Remove sections of the balance wheel (18) as necessary.

(2) When properly balanced, the rotating assembly will not assume a repetitive position when tapped or vibrated.

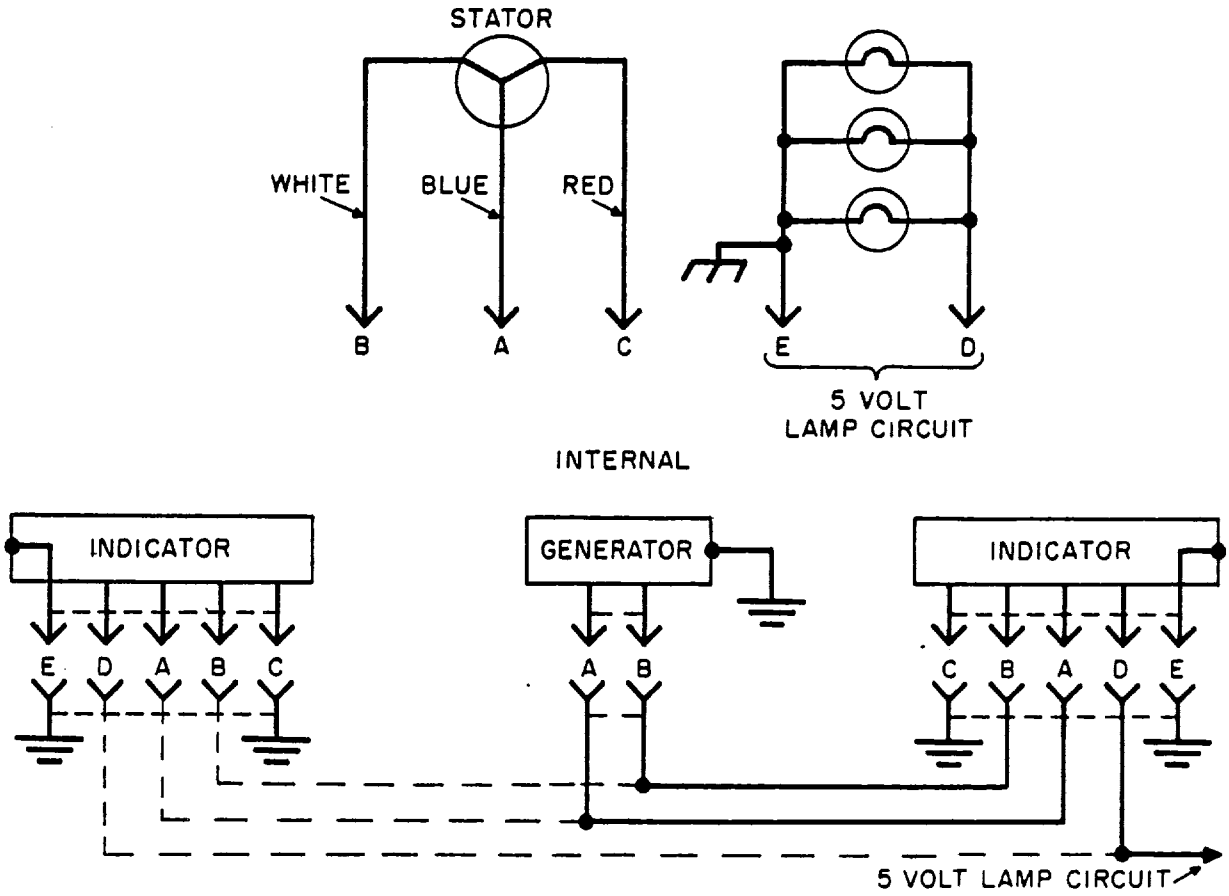
(h) Install the stator frame and coil assembly (36) as follows:

(1) Insert the stator frame and coil assembly in position in the motor housing assembly (31).



(2) Place the leads midway between two of the posts on cup support assembly (16) and stake the stator frame and coil assembly (36) to the motor housing assembly in three places (120 degrees apart) approximately 3/16 inch wide.

(i) Install the cup support assembly (16) as follows:



(1) Solder (using 63-37 solder) the stator leads to the connector as shown in figure 5.

NOTE: Position the leads by forming them carefully so that they do not touch the can or interfere with the balance wheel.

(2) Carefully spring the arms on the cup support assembly (16, figure 3) radially outward and set in place over the motor housing assembly (31), engaging the holes in the cup support assembly (16) with bosses on the motor housing assembly.

EXTERNAL

B. External and Internal Connections for 8DJ81LAA1 and 8DJ81LAA2

External and Internal Wiring Connections for Type DJ-81 Tachometer Indicators
Figure 5

C. ASSEMBLY OF HEAD ASSEMBLY.

(1) Slide jewel holder assembly (16, figure 4) into head and jewel assembly (18) and lock in place with screw (17).

(2) To assemble inner turn of control spring (8 or 8A) to spring anchor hub of center shaft and hub assembly (7 or 7A), proceed as follows:

(a) On CAE1 and LAA1 models, tin the ends of the control spring (8 or 8A) to be soldered using three percent zinc chloride (ZnCl) flux and 63-37 solder. If both parts (spring (8 or 8A) and mating part) are pre-tinned, no additional solder is necessary. When only one part is tinned, use a controlled amount of SAF-T-FLUX (number 2213) and 63-37 percent solder.

(b) On CAE2 and LAA2 models, slip inner end of spring (8A) into slot in the spring anchor hub of the center shaft and hub assembly (7 or 7A), and fasten with epoxy (Armstrong Adhesive A-12, G-E Spec A50W298A). Mix epoxy one part resin and one part activator, apply and quick cure by heating in a 125°C (275°F) oven for 15 to 20 minutes.

(c) Thoroughly clean all tinned parts. An acceptable method consists of washing the parts in boiling water, using three successive washes and a separate container for each wash. Then wash in isopropyl alcohol and air dry.

(3) Set center shaft and hub assembly (7 or 7A), subdial pointer shaft assembly (9 or 9A), and idler shaft and gear assembly (10) in place on the head and jewel assembly (18).

(4) Attach adjusting arm (4 or 4A) to place and jewel assembly (2 or 2A) with screws (5) and washer (6), in approximately its center position.

(5) Loosen screw (17), leaving jewel holder assembly (16) free to slide, and set plate and jewel assembly (2 or 2A) in place, carefully setting all shafts in their respective holes in plate and jewel assembly.

(6) Insert three screws (3) to fasten plate and jewel assembly (2 or 2A) to head and jewel assembly (18).

(7) Adjust endshake of center shaft and hub assembly (7 or 7A) to the tolerance given in Table VII by sliding jewel holder assembly carefully against the shaft, and tighten screw (17).

(8) Attach the outer turn of control spring (8 or 8A) to adjusting arm (4 or 4A) so that the turns of the spring lie flat using the following procedure:

(a) On CAE1 and LAA1 models, solder outer turn of control spring (8 or 8A) to the adjusting arm (4 or 4A) so that the turns of the spring lie flat.

(b) On CAE2 and LAA2 models, slip outer turn of spring (8A) into bent-over tab and hook the end of the spring onto the straight tab of the adjusting arm (4 or 4A). Pull the hooked portion of the spring tight against the straight tab. Level the spring and apply a small amount of epoxy (Armstrong Adhesive A-12, G-E Spec A50W298A) to the straight tab at the point of attachment of the control spring (8A).

NOTE: Mix epoxy thoroughly, one part resin to one part activator. Cure by heating in an 125°C (257°F) oven for 15 to 20 minutes.

NOTE: At this point check the action of the spring by adding pointer, temporarily, and turning through the complete range of rotation. The spring turns must remain in a flat plane without adjacent turns touching.

(9) Solder the disk and hub assembly (1 or 1A, figure 4) so that the distance from the disk to the bottom edge of the head and jewel assembly (18) is 0.533 ± 0.002 inch.

(10) Stabilize control spring (4 or 4A) by submitting head assembly to +70°C (+158°F) with the pointer shaft rotated and held at approximately 85% of full scale for 48 hours.

D. ASSEMBLY OF MOTOR AND HEAD ASSEMBLY.

(1) Place balance weight (12, figure 3) in position on counterweight arm of center shaft and hub assembly (7 or 7A, figure 4).

(2) Place the head assembly (39 or 39A, figure 3) and the motor assembly (13) together, carefully placing the shaft of the head assembly through the slot provided in the shaft and magnet assembly (24).

(3) Fasten the motor and head assembly together with three screws (14) and washers (15). In the lighted models apply epoxy cement (Hysol-6020-8328) to the groove in the motor housing assembly (31) and to light wire. Be sure that the wire lies flat in the groove. Solder the lead to pin D on receptacle.

(4) To install scale plate, use the following procedure:

(a) On unlighted models CAE1 and CAE2, install scale plate (9) and attach with two screws (11).

(b) On lighted models LAA1 and LAA2, install scale plate (9A) and plate diffuser (10) with two screws (11). Wrap the edge of the scale plate, plate diffuser, and plate and jewel assembly with tape (No. 805 Metallized Silver Mylar, 1/2 inch wide).

(5) Install pointers (7 or 7A and 8 or 8A) as follows:

(a) Move the adjusting arm (4 or 4A, figure 4) so that the counterweight arm just touches the pointer stop.

(b) Add the pointers, reaming their hubs as necessary with the Point Reamer (G-E Tool No. 404X84) to the shafts at approximately 2.5 percent RPM below the zero setting.

(c) Move the adjusting arm to bring the pointers onto the zero mark.

E. INSTALLATION OF MOTOR AND HEAD ASSEMBLY.

(1) Place the motor and head assembly (6, figure 3) into can assembly (4) along with bezel (5).

(2) Before sealing the indicator, perform successively the tests of Section 8, Testing. Perform the tests of Paragraphs A through L for unlighted models and Paragraphs A through N for integral lighted models.

(3) Seal instrument as follows:

(a) Re-tin the inside edge of the can assembly (4) and the outside edge of the motor and head assembly (6). Do not permit flux to flow into the can, and tin only the surfaces which will be sealed by solder. Use a resin flux (10 percent resin, 90 percent alcohol).

(b) Assemble instrument in case making sure that the receptacle key is located at the top.

(c) Using B20C12A solder and alcohol only, solder outside edge of the motor and head assembly (6) to case being sure that all voids are filled and being careful that there are no cold joints which will later open when subjected to thermal stress. Do not seal hole in cup support assembly (16).

CAUTION: IN NO CASE SHALL SOLDER OR FLUX BE PERMITTED TO RUN INSIDE THE INSTRUMENT.

NOTE: While heating the back end, care must be taken to keep the front end cool by wrapping the front end with a damp cloth.

(d) Place assembled instrument into a vacuum oven at a maximum of 85 microns absolute pressure at a temperature of 75°C (167°F) to 85°C (185°F) for a minimum of 16 hours.

(e) Within 30 seconds of bake, break vacuum by flushing instrument with helium (-65°C dew point).

Alternate instructions of motor and head assembly.

(1) Assemble support cup to motor such that receptacle key is at the top.

(2) Insert bezel (5, figure 3) and motor assembly (6) into can assembly (4).

(3) Perform the tests of Section 8, testing. Perform the tests of paragraphs A through L for unlighted models and paragraphs A through N for integral lighted models.

(4) Fasten instrument into case as follows:

(a) Tack solder outside edge of motor and head assembly (6) to the case at three points, approximately 1/4 inch wide and 120 degrees apart, using 50/50 solder. Use a resin flux (10 percent resin, 90 percent alcohol).

(b) Do not seal hole in cup support assembly.

(5) Stamp letter "A" after serial number on nameplate (1).

(6) Attach nameplate (1) with retaining ring (2).

(f) Immediately (within 30 seconds) after flush, seal cup support hole with rivet (3).

NOTE: Hold instrument with sealing hole down until just before final sealing.

(4) Run a Fog Test in accordance with Section 8, Paragraph O. There shall be no evidence of fog.

(5) Attach nameplate (1) with retaining ring (2).

7. FITS AND CLEARANCES.

A. GENERAL. A listing of fits and clearances for individual part and mating part is given in Table VII.

TABLE VII
TABLE OF FITS AND CLEARANCES

ITEMS INVOLVED	FIT OR CLEARANCE
Temperature Compensators (27, figure 3)	Adjust air gap to 0.045 + 0.005 - 0.000 inch.
Disk and Hub Assembly (1 or 1A, figure 4) and Temperature Compensators (27, figure 3)	Minimum dimension between Disk and Hub Assembly and Temperature Compensators to be 0.005 inch (both sides).
Ball Bearing (33) and Washer (34).	Total combined thickness of bearing and washer to be 0.165 ± 0.002 inch.
Center Shaft and Hub Assembly (7 or 7A, figure 4)	Adjust endshake to 0.0015 to 0.002 inch. (Dimension applies with center shaft against front jewel.)

8. TESTING.

A. GENERAL. Tests should be completed during assembly at specific points noted in the assembly procedures.

B. CONDITIONS OF TESTS.

(1) Make all adjustments in the order given.

(2) All room temperature tests shall be made at approximately 24°C (75.2°F).

(3) Unless otherwise specified, the indicator shall be tested in its normal operating position, with the dial vertical.

(4) Unless otherwise specified, the indicator shall be tapped gently axially before each test reading.

(5) Unless otherwise specified, voltages noted herein are a-c, RMS values. Voltmeters used to measure voltages to the indicator shall be free from wave form and frequency errors over the frequency range used and shall have a minimum resistance of 1000 ohms per volt.

C. INITIAL FULL-SCALE ADJUSTMENT.

(1) There shall be a minimum of 2.0 percent and a maximum of 5.0 percent pointer backtravel beyond the zero graduation.

NOTE: The following steps (2) and (3) apply only when a new or remagnetized magnet assembly is used.

(2) Connect the instrument to the calibrating tester (see Table X) and adjust the frequency to 3000 cycles per minute (CPM). With the synchronous motor running at 3000 CPM, apply a magnetic field of 50 oersteds, minimum perpendicular to the axis of the magnets. If the 50-oersted field produces excessive knockdown, either remagnetization of the drag magnet or a new drag magnet assembly is required.

CAUTION: IN APPLYING THE FIELD TO THE COUPLING MAGNETS, DO NOT APPLY IT TO THE ROTOR OF THE SYNCHRONOUS MOTOR.

(3) Increase the field strength as required to knock down the coupling magnets to such a strength that the indicator will read approximately one percent overscale at this speed.

D. TEMPERATURE COMPENSATION.

(1) Take temperature compensation readings at the input frequencies listed below:

Model	Frequency	Indication	% Change From R.T. Reading at	
			+70°C	-35°C
8DJ81CAE1	4200 CPM	100%	+0.0 -0.3	+1.0 -0.0
8DJ81CAE2	4200 CPM	100%	+0.0 -0.3	+1.0 -0.0
8DJ81LAA1	4200 CPM	100%	+0.0 -0.3	+1.0 -0.0
8DJ81LAA2	4200 CPM	100%	+0.0 -0.3	+1.0 -0.0

(a) Read the instrument after it has been subjected to -35°C for a minimum of two hours.

NOTE: Energize and read the instrument quickly in order to prevent any changes in temperature due to operation of the indicator.

(b) Allow the instrument to return to room temperature and take readings after the instrument has been at room temperature for two hours.

(c) Read the instrument after it has been subjected to +70°C for a minimum of two hours.

(d) All readings should be within the tolerances listed above. Make rough adjustments as outlined in paragraph 2.

(2) Adjust the temperature compensation not to exceed the limits specified in paragraph 1, using compensators (27, figure 3) and dummy compensators. Movement of a single compensator 0.038 inch toward or away from the air gap will change the compensation at -35° about 0.1% at 4200 cpm. At +70°C, the effect at 4200 cpm is approximately 0.07%. The addition of a single compensator 0.135 inch from the air gap or either the upper or lower magnets will increase the compensation 0.4% at -35°C and 0.3% at +70°C.

(3) If the indication is under-compensated at -35°C (indication is high), move the temperature compensator shunt(s) toward the air gap or add compensators. If the indicator is over-compensated at -35°C (indication is low), move the compensator(s) away from the air gap or remove compensators. For tests at +70°C, reverse the adjustments.

(4) Preferred compensation is obtained when the compensators are located a maximum distance from the gap. Thus, when 0.4 percent added compensation is needed, add one compensator and one dummy 0.135 inch from the air gap, in preference to sliding two compensators 0.076 inch toward the gap.

CAUTION: NEVER PLACE THE TEMPERATURE COMPENSATORS CLOSER THAN 0.060 INCH FROM THE AIR GAP.

NOTE: Temperature compensation at +70°C has been added to provide users with a check under more nearly standard operating temperature conditions.

(5) If the readings are not within the limits specified in paragraph 1, repeat the readings for temperature compensation accuracy at +70°C. Continue this adjustment until the readings are within limits.

(6) An alternate method of temperature compensation check follows:

The following simplified methods of temperature compensation are included for use where high accuracy of indication at low temperature extremes is not required or -35°C and/or +70°C temperature boxes are not available.

Indication accuracy at normal operating temperatures will not be adversely affected and may be improved.

(a) Operate the indicator at room temperature and record the reading at 4200 cpm. Then, place the indicator in a 40°C ambient and operate at 4200 cpm and 21 volts for 20 minutes, reading the indicator at the end of the period. The reading at 40°C shall not differ from the room temperature reading by more than 0.2%. Make any necessary compensation adjustments according to paragraphs (2), (3) and (4) of this section.
It is preferable that any change in indication at 40°C be in the negative direction as this will tend to compensate for any slight position change in the zero reading over a period of time.

(b) If a 40°C oven is not available for (a) above, a second alternate method may be used. Wrap the indicator in two layers of aluminum foil to reduce loss of heat. Place the indicator on a surface of low heat conductivity such as a wooden "V" block and proceed as in (a) above, omitting the oven. Self heat of the indicator will raise its internal temperature as required for the 40°C reading.

E. CALIBRATION.

(1) In paragraph C above, an initial full-scale adjustment within one percent was made. Finer adjustments for the purposes of this final calibration are made by varying the magnet gap of the coupling.

(2) Make calibration runs according to Table VIII, noting the error in reading at each point on this curve. Adjust as necessary.

TABLE VIII
CHECK POINTS DURING CALIBRATION RUNS

Type DJ-81 Indicators

GENERATOR FREQUENCY CPM	INDICATOR READING (%)	ERROR TOLERANCE (%)
200	4.8	0.50
400	9.5	0.50
800	19.0	0.50
1600	38.1	0.80
2400	57.1	0.80
3200	76.2	0.50
3400	80.9	0.50
3600	85.7	0.50
3800	90.5	0.50
4000	95.2	0.50
4200	100.0	0.50
4400	104.8	0.50

F. FRICTION CHECK

(1) Test for friction at 200, 800, 1600, 3200, 3600, and 4200 CPM input frequencies according to paragraph F(2) below. The change in indication before and after tapping shall not exceed 1.5% at 200, 0.6% at 800 and 0.5% at the other input frequencies.

(2) In making the tests for friction errors, increase the tachometer generator frequency up to but not exceeding the specified points. Do not read until the pointer comes to rest. When it does, read the indicator, tap it gently on the glass using a rubber tipped hammer (or pencil) to remove any friction error, and read again.

CAUTION: TO OBTAIN ACCURATE READINGS, TAKE PRECAUTIONS TO MINIMIZE EXTERNAL VIBRATIONS FROM HEAVY MACHINERY OPERATING NEARBY, BUILDING VIBRATIONS FROM TRAFFIC, ETC.

G. ATTITUDE ERROR CHECK. At 100 percent RPM, the position error shall not exceed 0.3 percent RPM when the indicator dial is shifted 45 degrees either up or down from the long axis and rotated 45 degrees to the left and to the right on the long axis.

H. POINTER ALIGNMENT CHECK. Check the pointer alignment at 90 and 96 percent RPM. When the large pointer is at the mark, the small pointer must be within 0.2 percent of zero and 6.0 percent respectively.

I. POINTER OSCILLATION CHECK. The pointer oscillation shall not exceed 0.5 percent from zero to 15 percent RPM, and 0.3 percent from 15 percent to 110 percent RPM on the sensitive pointer.

J. STARTING TEST.

(1) The procedures for making the starting test on each of the models of DJ-81 indicators are similar but the tolerances differ.

(2) To make the test, connect the indicator to a tachometer indicator tester having a voltage gradient at 0.0035 volts RMS per cycle per minute (see Table X, Tachometer Indicator Tester (TAKCAL) or equivalent), and increase the frequency from zero up to but not exceeding the value given for the model. After tapping or gently vibrating it, read the indicator. The reading should not be less than value specified for the model.

(3) The instrument shall meet the following requirements:

DJ-81 Model	Frequency (CPM)	Minimum Reading (% RPM)
CAE1	150	2.5
CAE2	150	2.5
LAA1	150	2.5
LAA2	150	2.5

K. FREE RETURN CHECK. With the indicator held at approximately 45 degree downward pitch, increase the frequency slowly up to 4000 CPM. With the indicator then held at 45 degree upward pitch, reduce frequency slowly from 4000 CPM to zero CPM. There shall be no catching or hesitation as caused by mechanical interference above five percent or 200 RPM, whichever is applicable.

L. HIPOT TEST. Wire all pins (except the pins for lighting) together, and apply 400 volts RMS a-c between the pins and the case for five seconds. There shall be no failure of insulation.

M. LAMP OPERATION TEST. For instruments with integral lighting, apply five volts a-c or d-c to the lighting circuit pins (D or 4 and E or 4) and measure the current in the circuit with a one-half ampere ammeter.

Ammeter Reading	Lamp Circuit Condition
Over 0.58	Short Circuit
0.48 to 0.59	Normal
0.31 to 0.39	1 Lamp Open
0.15 to 0.20	2 Lamps Open
0	Open Circuit

N. LAMP BRIGHTNESS CHECK. If it is desired to check the instrument brightness on internally lighted models, this should be done in a dark room before sealing. The following is suggested for this test.

(1) Use A Brightness Spot Meter, Model UB1/2, with external 115-volt, 60-cps power supply unit made by the Photo Research Corporation (or equivalent.- see Table X) calibrated with NBS No. 3215 filter.

(2) Using the brightness meter selected, in accordance with the manufacturer's instructions, take at least three brightness readings on each indicium. Record the average of the three readings on each indicium.

(3) Also record the brightness readings on the tip, midpoint, and the hub of the indicator pointer and average these readings.

(4) The values determined in the steps above should not be less than 0.4 foot lamberts or more than 1.8 foot lamberts. If any of the values found exceed 1.8 foot lamberts, the additional steps outlined below should be followed.

(a) Take readings on all indicia whose brightness readings exceed 1.8 foot lamberts.

(b) None of these readings should exceed 2.3 foot lamberts.

(c) Count all the indicia on the instrument face.

(d) The number of indicia whose brightness reading exceeds 1.8 foot lamberts but does not exceed 2.3 foot lamberts, should not exceed 5 percent of the number of indicia on the instrument face.

O. FOG TEST.

(1) Place sealed instrument in an oven at 80°C ± 5°C (176°F) for a minimum of 2 hours.

(2) Immediately upon removal from oven, connect to test equipment, place in cold box at -35°C (31°F) and operate for 10 minutes at approximately 90 percent of full scale.

(3) There shall be no evidence of fog.

9. TROUBLE SHOOTING.

A. GENERAL. The Trouble-Shooting Chart (Table IX) is provided should trouble be found during calibration and adjustment of the instrument after overhaul. The chart includes the symptoms, type or types of cause the symptom implies, and the remedy or corrective action required for each fault.

TABLE IX
TROUBLE-SHOOTING CHART

SYMPTOM	PROBABLE CAUSE	CORRECTIVE ACTION
1. Instrument not within calibration limits.	A. Coupling magnets not at correct strength.	(a) Resaturate, restabilize and knockdown 1 percent overscale.
	B. Coupling magnet gap not correct.	(b) Re-gap to give 1 percent overscale at 4200 CPM.
	C. Wrong spring tension.	(c) Replace spring.
	D. Motor does not come up to speed due to dirt or misalignment.	(d) Check for dirty or worn motor bearings; clean or replace.
2. Instrument out of limits on friction check.	A. Dirty jewel bearings.	(a) Examine; clean with isopropyl alcohol and pith stick.
	B. Dirty pointer shaft.	(b) Clean as above.
	C. Dirty or broken gears.	(c) Clean with petroleum base solvent (no residue) or replace.
3. Attitude error out of limits.	A. Pointer shaft assembly out of balance.	(a) Balance, using balance weight on balance arms.
4. Pointer alignment not within limits.	A. Gear eccentric with shaft.	(a) Check gears for concentricity.
5. Pointer oscillation out of limits.	A. Motor out of balance or rough bearing.	(a) Correct motor balance; or clean or replace rough bearing.
6. Starting test requirements not met.	A. Bearing friction or weak magnet rotor.	(a) Check ball-bearing torque (2 gr. mm max.). If bearings are O.K., replace magnet rotor.
7. Free return check shows mechanical interference.	A. Mechanical interference.	(a) Examine gear train, spring, pointer, bearings, endshake, etc. for interference, and replace parts as necessary.

10. STORAGE INSTRUCTIONS.

A. GENERAL. No special storage procedures are needed for this unit. Pack repaired units as required for storage conditions to be encountered. After removal from storage, and before use, make the following functional tests:

(1) Visual check -- examine the package for any obvious damage during shipment or storage; examine the unit for evidence of water, impact damage, etc.

(2) Make a check of the starting characteristic. See the section on Calibration and Adjustment.

(3) Check the scale error and friction error. See the section on Calibration and Adjustment.

11. SPECIAL TOOLS, FIXTURES, AND TEST EQUIPMENT.

A. GENERAL. Special tools required are given in Table X.

TABLE X
SPECIAL TOOLS, FIXTURES, AND TEST EQUIPMENT

MANUFACTURERS' PART NO.	NOMENCLATURE	SOURCE OF SUPPLY
404X84	Pointer Reamer	General Electric Company Instrument Dept., 40 Federal Street West Lynn, Massachusetts
A-659	Bearing Hand Staking Tool	General Electric Company Instrument Dept., 40 Federal Street West Lynn, Massachusetts
107A	Magnetizer	Radio Frequency Laboratories, Inc. Boonton, New Jersey
F11	Adapter (used with Magnetizer)	Radio Frequency Laboratories, Inc. Boonton, New Jersey
BH150	Tachometer Indicator Tester (TAKCAL)	B&H Instrument Company 3479 Vickery Boulevard Fort Worth, Texas
--	Evacuating Chamber (Capacity: 50 microns of pressure, absolute)	--
UB1/2	Brightness Spot Meter (use with NBS 3215 filter)	Photo Research Corp., 837 No. Cahuenga Boulevard Hollywood 38, California

NOTE: These tools and materials are recommended; however, the sources of supply are for information purposes only, and equivalent equipment from other suppliers may be used.

12. PARTS LIST.

IMPORTANT

DUE TO THE LARGE NUMBER OF MODELS COVERED IN THIS PARTS LIST, FAMILIARIZATION OF THE FOLLOWING PARAGRAPHS IS ABSOLUTELY NECESSARY.

A. INTRODUCTION. This section lists and describes all procurable assemblies and parts for the Type DJ-81 Tachometer Indicator. Models covered in this manual are listed in Table XI and associated Difference Data Sheets where applicable. It is not to be taken as the authority for the procedure of assembly or disassembly, but is intended for use in requisitioning, storing, issuing, identifying parts, and illustrating disassembly relationships.

B. INDEXING. All parts are indexed for cross-reference and easy identification on the exploded views given in figures 6 and 8.

C. DESCRIPTION COLUMN. The description is indented under numbers 1 through 7 to show the relationship of one part or assembly to another part or assembly.

D. ATTACHING PARTS. Those parts used to attach parts or assemblies to the main assembly, or to each other, are designated as "(ATTACHING PARTS)". In general, these attaching parts are listed immediately following the assembly or part they attach. However, in cases where one or more assemblies or parts have the same attaching parts, the attaching parts are listed only after the last assembly or part in that group. The symbol "---*---" denotes the end of the attaching parts and the continuation of the assembly listing.

E. USABLE ON CODE COLUMN.

(1) Assembly coding. When breakdowns of similar assemblies are combined in the same listing, a lower-case letter code appears in the "USABLE ON CODE" column. This code (see Table XIII) applies only to the parts list for figure 8, and shows interchangeability only between the components of that listing. Interchangeability may be determined by locating the code letter that applies to a specific component, and then checking vertically in that column of the table to determine on which assembly or assemblies the part is used. The user should refer to the footnote for the location of the code table.

F. UNITS PER ASSY COLUMN. The number appearing in the "UNITS PER ASSY" column is the total quantity of the listed part required in its immediate assembly. The letters "Ref" indicate that the listing of the part or assembly is repeated and that reference should be made to its previous listing in the Parts List.

G. IDENTIFYING PARTS WITH PART NUMBERS. Locate the part on the illustration and note its index number. Find the index number in the Parts List to determine the part number and description.

H. VENDORS' CODE. When the number listed is not a General Electric Company (Instrument Department) number, a code which denotes the Vendor from whom the part can be procured is shown in parentheses following the description. A Table listing these code numbers is shown below.

VENDORS' CODE DESIGNATION

CODE	VENDOR'S NAME AND ADDRESS
V71500	Carter Carburetor Division of ACF Industries Inc., St. Louis, Mo.

I. ILLUSTRATIONS. The basic model of the equipment and its components are shown in the main portion of each illustration. Visually different parts for similar models are shown on the same illustration in double line boxes.

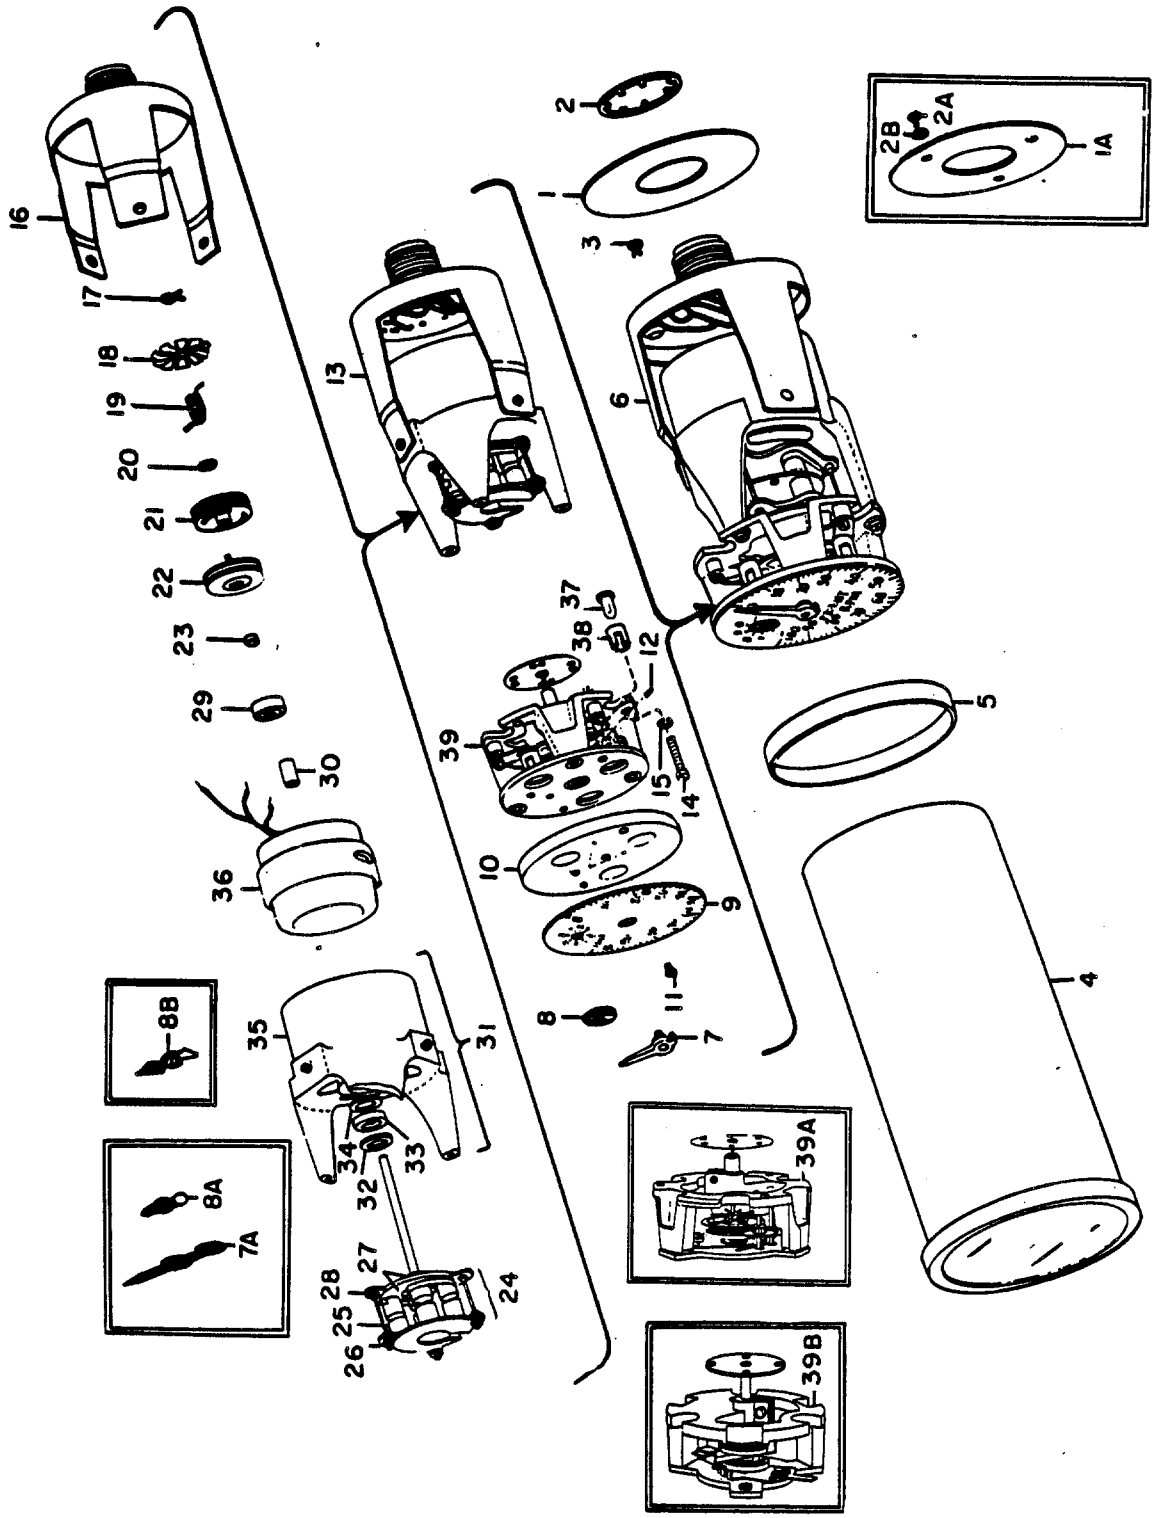
J. TERMS AND SYMBOLS. The following terms and symbols are used in the Parts List.

Coml - Hardware items procurable from normal commercial sources

AR - As required

NHA - Next higher assembly

K. NUMERICAL PARTS LIST INDEX.



(1) Contents. The Numerical Parts List Index (see Table XIV) is a numerical listing of all part numbers listed in the Parts List, showing their respective figure and index locations, and total quantities.

(2) Numerical Arrangement. Part number numerical arrangement starts in the left-hand column and continues from left to right, one column at a time, until part number numerical arrangement is determined. The order of precedence in determining part number arrangement is as follows:

(1) Space ( )
(2) Diagonal (/)
(3) Point (.)
(4) Dash (-)
(5) Letters A through Z (Alphabetical O's are listed as numerical zeros.)
(6) Numerals 0 through 9.

(3) "Coml" Parts. A part listed as "Coml" in the Parts List is listed alphabetically at the beginning of the Numerical Parts List Index by the principal noun of its description.

(4) Explanation of Quantity. The number shown in the "QTY PER INSTRUMENT" column is the total quantity of that part used in any one instrument.

TACHOMETER INDICATOR — TYPE 100% UNLIGHTED

THE INSTRUCTIONS CONTAINED IN THE PRECEDING SECTIONS OF THIS HANDBOOK APPLY EXCEPT FOR THE DIFFERENCES LISTED IN THIS DATA SHEET.

The models covered by this Difference Data Sheet are as follows:

8DJ81CAK1
8DJ81CAK2
8DJ81CAZ2

1. DESCRIPTION AND OPERATION. Same as for Models 8DJ81CAE1 and CAE2 except as noted below:

A. Replace applicable parts of Table II as follows:

(1) Scale

8DJ81CAK1	0-100%
8DJ81CAK2	0-100%
8DJ81CAZ2	0-100%

(2) Weight

8DJ81CAZ2	0.8 pounds

B. Scale plates

See figure 7 and parts list, Table XII, for scale plate part number and model application.

DISASSEMBLY. Same as for Models 8DJ81CAE1 and CAE2.

3. CLEANING. Same as for Models 8DJ81CAE1 and CAE2.

4. INSPECTION. Same as for Models 8DJ81CAE1 and CAE2.

5. REPAIR. Same as for Models 8DJ81CAE1 and CAE2.

6. ASSEMBLY. Same as for Models 8DJ81CAE1 and CAE2.

7. FITS AND CLEARANCES. Same as for Models 8DJ81CAE1 and CAE2.

8. TESTING. Same as for Models 8DJ81CAE1 and CAE2.

9. TROUBLE SHOOTING. Same as for Models 8DJ81CAE1 and CAE2.

10. STORAGE. Same as for Models 8DJ81CAE1 and CAE2.

11. SPECIAL TOOL AND TEST EQUIPMENT. Same as for Models 8DJ81CAE1 and CAE2.

12. PARTS LIST. See revised parts list dated 15 November 1961.

TACHOMETER INDICATOR — TYPE 103% UNLIGHTED

THE INSTRUCTIONS CONTAINED IN THE PRECEDING SECTIONS OF THIS HANDBOOK APPLY EXCEPT FOR THE DIFFERENCES LISTED IN THIS DATA SHEET.

The model covered by this Difference Data Sheet is as follows:

8DJ81CAY2

1. DESCRIPTION AND OPERATION. Same as for Models 8DJ81CAE1 and CAE2 except as noted below:

   A. Replace applicable parts of Table II as follows:

   (1) Receptacle
   8DJ81CAY2 — Bendix PTIH-10-6P

   (2) Mating Plug
   8DJ81CAY2 — Bendix Scintilla Pygmy PT06E-10-6S

   (3) Scale
   8DJ81CAY2 — 0-103%

   B. Scale plates

   See figure 7 and parts list, Table XII, for scale plate part number and model application.

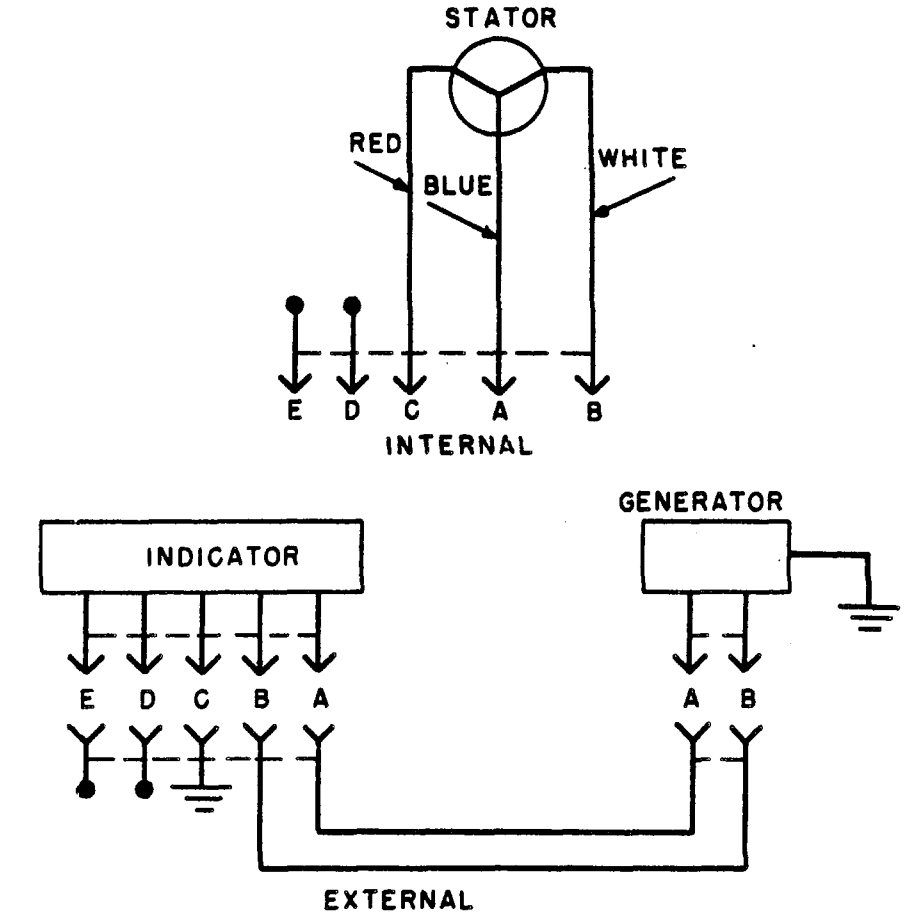
2. DISASSEMBLY. Same as for Models 8DJ81CAE1 and CAE2, except as noted:

   A. On Model CAY2 the nameplate (1A, figure 3) is attached by screws (2A) and lockwashers (2B).

3. CLEANING. Same as for Models 8DJ81CAE1 and CAE2.

4. INSPECTION. Same as for Models 8DJ81CAE1 and CAE2.

5. REPAIR. Same as for Models 8DJ81CAE1 and CAE2.



6. ASSEMBLY. Same as for Models 8DJ81CAE1 and CAE2, except as noted:

   A. For external and internal connections see figure 9.

   B. On Model CAY2 the nameplate (1A, figure 3) is attached by screws (2A) and lockwashers (2B).

7. FITS AND CLEARANCES. Same as for Models 8DJ81CAE1, CAE2, LAA1 and LAA2.

8. TESTING. Same as for Models 8DJ81CAE1 and CAE2.

COUNTER-CLOCKWISE ROTATION OF GENERATOR AS VIEWED FROM SHAFT END FOR CLOCKWISE ROTATION, INTERCHANGE LEADS A & B.

External and Internal Connections for 8DJ81CAY2
Figure 9

9. TOUBLE SHOOTING. Same as for Models 8DJ81CAE1 and CAE2.

10. STORAGE. Same as for Models 8DJ81CAE1 and CAE2.

11. SPECIAL TOOL AND TEST EQUIPMENT. Same as for Models 8DJ81CAE1 and CAE2.

12. PARTS LIST. See revised parts list dated 15 November 1961.

TACHOMETER INDICATOR — TYPE 110% UNLIGHTED

THE INSTRUCTIONS CONTAINED IN THE PRECEDING SECTIONS OF THIS HANDBOOK APPLY EXCEPT FOR THE DIFFERENCES LISTED IN THIS DATA SHEET.

The models covered by this Difference Data Sheet are as follows:

8DJ81CAA1	8DJ81CAH1
8DJ81CAB2	8DJ81CAH2
8DJ81CAF1	8DJ81CAS2
8DJ81CAF2	8DJ81CBB2

1. DESCRIPTION AND OPERATION. Same as for Models 8DJ81CAE1 and CAE2 except as noted below:

   A. Replace applicable parts of Table II as follows:

   (1) Receptacle

8DJ81CAB2	Bendix PTIH-10-6P
8DJ81CAS2	Bendix PTIH-10-6P
8DJ81CBB2	Bendix PTIH-10-6P

   (2) Mating Plug

8DJ81CAB2	Bendix Scintilla Pygmy PT06E-10-6S
8DJ81CAS2	Bendix Scintilla Pygmy PT06E-10-6S
8DJ81CBB2	Bendix Scintilla Pygmy PT06E-10-6S

   (3) Weight

8DJ81CAA1	0.8 pounds

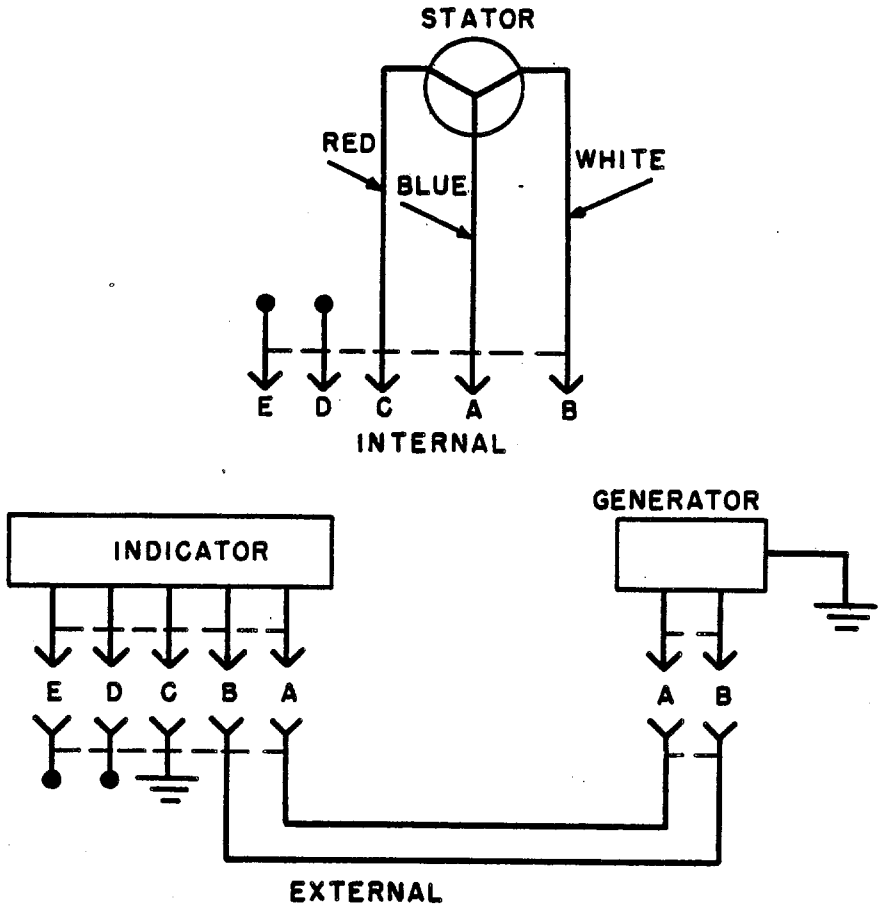
   B. Scale plates

   See figure 7 and parts list, Table XII, for scale plate part number and model application.

2. DISASSEMBLY. Same as for Models 8DJ81CAE1 and CAE2, except as noted:

   A. On Models CAB2, CAS2, and CBB2 the nameplate (1A, figure 3) is attached by screws (2A) and lockwashers (2B).

3. CLEANING. Same as for Models 8DJ81CAE1 and CAE2.



4. INSPECTION. Same as for Models 8DJ81CAE1 and CAE2.

5. REPAIR. Same as for Models 8DJ81CAE1 and CAE2.

6. ASSEMBLY. Same as for Models 8DJ81CAE1 and CAE2, except as noted:

   A. For internal and external connections for Model 8DJ81CAS2 see figure 10.

   B. On Models CAB2, CAS2, and CBB2 the nameplate (1A, figure 3) is attached by screws (2A) and lockwashers (2B).

External and Internal Connections for 8DJ81CAS2

7. FITS AND CLEARANCES. Same as for Models 8DJ81CAE1 and CAE2.

8. TESTING. Same as for Models 8DJ81CAE1 and CAE2.

9. TROUBLE SHOOTING. Same as for Models 8DJ81CAE1 and CAE2.

10. STORAGE. Same as for Models 8DJ81CAE1 and CAE2.

11. SPECIAL TOOL AND TEST EQUIPMENT. Same as for Models 8DJ81CAE1 and CAE2.

12. PARTS LIST. See revised parts list dated 15 November 1961.

DIFFERENCE DATA SHEET MODEL 8DJ81CCL2

THE INSTRUCTIONS CONTAINED IN THE PRECEDING SECTIONS OF THIS MANUAL APPLY EXCEPT FOR THE DIFFERENCES LISTED IN THIS DATA SHEET.

1. DESCRIPTION AND OPERATION. Same as for Model 8DJ81CAA1 except substitute the following:

   A. Replace applicable parts of table II as follows:

Scaleplate Background:	Dull black paint
Markings, other than range marks, white per Fed. Std. 595 No. 37875.	
Green Arc per Fed. Std. 595 No. 34108 from 50 to 101.5%.	
Red Radial per Fed. Std. 595 No. 31168, AT 102.6%.	
Receptacle	10SL-3P
Mating Plug	MS3106-10SL-3S or MS3108-10SL-3S
Range	0-110%

2. DISASSEMBLY. Same as for Model 8DJ81CAA1.

3. CLEANING. Same as for Model 8DJ81CAA1.

4. INSPECTION. Same as for Model 8DJ81CAA1.

5. REPAIR. Same as for Model 8DJ81CAA1.

6. ASSEMBLY. Same as for Model 8DJ81CAA1 except for the following:

   C. Assembly of Head Assembly Same as for Model 8DJ81CAA1.

   (1) Slip the outer turn of the spring through the support eye and bend the spring end up and out, at a right angle to the turn, to form the spring tab. Reposition the spring, with the bent-up portion, against the anchor arm.

   (2) Continue assembly in accordance with the overhaul manual. When the instrument is assembled, less the can, level the spring and apply a small amount of epoxy (Armstrong Adhesive A-12) to the spring tab at the point of attachment.

   NOTE: Armstrong Adhesive A-12 should be quick cured by heating in a 125°C oven for 15 to 20 minutes. Quick curing will eliminate the possibility of movement of the spring under extended cure at room temperature, and guarantee proper flowing of the epoxy. Removal of the epoxy may be facilitated by using a soldering iron to break the bond of the epoxy and allow it to be chipped away. The epoxy stripper should be used for cleaning only. It is similar to Number 688 Cold Stripper, manufactured by Fidelity Chemical Products Corp., Neward, New Jersey.

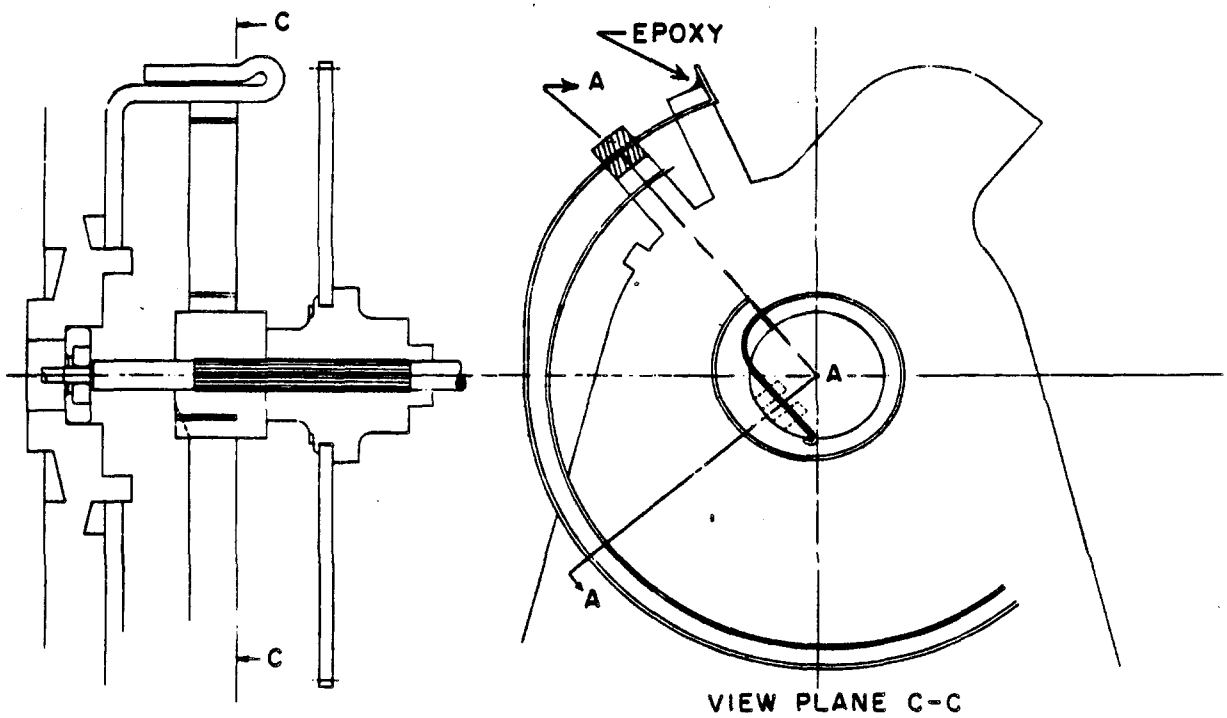

Fig. 1. Layout of spring clamping method

7. FITS AND CLEARANCES. Same as for Model 8DJ81CAA1.

8. TESTING. Same as for Model 8DJ81CAA1 except for the following:

D. Temperature Compensation

(1) Temperature Compensation Check - High and low Temp.

Frequency	Indication	% Change from R.T. Reading AT +70°C	% Change from R.T. Reading AT -35°C
4200 CPM	100%	+0.0 -0.3	+1.0 -0.0

(a) Take temperature compensation readings at -35°C at the input frequency listed above. Read the instrument after it has been subjected to -35°C for a minimum of two hours. Allow the instrument to return to room temperature and take readings after the instrument has been at room temperature for two hours.

9. TROUBLE SHOOTING. Same as for Model 8DJ81CAA1.

DIFFERENCE DATA SHEET MODEL 8DJ81CCL2

10. STORAGE INSTRUCTIONS. Same as for Model 8DJ81CAA1.

11. SPECIAL TOOLS, FIXTURES, AND TEST EQUIPMENT. Same as for Model 8DJ81CAA1.

OVERHAUL WITH PARTS BREAKDOWN TEMPERATURE INDICATOR, LEWIS 152B206

DESCRIPTION AND OPERATION

1. Introduction

The Type 152B206 is a thermo-couple temperature indicator, having a temperature range of 0-1200°C. This indicator is manufactured by the Lewis Engineering Company, Naugatuck, Connecticut, U.S.A.

2. Description

A. General: The indicator is housed in a 2" steel case, suitable for clamp mounting, or may be flange mounted by means of a standard bezel. Electrical connections are brought out to terminals at the rear of the case. Refer to Figure 1 for details of dimensions and mounting.

B. Dial Configuration: The dial markings are dull white (FED. STD 595, color 37875) for numerals, lettering and both major and minor graduations. The background is durable dull black (FED. STD 595, color 37038). Other markings are as follows:

(1) Arc from 400°C to 705°C in lusterless green (FED. STD 595, color 24260).

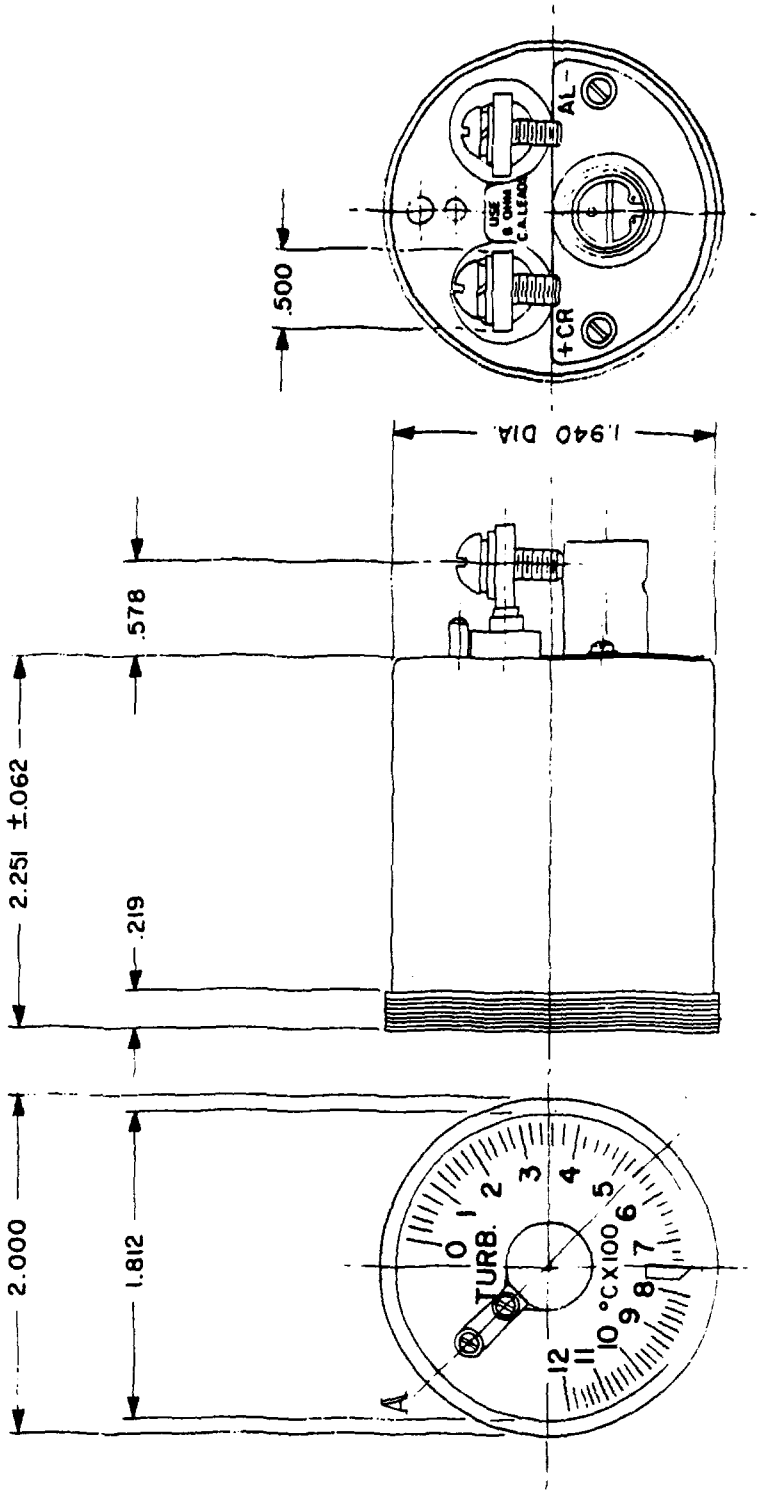
(2) Arc from 705°C to 750°C in lusterless yellow (FED. STD 595, color 33538).

(3) Radial line at 750°C in lusterless red (FED. STD 595, color 31136).

(4) Because of the space occupied by the red radial line at 750°C there are no minor graduations at 760°C and 780°C.

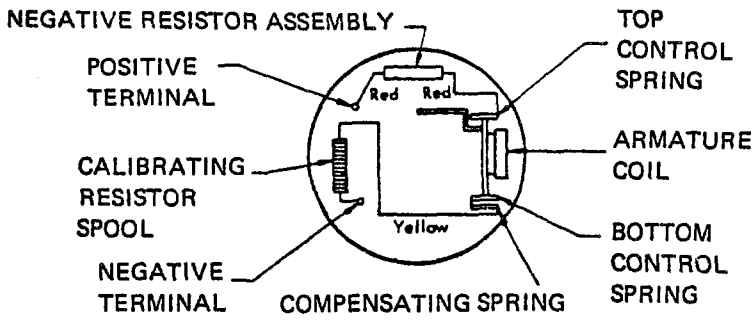
C. Thermo-couple: The 152B206 indicator is calibrated for use with chromel-alumel thermocouples having 8 ohm leads.

D. Circuit Description: Refer to Figure 2, which is a schematic diagram showing the internal wiring of the indicator. The basic indicator is a sensitive moving-coil milli-voltmeter having a copper armature coil which is fed electrically via top and bottom control springs. The armature has a coil of resistance wire, wound on a plastic spool, in series with its negative lead and another resistance with a negative temperature co-efficient in series with its positive lead. The resistance coil provides a means of calibration, since turns of wire can be removed during the test procedure to adjust the meter reading. The negative resistor provides automatic temperature compensation for changes in armature coil resistance due to changes in ambient temperature.



2.(D) - Cont'd.

Since the millivoltage generated in the thermo-couple circuit is dependent on the difference in temperature between the thermo-couple (hot junction) and the cold junction (in the indicator), a bi-metallic spring is connected to the bottom control spring to compensate the indicator for millivolt changes due to variations in ambient temperature. The positive terminal stud of the indicator (10-32 thread) is made of brass and the negative terminal stud (8-32 thread) is of constantan. This preserves the continuity of thermo-couple material into the instrument case where copper and constantan wires are used to the cold junction.



3. Operation:

A. The thermo-couple indicator operates when connected to the external circuit shown in Figure 3. The external wiring consists of the thermo-couples and harness on the engine, extension leads and a balancing resistor AN 5534-2 (Lewis P/N 8T851B3) in series with the negative lead. The indicator is calibrated to operate into an 8 ohm external circuit, therefore since the external circuit resistance will vary according to the length of the leads and the number of thermo-couples in use, the AN 5534-2 balancing resistor contains two spools of constantan resistance wire, one of which is adjusted until the external circuit resistance is 8 ± 0.05 ohms. The other spool is a spare. The external circuit resistance is determined by measuring it with a Wheatstone Bridge. This measurement should be taken twice, with the leads to the bridge reversed the second time. The average of the two readings should then be calculated. This is necessary as slight millivoltages developed due to temperature differential between the ends of the leads and the thermo-couples will deflect the galvanometer of the bridge.

DISASSEMBLY

1. Refer to Figure 1101. Disassemble the indicator in approximately the same order as the index numbers assigned to this figure.

   NOTE: These instruments operate on jewelled bearings. Handle them as you would an expensive watch.

   Disassembly procedure is as follows:

   A. Using an induction heater or large soldering iron, apply it to sealing strap (1) to soften solder bond. Peel off strap and discard.

   B. Remove screws (3) and slide off housing assembly (2). Do not remove lining strip (4) or window (5) from front and body assembly (6) unless they have been damaged.

   C. Remove screws (10) and lockwashers (11). This releases the dial (7), mask (8) and bumper assembly (9). When removing dial (7), take care not to damage pointer of armature assembly (19).

   D. Remove screws (14A) and lift off the dial mounting plate (13). Remove spacers (14).

   E. Carefully unsolder the wires from fixed resistor (43) and thermal resistor (44). The constantan wire (yellow) from the fixed resistor connects to regulator terminal (29) and the red wire from the thermal resistor connects to the terminal on top bridge assembly (16). Remove movement assembly (12) from base assembly (42).

   F. Unsolder outer ends of control springs (20, 24). Remove screws (17) and lockwashers (18), this releases top bridge (16).

   G. Grasp armature assembly (19) by pointer, lift and turn carefully to remove it from pole piece assembly (38). Slide armature coil through slotted core.

   H. Do not disassemble armature assembly (19) further unless control springs (20, 24), pivots (23) or balance weights (21, 22) require replacement. If any other part of the armature assembly is damaged, replace the entire assembly.

CLEANING, INSPECTION AND REPAIR

1. Cleaning and Inspection

Refer to Table 201. Carry out the inspection and cleaning procedures listed therein.

PART	HOW TO CLEAN OR INSPECT
Jewels (26 and 15)	Clean with orangewood stick. Insert fine pointed needle into and over jewel cup to detect fractures.
Pivots (23)	Examine with seven power eye loupe. Clean by rotating pithwood on point.
Dial (7)	Check for chipped or discolored paint. Clean with soft camel-hair brush.
Terminals (52 and 57)	Examine for cracked window insulation and damaged threads.
Zero adjuster (65) and insulator (64)	Operate one full turn to check operation. Check condition of insulator.
Armature (19)	Check for discolored paint on pointer. Check coil with ohmmeter. Resistance should be 22-1/2 ohms ± 2 ohms.
Control springs (20 and 24)	If mis-shapen, re-position by means of fine tweezers. Clean with fine camel-hair brush and trichlorethylene. (Federal Specification No. O-T-634A).
Negative resistor assembly (44)	Test with ohmmeter to terminal wires. Do not disturb constantan shunt winding. Resistance of shunted carbon resistor assembly should be 8.1 ohms ± .4 ohm.
Window (5)	Check for striae or chipped surface. Clean with moist chamois.

Table 201 Cleaning and Inspection Procedures

CLEANING, INSPECTION AND REPAIR (CONT'D)

2. Repair:

When necessary, the following repairs may be made.

A. Replace fractured jewels (26, 15).

B. Replace chipped or flattened pivots (23). Use tool #34 (ref. Table 1001).

C. Replace dial (7) if bent. Refinish if paint chipped or discoloured.

D. To replace damaged terminals (52, 57), place shield (62) on an electric hotplace and use large soldering iron to soften solder. Lift out defective terminals and place new terminal in recess. Flow solder around terminal with soldering iron.

E. Proceed similarly to change defective adjuster (61).

F. To replace defective window (5) place housing (6) on electric hot plate to soften solder bond to window, scrape excess solder from inside housing. Place new window in housing. Cut a piece of 1/32 inch diameter solder to form a ring inside housing in such a position that, when the solder melts, it will flow evenly around edge of window. Add solder if required. Do not overheat. An induction heater may be substituted for the hotplate.

3. Lubrication:

No lubrication is necessary.

ASSEMBLY

1. Preliminary

Assembly is performed in approximately the reverse order of index numbers on Figure 1101.

CAUTION: NEVER TIGHTEN JEWELS SUFFICIENTLY TO CAUSE THEM TO BIND ON PIVOTS AS CRACKED JEWELS OR DAMAGED PIVOTS WILL RESULT.

Proceed as follows:

A. With bottom bridge assembly (32) in place on bottom of pole piece (38), insert armature assembly (19) by carefully sliding through slotted core until bottom pivot rests in cup of bottom jewel (26).

B. Attach top bridge (16) to magnet and gradually lower top jewel (15) until the top pivot is within the cup of the top jewel.

C. Grasp tail arm of quadrant and gently rock armature (19) from side to side to observe side-play of top pivot in top jewel (15). Slowly tighten top jewel (use Tool 36) until side play is approximately 0.004 inch.

D. Re-solder constantan lead to terminal of bottom regulator (29). Attach movement assembly (12) to base assembly (42) and solder lead to top bridge. (See internal wiring diagram, Figure 2). Be sure regulator (30) meshes with zero adjuster (61).

E. Slide movement assembly (12) onto posts of base assembly (42). Install spacers (14) on the threaded ends of the posts.

F. Attach dial mounting plate (13) using screws (14A).

NOTE: When tightening screws (14A) be sure that front bridge (16) is not pressed downward to cause jewels to bind pivots. Re-check side play and re-adjust top jewel (15) if necessary.

G. Attach dial (7), mask (8) and bumper assembly (9) to dial mounting plate (13), using screws (10) and lockwashers (11).

H. Re-solder control springs (20, 24) to terminals on top of front bridge and bottom regulator respectively.

ASSEMBLY (CONT'D)

I. Balance armature with pointer in horizontal and vertical position, moving tail (21) and side (22) weights with wrench 16 or 16B as required (ref. Table 1001).

J. Carry out test procedures detailed in Section 701.

2. Sealing Evacuation and Filling

After successful completion of the test procedures (Section 701), fill and seal the indicator case with a dry gas mixture of 90% nitrogen and 10% helium. Filling and sealing procedure is as follows:

A. Support indicator in LF30 sealing fixture and solder sealing strap (1) in place. Use a 150 watt soldering iron to flow solder from strap to housing. Remove excess solder with coarse file.

B. Test for leaks by immersing indicator in a water jar with filler tube connected to a DRY compressed air supply of 30 psi max. If no leaks are detected remove air hose, hold finger over filler tube and dry indicator by blowing off excess moisture.

C. Place indicator in an air oven heated to about 70°C (158°F) for 30 minutes.

D. Connect filler tube to gas supply and vacuum pump as shown in Figure 501. Evacuate to approximately two mm of mercury as indicated on the vacuum (absolute pressure) gauge. Close valve "B" and slowly open valve "A" to fill indicator with gas.

E. Close valve "A" and open "B" to again evacuate indicator. Close valve "B" and open "A" to again fill with gas.

F. Close valve "A", pinch tube closed with pliers, remove hose and cut off excess length of tube and solder cut end of tube closed.

G. Make final leak test by placing indicator in desiccator jar as shown in Figure 502. Close valve "B" and open "A". Draw a vacuum of about 25 mm of mercury then close valve "A" and slowly open "B" until vacuum falls to about 63 mm of mercury.

H. Check indicator carefully for leaks by watching for a continuous flow of bubbles. If no leak is observed, SLOWLY open valve "B" to equalize pressure within desiccator with atmosphere.

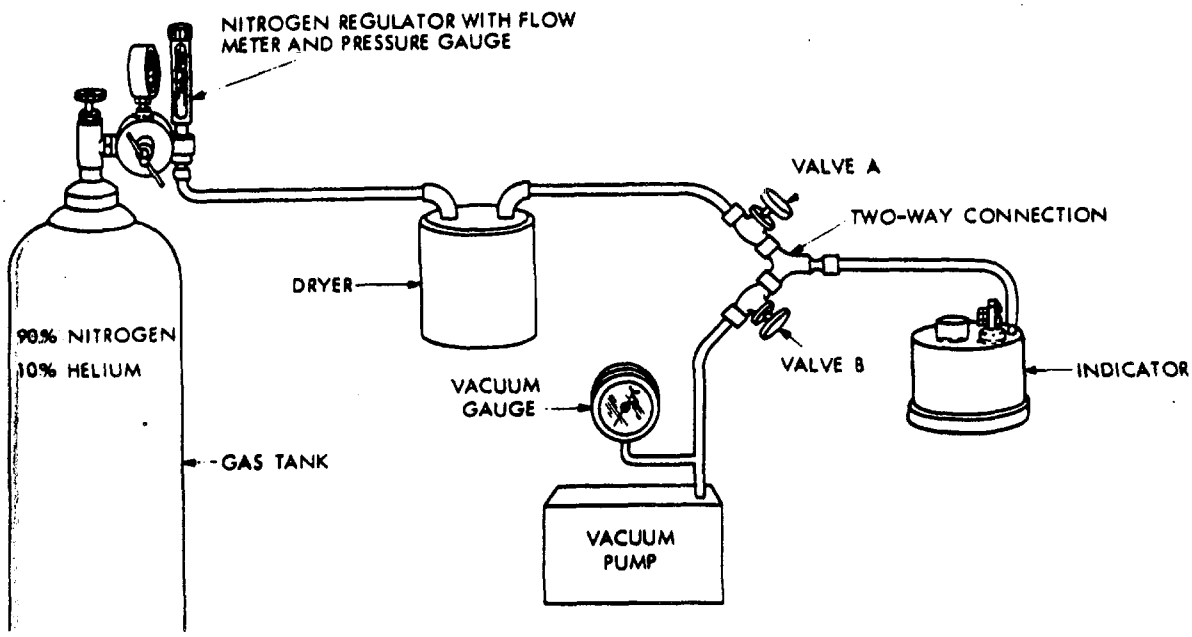
ASSEMBLY (CONT'D)

I. Thoroughly dry indicator and paint with dull black instrument lacquer, Fed. Std. 595 Color 37038.

J. Repeat scale error test described in Section 701 making sure that zero adjuster has been properly operated to bring the pointer on the 90° division while applying the appropriate millivoltage to the indicator terminals for 90°C at room temperature reference through the applicable external resistance. Connect a wire jumper across indicator terminals to dampen pointer swings during handling.

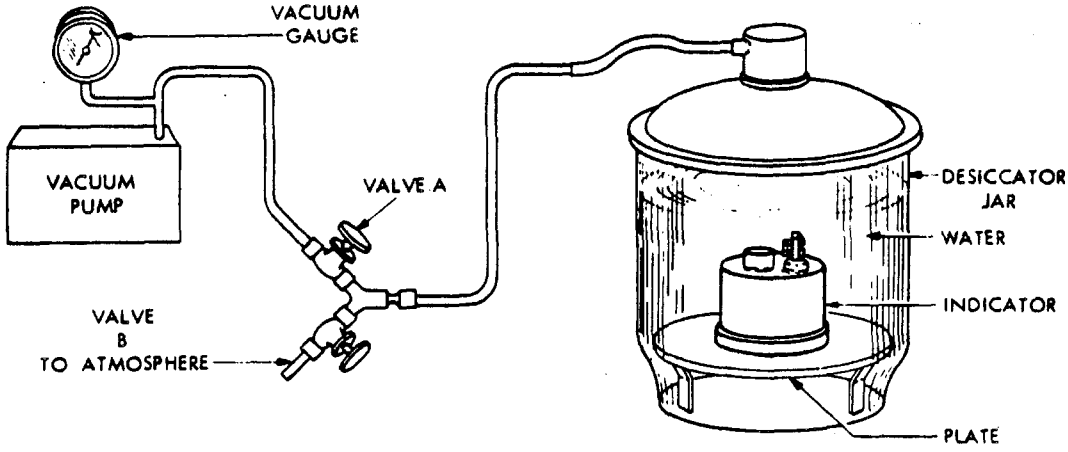
K. Repeat friction and balance tests.

3. Packing for Transportation or Storage



A. Use specification PPB-B-636 Type I, Class II carton 7-1/2 x 7-1/2 x 7-1/2 inches. Insert a pad eight inches wide by five foot long by one-half inch thick, specification PPB-C-843A Type 2, crepe celulose wadding on bottom of carton.

B. Wrap indicator in crepe cellulose wadding three inches wide by ten foot long by one-half inch thick and place in carton.



C. Place another pad of eight inch wide by five foot long by one-half inch thick crepe cellulose wadding on top of indicator.

D. Seal carton with specification UU-T-116 tape.

NOTE: To prevent damage to internal components, NEVER ship an indicator unless it has a minimum of three inches of cushioning material on all sides.

Evacuation and Gas Filling Equipment
Figure 501

Final Leak Test Under Vacuum
Figure 502

TESTING

1. Test Procedures. Scale Error Test

The following test procedures are to be carried out after assembly is completed, but before the instrument case is sealed and filled with gas. Before test or adjustment the indicator must remain at a constant temperature for one hour. Removing resistance wire from calibrating resistor (47) will raise pointer indication and vice versa. Tap indicator with fingertip while taking readings. Three methods of scale error testing are given:

A. Using Type N3A Thermometer Tester (Lewis part number 81T27).

B. Using TTU-104/A Thermometer (Lewis part number 81T28).

C. Using Type K2 Potentiometer and ice bath.

2. Type N3A Method

This tester provides chromel alumel calibration millivoltages, through the required eight ohm lead resistance, by turning a master selector switch to the required test temperature.
The test millivoltage output is referenced to zero °C, so there is no ambient (room) temperature compensation in the tester, therefore the ambient temperature, as observed on the liquid-in-glass thermometer supplied with the tester, MUST be physically added to the test temperature, by turning the zero adjuster screw.
First, however, carry out the scale error test as follows:

A. Turn tester selector switch to 900 (this being the value having the smallest tolerance).

B. Turn indicator zero adjuster until pointer reads 900°C.

C. Set the tester selector switch to the scale error test points listed in Table 701. Readings shall be within the °C tolerances given. Adjust calibrating resistor value as described in para 1, if necessary.

To adjust the indicator for ambient temperature, set tester switch to 900. Take reading of liquid thermometer (for example 25°C), then set indicator zero adjuster to make pointer read 925°C.
Full operating instructions are provided with each N3A tester.

TESTING (CONT'D)

3. Type TTU-104/E Method

This tester provides chromel-alumel calibration millivoltages through the required 8-ohm lead resistance, by turning a master selector switch to the required test temperature. The test millivoltage output is automatically referenced to ambient temperature by an internal electrical cold junction compensating circuit in the tester, therefore the reading of the indicator under test should agree with the setting of the selector switch, within allowable tolerances. To run a scale error test on the indicator, set tester selector switch at 900 and set zero adjuster on indicator to bring the pointer to 900. Turn tester selector to each of the test points listed in Table 701. Readings shall be within tolerances given. Adjust calibrating resistor if necessary. Full operating instructions are provided with each TTU-104/E Tester.

4. K-2 Potentiometer and Ice Bath Method

This method electrically removes the cold junction from the indicator and places it at zero °C in the ice bath, thus eliminating any reference to ambient temperature. Connect the equipment together as illustrated in Figure 701.
Apply the millivoltage value for 900°C (37.36 mv) and turn zero adjuster on indicator to bring the pointer to 900 on the scale. Set millivolt supply to the other test values listed in Table 701. The pointer shall indicate the test values within the tolerances given. After completing the scale error test, return to 37.36 mv and the pointer shall again read 900°C within tolerance. Adjust calibrating resistor if necessary.

5. Friction Test

Hold indicator in operating position, and gradually deflect pointer, using any one of the methods described in paras 3, 4 or 5, without tapping, from zero °C to 900°C. Then tap lightly and note change in pointer indication. Change is friction error, which shall not exceed ± 30°C. Clean air gap with needle or replace jewels and pivots if error is greater than the specified value.

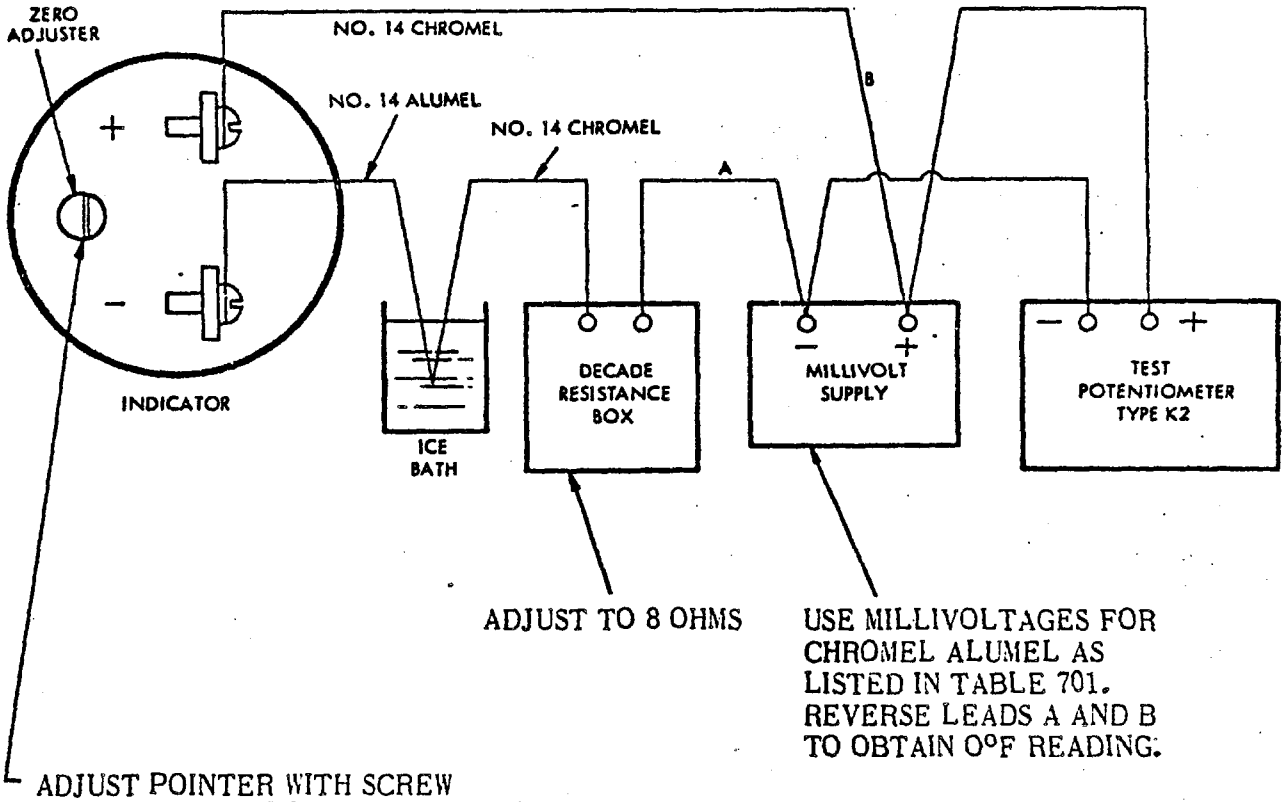
6. Balance Test.

Apply 37.36 mv to deflect pointer to 900°C while holding the indicator with the dial in a horizontal plane. Tap indicator while taking readings. Turn indicator so that dial is vertical and pointer horizontal with the 900°C mark on the left. If reading changes, adjust tail balance weight (Figure 1101, -21)

TESTING (CONT'D)

6. Balance Test (Cont'd)

until reading agrees.
Rotate indicator clockwise so that 900°C is at the top. Adjust either or both side balance weights (-22) if necessary to bring pointer to 900°C mark. Hold indicator in normal operating posistion and rotate 90° clockwise and counterclockwise. The maximum change in pointer position shall not exceed ± 25°C.



7. Zero Adjuster.

Deflect pointer to 900°C. Turn zero adjuster (65) throughout its range. The resulting pointer motion should be not less than 40°C above and below the setting point. Tap indicator when reading. If necessary to equalize pointer deflection, turn zero adjuster so that regulator (30) is approximately in the center of its travel, then turn terminal (29) to bring pointer to 900°C mark.

8. Final Test

Install housing assembly (2) on indicator and repeat the scale error test using any of the three methods described in paragraphs 2, 3 or 4. If all tolerances are met, carry out the sealing, evacuation and filling procedures described in paragraph 2, Section 501.

CODE NUMBERS OF UNITS
COVERED BY THIS MANUAL
ARE LISTED ON PAGE 2.

STATEMENT OF INITIAL CERTIFICATION

This manual complies with British Civil Airworthiness Requirements, Section A, Chapter A6-2.

Signed J. L. Hollyer *Date* October 1975

C.A.A. Design Approval No. DAI/1671/41

NOTE: The above certification does not apply to revisions or amendments made after the date of initial certification by other Approved Organisations.
Revisions or amendments made by other Approved Organisations must each be separately certified, and recorded on separate record sheets.

Failure to follow the applicable instructions given in this publication as amended from time to time by SMITHS INDUSTRIES revisions may endanger safety.

MILLIVOLTMETER TEMPERATURE INDICATORS

MODIFICATIONS

1. GENERAL

When modifications are introduced on units covered by this manual, the text will be revised to cover the latest modification state. The modifications will be listed below together with a statement on whether the overhaul information is affected when any modification is not embodied. When overhaul is affected, the list will cross-refer to details.

2. MODIFICATION DETAILS

Modification No.	Service Bulletin or Modification Sheet No.	Codes Affected	Effect on Overhaul
01	77-102	All	See para. 3. A.
02	77-119	All except *727MV/BU/42/690 *727MV/BU/54/690	See para. 3. B.

PRINTED IN ENGLAND

3. EFFECT OF MODIFICATIONS

A. If modification 01 has not been embodied the overhaul instructions are affected as follows :

(1) REPAIR

Ignore the instructions given in para. 2. G. 1.

(2) ASSEMBLY

(a) Para. 3. S. (1) should read :

Referring to fig. 503, solder the case back sealed terminal leads to their appropriate inserts in the terminal block.

(b) Ignore the instructions given in para. 3. R. (2).

B. If modification 02 has not been embodied the overhaul instructions are affected as follows :

(1) INSPECTION

Para. 3. G. (2) should read :

Measure the resistance of the thermistor. The resistance at 20°C should be between :

(a) All codes except */727MV/BU/42/690 and */727MV/BU/54/690

8 and 12Ω.

(b) */727MV/BU/42/690 and */727MV/BU/54/690

18 and 22Ω.

MILLIVOLTMETER TEMPERATURE INDICATORS

DESCRIPTION, OPERATION AND DATA

1. DESCRIPTION

A. General

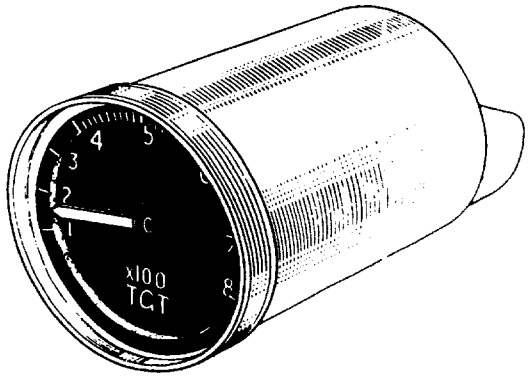

Fig. 1 Typical view

The millivoltmeter temperature indicators covered by this manual operate in conjunction with a thermocouple system, and indicate the temperature of the engine exhaust gases. A general view of a typical indicator is shown in fig. 1. To enable the operating temperature range of a particular engine to be more easily read and to provide an improvement in accuracy, the indicator scale is graded so as to expand the scale over this range, and yet retain the normal full scale range from zero. Within the expanded scale is a band of 100°C (see DATA) which provides a further improvement in accuracy. The indicator codes differ in the temperature range presented, the degree of cold junction temperature compensation provided and the total external resistance required.

The indicator movement is housed in a 2 in nitrogen filled, hermetically sealed case, electrical connections being made to a terminal block at the rear of the indicator.

Some indicators, used in two series connected thermocouple systems, are fitted with a third terminal designated TEST +. This is to enable calibration acceptance tests to be carried out using temperature/e.m.f. constants as for a single thermocouple system.

B. Detail (fig. 501)

The indicator consists of a moving coil movement housed in a main case complete with glass, and a case back, and is hermetically sealed by soldering an iron wire sealing ring in the recess formed between the main case and case back. A capillary tube used for gas filling the indicator is soldered into the case back, and the terminal block is secured to the case back by two screws.

PRINTED IN ENGLAND

The indicator zero adjustment mechanism comprises a zeroiser shaft and pinion meshing with a gear wheel in the movement. The rear portion of the zeroiser shaft is housed in a bush fitted on the case back, while the front of the shaft is supported in a hole in the movement mounting plate.

The zeroiser shaft bush is sealed by two sealing rings fitted in grooves in the zeroiser shaft. Rotary movement of the shaft is limited to 180 deg by means of a stop pin.

A back plate, secured to pillars on the case back carries a thermistor and shunt resistor, and on indicators fitted with the TEST + terminal, the test circuit series resistor. This additional resistor is not illustrated. Ceramic inserts in the plate permit connections between the movement and terminal block. The plate is also secured to two pillars extending from the movement mounting plate, and the two pillars are screwed onto two movement fixing studs which project through holes in the movement mounting plate. Two resistors, a padding resistor and the series resistor, are mounted on the movement mounting plate.

The movement consists of a moving coil assembly and a magnet arm assembly. The moving coil assembly consists of a magnet assembly carried in a frame formed by front and rear plates, and a moving element pivoted in jewel bearings fitted in the centre and rear bridge pieces.

The front and rear plates are spigoted into the outer pole piece of the magnet assembly and carry pillars which support the centre and rear bridge pieces. A magnet shield is also supported by the centre bridge piece pillars and an upper support post, and is secured by two front pillars and a hexagonal nut. The shield serves as a screen between the magnet and magnet arm assemblies, and also carries three rubber washers which act as buffer rings.

The moving element (fig. 2) consists of an aluminium spindle to which is secured a pointer spider, a formerless coil, a hairspring and a wire ligament. The coil is bonded to the spindle, and two bent tag connectors are secured on either side of the spindle by two lengths of silicone rubber sleeving, the whole being bonded in position on the spindle with Araldite.

The spindle is hard anodized to insulate the tags. The ends of the moving coil are spot welded to the end of the tags, one end to the end of each tag, and the inner ends of the hairspring and ligament are soldered to the bent portion of the tags, one to each tag. The outer end of the hairspring is soldered to a tag on the rear bridge piece, and the outer end of the ligament is soldered to an anchor tag fitted on a shield post. Electrical connections to the coil are made through the hairspring and ligament. The hairspring

PRINTED IN ENGLAND

and ligament are prevented from fouling each other by a shield which fits between them and is secured to a shield post screwed into the rear plate of the magnet assembly. The shield post and anchor tag are shown exploded in fig. 501 for clarity. The front end of the spindle carries a pointer and pointer spider, to which a small double sided stop magnet is fitted, and a pivot which runs in a solid mounted jewel bearing housed in the centre bridge piece.

The rear pivot seats in a jewelled screw bearing in the rear bridge piece which provides adjustment for spindle end shake. The moving element is balanced by the adjustment of counterweights which are carried on the arms of the pointer spider.

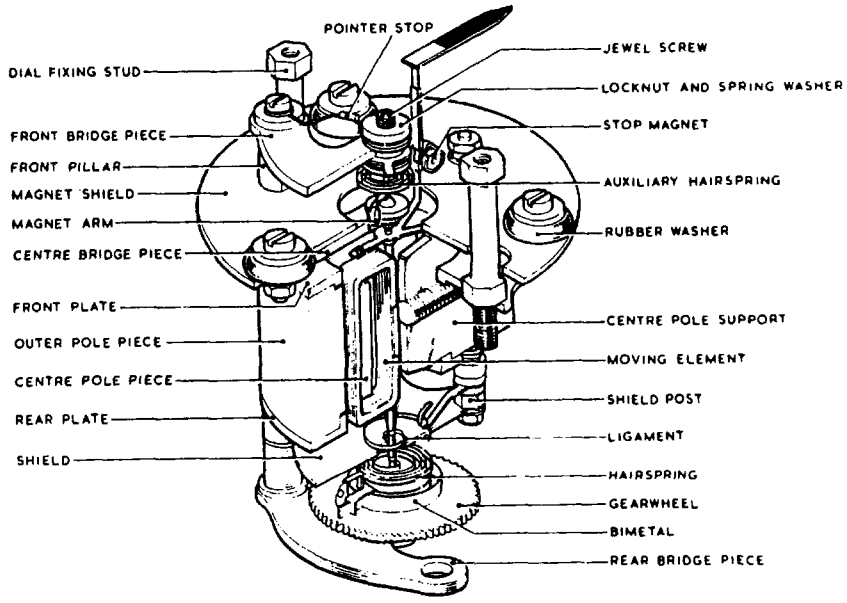

Fig. 2 Part sectioned view of movement

The magnet assembly consists of two magnets, the outer pole piece and a centre pole piece with a centre pole support. The centre pole piece is secured to the centre pole support by a special screw, while the magnets are bonded to the ends of the outer pole piece. The outer pole piece and the centre pole piece are of opposite polarity. An exploded view of the magnet assembly is shown in fig. 401.

The rear bridge piece assembly (fig. 3) carries a central bush which houses the jewelled screw bearing. A gearwheel, compensator arm, rear tag and bimetal are carried on the bush, they are free to rotate but are retained by the end of the bush being spun over. One arm of the rear tag protrudes

PRINTED IN ENGLAND

through a slot in the gearwheel and is soldered to the inner end of a bimetal the outer end of which is held in a fork in the compensator arm. The end of the compensator arm is split and the two sections are bent at right angles to each other, the outer end of the moving element hairspring being soldered to one section. The hairspring is thus connected to the rear tag through the compensator arm and bimetal, to ensure a good electrical connections between the compensator arm and bimetal a short length of copper wire is soldered across them. The gear wheel meshes with the pinion of the zero adjuster shaft so that adjustment of the indicator zero mechanism turns the gear wheel and moving element hairspring to alter the position of the pointer. With the gear wheel, and thus the inner end of the bimetal held fixed, the outer end of the bimetal moves with the variations in temperature to adjust the pointer zero and compensate for differences in ambient temperature between the movement and the external thermocouple system. The degree of cold junction compensation depends on the length of the bimetal. The units dealt with in this manual fall into two categories; those that are designed for use in systems incorporating T_1 compensation, and those that are not. The former have a short bimetal and are identified thus in DATA.

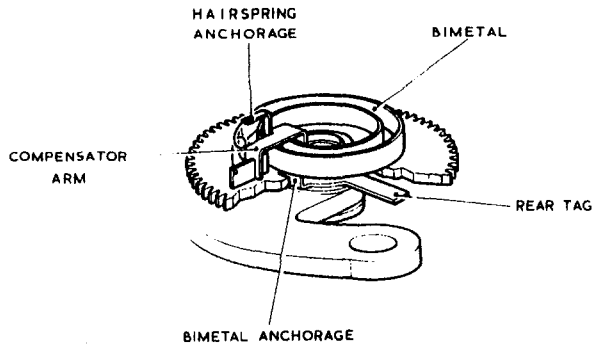

Fig. 3 Rear bridge piece bush assembly

The magnet arm assembly consists of two small stop magnets at either end of a magnet arm which is pivoted at its centre and carries an auxiliary hairspring. The magnet arm rear pivot rotates in a solid mounted jewel bearing housed in the centre bridge piece, the front pivot rotates in a jewel screw bearing housed in the threaded bush of a front bridge piece which is secured to the front pillars of the moving coil assembly. The auxiliary hairspring is anchored to a tag on the front bridge piece, and two pointer stops are secured in position by the two front bridge piece securing screws. The two small stop magnets on the magnet arm are of opposite polarity and are positioned so that they oppose the double sided magnet on the moving element spider.

A front shield, which is made of aluminium is secured on dial fixing studs and to it the instrument dial and dial mask are fitted. The pointer spider of the moving element passes through the annular gap between the dial and dial mask.

PRINTED IN ENGLAND

2. OPERATION (fig. 4 or 5)

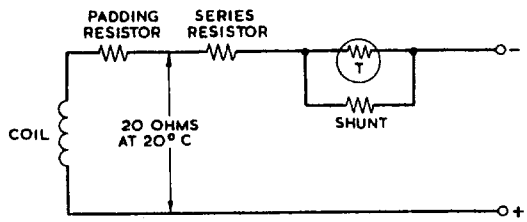

Fig. 4 Circuit diagram

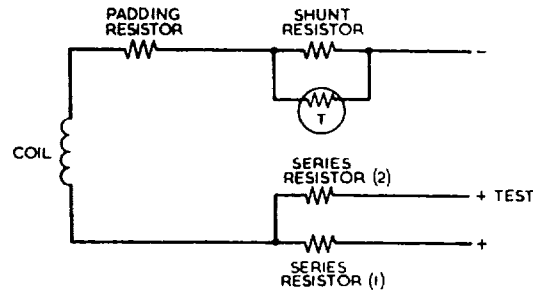

Fig. 5 Circuit diagram (Indicators with TEST + terminal)

The indicator is a moving coil millivoltmeter, and when connected to a thermocouple system, measures the potential difference between the thermocouple hot and cold junctions.

A temperature difference between the thermocouple junctions causes a current to flow in the indicator coil. Since the coil is pivoted in a magnetic field it is deflected an amount proportional to the current in the coil. The pointer then shows the temperature of the hot junction. Over the expanded portion of the scale the moving element of the moving coil assembly is free to act as a normal movement; in the upper and lower ranges of the scale the hairspring on the moving element is opposed by an auxiliary hairspring included in the magnet arm assembly. The movement is therefore suppressed at each end of the scale, the moving element torque and the magnet arm torque being balanced at the indicator zero.

Compensation for change of resistance of the aluminium moving coil due to temperature changes is achieved by means of a thermistor shunted by a wire wound resistor. A copper wound padding resistor is connected in series with the aluminium coil so that the value to be compensated is practically constant.

On indicators fitted with the TEST + terminal, two resistors are connected in series with the moving coil, one being in circuit when the TEST + terminal is connected and the other in circuit when the indicator + terminal is connected (fig. 5). On all other indicators, a single resistor is connected in series with the padding resistor (fig. 4). These series resistors are used where necessary for small adjustments when ranging the instrument.

NOTES:
1. The asterisk prefixing an indicator code number is in place of the dial finish e.g. PW.
2. The three figure suffix included in the code number of some indicators denotes the SET point referred to during overhaul. On indicators without this suffix, the Set point is marked on the dial.
3. Any indicator marked thus * in the Remarks column is used in a two series-connected thermocouple system. All other indicators are used in single thermocouple systems.

MILLIVOLTMETER TEMPERATURE INDICATORS

DISASSEMBLY

1. PREPARATION AND GENERAL PRECAUTIONS

Observe absolute cleanliness of workbench, tools and parts. Some of the screws, nuts and pillars on the indicator are locked with lockant G. If necessary this may be softened with solvent C. Details of cleansers and materials are given in SPECIAL TOOLS, FIXTURES AND EQUIPMENT.

2. PROCEDURE (refer to fig. 501)

The following procedure applies to all codes except where specified.

A. Case and Case Back

(1) Remove the terminal screws and the two screws and the washers securing the terminal block and withdraw the block to the extent allowed by the leads. Unsolder the leads from the terminal block inserts and withdraw the block.

(2) Remove the tinned iron wire sealing ring from between the main case and the case back by applying heat and pulling on the free end of the wire with a pair of pliers. Clean off any residual solder and withdraw the case.

(3) Remove the stiffnuts and washers securing the case back. Withdraw the case back as far as the leads will allow and disengage the zeroiser shaft from its bush and the pinion from the gearwheel.

(4) Referring to fig. 503, unsolder the case back sealed terminal leads from their distant terminations. Remove the case back and zeroiser shaft.

(5) Unsolder the capillary tube from the case back. Discard the tube.

B. Zeroiser Shaft

Remove the zeroiser shaft from the bush in the case back. Remove and discard the sealing rings and bowed washer.

PRINTED IN ENGLAND

C. Back Plate

(1) Indicators fitted with TEST + terminal (fig. 503)

Unsolder the lead connecting the padding resistor to the thermistor and shunt insert terminal, and the lead connecting series resistor (1) to series resistor (2) and the moving coil.

(2) All other codes (fig. 503)

Unsolder the lead connecting the series resistor to the thermistor and shunt insert terminals.

(3) Remove the two stiffnuts and small plain washers securing the back plate to the mounting plate pillars, and remove the back plate.

D. Movement Mounting Plate

Unsolder the lead connecting the padding resistor to the rear tag of the rear bridge piece. Unscrew and remove the two movement mounting plate pillars from the movement fixing studs. Remove the movement mounting plate from the movement fixing studs.

E. Dial and Front Shield

(1) Remove the special screw securing the dial mask, and lift off the mask taking care not to damage the pointer.

(2) Remove the two special screws securing the dial, and lift off the dial taking care not to damage the pointer.

(3) Remove the two screws securing the front shield. Lift off the shield taking care not to damage the pointer.

F. Front Bridge Piece

(1) Unsolder the outer end of the auxiliary hairspring.

(2) Remove the two screws, special washers, pointer stops and small plain washers securing the front bridge piece to the front pillars.

(3) Lift off the front bridge piece and the four insulated bushes. Unscrew and remove the jewel screw and remove the locknut and spring washer. Discard the spring washer.

G. Magnet Arm

Lift the magnet arm assembly from the centre bridge, taking care not to damage the pointer assembly.

PRINTED IN ENGLAND

H. Centre Bridge Piece

(1) Unscrew and remove the two front pillars.

(2) Remove the nut, special washer and small plain washer securing the magnet shield to the upper support post. Rotate the moving element until the stop magnet on the spider is aligned with the slot in the shield. Lift off the magnet shield taking care not to damage the pointer. Remove and discard the three rubber washers fitted to the magnet shield.

(3) Carefully lift the centre bridge piece off the front plate pillars, taking care not to damage the moving element pivot.

I. Rear Bridge Piece

(1) Remove the nut and plain washer securing the hairspring shield to the shield post. Withdraw the shield clear taking care not to damage the hairspring.

(2) Unsolder the outer end of the hairspring from the hairspring anchorage on the bimetal assembly.

(3) Remove the two special screws and two special washers securing the rear bridge piece to the rear plate pillars of the magnet assembly.

(4) Lift off the rear bridge piece and four insulated bushes, taking care not to damage the moving element pivot.

(5) Unscrew and remove the jewel screw from the rear bridge piece and remove the locknut and spring washer. Discard the spring washer.

(6) Unsolder and remove the copper wire connected to the rear tag of the rear bridge piece and to the tag fixed by the rear bridge piece securing screw.

MILLIVOLTMETER TEMPERATURE INDICATORS

CLEANING

1. PROCEDURE

A. Movement

(1) Wash out the jewel screws and fixed jewel bearings using a small syringe, camel hair brush and cleanser B. Allow to drain dry.

(2) Wipe the gap faces of the magnet assembly using a small piece of adhesive tape to ensure that all dust and ferrous particles are removed.

(3) Clean the front bridge piece, centre bridge piece and rear bridge piece with a lint free cloth and cleanser B.

(4) Carefully clean the moving element and magnet arm assembly pivots with a camel hair brush and cleanser B.

B. Case and Frame

Remove all dust from the component parts of the case and frame with a lint free cloth.

C. Electrical Connections

Clean, and re-tin if necessary, the tags of the sealed terminals, anchor tags, ceramic inserts, bobbin resistors, and thermistor. Remove surplus flux with cleanser A.

D. Screws and Nuts

Remove all traces of lockant from screws, nuts, tapped holes, and any other areas which have been so treated with solvent C.

2. CLEANING AGENTS

Cleaning agents and materials are listed in *SPECIAL TOOLS, FIXTURES AND EQUIPMENT.*

PRINTED IN ENGLAND

MILLIVOLTMETER TEMPERATURE INDICATORS

INSPECTION

1. GENERAL PROCEDURE

Apply the following general procedure to the individual components of the transmitter, including new components to be fitted. Any additional inspection necessary is given in paragraph 2.

A. All Components

Examine as applicable for :

(1) Cleanliness
(2) Distortion
(3) Cracks (visual)
(4) Scores
(5) Dents
(6) Evidence of wear (visual)
(7) Corrosion, including deterioration of protective finish
(8) Serviceability of items not disassembled
(9) Fatigue or deterioration of new sealing rings.

B. Electrical Components

Examine for :

(1) Deterioration if insulation
(2) Security of tags
(3) Evidence of overheating

2. EQUIPMENT REQUIRED

To carry out the inspection of the indicator, items 17 and 26 of the list on page 1002 will be required.

3. DETAILED PROCEDURE

NOTE : Reference is made below to wear of gear teeth. If, when compared with a new gear, it is possible to detect that the teeth curvature has departed from its original involute form, the assembly must be rejected.

A. Moving Element

(1) Ensure that the spindle and pointer spider are not distorted, and that the pivots are undamaged and free from wear. If the spindle, pointer spider, or pivots are damaged, the moving element must

PRINTED IN ENGLAND

be renewed; see REPAIR.

(2) Ensure that the hairspring and ligament are undamaged and that they are securely fastened to the spindle. If the hairspring or ligament is damaged it must be renewed, see REPAIR.

B. Magnet Arm Assembly

(1) Ensure that the magnet arm assembly is not distorted, and the pivots are undamaged and free from wear. If the magnet arm or pivots are damaged, the assembly must be renewed.

(2) Ensure that the stop magnets are secure on the magnet arm. If the stop magnets are insecure, renew the assembly.

(3) Ensure that the auxiliary hairspring is undamaged and that the hairspring and collet is securely fastened to the spindle. If the hairspring is damaged it must be renewed, see REPAIR.

C. Jewel Screws

(1) Using a binocular microscope, examine the spring loaded jewel screws for signs of wear or pitting, and the spring for freedom of movement.

D. Jewel Bearings

Using a binocular microscope, examine the solid mounted jewel bearing in the centre bridge piece for signs of wear or pitting. If the jewel is damaged, renew the jewel assembly as described in REPAIR.

E. Rear Bridge Piece

(1) Ensure that the teeth on the gear wheel, as inspected through a binocular microscope, are undamaged and unworn.

(2) Examine the bimetal for security of fixing, and for any signs of distortion or damage. If the bimetal is distorted or damaged it must be renewed as described in REPAIR.

F. Zeroiser Shaft

(1) Ensure that the teeth on the pinion, as inspected through a binocular microscope are undamaged and unworn.

(2) Ensure that the shaft is free from distortion or damage.

(3) Should the zeroiser shaft be damaged, it must be renewed.

PRINTED IN ENGLAND

G. Electrical Components

Using a multi-range test meter set to ohms (÷ 100) :

(1) Measure the resistance of the shunt bobbin resistor. The nominal resistance of the shunt resistor is 15 ohms ± 1%.

(2) Measure the resistance of the thermistor. The resistance at 20°C must be between 18 and 22Ω.

PRINTED IN ENGLAND

MILLIVOLTMETER TEMPERATURE INDICATORS

REPAIR

1. GENERAL

Faulty parts should be replaced by approved spares only, after inspection for serviceability. To renew a particular component, refer to DISASSEMBLY and disassemble the unit to the extent necessary, fit the replacement component and re-assemble as described in ASSEMBLY. Unless the procedure is obvious, instructions for the renewal of components not covered in the above topics are given below. After any component has been renewed or repaired, carry the full procedure detailed in TESTING. Details of cleaning agents and materials are given in SPECIAL TOOLS, FIXTURES AND EQUIPMENT.

2. PROCEDURE

A. Movement (refer to fig. 401)

If it is required to renew the magnet assembly or moving element, then item 3 of the list of page 1001 will be required. Proceed as follows :

(1) Use the demagnetizer 99 LMT to demagnetize the magnet assembly.

(2) Remove the pointer from the spider by heating the spider with a warm soldering iron, and gently pulling the pointer.

(3) Remove the two dial fixing studs securing the front plate and lift off the front plate.

(4) Unsolder the outer end of the ligament from the shield post anchor tag.

(5) Remove the two movement fixing studs securing the rear plate, and lift off the rear plate.

PRINTED IN ENGLAND

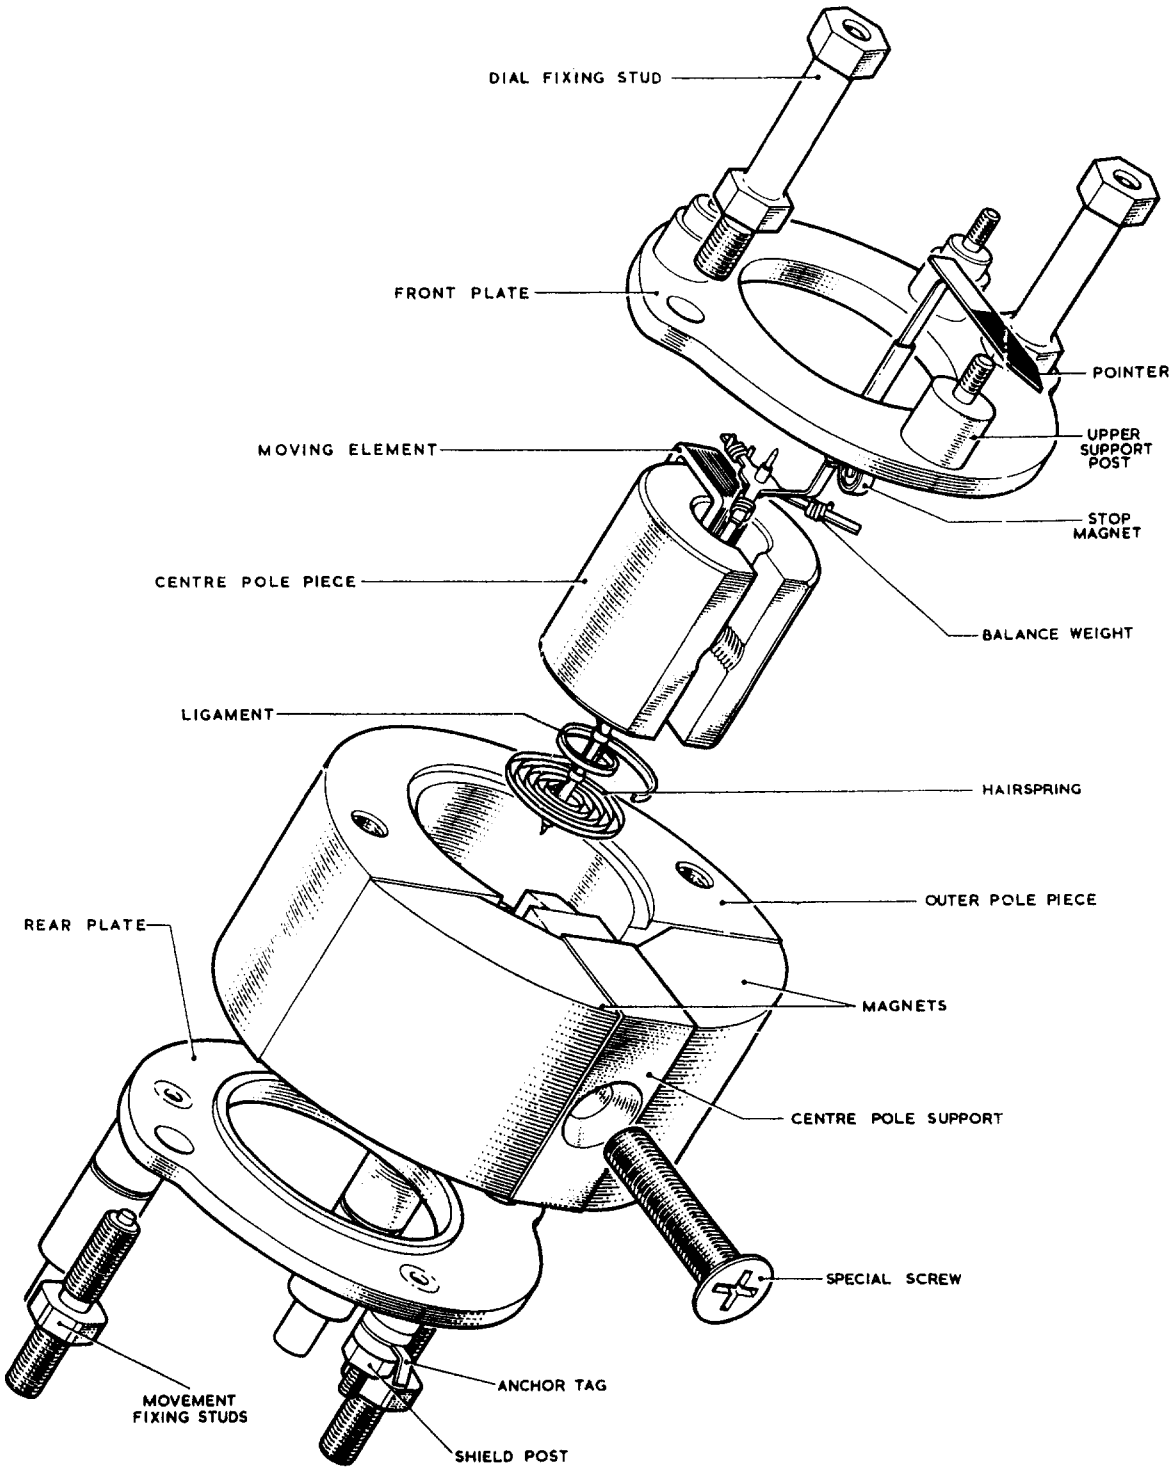

Fig. 401 Exploded view of movement

PRINTED IN ENGLAND

(6) Clearly mark the corresponding faces of the component parts of the magnet assembly.

(7) Remove the special screw which passes through the centre pole support and secures the centre pole piece.

(8) Life out the centre pole piece, complete with moving element.

(9) Remove the moving element from the centre pole piece.

(10) Renew the magnet assembly or moving element whichever is defective. If the magnet assembly is renewed, mark the corresponding faces of the component parts before disassembly.

(11) Thread the centre pole piece through the coil of the moving element ensuring that the spindle of the moving element is at the axis of the centre pole piece.

(12) Place the centre pole piece in position on the tongue of the centre pole support, ensuring that the centre pole piece is the correct way up, by observing the marks previously made.

(13) Secure the centre pole piece with the special screw, and lock with lockant G.

NOTE: The magnet assembly will be magnetized and agred during the assembly of the indicator.

(14) Place the rear plate in position on the magnet, and secure it to the magnet with two movement fixing studs, and lock the studs in position with lockant G.

(15) Insert a piece of paper into the movement to hold the moving element in the approximate zero position and pull the outer end of the ligament so that it is as short as possible. Solder the ligament to the shield post anchor tag and remove the paper from the moving element.

(16) Secure the front plate to the magnet with two dial fixing pillars, and lock the pillars in position with lockant G.

PRINTED IN ENGLAND

(17) Replace or renew the pointer as applicable. Secure the pointer to the spider with adhesive E in accordance with the maker's instructions.

B. Moving Element Hairspring

To renew the moving element hairspring proceed as follows:

NOTE: Do not apply excessive heat to the tag during soldering, as this will weaken the Araldite joint.

(1) Unsolder the inner end of the hairspring and remove.

(2) Place the new hairspring on the movement spindle so that the hairspring is centralized about the axis of the spindle, and develops anti-clockwise from the centre looking towards the moving coil.

(3) Care is to be taken to ensure that the hairspring is flat and concentric with the spindle. The outer turn of the hairspring must be set if necessary so that the turns are equally spaced when the pointer is approximately at two thirds of full scale deflection.

(4) Solder the inner end of the hairspring to the tag, using solder B.

C. Ligament

To renew the ligament proceed as follows:

NOTE: Do not apply excessive heat to the spindle tag during soldering, as this will weaken the Araldite joint.

(1) Unsolder the outer end of the ligament from the shield post anchor tag; unsolder the inner end from the spindle tag. Remove the defective ligament.

(2) Place the new ligament on the movement spindle so that the ligament develops anti-clockwise from the centre looking towards the moving coil, and is flat and concentric with the spindle.

(3) Solder the inner end of the ligament to the tag using solder B. Insert a piece of paper into the movement to hold the moving element in the approximate zero position and pull the outer end of the ligament so that it is as short as possible. Solder the ligament to the shield post anchor tag and remove the paper from the moving element.

PRINTED IN ENGLAND

D. Movement Front Jewel Bearing and Magnet Arm Jewel Bearing

The movement front bearing and magnet arm bearing are both housed in the bush fitted into the centre bridge piece. This bush is a push fit into the bridge piece and is repaired by replacement.

E. Bimetal (Refer to fig.3)

To renew the bimetal proceed as follows :

(1) Unsolder the length of copper wire from the outer end of the bimetal.

(2) Remove the outer end of the bimetal from the slot in the compensator arm by bending up the ends of the arm.

(3) Unsolder the inner end of the bimetal from the rear tag protruding through a slot in the gear wheel.

(4) Place the new bimetal in position.

(5) Using a very hot soldering iron, solder the inner end of the bimetal to the rear tag.

(6) Place the outer end of the bimetal in the slot in the compensator arm and reset the ends ensuring that the bimetal moves freely in the slot with as little side play as possible. Solder the length of copper wire to the outer end of the bimetal using solder B.

F. Auxiliary Hairspring and Collet

To renew the auxiliary hairspring and collet, proceed as follows :

(1) Remove the auxiliary hairspring and collet from the magnet arm assembly spindle.

(2) Press the new hairspring and collet on the magnet arm assembly spindle so that the hairspring develops clockwise from the centre looking towards the movement and, with the spring slot uppermost, so that the outer end of the hairspring coincides approximately with the stop magnet arm, zero side.

G. Wiring

(1) Renewing case back wiring

(a) Unsolder the faulty wire from its sealed terminal and withdraw the wire.

NOTE : In the following para. the distance quoted is not critical but it is essential that the wire length is not altered after the indicator has been ranged.

(b) Thread the silver plated wire (alumel) through sealed terminal 1 and/or the gold plated wire (chromel) through sealed terminal 2 until $1\frac{1}{2}$ in (38.1 mm) protrudes from the terminal on the inner face of the case back. Bend and solder the wire to the sealed terminal tag and sleeve the wires to the colours specified in fig. 503.

(2) Other wiring

Wiring information is given in ASSEMBLY.

PRINTED IN ENGLAND

MILLIVOLTMETER TEMPERATURE INDICATORS

ASSEMBLY

1. GENERAL

Faulty parts should be replaced by approved spares only, after inspection for serviceability. Tab and spring washers, rubber washers and sealing rings must be renewed. Electrical connections, except where stated, must be made with solder B using the smallest amount necessary to achieve an efficient joint. All screw threads not otherwise locked are to be locked with lockant G. Details of materials are given in SPECIAL TOOLS, FIXTURES AND EQUIPMENT.

NOTE : The three-figure suffix included in the code number of some units denotes the SET point referred to in the following procedure. On units with code numbers without this suffix, the SET point is engraved on the dial.

2. EQUIPMENT REQUIRED

To carry out the assembly of the indicator, items 1 to 15 inclusive, 17, 22, 23, 24, and 25 of the list on page 1001 will be required for indicators used in single thermocouple systems; item 1 to 9 inclusive, 14, 15 and 17 to 25 inclusive, for indicators used in two series connected thermocouple systems.

3. PROCEDURE (refer to fig. 501)

NOTE : The following procedures apply to all codes unless specified otherwise.

A. Movement and Frame

(1) Rear bridge piece

(a) Using a piece of spade ended 0.002 in diameter wire as an oiler, apply one spot of lubricant A to the rear jewel screw. Avoid applying excess oil.

(b) Position a spring washer and jewel locknut on the rear bridge piece, ensuring that the spigot on the locknut is located in the slot in the bridge piece bush. Press the locknut until the spring washer is fully compressed, and screw the jewel screw a few turns into the locknut and bridge piece. It is essential that the spring washer shall be almost fully compressed, and unless the gap between the locknut and bush is less than 0.012 in (0.3 mm) after assembly, the jewel screw must be unscrewed and re-engaged with the bridge piece bush whilst under increased pressure. Turning the locknut through 180 deg in a clockwise direction brings the but closer to the bush by approximately 0.005 in (0.13 mm). If a piece of wire 0.006 in (0.15 mm) diameter can be inserted between the washer and the bush at the widest gap, then the gap is suspect.

PRINTED IN ENGLAND

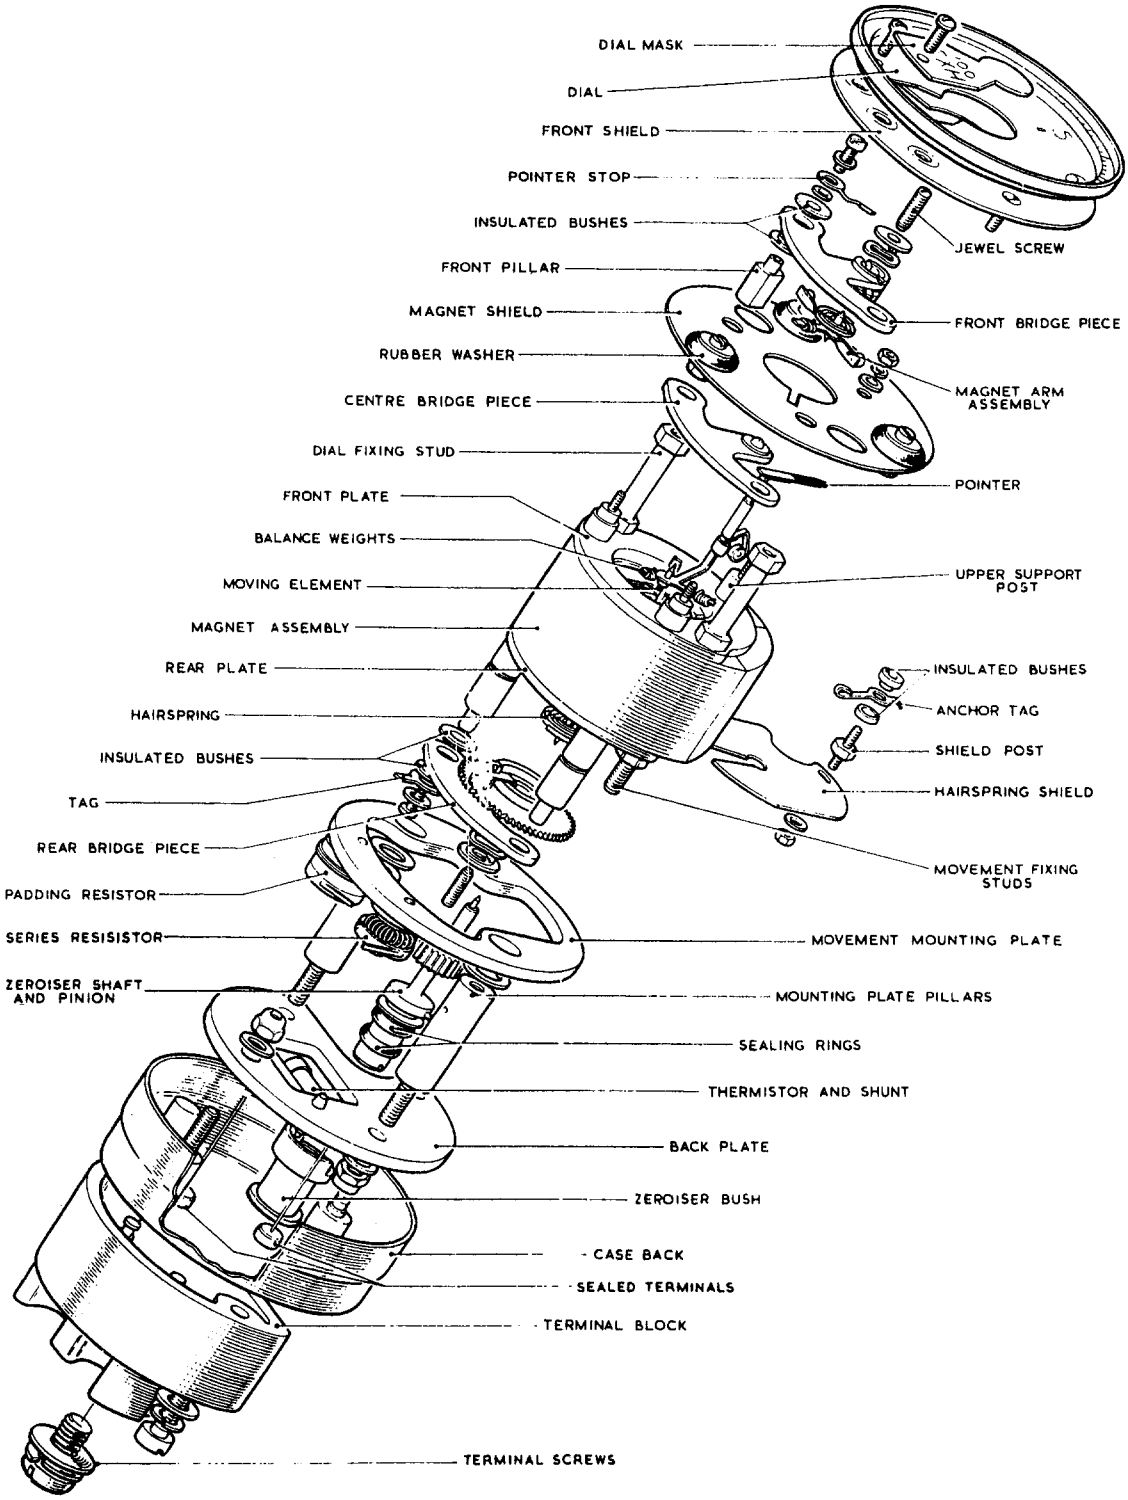

Fig. 501 Exploded view - main case removed

PRINTED IN ENGLAND

(c) Taking care not to damage the moving element pivot, secure the rear bridge piece to the rear plate pillars with two special screws, special washers, 12BA small plain washers and four insulated bushes, with the insulated bushes positioned one either side of each screw hole in the rear bridge piece, and the anchor tag located on the shoulder of the rear bush of the left hand pair.

(2) Centre bridge piece

Place the centre bridge piece on the front plate pillars ensuring that the front pivot of the moving element locates in the jewel.

(3) Magnet shield

(a) Fit 3 new rubber washers to the rim of the magnet shield, and secure the washers in position each with a 0-80NF-2A x 1/4 in screw, 0-80NF plain and special washers, and a 0-80NF nut.

(b) Place the magnet shield over the centre bridge piece and upper support post and screw the front pillars on to the threaded portion of the front plate pillars. Secure the magnet shield to the upper support post with a 0-80NF nut, special washers, and a 0-80NF plain washer.

(4) Moving element endshake

Great care must be taken when assembling the rear jewel bearing to ensure that the pivot tip does not come into contact with the insulated bead in the jewel assembly. Adjust the rear bridge piece jewel screw until it engages the moving element rear pivot, and the moving element is supported by the rear jewel screw and the front fixed jewel. Adjust the rear jewel screw until the spindle endshake is reduced to a minimum consistent with minimum friction. Ensure that the clearance between the stop magnet and the magnet shield is at least 0.030 in. (0.76 mm). Insert a piece of paper into the movement to hold the moving element in the approximate zero position.

(5) Hairspring

(a) Rotate the rear bridge piece gearwheel until the hairspring anchorage (fig. 3) is aligned with the outer end of the hairspring. Solder the hairspring to the tag with solder B.

(b) Remove the piece of paper holding the moving coil in the zero position.

(c) If the magnet assembly has been demagnetized during REPAIR, carry out the magnetization procedure described in the following paragraph B. If the magnet assembly has not been demagnetized during REPAIR, proceed to paragraph C.

B. Magnetization

NOTE : The magnet is manufactured from Alcomax III.

(1) Place the movement in the magnetizing blocks, 218 LMT, and position the blocks on the magnetizer so that the centre pole support (see fig. 401) is remote from the North pole of the magnetizer. Operate the equipment to magnetize to saturation point.

(2) Remove the movement and magnetizing blocks from the magnetizer.

C. Hairspring Shield

(1) Place the hairspring shield in position between the movement hairspring and the ligament, ensuring that the shield is securely seated in the slots in the back plate pillars.

(2) Secure the shield to the shield post with a 12BA nut and a 12BA large washer.

PRINTED IN ENGLAND

D. Dial

(1) If the existing dial is damaged, mark out a new blank dial in pencil as shown in fig. 502. Taking care not to damage the pointer, secure the front shield to the dial fixing pillars with two 0-80NF x 1/8 in c. sk. screws, and secure the dial to the front shield with two special dial screws.

(2) If the original dial is being refitted, lightly mark in pencil the 0 deg and 250 deg marks as indicated in fig. 502. Taking care not to damage the pointer, secure the front shield to the dial fixing pillars with two 0-80NF x 1/8 in csk. screws, and secure the dial to the front shield with two special dial screws.

(3) Ensure that the pointer is free to travel over the complete range of the indicator and set the pointer to the zero mark by means of the rear bridge piece gear wheel.

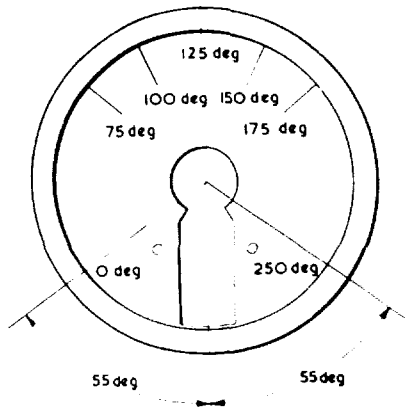

Fig. 502 Blank dial - markings

(4) Solder one end of a 3 in (75 mm) length of 30 SWG tinned copper wire to the tag fixed to the rear bridge piece securing screw. Wind the wire loosely once around the jewel locknut and solder the other end to the tag on the rear bridge piece gear wheel.

E. Movement Mounting Plate and Back Plate

(1) Place the movement mounting plate in position on the movement rear plate so that the movement fixing studs locate in the holes in the mounting plate. Place a plain washer over the movement fixing stud and secure the mounting plate in position by screwing the mounting plate pillars on to the movement fixing studs. Tighten the pillars by using a small tommy bar in the hole provided, and lock the pillars and plate with Akard red lacquer.

(2) Place the back plate in position so that the mounting plate pillars protrude through the holes in the back plate, and secure with two 4-40 UNC stiffnuts and 4-40 UNC plain washers.

PRINTED IN ENGLAND

F. Zeroiser Shaft and Case Back

(1) Insert a new capillary tube in the case back and solder in position with solder D.

(2) Place a new spring washer against the shoulder on the slotted head of the zeroiser shaft.

(3) Fit two new sealing rings to the shaft, lubricate the rings with lubricant F and insert the shaft into the case back bush.

(4) Position the case back so that its pillars protrude through the back plate. Do not locate the zeroiser shaft in the movement mounting plate or engage the pinion with the gear wheel.

G. Wiring

(1) Excluding the terminal block connections, wire the indicator in accordance with the appropriate diagram of fig. 503.

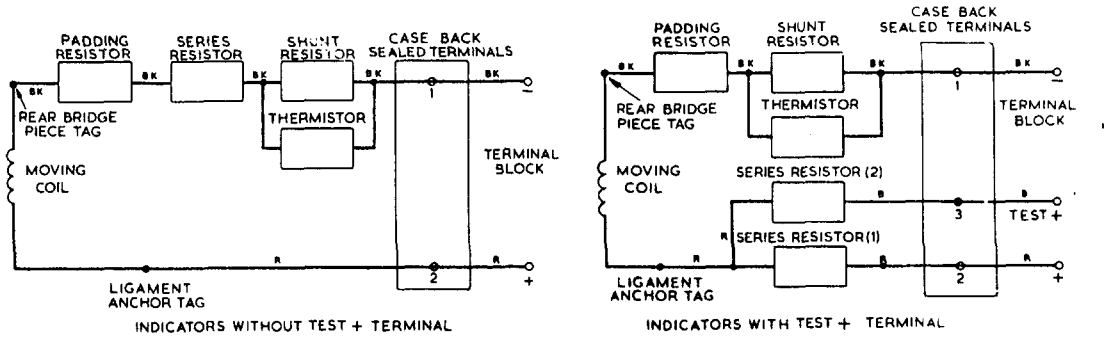

Fig. 503 Wiring diagrams

(2) If the moving coil or the padding resistor have been renewed, check that the resistance of the coil, less the hairspring and ligament, in series with the padding resistor is between 17 and 17.2 ohms at 20°C. If the resistance is high remove wire from the padding resistor. If the resistance is low, renew the padding resistor and adjust as necessary.

PRINTED IN ENGLAND

NOTE : To determine the appropriate table for subsequent procedures, refer to table 501. Tables are located at the end of this topic.

H. Movement Balancing

(1) Connect the extreme ends of the indicator leads to the test circuit shown in fig. 504.

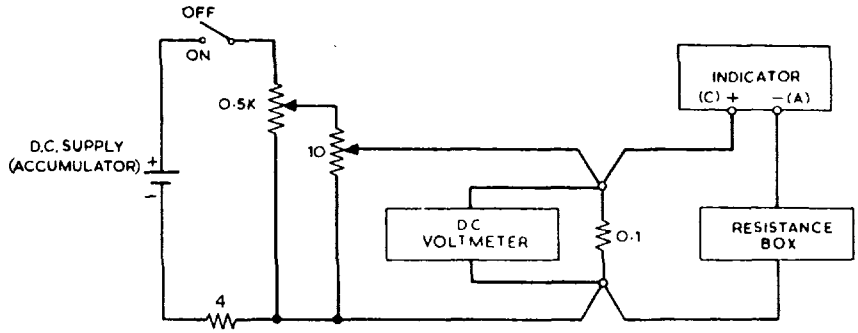

Fig. 504 Test circuit

NOTE PLUG PIN CONNECTIONS ARE SHOWN IN BRACKETS

(2) Referring to DATA, set the decade resistance box to the external resistance of the indicator. Set the controls (variable resistors) to the minimum voltage position and switch on the supply.

(3) Position the indicator so that the dial is in the horizontal plane, and adjust the controls until the pointer is aligned to a mark approximately on the dial vertical centre line.

(4) Position the indicator so that the dial is in the vertical plane.

(5) Turn the indicator so that the pointer successively points horizontally left, vertically upwards, horizontally right and vertically downwards, and at each position check that any deviation of the pointer from the selected scale mark does not exceed ± 8 °C.

(6) If the indications are outside tolerance, adjust the counterweights using the adjusting tools 235 LMT in the manner detailed below and then repeat the procedure in paras. (3), (4) and (5) and if necessary this para. until satisfactory results are obtained.

(a) To move a counterweight inwards, pass the straight slotted end over the counterweight so that the outer tag is engaged by the slot and the inner tag remains free. Turn clockwise.

PRINTED IN ENGLAND

(b) To move a counterweight outwards, pass the L slotted end of the tool over the counterweight so that the outer tag is free in the cross slot and the inner tag bears on the side of the long slot. Turn anti-clockwise.

I. Centralising the Zeroiser Shaft

(1) Referring to the dial drawing (listed in SPECIAL TOOLS, FIXTURES AND EQUIPMENT) and to the appropriate table, determine the voltage equivalent to the temperature indicated by the scale vertical centre line.

(2) Adjust the controls to inject this voltage and align the pointer to the centre line by rotating the rear bridge piece gear wheel. Switch off the supply.

(3) Rotate the zeroiser shaft so that it is in the centre of its travel and, ensuring that the shaft engages the movement mounting plate bush, mesh the zero adjusting pinion and gearwheel by closing the case back to the back plate. Secure the case back with two 4-40 UNC stiffnuts and plain washers.

NOTE : If the magnet assembly has not been demagnetised during REPAIR, proceed to Ranging.

J. Magnet Ageing

(1) Rotate the rear bridge piece gearwheel to set the indicator pointer to the left-hand (zero) pencilled mark on the dial.

(2) Switch on the supply and adjust the controls to align the pointer with the dial vertical centre line. Note the voltmeter indication.

(3) Increase the noted voltage by 3%.

(4) Pass the indicator rapidly in and out of the fringe of the field surrounding the coil of the 99 LMT until the pointer has returned to the dial vertical centre line.

K. Ranging

NOTES : 1. Indicators with TEST + terminal

The following procedure must first be carried out with the TEST + terminal connected using voltage equivalents for single systems and then repeated with the + terminal connected using voltage equivalents for double systems (see table).

PRINTED IN ENGLAND

2. After ranging it is essential that the length of the wire protruding from the sealed terminals is not altered.

(1) Temporarily fit the indicator into the case. Referring to the table and the dial drawing, adjust the controls to inject the voltage equivalent to the temperature indicated by the dial vertical centre line. Rotate the zero adjuster to align the pointer with this mark.

(2) Adjust the controls to set the pointer, in turn, to the scale mark 100°C less than and 100°C greater than that at the centre line and at each setting check that the voltmeter indication is within the following tolerance of that specified in the table.

(a) Indicators used in double systems ± 0.32mV.

(b) All other indicators ± 0.16mV.

(3) If the indication is excessive, crop the movement hairspring from the outside. It is important that when re-soldering the hairspring, it is aligned as described in REPAIR.

(4) If the indication is less than that required, small adjustments can be made by trimming the series resistor.

(5) Repeat the ranging procedure until satisfactory results are obtained.

(6) Switch off the supply and disconnect the indicator from the test circuit.

L. Temperature Cycling

(1) With the case fitted, place the indicator in a refrigerator and maintain it at a temperature of -65°C for one hour.

(2) Remove the case, place the movement in an oven and maintain it at a temperature of +90°C for one hour.

(3) Allow the mechanism to stabilize at room temperature (20 ± 5°C) before proceeding.

M. Magnet Arm

(1) Remove the two special screws securing the dial and remove the dial.

(2) Remove the two screws securing the front shield to the dial fixing pillars, and remove the shield.

(3) Using a piece of spade-ended 0.002 in diameter wire as an oiler, apply one spot of lubricant A to the front bridge piece jewel screw and centre bridge solid mounted jewel bearing. Avoid applying excess oil.

PRINTED IN ENGLAND

(4) Position a spring washer and jewel locknut on the front bridge piece, ensure that the spigot on the locknut is located in the slot in the bridge piece bush. Press the locknut until the spring washer is fully compressed and screw the jewel screw into the locknut and bridge piece. It is essential that the spring washer be almost fully compressed, and unless the gap between the locknut and the bush is less than 0.012in (0.3 mm) after assembly, the jewel screw must be unscrewed and re-engaged with the bridge piece bush whilst under increased pressure. Turning the locknut through 180 deg in a clockwise direction brings the nut closer to the bush by approximately 0.005 in (0.13 mm). If a piece of wire 0.006 in (0.15 mm) dia. can be inserted between washer and bush at the widest gap, the gap is suspect.

(5) Secure the front bridge piece to the front pillars with two 0.80NF-2A x 3/16 in pan hd. screws, two special washers, two plain washers and four insulating bushes, with a pointer stop fitted between the two washers on each screw.

(6) Temporarily place the magnet assembly complete with the auxiliary hairspring, between the centre and front bridge pieces.

(7) Great care must be taken when assembling the jewel bearings to ensure that the pivot tip does not come into contact with the insulating bead in the jewel assembly. Engage the rear pivot in the solid jewel bearing, and adjust the jewel screw until it engages the front pivot.

(8) Check that the stop magnets line up accurately with the stop magnet on the pointer spider. Adjust by bending the magnet arms or the pointer stop magnet assembly.

(9) Unscrew the jewel screw and remove the magnet arm assembly.

(10) Place the magnet arm assembly in the balancing fixture 892 LMT, and adjust the pivot screws to achieve freedom of movement of the magnet arm consistent with minimum friction. Balance the magnet arm by adjusting the balance weight, ensuring the auxiliary hairspring cannot catch on the balance weight tail. Remove the arm from the fixture.

(11) Place the magnet arm assembly complete, between the centre and front bridge pieces.

(12) Engage the rear pivot in the solid jewel bearing and adjust the jewel screw until it engages the front pivot. Adjust the magnet arm endshake by gently oscillating the arm and screwing down the jewel screw until some friction is observed. Undo the jewel screw an amount approximately equal to the width of the slot at the periphery

PRINTED IN ENGLAND

of the screw.

(13) Solder the auxiliary hairspring to the extreme end of the anchor tag and ensure that there are no projections which could interfere with the hairspring under vibration conditions.

(14) Check that the hairspring moves concentrically with the spindle, and that it tightens when the arm is moved in an anticlockwise direction.

(15) Secure the front shield to the dial fixing pillars with two 0-80 NF x 1/8 in csk. screws, and secure the dial to the front shield with two special dial screws. Check the position of the pointer stops. The stops must be set so that the pointer can travel 4 deg. beyond both the 0 deg. and 250 deg. marks respectively.

NOTE : Effect the procedure detailed in paras. (16) to (19) only if the original dial is to be used.

(16) Rotate the auxiliary hairspring anchor tag in a clockwise direction until the pointer is aligned to the zero mark on the dial.

(17) Connect the indicator to the test circuit and switch on the supply. Adjust controls to inject an increasing voltage into the indicator. Note the angular deflection at which the magnet arm ceases to have an effect on the pointer.

NOTE : If a new auxiliary hairspring is to be fitted, if necessary, up to two turns can be removed from the outside of the spring. The outer turn must be bent outwards to meet the tag so that the remaining turns are concentric.

(18) Adjust the torque of the auxiliary hairspring by cutting from the outside, until, in addition to arresting the pointer at the zero mark, the magnet arm comes to rest (with no tension in the auxiliary hairspring) as the pointer, with increasing input, reaches the calibrated position of the lowest scale mark on the expanded scale range (see dial drawing) within + 1 deg. - 3 deg. Disconnect the indicator from the test circuit.

(19) If the pointer stop magnet has been adjusted in paragraph (8), carry out the procedure in movement balancing. Adjust the movement balance weights if the pointer stop magnet has been disturbed.

PRINTED IN ENGLAND

NOTES : 1. Before commencing the procedure in para. M or N, the indicator must be maintained at a temperature between 15 and 25 °C for one hour. It is important that the temperature remains substantially constant. If the ambient temperature is not 20 °C, correct the voltages given in the tables as follows :

Indicators with short bimetal. Add 0.03mV for each deg C below 20 °C or subtract 0.03mV for each deg C above 20 °C.

All other indicators. Add 0.04mV for each deg C below 20 °C or subtract 0.04mV for each deg C above 20 °C.

2. The indicator must be positioned in the normal viewing attitude. If the original dial is being used, effect the procedure in para. N. To calibrate a new dial, effect the procedure in para. O.

3. The three figure suffix included in the code number of some units denotes the SET point of the indicator. On units with code numbers without this suffix, the SET point is marked on the dial.

4. Indicators fitted with TEST + terminal

The check calibration procedure must first be carried out with the TEST + terminal connected using voltage equivalents for single systems and then repeated with the + terminal connected and using voltage equivalents for double systems (see table).

N. Check Calibration

(1) Temporarily fit the indicator in its case, connect the indicator to the test circuit and switch on the supply.

(2) Adjust the controls to inject the voltage equivalent to the SET point. Adjust the zero adjuster to align the pointer with the SET point.

(3) Adjust the controls to align the pointer, in turn, with each scale mark specified in the table and at each setting check that the voltmeter indication is within the specified tolerance.

(4) If the indications are within tolerance, switch off the supply. Fit the dial mask to the front shield and secure with the special screw. Proceed to Friction Test.

PRINTED IN ENGLAND

(5) If the indications are not within tolerance, small adjustments may be made by trimming the series resistor. After any adjustment repeat the Check Calibration and if the indications are still not within tolerance the indicator dial must be removed and discarded. A new dial marked in pencil as shown in fig. 502 must be secured to the front shield and calibrated as detailed in the following procedure.

NOTE : To facilitate the accuracy of subsequent dial location, the dial may be temporarily secured with countersunk screws in the absence of the dial mask.

O. Blank Dial Calibration

(1) Temporarily fit the indicator in the dummy case and with the indicator connected to the test circuit, switch on the supply.

NOTE : Indicator dials differ in their presentation as listed below. Before commencing calibration, refer to the dial drawing to determine the type and effect the procedure in the para. appropriate to that type.

(a) A 100 or 50°C scale mark and the SET point coincident with the dial vertical centre line, refer to para. (2).

(b) A 100 or 50°C scale mark, but not the SET point, coincident with the dial vertical centre line, refer to para. (3).

(c) The indicator turned to bring the SET point on the horizontal or vertical axis, refer to para. (4).

(d) The indicator turned to bring the relevant 100 or 50°C mark on the horizontal or vertical axis, refer to para. (5).

(2) Adjust the controls to inject the voltage equivalent to the SET point of the indicator. Adjust the zero adjuster to align the pointer with the SET point.

(3) Adjust the controls to inject the voltage equivalent to the temperature indicated by the dial vertical centre line. Adjust the zero adjuster to align the pointer with the dial vertical centre line.

(4) Rotate the indicator to the position shown by the dial drawing, then adjust the controls to inject the voltage equivalent to the SET point. Adjust the zero adjuster to align the pointer with the relevant axis.

PRINTED IN ENGLAND

(5) Rotate the indicator to the position shown by the dial drawing, then adjust the controls to inject the voltage equivalent to the relevant temperature. Adjust the zero adjuster to align the pointer with the relevant axis.

(6) Inject voltages equivalent to the scale marks shown in the table and at each point mark the dial in pencil.

(7) Effect the procedure detailed in para. M, sub-paras. (16) to (19).

(8) Switch off the supply and disconnect the indicator from the test circuit.

(9) Remove the two screws securing the dial and remove the dial.

(10) Sub-divide and mark the dial in accordance with the dial drawing.

(11) Secure the finished dial and the mask to the front shield with the special screws.

(12) Carry out the Check Calibration procedure.

P. Friction Test

(1) Switch on the supply. With the dial in the vertical plane, adjust the controls to align the pointer with the dial vertical centre line.

(2) Adjust the controls to align the pointer at the minimum end of the scale. Lightly tap the indicator.

NOTE : During the following procedure it is important that :

(a) The pointer does not overshoot the selected scale mark. If pointer overshoot does occur, the procedure must be repeated.

(b) The indicator is not subjected to vibration except where specified.

(3) Gradually adjust the controls until the pointer is aligned to a scale mark on or near the dial vertical centre line. Record the voltmeter indication.

(4) Adjust the controls so that the pointer is at the maximum end of the scale. Lightly tap the indicator.

(5) Adjust the controls until the pointer is aligned with the scale mark selected in para. (3). Record the voltmeter indication.

PRINTED IN ENGLAND

(6) Check that the difference in the recorded voltmeter indications does not exceed :

(a) Indicators used in double systems, 0.76mV

(b) All other indicators, 0.48mV.

Switch off the supply.

(7) If the friction error exceeds the specified tolerance, check the endshake of the movement and magnet arm spindles. Adjust the jewel screws if necessary. If the endshake is correct, disassemble the indicator and examine the movement and magnet arm pivots and bearings. Renew if necessary and repeat the assembly procedure.

Q. Moisture Removal

(1) Place the instrument, less case, in an oven at 70°C for 12 hours.

(2) Retain the instrument in a drying cabinet until it is to be sealed in the case.

R. Insulation Resistance Test

Fit the main case to the indicator and using a 500V d.c. insulation tester, measure the insulation resistance between the terminals and the case. The resistance must not be less than 20 megohms.

S. Case Sealing

NOTE : To avoid damaging the instrument by excessive heat during soldering operations, the joint between the case back and the main case may be soldered using high frequency heating equipment, if available. This ensures that there is no heating of the instrument apart from the faces which are to be soldered. If high frequency heating equipment is not available a large soldering iron may be used, but great care must be taken to avoid over-heating of the instrument.

(1) Feed a length of silicone rubber string, sufficient to give two complete turns, into position around the edge of the case back and press well down into the recess formed by the case back and main case. Ensure that the ends are well below the surface.

(2) Place a 19 SWG tinned iron wire sealing ring into the recess, pressing down, but leaving the end free.

(3) Place the instrument, dial end downward, in the high frequency heating equipment, switch on and heat the area to be soldered.

PRINTED IN ENGLAND

Make the joint, using solder B, but leave the free end of the wire sealing ring unsoldered to facilitate subsequent unsealing.

(4) Switch off the heating equipment and leave the instrument to cool before carrying out the leak testing procedure.

(5) Mask the sealed terminals and screw threads, and apply a coat of paint H to areas on the case back where the finish has been damaged during overhaul. Allow to dry and remove the masking.

T. Leak Testing and Gas Filling

(1) Using the leak testing, evacuation and gas filling equipment, leak test the indicator. The maximum permissible leak is 10^{-2} lusec.

(2) Flush and finally fill the indicator with gas I at a pressure of 3 lb/in^2 above atmospheric pressure.

(3) Shut off the gas supply and using the special crimping pliers, sever the end of the capillary tube a minimum distance of 9/32 in (7.2 mm) from the case back.

(4) Solder the crimped end of the tube.

U. Terminal Block

(1) Referring to fig. 503, connect the case back sealed terminal leads to the terminal block by passing the leads from sealed terminals 1 and 2 through the appropriate hole in the terminal block and soldering the leads to the flat on the outer face of each terminal block insert.

(2) Indicators with TEST + terminal

Solder the blue lead to the remaining terminal block insert.

(3) Secure the terminal block to the case back with two 4-40 UNC x 5/8 in ch. hd. screws and 6BA plain and spring washers.

(4) Fit the terminal screws to the appropriate terminal block inserts.

V. Testing

Carry out the full procedure on the indicator as detailed in TESTING.

W. Connect the two terminals (fig. 503) together with a suitable shorting strap for movement protection and tighten the terminal.

TESTING

LIST OF CONTENTS

1. GENERAL ... ... Page 701

2. EQUIPMENT REQUIRED ... ... Page 701

3. PROCEDURE
   - A. Insulation Resistance ... ... Page 701
   - B. Accuracy Test ... ... Page 702
   - C. Friction Test ... ... Page 703
   - D. Balance Test ... ... Page 703
   - E. Damping Test ... ... Page 704

1. GENERAL

The following tests are those which are to be carried out after overhaul or whenever any component has been renewed or repaired. They are also the only tests necessary to establish the serviceability of an indicator.

The tests are to be made at an ambient temperature of 15°C to 25°C and, unless otherwise stated, with the instrument in the normal viewing attitude. Light tapping of the indicator is permitted in all tests except the friction test.

NOTE : The three-figure suffix included in the code number of some units denotes the SET point referred to in the following procedure. On units with code numbers without this suffix, the SET point is engraved on the dial.

2. EQUIPMENT REQUIRED

To carry out the testing of the indicator, items 1, 8, 9, 10, 11, 12, 13 and 15 of the list on page 1001 will be required for indicators used in single thermocouple systems; items 1, 8, 9, 15, 18, 19, 20 and 21 for indicators used in two series connected thermocouple systems (see DATA).

3. PROCEDURE

Remove the shorting strap from between the terminal screws.

A. Insulation Resistance

Using a 500V d.c. insulation tester, measure the insulation resistance between the terminals and the case. The resistance must not be less than 20 megohms.

PRINTED IN ENGLAND

NOTES : 1. To determine the appropriate table for subsequent procedures, refer to table 701. Tables are located at the end of this topic.

2. Before commencing the following procedures, the indicator must be maintained at a temperature between 15 and 25 °C for one hour. It is important that the temperature remains substantially constant. If the ambient temperature is not 20 °C, correct the voltages given in the tables as follows :

(a) Indicators with short bimetal. Add 0.03mV for each deg C below 20 °C or subtract 0.03mV for each deg C above 20 °C.

(b) All other indicators. Add 0.04mV for each deg C below 20 °C or subtract 0.04mV for each deg C above 20 °C.

3. Indicators with TEST + terminal

The tests must first be carried out with the TEST + terminal connected using voltage equivalents for single systems and then repeated with the + terminal connected and using voltage equivalents for double systems (see table).

B. Accuracy Test

(1) Connect the indicator to the test circuit as shown in fig. 701. Set the decade box to the appropriate external resistance of the indicator under test (see DATA).

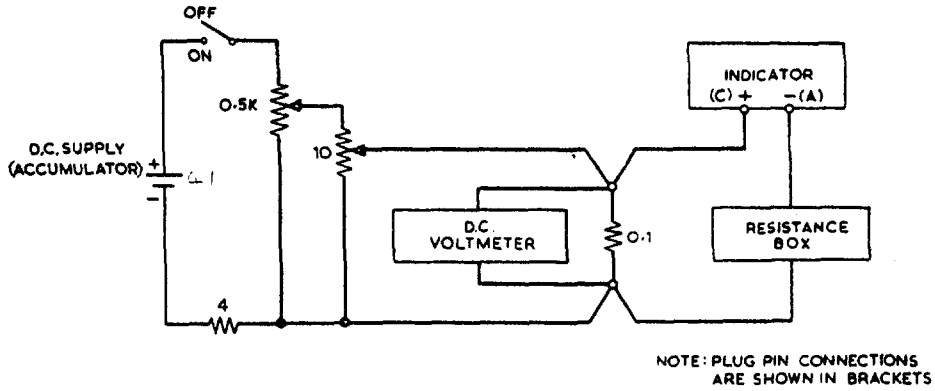

Fig. 701 Test circuit

(2) Switch on the supply and, referring to DATA and the table, adjust the controls to inject the voltage equivalent to the SET point. If necessary, adjust the zero adjuster to align the pointer with the SET point.

(3) Adjust the controls to align the pointer, in turn, with each scale mark specified in the table and at each setting check that the voltmeter indication is within the specified tolerance.

PRINTED IN ENGLAND

C. Friction Test

The indicator remains connected as for the previous procedure.

(1) With the dial in the vertical plane, adjust the controls to align the pointer with the dial vertical centre line.

(2) Adjust the controls to align the pointer at the minimum temperature scale mark. Lightly tap the indicator.

NOTE : During the following procedure it is important that :

(a) The pointer does not overshoot the selected scale mark. If pointer overshoot does occur, the procedure must be repeated.

(b) The indicator is not subjected to vibration except where specified.

(3) Gradually adjust the controls until the pointer is aligned to a scale mark on or near the dial vertical centre line. Record the voltmeter indication.

(4) Adjust the controls so that the pointer is at the maximum end of the scale. Lightly tap the indicator.

(5) Adjust the controls until the pointer is aligned with the scale mark selected in para.(3). Record the voltmeter indication.

(6) Check that the difference in the recorded voltmeter indications does not exceed :

(a) Indicators used in double system, 1.60mV.

(b) All other indicators, 0.80mV.

D. Balance Test

The indicator remains connected as shown in fig.701.

(1) Position the indicator so that the dial is in the horizontal plane and adjust the controls until the pointer is aligned to a scale mark on or near the dial vertical centre line.

(2) Position the indicator so that the dial is in the vertical plane.

(3) Turn the indicator so that the pointer successively points horizontally left, vertically upwards, horizontally right and vertically downwards and at each position check that any deviation of the pointer from the selected scale mark does not exceed ±10°C.

E. Damping Test

The indicator remains connected as shown in fig. 701.

(1) Adjust the controls to set the indicator pointer to 80% of full scale deflection. Switch off the supply.

(2) Switch on the supply and check that the pointer, on its first overswing, does not exceed full scale deflection.

(3) Switch off the supply and disconnect the indicator from the test circuit.

F. Final

(1) Connect the terminals together with a suitable shorting strap to protect the movement.

(2) Tighten the terminal screws.

MILLIVOLTMETER TEMPERATURE INDICATORS

TROUBLE SHOOTING

1. GENERAL

It must be noted that whenever any adjustment, repair, or component replacement has been carried out, the unit must be subjected to the complete series of tests described in TESTING.

2. FAULTS LIKELY IN SERVICE

The design of this instrument is such that faults do not fall into the two distinct patterns of those likely in service and those likely after overhaul. Furthermore, investigation of any fault is best carried out at an overhaul base. For these reasons, all procedures are covered as 'Faults Likely After Overhaul'.

3. FAULTS LIKELY AFTER OVERHAUL

A. When the serviceability of an indicator is suspect, it should be subjected to the sequence of tests described in TESTING until it fails to pass a particular test. Reference should then be made to the appropriate paragraph below, and remedial action taken as appropriate. The unit should then again be subjected to the sequence of tests, until either it fails to pass a particular test or, alternatively, passes successfully through the entire sequence. Should another fault be encountered, the tracing, repair and re-testing cycle should be repeated until all test results are satisfactory.

B. Accuracy Test

(1) Failure to pass the accuracy test, described in TESTING 3.B., can be caused by:

(a) Defective series resistor.

(b) Defective hairspring or ligament.

(c) Defective moving element coil and padding resistor.

(d) Moving element end shake incorrect.

(e) Hairs or foreign particles in the magnet gaps.

(f) Defective pivots or jewel bearings.

(g) Movement out of balance.

PRINTED IN ENGLAND

(2) If the pointer does not move when a voltage is applied to the indicator, remove the instrument case and check the series resistor for open circuit. A defective series resistor must be renewed and adjusted, see ASSEMBLY.

(3) If the series resistor is not defective, check the ligament and hairspring connections. Resolder if necessary. If the connections are satisfactory, check the moving coil and padding resistor for open circuit. Renew the moving coil or padding resistor as necessary and adjust the padding resistor as described in ASSEMBLY.

(4) If the pointer movement is jerky, or erratic, remove the case, check, and if necessary, adjust the moving element endshake or the magnet arm endshake as described in ASSEMBLY.

(5) If the endshake is correct, remove the dial, dial mask and front shield, and using an eyeglass, examine the magnet gaps for foreign particles.

(6) If the pointer movement is still erractic or jerky, examine the moving element or magnet arm pivots. Renew either the moving element as described in REPAIR, or the magnet arm as necessary. Examine the jewel bearings and renew as necessary.

(7) If the pointer moves smoothly over the dial, but indicates a progressive error, remove the case and examine the hairspring. If necessary renew as described in REPAIR.

(8) If the pointer moves smoothly over the dial, but shows inconsistent errors, check the balance of the instrument, and if necessary, re-balance the movement as described in ASSEMBLY.

(9) If the pointer readings are still out of tolerance, calibrate a new blank dial.

(10) After correction, repeat TESTING.

C. Friction Test

(1) Failure to pass the friction test described in TESTING 3.C can be caused by:

(a) Defective moving element or magnet arm pivots.

(b) Defective moving element or magnet arm jewel bearings.

(c) Insufficient endshake on the moving element or magnet arm spindle.

(2) Disassemble the indicator and examine the moving element or magnet arm pivots and jewel bearings. If the moving element pivots are defective, renew the moving element as described in REPAIR. If the magnet arm pivots are defective, renew the magnet arm. Renew any defective jewel bearings. Adjust the endshake of the moving element pivot and magnet arm pivot as described in ASSEMBLY.

(3) After correction, repeat TESTING.

D. Balance Test

(1) Failure to pass the balance test described in TESTING 3.D is caused by faulty movement balance.

(2) Disassemble the indicator from the case and re-balance the movement as described in ASSEMBLY.

(3) After correction repeat TESTING.

MILLIVOLTMETER TEMPERATURE INDICATORS

STORAGE INSTRUCTIONS

NOTE: *These instructions are applicable to temperate and tropical* climates and the packaging is suitable for storage and transit purposes.

1. PACKAGING PROCEDURE

A. Ensure the shorting strap is fitted between the terminals.

B. Record the details shown on the unit nameplate. Attach warning label (Smiths Code 86-837-384) to the unit.

C. Wrap the unit in waxed paper and secure a protective pad to each end of the unit with adhesive tape.

D. Place the unit in a polythene bag with a label showing the code and serial number of the unit.

E. Partially heat-seal the bag, expel as much air as possible and complete the seal.

F. Place the unit in the container. If necessary wrap the unit so that it fits securely into the shock-resistant material.

G. Close the container lid and secure it with waterproof adhesive tape.

H. Secure to the container a label giving the following information:

(1) Name, code and serial number of the unit.

(2) Modification state.

(3) Date of last overhaul.

(4) Note and date of any component change.

(5) Reason for return, if applicable.

Protect the label with transparent adhesive tape.

2. STORAGE CONDITIONS

For this information refer to publication SAV/OH/SPR.

PRINTED IN ENGLAND

3. STORAGE LIMITING PERIOD

For this information reference should be made to publication SAV/OH/SPR. Re-certification and re-storage after this period is dependent upon satisfactory completion of the following procedure:

A. Remove the unit from its packing.

B. Examine the unit visually for signs of corrosion or damage.

C. Carry out the complete procedure described in TESTING.

D. Pack the unit in accordance with 1. above.

SPECIAL TOOLS, FIXTURES AND EQUIPMENT

1. GENERAL

Items with an LMT part number are for local manufacture. Full manufacturing information for these items may be obtained from the vendor. When requesting information please quote the part number.

2. TOOLS, FIXTURES AND EQUIPMENT

Item	Description	Part No. or Ref.	Vendor
1	D.C. Potentiometer and galvanometer or digital valve voltmeter. Accuracy better than 0.1% over the range 0-50mV. (0-100mV for indications in double systems)	As available	
2	Magnetizer	As available Magnetech MC2000J is suitable (see NOTES)	Magnetech
3	Demagnetizer	99 LMT	Smiths Industries
4	Magnetizing blocks	218 LMT	Smiths Industries
5	Leak testing, evacuation, and gas filling equipment	As available M59VBC is suitable	Veeco
6	Counterweight adjusting tools	235 LMT	Smiths Industries
7	Oven (90°C)	As available	
8	Insulation tester (500V d.c. 20 MΩ)	As available	
9	Decade box 0-1000Ω, accuracy better than ±0.1%	As available	
*10	Resistor 4Ω ± 1%, 1W	As available	
*11	Variable resistor 0.5kΩ, 1W	As available	
*12	High resolution variable resistor 10Ω, 1W	As available	
*13	2V accumulator	As available	

PRINTED IN ENGLAND

Item	Description	Part No. or Ref.	Vendor
14	Bridge megger	As available	
15	Standard resistance 0.1Ω ± 0.1%	As available	
16	Multi-range testmeter	As available	
17	Crimping tool	A-MP47386/8	A-MP
**18	Resistor 4Ω ± 1%, 4.5 W	As available	
**19	Variable resistor 0.5 K, 4.5 W	As available	
**20	High resolution variable resistor 10Ω, 5 W	As available	
**21	4 V accumulator	As available	
22	Balancing fixture	892 LMT	Smiths Industries
23	Dummy case (see NOTES)	1402/1 TE	Smiths Industries
24	Dial detail drawing	See para. 6.	Smiths Industries
25	Refrigerator	As available	
26	Binocular microscope (magnification x 30)	As available	

NOTES: (1) Items marked thus * are required for indicators used in single thermocouple systems only. Items marked thus ** are required for indicators used in two series connected thermocouple systems only.

(2) A spare indicator case with the glass removed can be used in place of 1402/1 TE.

(3) The magnet is manufactured from Alcomax III.

3. CLEANING AGENTS

Category		Nomenclature and British Specification or Vendors Trade Name	Alternative Specification	Vendor
Cleanser	A	Iso-propyl alcohol or methylated spirits		Commercially available
Cleanser	B	Trichlorotrifluoroethane 1.1.2		
Solvent	C	Methyl ethyl ketone		

4. MATERIALS

Category		Nomenclature and British Specification or Vendors Trade Name	Alternative Specification	Vendor
Lubricant	A	Oil to DEF STAN 91-49		Commercially available
Solder	B	BS219 Grade K, BS441		Multicore Solders
Solder	C	Comsol		
Solder	D	Pure tin solder		
Adhesive	E	Bostik 1768		Bostik
Lubricant	F	Kalubleum M.O.L.T.		Ragosine
Lockant	G	Akard, CS2465, Type D (18683)		Llewellyn Ryland
Paint	H	Semi-matt black 2SL/5459. Catalyst CSL 6201A. Thinners TSL 5373		International Paints
Gas	I	Oxygen-free nitrogen		As available

5. VENDOR'S ADDRESSES

Vendor	Full Name and Address
Smiths Industries	Smiths Industries, Aerospace and Defence Systems Limited, Product Support, Northolt Road, Heathrow Airport London, Hounslow, Middlesex, TW6 2LW, U.K.
Multicore Solders	Multicore Solders Limited, Multicore Works, Hemel Hempstead, Herts., U.K.
Llewellyn Ryland	Llewellyn Ryland Limited, Balsall Heath Works, Birmingham, 12, U.K.
Bostik	Bostik Ltd., Ulverscroft Road, Leicester.
Veeco	Veeco Instruments Limited, Marshalands Road, Farlington, Portsmouth, Hants., U.K.
International Paints	International Paints, 380 Richmond Road, Kingston-on-Thames, Surrey, KT2 5PS. U.K.
Magnetech	Magnetech Magnatising Techniques Ltd., Flemming Way, Crawley, Sussex RH10 2JY.

PRINTED IN ENGLAND

Vendor	Full Name and Address
Ragosine	Ragosine Oil Co. Limited, Alanzol Refinery, Bream, Glos., U.K.
A-MP	Aircraft Marine Products Limited, 60, Kingly Street, Regent Street, London W.1, U.K.

ILLUSTRATED PARTS LIST

WARNING: ONLY SPARES AND COMPONENTS SPECIFIED BY SMITHS INDUSTRIES SHOULD BE USED.

NOTE:

ORDERING

Certain spare parts listed in the IPL are manufactured by other contractors and have the manufacturer's number or British Standards reference quoted in addition to the part number which Smiths Industries Aerospace & Defence Systems Company supply.

When ordering from SI please quote the SI part number, the other manufacturer's number or British Standards reference and the code number of the LRU on all orders or enquiries.

When ordering from other manufacturers please quote the manufacturer's number and/or British Standards reference only.

NOTES:
1. The asterisk prefixing a part number is in place of the dial finish e.g. PW.

2. ILLUSTRATED PARTS LISTS for codes of Millivoltmeter Temperature Indicators not included in this page block, will be supplied on request.

OVERHAUL INSTRUCTIONS WITH PARTS BREAKDOWN

25510A122A8A2 - OVERHAUL

1. Description and Operation.

The 25510A122A8A2 indicator is a hermetically sealed single synchro indicator. It consists of a single pointer mounted directly on the shaft of a receiver synchro. The receiver synchro is remotely connected to a synchro transmitter monitoring oil pressure at its source and transmitting an electrical signal to the receiver. The signal is converted to a visual indication of pressure as the receiver synchro rotates the pointer over a graduated dial. The mechanism is mounted in a hermetically sealed case that incorporates a quick disconnect connector.

The indicator is a clamp-on type that allows it to be rotated in order that all pointers on the instrument panel may be aligned under normal operating conditions.

Table 1. Leading Particulars

Operating Voltage	26 volts 400 Hz
Dial spread	320 Degrees
Case diameter	1.500 inches
Range	0 to 125 PSI
Case length	2.56 inches

2. Disassembly.

A. Disassemble the indicator in accordance with the following sequence of instructions: (See figure 2)

(1) Remove locking ring (2) with a screwdriver or other suitable tool.

(2) Remove identification plate (1) by lifting over receptacle (6).

(3) Remove evacuation plug (3) by heating with soldering iron and lifting out with needle nose pliers or screwdriver.

(4) Heat around edge of case and end cover assembly (5) with soldering iron and remove end cover assembly (5) by inserting a wire or hook into the evacuation plug hole and pulling as solder becomes molten.

CAUTION: DO NOT REMOVE END COVER ASSEMBLY (5) BY PULLING ON RECEPTACLE (6). HEAT MAY LOOSEN SOLDER AND RECEPTACLE (6) WILL SEPARATE FROM END COVER (7).

NOTE: Do not remove receptacle (6) from end cover (7) unless necessary to replace a damaged part.

(5) Unsolder wires from end cover assembly (5) and remove tubing (4).

(6) Remove entire mechanism from case and glass assembly (16).

(7) Remove pointer (9) by pulling straight away from dial (10).

(8) Remove dial screws (11) and dial (10).

(9) Remove screws (13) and dial plate (12).

NOTE: Do not disassemble case and glass assembly (16) unless necessary to replace a damaged part.

3. Cleaning.

A. Clean the indicator parts as outlined in the following procedure:

WARNING: NAPTHA IS HIGHLY VOLATILE. USE IN A WELL VENTILATED AREA. DO NOT INHALE OR ALLOW TO COME IN CONTACT WITH SKIN. KEEP NAPTHA AWAY FROM ANY SOURCE OF IGNITION.

(1) Clean metal parts with naptha or an approved solvent. Keep parts clean and free from dust.

CAUTION: DO NOT IMMERSE SYNCHRO RECEIVER (14) IN NAPTHA OR SOLVENT.

(2) Clean glass (18) and dial (10) with a mild soap and water. Rinse and dry thoroughly. Keep parts free from finger marks.

4. Inspection/Check

A. Inspect indicator components as outlined in the following steps:

(1) Visually inspect terminal pins of receptacle (6) for bent, loose or broken pins. Inspect for damaged insulation.

(2) Inspect glass (18) for cracks, chips or discoloring.

(3) Inspect synchro (14) for damaged leads at point where leads enter housing.

(4) Inspect dial (10) and pointer (9) for damaged or chipped paint.

5. Repair.

A. No repair of any parts is recommended. Replace all parts that are not in a like new condition.

6. Assembly.

A. Assemble the indicator in the following steps:

(1) Place dial plate (12) on synchro (14) and secure in place with two flat fillister head screws (13).

(2) Apply a drop of purple glyptal lacquer to a wire 0.010 to 0.015 inch in diameter. Insert glyptal into threaded dial screw hole in dial plate (12). Distribute glyptal in hole evenly. Repeat for second dial screw hole.

(3) Place dial (10) on dial plate (12) and secure with two dial screws (11).

(4) Pass wires of synchro (14) through compression ring (8). Place one piece of tubing (4) over two black wires and one piece over each of the red, yellow and blue wires.

(5) Solder wires to receptacle in end cover assembly (5) as shown in wiring diagram, figure 1 shown under 9. Trouble Shooting.

(6) Connect receptacle (6) to Autosyn precision transmitter 13695-2-A. Actuate the electrical zero to position the synchro at its electrical zero position.

(7) Press pointer assembly (9) on shaft of synchro (14) with the top of the pointer at 62.5 PSI mark of dial (10). Tip of pointer should be 0.040 inch from face of dial.

(8) Place dial spacer (15) in case and glass assembly (16).

(9) Insert assembly mechanism of indicator into case and glass assembly (16). The key of the receptacle (6) must line up with the top center-line of dial (10).

(10) Put a slight pressure on receptacle (6) to keep end cover (7) flush with back edge of case and glass assembly (16) and solder end cover to case.

(11) Pressurize the indicator to 20 psig and immerse it completely in clean, clear alcohol. Any bubbles coming from within indicates a leak which must be repaired. Mark leaks for repair.

(12) Repair any leaks at solder joints.

(13) Place indicator under bell jar supplied with hermetic sealing stand 13693-1-B and connect to vacuum pump.

(14) Evacuate the bell jar to a pressure of 50 microns or less. Switch the dual manifold to draw from a helium-nitrogen mixture and back-fill the indicator with one atmosphere of dry helium nitrogen mixture.

NOTE: The mixture recommended is 88 to 92% nitrogen and the remainder helium.

(15) Place evacuation plug (3) in end cover assembly and solder in place.

(16) Paint any uncovered parts of indicator with dull black enamel.

7. Fits and Clearances.

A. Only clearance involved for entire assembly is called out in paragraph 6, A (7), assembly of pointer assembly (9) to shaft of synchro assembly (14).

8. Testing.

A. Following tests shall be performed at standard atmospheric pressure (approximately 29.92 inches of Hg.) and room temperature (approximately +25°C). Indicator and standard transmitter shall be connected to a 26 volt 400 Hz source and shall be vibrated during all tests unless otherwise specified.

(1) Insulation Breakdown. Apply a voltage of 200 volts at a commercial frequency between any pin of receptacle and ground. There shall be no breakdown of insulation.

(2) Electrical Zero. Electrical zero shall be imposed on indicator. Tip of pointer shall be within 0.010 inch of 62.5 PSI reading.

(3) Scale Error and Friction. Knob of standard transmitter 13695-2-A shall be rotated to each of the readings indicated in Table 2, Calibration. Two readings shall be taken; the first before and the second after the indicator is vibrated or tapped. The difference between the first and second readings shall not exceed 1.5 degrees. The second reading shall not exceed the scale error tolerance specified in Table 2, Calibration.

(4) Position Error. Set standard transmitter and lock at any reading. Reading of transmitter, while held in any position, shall not vary by more than 1.0 degree.

(5) Sealing. A leak rate of one micron-cubic foot at a pressure differential of approximately one atmosphere must not be exceeded when tested on a helium leak detector.

Table 2. Calibration

Test Points (PSI)	Desired Reading (Degrees)	Scale Error Tolerance (± Degrees)
0	20.0	2.0
20	71.2	2.0
40	122.4	2.0
60	173.6	1.0
80	224.8	1.0
100	276.0	1.0
120	372.2	2.0
125	340.0	2.0
EZ-180° at 62.5 PSI Friction Error 1.5° Position Error 1.0°		

9. Trouble Shooting.

A. Table 3 contains a list of causes and remedies for trouble shooting.

Table 3. Trouble Shooting

Trouble	Possible Reason	Remedial Steps
Pointer (9) not at E.Z. mark when E.Z. is applied	Pointer (9) loose on shaft	Press pointer on shaft securely.
Indicator not within test tolerances	Faulty synchro assembly (14)	Replace synchro assembly
Indicator will not operate	Improper wiring connection	Check electrical connection. Check indicator for loose or broken wires

Table 4. Wiring Data

Wire Color		Receptacle Pin
Rotor	Black/White	A
	Red/White	B
Stator	Black	A
	Yellow	C
	Blue	D

10. Storage Instructions.

A. The indicator should be stored in a suitable cardboard box of an appropriate size. Cushion the indicator in the box with a commercial dunnage such as Kimpack. Make certain that glass (17) is well protected and indicator is not loose in sealed box.

11. Special Tools, Fixtures and Equipment.

A. Table 5 contains a list of the special tools required to overhaul and test the indicator. If the listed tools are not available a suitable equivalent may be used. Unless otherwise indicated the tools listed are manufactured by the Bendix Corporation.

Table 5. Special Tools and Equipment

Part No.	Nomenclature	Application
13693-1-B	Hermetic sealing stand	Used in operations required to seal indicator.
13695-2-A	Autosyn Precision Transmitter	Used in calibrating and testing indicator.
13700-1-C	Insulation Breakdown Test Set	Used in insulation breakdown test.
Model 25 Hyper Vac	Vacuum Pump Central Scientific Co. Chicago, Ill.	Used to evacuate indicator housing prior to backfill.
Model 24-120A	Helium Leak Detector Consolidated Engineering Pasadena, Calif.	Used to check indicator for leaks.

GAGE PRESSURE SWITCH 1G177-7, -9, -15 OVERHAUL MANUAL

1. DESCRIPTION AND OPERATION

Models 1G177-7, 1G177-9, and 1G177-15 are pressure actuated switches designed to sense gage pressure. Pressure is applied to a diaphragm. The resultant force created by the gage pressure on the diaphragm is conveyed to a negative rate disc spring by the diaphragm. When the increasing gage pressure reaches a preset actuation point, the disc spring snaps over center allowing the pressure plate to actuate the electrical assembly. Upon decreasing gage pressure, at a preset value below the actuation point, the disc spring snaps back to its original position returning the pressure plate and electrical assembly to their original positions.

These models are used on commercial aircraft in the engine oil system for low oil pressure warning.

TABLE I LEADING PARTICULARS

Service Media.....Oil per MIL-L-7808

Actuation Points:

Model	Increasing Pressure	Decreasing Pressure
1G177-7	At 39 ±1 PSIG	At 36 ±1 PSIG
1G177-9	At 50 ±1 PSIG	At 46 ±1 PSIG
1G177-15	At 45 ±1 PSIG	At 41 ±1 PSIG

Proof Pressure:
- 1G177-7.....200 PSIG
- 1G177-9.....250 PSIG
- 1G177-15.....200 PSIG

Ambient Temperature Range.....-54°C to +121°C
-65°F to +250°F

Pressure Port.....Per AND10050-4
7/16-20 UNF-3B

Mounting Provisions.....Two .199 inch dia. holes
on 1.25 inch centers

Electrical Data:
- Switching Element.....SPDT
- Current.....5 amps resistive at 28 VDC
- Receptacle:
  - 1G177-7, -15.....Per MS3102-10SL-3P
    mates with MS3106R10SL-3S

    mates with MS3106R12S-3S

Overall Dimensions
- Height.....3.50 inches max
- Width & Depth.....1.87 inches typ
- Weight.....4 ounces est

GAGE PRESSURE SWITCH 1G177-7, -9, -15 OVERHAUL MANUAL

2. DISASSEMBLY (See Figures 3 and 4)

A. Cut and remove lockwire from electrical assembly [13], port cap [2], and body [11].

NOTE: Observe method used to lockwire unit. Use same method to replace lockwire during assembly.

B. Using a 66-4 tool (1G177-7, -15) or a 66-10 tool (1G177-9), remove electrical assembly [13] from body [11]. Remove O-ring [12] from electrical assembly [13].
C. Using a 66-1 tool and a 66-56 tool, remove body [11] from port cap [2].
D. Remove pressure plate [8], disc spring [9], register ring [10], diaphragm [7], O-ring [6], adjustment shoe [5], and helical spring [4] from port cap [2] or body [11].
E. Using a 66-5 tool, remove adjustment screw [3] from port cap [2].

3. CLEANING

A. Clean all metal parts with dry cleaning solvent per Federal Specification P-D-680, Type 1, or equivalent; use a stiff bristle brush and/or a clean, lint-free cloth.

WARNING: AVOID SOLVENT CONTACT WITH SKIN AND AVOID BREATHING SOLVENT VAPORS. OBSERVE FIRE PRECAUTIONS.

B. Dry parts thoroughly with moisture free, compressed air, and/or allow to air dry.

4. INSPECTION/CHECK (See Figures 1, 2, and 4)

A. Inspect all machined surfaces for cracks, burrs, nicks, corrosion, or any other condition which could cause a malfunction in service.
B. Inspect all threaded parts for crossed or stripped threads.
C. Check all plated parts for deterioration.
D. Check helical spring [4] for distortion, length, and rate.
(1) Roll spring on flat surface; there must be no wobble.
(2) Free length should be .360/.390 inch.
(3) With spring deflected to solid height, reaction force should be approximately 4.2 pounds.
E. Using an ohmmeter or other suitable device, check electrical circuitry of electrical assembly [13].
(1) With electrical assembly [13] in the deactuated position there must be:
(a) 1G177-7, -15; closed circuit between receptacle pins A and B; also an open circuit between pins A and C.

(b) 1G177-9; closed circuit between receptacle pins A and B.

(2) Actuate electrical assembly [13] by applying slight pressure to actuating plunger of assembly.

(3) With electrical assembly [13] actuated there must be:

(a) 1G177-7, -15; closed circuit between receptacle pins A and C; also an open circuit between pins A and B.

(b) 1G177-9; open circuit between pins A and B.

F. Test dielectric strength of electrical assembly [13].

(1) With output limited to 18 milliamperes, apply 800 volts RMS 60 cycles between each receptacle pin and the receptacle shell for a period not to exceed one minute.

CAUTION: THE OUTPUT CURRENT MUST BE LIMITED DURING THIS TEST AS A PRECAUTIONARY MEASURE IN ORDER TO PREVENT PERMANENT DAMAGE TO THE ASSEMBLY.

(2) There must be no arcing.

(3) Maximum permissible leakage is 2 milliamperes.

G. Inspect nameplate [14] for legibility and security of attachment to body [11].

5. REPAIR (See Figure 4)

A. Adjustment screw [3] and electrical assembly [13] contain nylon locking inserts. If required, these inserts should be removed and replaced with new nylon pellets of appropriate size.

B. Remove any minor nicks, corrosion, or burrs from aluminum parts with an aluminum oxide abrasive cloth per Federal Specification P-C-451.

C. Remove defects from stainless steel parts using crocus cloth per Federal Specification P-C-458, grade 600 or finer.

D. Repair minor thread damage by carefully chasing threads with an appropriate tap or die.

E. Replace any parts on which the plating has deteriorated.

F. Replace all parts that cannot be made serviceable by steps 5.A. thru 5.D.

6. ASSEMBLY (See Figures 1 thru 4)

A. Apply a thin film of lubricant to O-rings [6 and 12].

NOTE: Recommended lubricant is Insulgrease #G624 manufactured by General Electric Co., Waterford, New York (V01139).

B. Using a 66-5 tool, thread adjustment screw [3] into port cap [2]. Thread as far as possible; then back off 1/4 turn.
C. Install helical spring [4], adjustment shoe [5], O-ring [6], and diaphragm [7] into port cap [2].
D. Install register ring [10], disc spring [9], and pressure plate [8] into body [11].
E. Using 66-1 and 66-56 tools, assemble body [11] to port cap [2]. Tighten to 15 foot pounds torque.

CAUTION: DO NOT EXCEED 15 FOOT POUNDS TORQUE.

F. Install and synchronize electrical assembly [13].
(1) Place O-ring [12] around electrical assembly [13].
(2) Connect the partially assembled unit to a test setup such as shown in Figure 2.
(3) Increase test pressure to actuate disc spring [9] and hold pressure.
(4) Using a 66-4 tool (1G177-7, -15) or a 66-10 tool (1G177-9), thread electrical assembly [13] into body [11] until assembly actuates.

CAUTION: INTERNAL DAMAGE TO ELECTRICAL ASSEMBLY [13] CAN RESULT IF IT IS THREADED TOO FAR.

(5) Reduce test pressure to zero.
(6) Thread electrical assembly [13] an additional 1/6 turn (60°) into body [11].

NOTE: Electrical assembly [13] is now synchronized and should not be rotated again.

G. After unit has been tested and adjusted per paragraph 8, lockwire electrical assembly [13] and port cap [2] to body [11]. Use wire per MS20995C32 or MS20995F32 installed per MS33540.

7. FITS AND CLEARANCES (Not Applicable)

8. TESTING (See Figures 1 thru 4)

A. Connect the completely assembled unit between the valves of a test setup such as shown in Figure 2. The inlet manifold should be connected to a source of clean, dry, compressed air which delivers at least 250 PSIG.
B. Test unit for leakage by slowly applying test pressure (see Table II) to pressure port. Shut off inlet valve and maintain a static pressure head for one minute. If leakage occurs, refer to paragraph 9, TROUBLE SHOOTING.

CAUTION: DO NOT EXCEED MAXIMUM RATED PRESSURE.

C. Test unit operating limits.
(1) With test lamp circuit connected to receptacle, slowly increase test pressure to pressure port until the circuit between receptacle pins A and B opens (A-C closes; 1G177-7, -15 only). Note the exact gage reading the instant this occurs.
(2) Slowly decrease the test pressure until the circuit between receptacle pins A and B closes (A-C opens; 1G177-7, -15 only). Note the exact gage reading the instant this occurs.
(3) If required, adjust unit operation to conform with data given in Table II. Using a 66-5 tool, rotate adjustment screw [3] in small increments and repeat steps 8.C.(1) and 8.C.(2). To increase pressure settings, rotate adjustment screw [3] counterclockwise; to decrease settings, turn clockwise.

D. Test dielectric strength of electrical assembly [13].
(1) With output limited to 18 milliamperes, apply 800 volts RMS 60 cycles between each receptacle pin and the receptacle shell for a period not to exceed one minute.

CAUTION: THE OUTPUT CURRENT MUST BE LIMITED DURING THIS TEST AS A PRECAUTIONARY MEASURE IN ORDER TO PREVENT PERMANENT DAMAGE TO THE ASSEMBLY.

(2) There must be no arcing.
(3) Maximum permissible leakage is 2 milliamperes.

TABLE II UNIT OPERATING CHARACTERISTICS

MODEL	PROOF PSIG	TEST PRESSURE	PRESSURE PSIG	CIRCUIT	
				A-B	A-C
1G177-7	200	Increasing	At 39 ±1	Opens	Closes
		Decreasing	At 36 ±1	Closes	Opens
1G177-9	250	Increasing	At 50 ±1	Opens	none

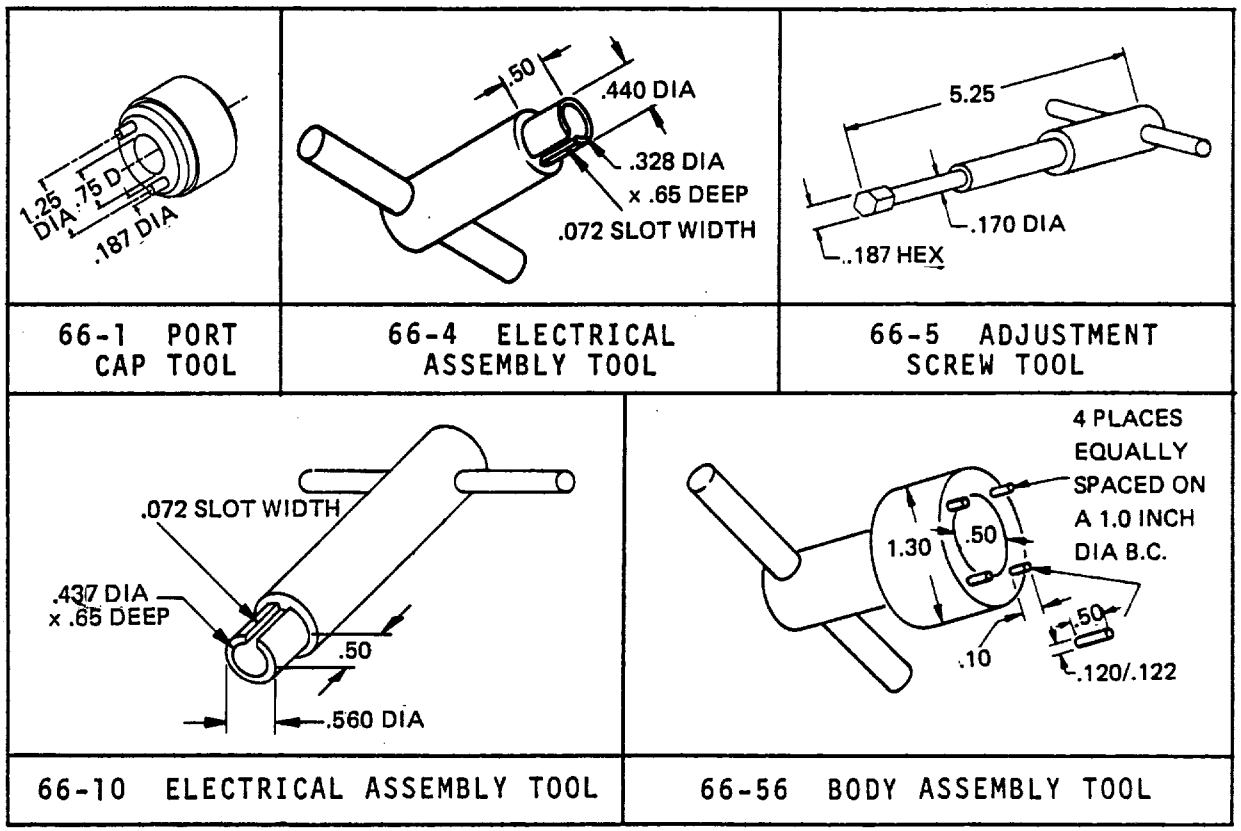
9. TROUBLE SHOOTING (See Figure 4)

TABLE III

TROUBLE	PROBABLE CAUSE	REMEDY
Leakage	Defective O-ring [6]	Replace O-ring [6].
	Ruptured diaphragm [7]	Replace diaphragm [7].
Unit fails to operate or operate within pressure limits	Defective electrical assembly [13]	Check per paragraphs 4.E. and 4.F. If defective, replace electrical assembly [13].
	Defective disc spring [9]	Replace disc spring [9].
	Improper adjustment screw [3] setting	Readjust adjustment screw [3] per paragraph 8.C.
	Incorrect synchronization of electrical assembly [13]	Resynchronize electrical assembly [13] per paragraph 6.F.



GAGE PRESSURE SWITCH 1G177-7, -9, -15 OVERHAUL MANUAL

10. STORAGE INSTRUCTIONS

Cap pressure port and electrical receptacle with closures per MIL-C-5501. Place unit in a suitable plastic bag and/or corrugated cardboard container.

11. SPECIAL TOOLS (See Figure 3)

Tools similar to those shown in Figure 3 will aid in the assembly, disassembly, and adjustment of the unit. These tools may be made in the average machine shop, or they may be procured from Custom Aviation Supply under part numbers 66-1, 66-4, 66-5, 66-10, and 66-56.

66-1 PORT CAP TOOL | 66-4 ELECTRICAL ASSEMBLY TOOL | 66-5 ADJUSTMENT SCREW TOOL

66-10 ELECTRICAL ASSEMBLY TOOL | 66-56 BODY ASSEMBLY TOOL

OIL PRESSURE INDICATOR NO. 290-02240 GENERAL INFORMATION

1. Introduction

This manual contains instructions for the overhaul of EDISON Aircraft Oil Pressure Indicator, part No. 290-02240.

It is prepared in accordance with ATA Specification No. 100 including the Uniform Chapterization and Numbering System designated therein so that the pages may be inserted into their proper locations in the basic aircraft overhaul manual if desired.

All of the material in this manual falls within the classification "Oil System - Chapter 79".

OIL PRESSURE INDICATOR NO. 290-02240 OVERHAUL INSTRUCTIONS

1. Description and Operation

The pressure indicator covered by these overhaul instructions is part of the EDISON variable reluctance type Oil Pressure Indicating System. (Ref. Fig.1)

The Indicator
Figure 1

Table of Leading Particulars
Power Supply .. 26 V single phase 400 cps
Pressure Range .....0 to 100 psi

It is an hermetically sealed instrument designed to be secured to an instrument panel by means of a standard mounting clamp. An electrical connector on the rear provides for connection to the transmitter and power supply.

The function of the indicator is to translate into percent torque the voltage applied to its moving coil by the pressure transmitter. This is accomplished through the use of several simple principles as follows:

A. When the current flows in the same direction through two coils, their magnetic flux is in the same direction. Thus their opposite magnetic poles are next to each other, so the coils are attracted to each other. (Ref. Fig. 2A)

B. When alternating current flows through a coil, the resulting flux cutting across a second coil induces a current within it if its circuit is complete. At any given instant the induced current flows in the direction opposite to the applied current. (Ref. Fig. 2B) Thus the induced fluxes are opposed and the coils repel each other.

C. In the indicator a constant 26 volt 400 cycle current flows through the stationary field coil making a flux pattern through the core and across the air gap. (Ref. Fig. 2C) The flux is strongest near the base of the hook-shaped part of the core and decreases uniformly along its length.

D. The moving coil with attached pointer is pivoted to rotate with the core hook at its center. (Ref. Fig. 2D) Two hairsprings transmit applied voltage to coil and furnish torque to swing pointer off low end of scale when no voltage is applied.

OIL PRESSURE INDICATOR NO. 290-02240 OVERHAUL INSTRUCTIONS

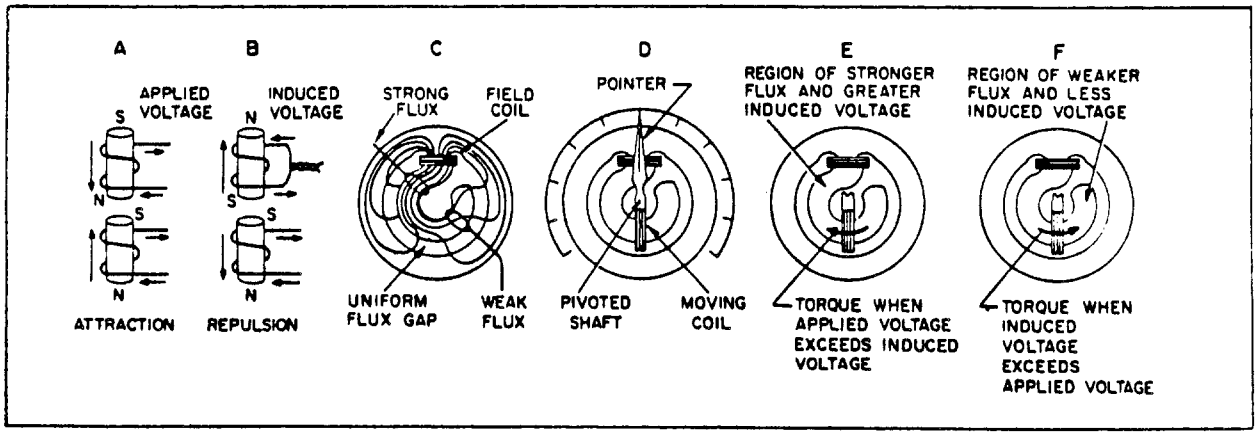
E. When the transmitter applies voltage to the moving coil it causes a current at any given instant to be in the same direction as that in the field coil (in phase).

F. At the same time, since the coils are energized with alternating current, the transformer effect is inducing an opposing voltage (180° out of phase) in the moving coil.

G. If the moving coil is at a position where applied voltage is greater than induced voltage, current will flow in the same direction as that of the field coil and the resulting torque will move the coil toward the base of the hook where the field coil flux is greater. (Ref. Fig. 1E) As it moves the induced voltage increases, the current and resulting torque decrease until the coil comes to rest at the point where applied voltage is just enough greater than induced voltage to overcome hairspring torque.

H. If applied voltage decreases below induced voltage, the resulting torque will cause the coil to swing toward the end of the hook until it reaches a point where equilibrium is again achieved. (Ref. Fig. 2F)

I. Because the voltage applied to the moving coil is obtained from two similar inductive, resistive voltage dividers, any variations in power supply voltage cause proportional changes in all voltages involved, hence do not affect the position assumed by the moving coil. (Ref. Fig. 3)



J. In order to compensate for resistance changes in the copper field coils, thermistors are connected in series with them.

2. Disassembly (Ref. Fig. 9)

CAUTION: USE EXTREME CARE TO KEEP DUST, FIBERS AND OTHER FOREIGN MATTER OUT OF SILICONE FLUID IMPREGNATED BEARINGS. DO NOT IMMERSE MECHANISM IN CLEANING SOLVENT.

A. Remove case and mask assembly (6).
(1) Use induction heater (Ref. Section 11) to unsolder case and mask assembly (6) from base and receptacle assembly (46) of complete movement assembly.

NOTE: No further disassembly of case and mask assembly is recommended.

Principles of Indicator Operation
Figure 2

OIL PRESSURE INDICATOR NO. 290-02240 OVERHAUL INSTRUCTIONS

B. Remove evacuation hole rivet (5).
   (1) Remove the two screws (2) and washers (3, 4) and nameplate (1).
   (2) Unsolder and remove rivet (5) from hole in base and receptacle assembly (46).

   NOTE: No further disassembly of the movement assembly is required to permit cleaning, inspection and check of detail parts. If parts are found to be defective, continue disassembly as required.

C. Remove dial (11).
   (1) Remove dial nut (12), screw (13), washers (14, 15), and bushing (16).
   (2) Tip dial (11) and carefully slide it out from under pointer of rotor and hairspring assembly (22).

D. Remove rotor balance weights (17).
   (1) Grasp weight (17) with tweezers in manner to straighten the slight bend in the weight so that it may be slipped off of the balance cross of the rotor.

E. Remove front housing and bearing assembly.

   NOTE: If rotor and hairspring assembly (22) is to be removed, delay this step until top plate (20) has been removed.

   (1) Loosen front bearing nut (18).
   (2) Unscrew and remove housing and bearing assembly (19) and nut (18).

F. Remove rotor and hairspring assembly (22).
   (1) Bend cut wire (27), which forms upper snubber, away from rotor shaft to clear outer turn of hairspring (23).
   (2) Unsolder hairsprings (23) from terminal of plate and terminal assembly (28) and board and adjuster assembly (45).
   (3) Remove self-locking nuts (21) and lift off top plate (20) using care not to damage pointer.
   (4) Turn and lift out rotor and hairspring assembly (22).

   NOTE: Removal of pivots (24) from rotor body assembly (25) is not recommended.

G. Remove Hairsprings (23) from rotor and hairspring assembly (22).

H. Remove stator assembly (27-39 assembled) and board and bearing assembly (41-45 assembled).

Basic Principle of Operation of the System
Figure 3

OIL PRESSURE INDICATOR NO. 290-02240 OVERHAUL INSTRUCTIONS

(1) Lift off top bushings (26).
(2) Unsolder leads from base and receptacle assembly (46).
(3) Lift off stator assembly with board and bearing assembly attached.
(4) Take out bottom bushings (40).
(5) Unsolder fixed coil leads from board and adjuster assembly (42), thus separating stator assembly and board and bearing assembly.

I. Remove fixed coil (38).
(1) Unsolder fixed coil lead from terminal of plate and terminal assembly (28).
(2) Unsolder and remove cut wire (27) only if replacement is required.
(3) Remove rivet (25).
(4) Remove plate and terminal assembly (28) and bottom plate (29).
(5) Push out inside core (31).
(6) Remove screws (32, 33), lock washer (34), and shunt nut (35).
(7) Slide shunt (38) and coil bracket (37) from under fixed coil (38).
(8) Slide fixed coil (38) from outside lamination assembly (39).

J. Disassemble board and bearing assembly (41-45 assembled).
(1) Unscrew and remove rear housing and bearing assembly (41).
(2) Unsolder and remove thermistors (43).
(3) Unsolder and remove snubber (44).

3. Cleaning (Ref. Fig. 9)

A. Carefully clean solder from case and mask assembly (6) and base and receptacle assembly (46) so they will be ready for resealing case after assembly.

B. If microscopic inspection of bearings shows hairlike fibers in the bearing cavity, remove with tweezers. Use no other cleaning method on bearings since they are factory impregnated with a special silicone fluid.

C. Vapor degrease all parts made solely of metal, using trichlorethylene.

WARNING: AVOID BREATHING FUMES OR PERMITTING TRICHLORETHYLENE TO CONTACT SKIN.

4. Inspection/Check (Ref. Fig.9)

A. Visual
(1) Check cover glass (9) for cracks or chips.
(2) Check dial (11) for scratches or stains.
(3) Check hairsprings (23) for distortion.
(4) Check pointer of rotor and hairspring assembly (22) for distortion or chipped paint.

B. Microscope (30X)
(1) Check pivots (24) for pits, grooves or distortion.
(2) Check housing and bearing assemblies (19, 41) for dents in bearing cap, foreign matter, and loss of clear fluidity of silicone fluid.

C. Ohmmeter
(1) Check moving coil with ohmmeter across terminal "C" and upper hairspring terminal of assembled indicator, or directly across coil of rotor body assembly (25). Acceptable resistance: 25 $\pm$ 8 ohms.
(2) Check fixed coil (38) with ohmmeter across lower terminals. Acceptable resistance: 46 $\pm$ 15 ohms.

OIL PRESSURE INDICATOR NO. 290-02240 OVERHAUL INSTRUCTIONS

(3) Check thermistors (43) with ohmmeter across leads. Acceptable resistance at 25°C (77°F): 5.6 ± 0.1 ohm.

5. Repair

Replace all defective or damaged parts.

6. Assembly (Ref. Fig. 9)

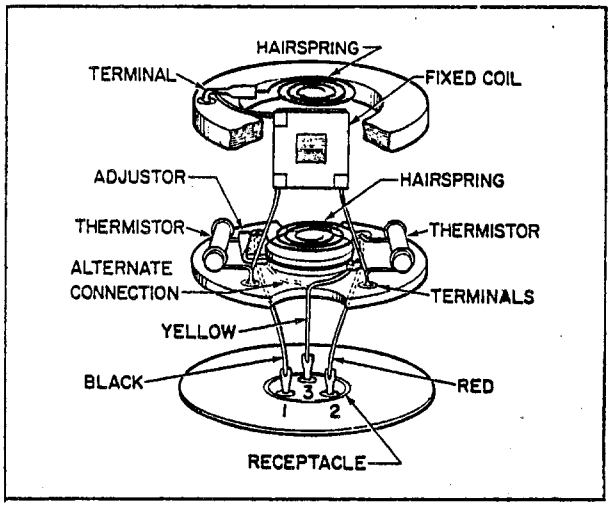
A. Assemble board and bearing assembly.
(1) Slide snubber (44) to bottom of higher prong of hairspring adjuster of board and adjuster (45). Position the snubber so its projecting wire is over the outer edge of the adjuster, then solder its coil to the adjuster prong.
(2) Place thermistors (43) on lower face of board and adjuster (45) and solder one lead of each together with red or black base connection lead wire (Ref. Fig. 4) in eyelet terminal.
(3) Screw and tighten rear housing and bearing assembly (41) into rear of board and adjuster (45).

B. Assemble stator assembly.
(1) Place fixed coil (38) on hook of outside lamination assembly (39) in position shown. (Ref. Fig. 4)
(2) Slip end of coil bracket (37) between upper face of outside lamination assembly (39) and fixed coil (38).
(3) Slip end of shunt (36) between lower face of outside lamination assembly (39) and fixed coil (38).
(4) Pass screw (33) through lock washer (34), coil bracket (37), outside lamination assembly (39) and shunt (36) and tighten in shunt nut (35).
(5) Pass screw (32) through outer end of shunt and turn it a few turns into shunt nut (35).
(6) Press inside core (31) into outside lamination assembly (39).
(7) Position bottom plate (29) and plate and terminal assembly (28) on previous assembly and secure. Check to be sure holes through plates and inside core are aligned to permit later assembly onto studs of base and receptacle assembly (46).
(8) Make a hook in the end of cut wire (27) as shown and solder it and the center top lead of fixed coil (38) to the neck of the hairspring terminal of plate and terminal assembly (28).

C. Assemble board and bearing assembly and stator assembly on base and receptacle assembly.
(1) Slide board and bearing assembly onto studs.
(2) Slide stator assembly onto studs in position that permits fixed coil leads to run directly down into eyelet terminals with thermistor leads not already soldered in. (Ref. Fig. 4)
(3) Solder thermistor and fixed coil leads to terminals.
(4) Solder black lead to "A" terminal of receptacle and red lead to "B" terminal.

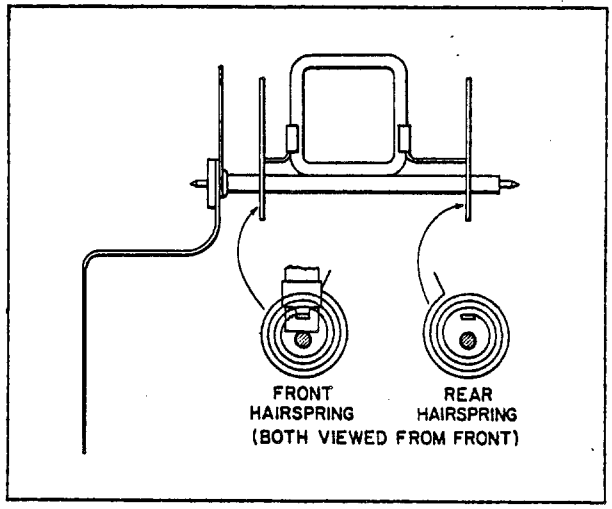
D. Assemble rotor and hairspring assembly.
(1) Solder hairspring (23) to terminals of movable coil on rotor body assembly (25). (Ref. Fig. 5)
(2) If necessary, reshape hairspring slightly so that turns are equally spaced and lie in a plane at right angles to rotor shaft.

E. Install rotor and hairspring assembly.
(1) Place rotor and hairspring assembly (22) in stator assembly with hook



OIL PRESSURE INDICATOR NO. 290-02240 OVERHAUL INSTRUCTIONS

of outside lamination assembly (39) passing through its moving coil.
(2) Slide top bushing (26) on studs of base and receptacle assembly (46).
(3) Carefully slide tipped top plate (20) over pointer of rotor and hairspring assembly (22) and seat it on studs of base and receptacle assembly (46).
(4) Install and tighten self-locking nuts (21) on studs.
(5) Place front bearing nut (18) on housing and bearing assembly (19).
(6) Screw housing and bearing assembly (19) into top plate (20) and seat pivots (24) of rotor and hairspring assembly (22) in both upper and lower bearings. Be careful pivot is in bearing and not resting against cap of housing.
(7) Adjust housing and bearing assembly (19) to provide 0.001 to 0.002 inch rotor end play, then lock in position by tightening front bearing nut (18). Be careful not to change end play when tightening nut.
(8) Solder hairsprings to their respective terminals. (Ref. Fig. 4)



F. Install dial and adjust movement.
(1) Carefully slide tipped dial (11) over pointer and attach to top plate (20) by means of dial nut (12) and dial screw (13) which passes through dial bushing (16) between dial and top plate. Use washers (14, 15).
(2) Bend upper snubber made from cut wire (27) and lower snubber (44) to position. (Ref. sub-section 7A)
(3) Bend pointer to position. (Ref. sub-section 7B)
(4) Adjust lower hairspring to proper torque. (Ref. sub-section 7C)
(5) Solder yellow lead to terminal "C" of receptacle and to most accessible end of hairspring adjuster.

G. Calibrate the indicator. (Ref. Section 8)

H. Install case and ring assembly and seal indicator.
(1) Install case assembly with mask (7) in proper position over dial (11).
(2) Solder case assembly (8) to base and receptacle assembly (46) with 63-37 resin core solder using induction heater. (Ref. Section 11).
(3) Check to be sure rivet (5) fits hole in base and receptacle assembly (46) but leave out of hole.
(4) Heat inductor to 75 ± 5°C (167 ± 9°F) for 30 minutes.
(5) Place indicator in autoclave and evacuate to 200 microns and hold for five minutes.
(6) Admit dry helium, dew point below -55°C (-67°F), to autoclave to

Internal Wiring
Figure 4

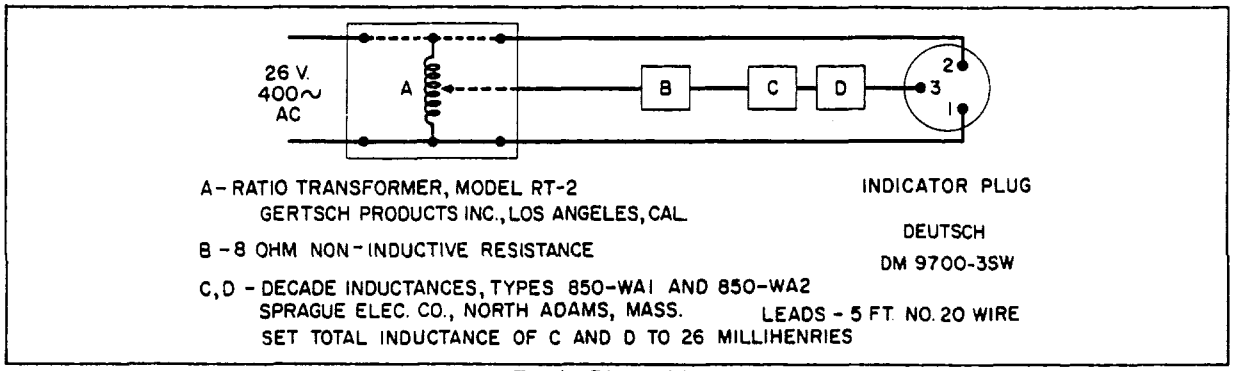
Detail of Hairspring Position
Figure 5

OIL PRESSURE INDICATOR NO. 290-02240 OVERHAUL INSTRUCTIONS

pressure of one atmosphere (760 mm mercury).
(7) Re-evacuate to 200 microns then refill with dry helium to one atmosphere of pressure.
(8) Remove indicator from autoclave and immediately place rivet (5) in hole in base and receptacle assembly (46) and seal in place with a minimum of solder.
(9) Using screw (2) and washers (3, 4), install nameplate (1).
(10) Touch up case with dull black paint or lacquer.

7. Fits and Clearances

A. Bend snubbers to lie parallel to base, approximately 1/16 inch from hairspring, and approximately 1/32 inch from rotor shaft.



B. Bend pointer so it is parallel with and 0.02 to 0.04 inch from dial, covers half of the length of a minor graduation line and is over offscale reference mark when against low-end stop.

C. With the dial horizontal, rotate the hairspring adjuster to swing the pointer against the low-end stop. Continue turning the adjuster in the down-scale direction an additional 90 to 100 degrees.

8. Testing

A. Calibration Procedures - uncased indicator. (Ref. Fig. 9)

(1) Connect indicator to test circuit. (Ref. Fig. 6)
(2) Check to be sure power applied to ratio transformer is 26 ± 0.5 volts, 400 ± 8 cycles, a.c.
(3) Set ratio transformer to ".5980".
(4) Holding indicator with dial horizontal, use a screwdriver to avoid moving the housing and bearing assembly (19), loosen dial nut (12).
(5) Loosen dial screw (13).
(6) Rotate dial (11) until pointer indicates 0 psi.
(7) Tighten dial screw (13).
(8) Reduce voltage applied to ratio transformer to 15 volts.
(9) Set ratio transformer to move pointer to exact middle of scale. Since indicator has not yet been calibrated, this will not necessarily be specified mid-scale value.
(10) Install balance weights (17) as required to make pointer position remain unchanged when dial is moved from horizontal to normal vertical operating position, then rotated 90, 180 and 270 degrees.

Test Circuit
Figure 6

OIL PRESSURE INDICATOR NO. 290-02240 OVERHAUL INSTRUCTIONS

(11) Increase applied voltage to 26 ± 0.5 volts.
(12) Set ratio transformer to ".5980".
(13) With indicator in normal operating position, if necessary, loosen dial screw (13) and rotate dial until pointer indicates 0 psi, then tighten dial screw (13).
(14) Set ratio transformer to ".4020".
(15) Turn shunt adjusting screw (32) to open or close the shunt (36) until the pointer indicates 100 psi. If necessary, remove and discard screw (32) and bend shunt (36) to obtain correct pointer position.
(16) Set ratio transformer to ".5600", then turn power off. If pointer fails to swing off low end of scale without tapping, increase lower hairspring tension as required. Test the indicator in all four dial vertical positions and with dial horizontal.
(17) Check indications at all test values. (Ref. Fig. 7)
(18) Repeat steps 13 and 15 as required to bring all indications within tolerance.
(19) Holding housing and bearing assembly (19) with screwdriver, tighten dial nut (12).
(20) Place a drop of glyptal on shunt screw (32), if used, to seal it in place.

B. Test Procedure - sealed indicator.

(1) Connect the indicator to test circuit. (Ref. Fig. 6)
(2) Check to be sure power supply to ratio transformer is 26 ± 0.5 volts, 400 ± 8 cycles a.c.
(3) With indicator at room temperature and with dial in normal operating position, successively set ratio transformer at each test value shown in Figure 7. Notice indication before and after lightly tapping the indicator. The difference caused by tapping shall not exceed specified Friction Test Tolerance, nor shall the indication after tapping be out of tolerance for the test value involved.
(4) Set ratio transformer to mid-scale value and note pointer position after tapping. Rotate indicator 90, 180 and 270 degrees, then to position with dial horizontal. The difference between the indication in normal position and any other position shall not exceed specified Position Error Tolerance. (Ref. Fig. 7)
(5) Turn off power supply. Pointer shall swing off scale without tapping.

9. Trouble Shooting

The only troubles which can occur in an indicator, other than external physical damage, cause failure to pass test specified in sub-section 8B. When it has been determined in which test the trouble occurs, the indicator must be opened (Ref. sub-section 2A) after which possible causes as listed in Figure 8 may readily be checked to isolate the trouble.

Transformer Setting	Indicated PSI	Tolerance ± PSI	Transformer Setting	Indicated PSI	Tolerance ± PSI
.5980	0	0.50	.4793	60	0.75
.5777	10	0.50	.4600	70	0.75

10. Storage Instructions

No special storage requirements apply to this indicator. It is an hermetically sealed unit subject only to damage from rough handling.

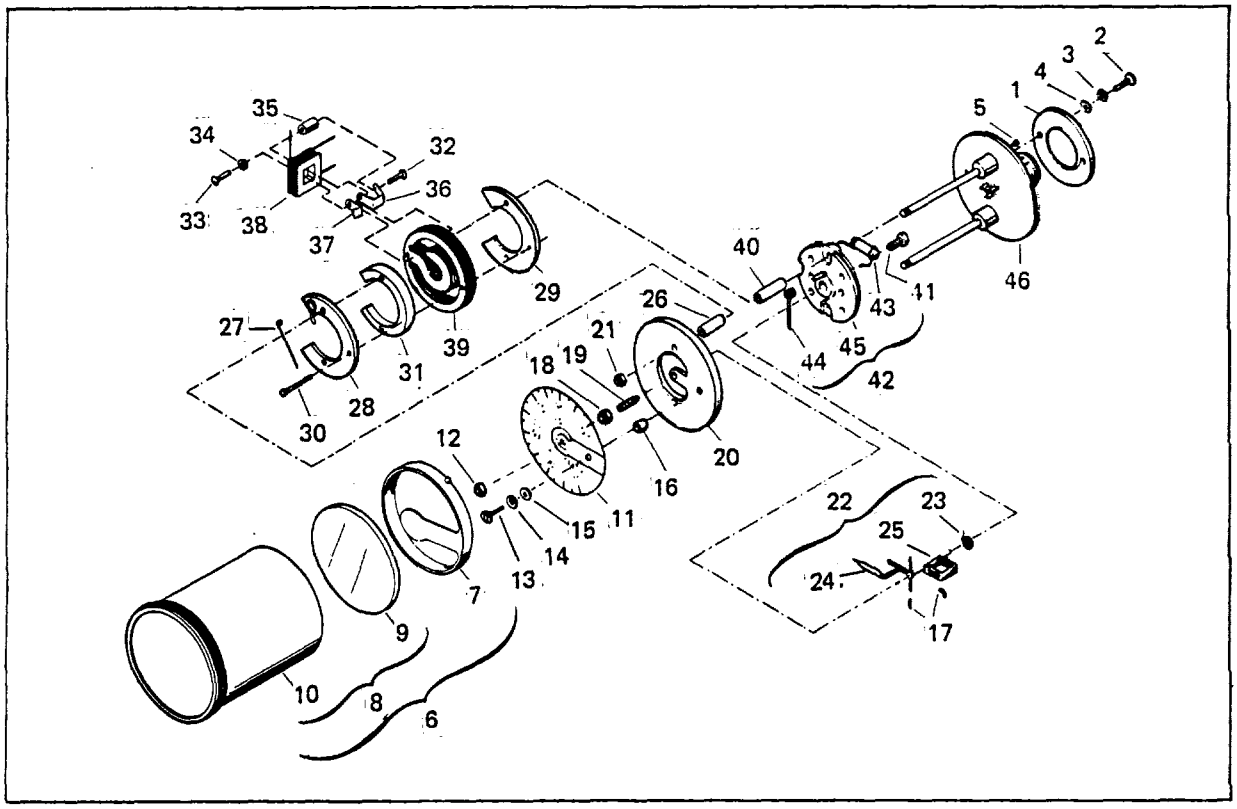
11. Special Tools, Fixtures, and Equipment

Autoclave (4 qt. home pressure cooker - modified, add connector and valve) ("Mirro-Matic" or equivalent)

Vacuum Pump (Central Sci. Co., Chicago, Ill. "Cenco-Magnavac" or equivalent)

Induction Heater, 2 KW, RF (McDowell Electronics Inc., Metuchen, N.J., Model 2KW-2 or equivalent)

Ratio Transformer (Gertsch Products Inc., Los Angeles, Calif. Model RT-2)



Resistor - 8 ohm non-inductive

Decade Inductances (Sprague Elec. Co., North Adams, Mass., Types 850-WA1 and 850-WA2 - one of each required)

TROUBLE	PROBABLE CAUSE	REMEDY
SCALE ERROR TEST		
POINTER OFF SCALE AT ALL VALUES	Open lead or leads	Connect or replace lead
	Open hairspring	Connect or replace hairspring
	Open moving coil	Replace rotor assembly
POINTER SLAMS LOW	Shorted moving coil	Replace rotor assembly
POINTER SLAMS HIGH OR LOW	Open fixed coil	Replace coil
	Open lead	Connect or replace lead
	Open thermistor	Replace thermistor
ERROR AT LOW VALUES	Incorrect zero and span adjustment	Readjust
ERROR AT HIGH VALUES	Incorrect span adjustment	Readjust
ALL READINGS EQUALLY HIGH OR LOW	Incorrect zero adjustment	Readjust
ERROR AT INTERMEDIATE VALUES	Irregular air gap in laminations	Replace inside laminations, outside laminations assembly, or both
POWER FAILS TO RETURN OFF SCALE	Rotor assembly unbalanced	Rebalance rotor assembly
	Incorrect hairspring adjustment	Increase hairspring tension
	Incorrectly shaped pointer	Bend to proper shape
FRICTION TEST		
EXCESSIVE ERROR	Pivot out of bearing	Adjust position
	No end play	Adjust end play
	Defective pivots	Replace pivots
	Defective or dirty bearings	Replace housing and bearing assembly
	Lint in air gap	Clean
POSITION ERROR TEST		
EXCESSIVE ERROR	Rotor assembly unbalanced	Rebalance rotor assembly
POINTER FAILS TO RETURN OFF SCALE IN SOME POSITIONS	Rotor assembly unbalanced	Rebalance rotor assembly
	Incorrectly shaped pointer	Bend to proper shape

TORQUE PRESSURE TRANSMITTER NO. 318-100, 318-00040, 318-100C and 318-00140

GENERAL INFORMATION

1. Introduction

This Manual contains instructions for the overhaul of EDISON Aircraft Torque Pressure Transmitters, part No. 318-100, 318-00040, 318-100C and 318-00140.

It is prepared in accordance with ATA Specification No. 100 including the Uniform Chapterization and Numbering System designated therein so that the pages may be inserted into their proper locations in the basic aircraft overhaul manual if desired.

All of the material in this Manual falls within the classification "Engine Indicating - Chapter 77".

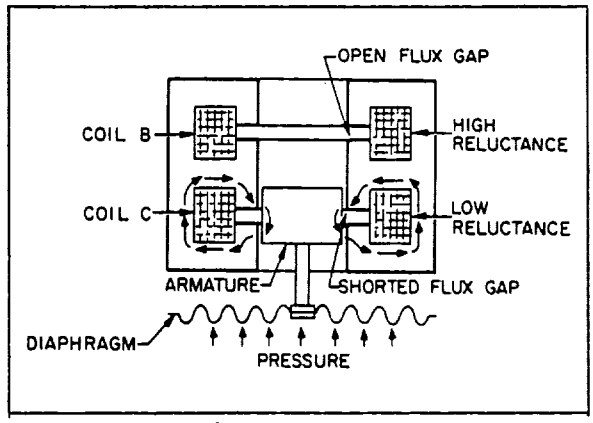
TORQUE PRESSURE TRANSMITTER NO. 318-100, 318-00040, 318-100C and 318-00140

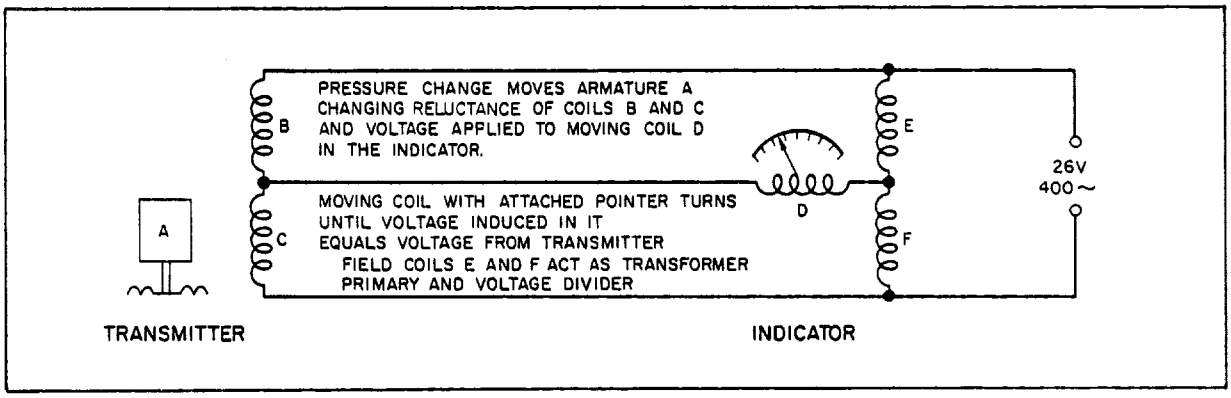
OVERHAUL INSTRUCTIONS



1. Description and Operation

The pressure transmitter covered by these overhaul instructions is the sensing unit of the EDISON variable reluctance type Torque Pressure Indicating System. (Ref. Fig. 1)

It is a factory sealed unit, the lower end of which is provided with both external and internal threads for pressure connection. It can be installed directly on a pressure boss on the engine by means of the external thread. It may also be mounted on a bracket by means of these threads, pressure connection being made to the internal threads by means of fittings and tubing. A pressure boss at the top of the transmitter permits connection of a vent pressure line if differential pressure is to be measured. A removable plug cap at the top of the transmitter gives access for calibration adjustment. An electrical connector receptacle is also on the top of the transmitter.



The Transmitter
Figure 1

Principle of Transmitter Operation
Figure 2

Table of Leading Particulars
Power Supply .... 26 V single phase 400 Hz
Pressure Range ..... 0 to 100 psi

Basic Principle of Operation of the System
Figure 3

TORQUE PRESSURE TRANSMITTER NO. 318-100, 318-00040, 318-100C and 318-00140

OVERHAUL INSTRUCTIONS

The function of the transmitter is to furnish to the indicator an electrical potential which varies according to the applied pressure. In the transmitter a diaphragm moves a magnetic armature inside of two stationary coils whenever there is a change in applied pressure. (Ref. Fig. 2) These coils are connected in series with a 26 volt 400 hertz power source and act as a variable reluctance voltage divider. The armature position determines the effective flux gaps in the magnetic housing of the coils, hence the reluctance of the coils. As connected to the indicator, which contains a similar but fixed voltage divider, a voltage regulated by the transmitter is applied to the moving coil of the indicator. (Ref. Fig. 3)

2. Disassembly (Ref. Fig. 6)

A. Remove plug cap to permit calibration adjustment.
   (1) Remove lockwire.
   (2) Remove screws (2) and lock washers (3).
   (3) Remove plug cap (1) with "O" ring (5) attached.
   (4) Remove nameplate (4).
   (5) Remove "O" ring (5) from plug cap (1).

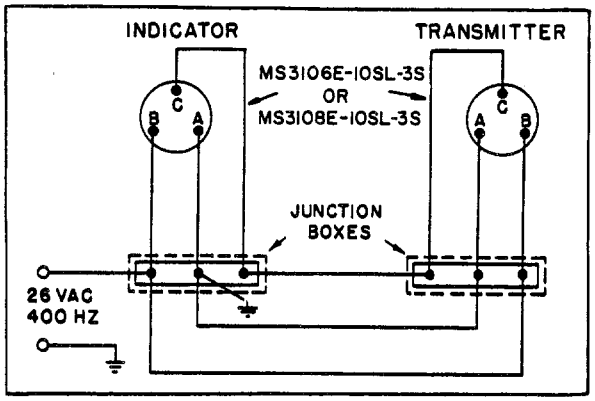
B. Attempt no other disassembly.

3. Cleaning

A. Wash outside with trichlorethylene and blow dry.

WARNING: AVOID BREATHING FUMES OR PERMITTING TRICHLORETHYLENE TO CONTACT SKIN.

4. Inspection/Check



None required.

5. Repair

Non-repairable.

6. Assembly (Ref. Fig. 6)

A. Install plug cap following calibration adjustment.
   (1) Install new "O" ring (5) on plug cap (1).
   (2) Place nameplate (4) on transmitter.
   (3) Install plug cap and "O" ring assembly on transmitter.
   (4) Secure with screws (2) and lock washers (3).
   (5) Install new lockwire.

Test Connections
Figure 4

Test Pressure PSI	Indicated PSI	Tolerance ± PSI

OVERHAUL INSTRUCTIONS

7. Fits and Clearances

None applicable.

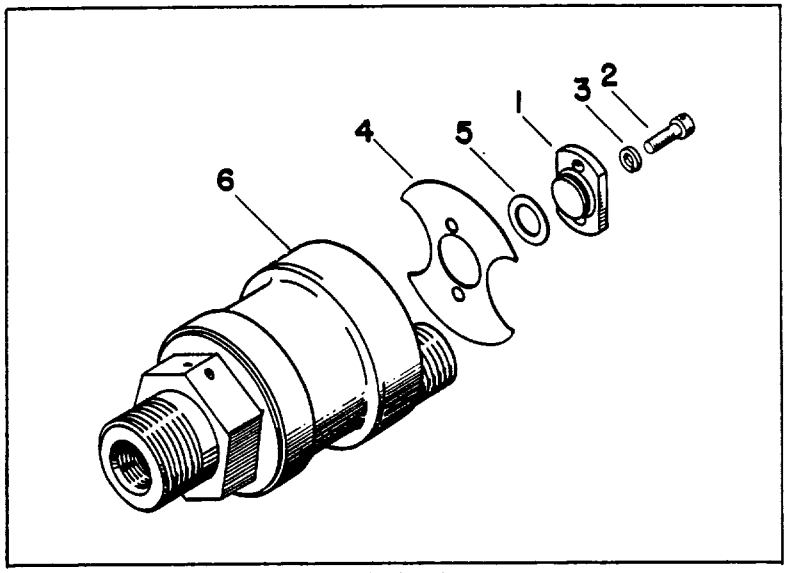
8. Testing

A. For equipment required, refer to sub-heading 11.
B. Test calibration:
(1) Mount the transmitter in vertical position on a dead weight or other type of pressure tester capable of supplying accurate pressure of dry air in the range involved.
(2) Connect the transmitter to EDISON Transmitter Test Indicator, part No. 389-1, or 389-00340, which has been checked for accuracy.(Ref.Fig.4)
(3) Energize the circuit with 26 ± 0.5 volts, 400 ± 5 hertz.
(4) Apply pressure, testing transmitter at each applicable value marked on indicator dial. Before reading indicator, lightly tap both transmitter and indicator. All readings shall be within tolerances as marked on dial.
C. Adjust calibration if necessary.
(1) Leave transmitter connected to indicator and power on.
(2) Set pressure to zero psi value.
(3) Remove plug cap (Ref. sub-heading 2).
(4) Using zero adjusting tool, part No. 41486, turn armature assembly inside transmitter until indicator reads approximately correctly.
(5) Apply maximum pressure for range.
(6) Using both zero adjusting tool, part No. 41486,and scale span adjusting tool, part No. 42015, hold zero adjusting tool stationary while turning scale span adjusting tool to give indicator reading within tolerance after tapping.
(7) Reduce pressure to zero psi value.
(8) Hold span adjusting tool stationary while turning zero adjusting tool to give indicator reading within tolerance after tapping.
(9) Repeat steps (5) through (8) until both readings are within tolerance with tools removed before reading indicator.
(10)Check readings at all test values.
(11)Replace plug cap (Ref. sub-heading 6).
(12)Replace lock wire using No. 20 corrosion resistance steel wire.
D. Test for leakage:
(1) Disconnect wiring and pressure connection.
(2) Connect "VENT" boss to pressure tester by means of flexible tubing.
(3) With transmitter in vertical position, immerse it in alcohol until only the upper half of the electrical connector receptacle projects above the alcohol.
(4) Apply 15 psi air pressure to the "VENT". No evidence of leakage shall be visible.
(5) Remove from alcohol, blow dry, release pressure, and disconnect pressure tube.

9. Trouble Shooting

None required. If transmitter leaks, or can not be calibrated within tolerance, it must be scrapped since no repairs are possible.

10. Storage Instructions



Cover pressure and vent ports and electrical connector to keep out foreign matter during storage. Use shipping caps such as Edison No. 14234, 14235, and 14236, or other suitable means.

11. Special Tools, Fixtures and Equipment

OVERHAUL INSTRUCTIONS
ALUMINUM PLATE TYPE LIQUID-TO-AIR COOLERS

1. GENERAL INFORMATION

A. This service bulletin provides overhaul instructions for commercial aluminum plate-type liquid-to-air coolers. Instructions are included for lightweight and standard thickness plate material. Lightweight material is designated by the letter "N" in the model number; standard weight thickness by the letter "U". For example, AP16AN09-01 indicates lightweight tube material while AP12AU09-01 would indicate standard thickness.

B. All lightweight units prior to Serial Number KK-4334 (and date 1/9/58) and having the letter "N" in the model number have been heat treated. On these units, it is recommended that no repairs be attempted.

C. Records should be kept of the type and extent of repairs performed and the test data prior to re-installation. Over a period of time, this data will provide a standard for repairs and service.

2. BASIC CONSTRUCTION

A. Cooler assemblies fall into several basic classifications, determined by the physical configuration, and design of the units. Examples of characteristics which classify a unit are: Lightweight design; drawn cup design; round, square, crescent (saddle) profile; with or without by-pass tube (s); and with or without thermostatic and pressure relief valves.

B. The basic constructions used for the cooling plate are shown in figure 1 and explained below.

(1) Bar and plate construction consists of two (2) tube plates with bars at the edges.

(2) Drawn cup type construction consists of two equal size plates incorporating end tanks as part of the plate.

(3) Formed plate-fin type construction consists of a male and female stamping.

(4) Prime surface type construction consists of stacked stampings.

(5) All four designs incorporate turbulator features which break up the liquid stream, add to the structural strength, and improve heat transfer.

C. The entire core mass is brazed and welded together. Under no circumstances can it be disassembled.

D. Some units incorporate an oil by-pass passage. The flow through the by-pass is usually controlled by a combination thermostatic and pressure relief valve on the outlet side of the system. With cold oil (or with pressures exceeding the valve setting), the valve is open permitting the oil to flow through the by-pass and back to the system. When fully closed the thermostat plugs the by-pass passage and full cooling action is effected on the oil going through the cooling plates.

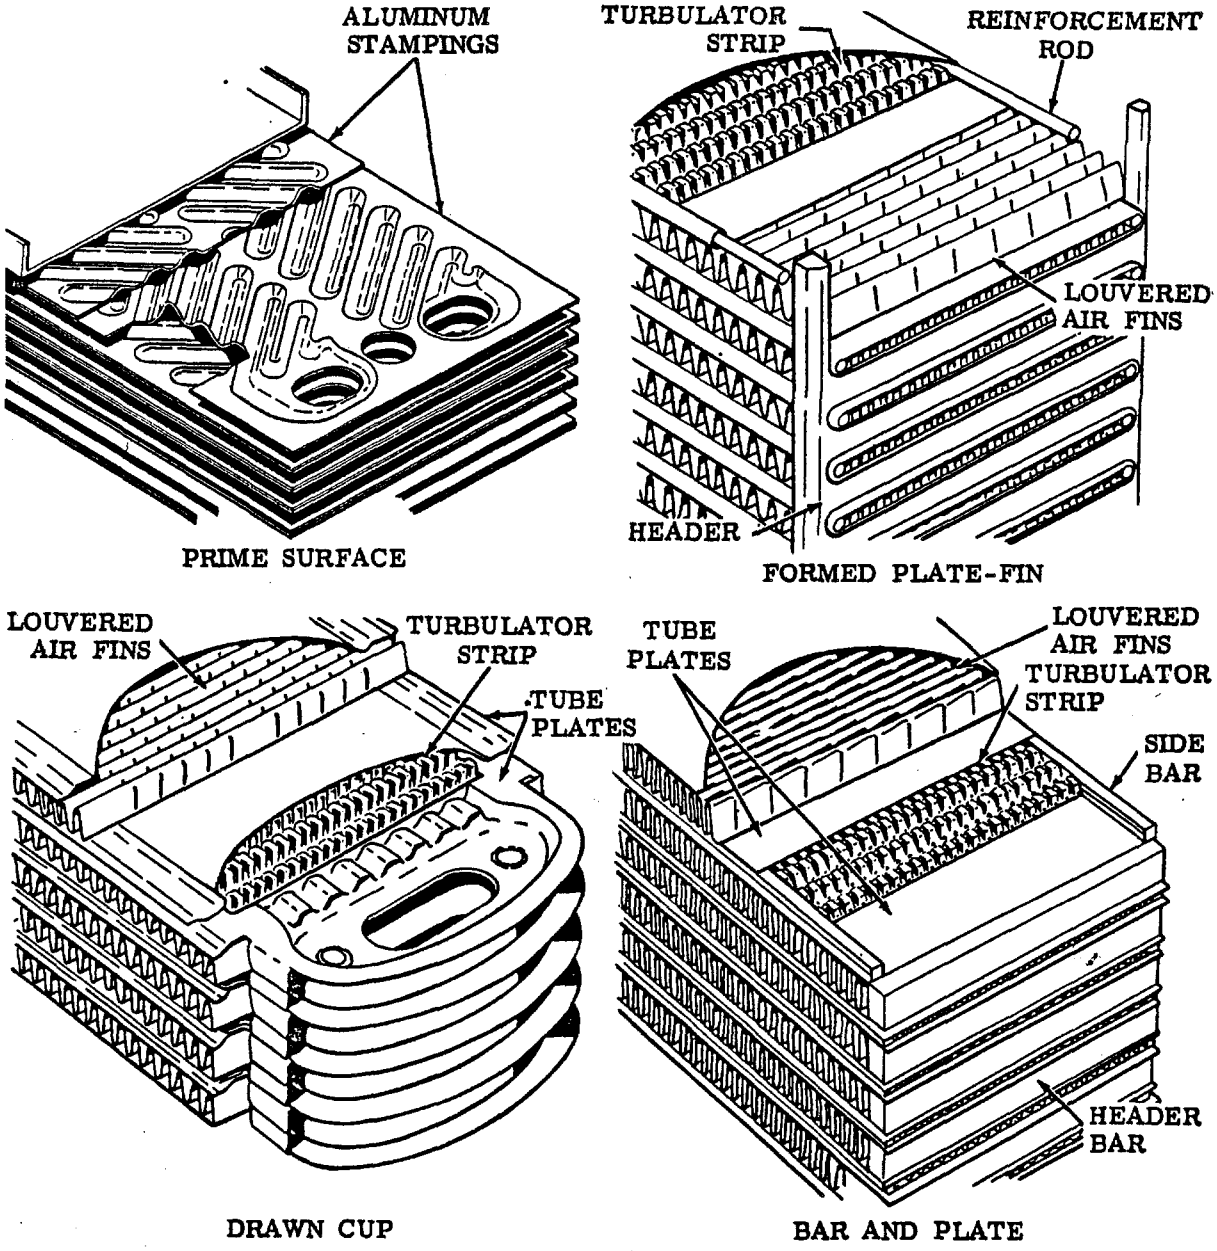

Figure 1. Basic Construtions, Cutaway

3. TOOLS, FIXTURES AND EQUIPMENT

A. Cleaning equipment and supplies required for cleaning operations performed in paragraph 4 follows:

(1) Four (4) storage tanks with inlet at top and outlet at the bottom. These tanks should be large enough to give flows required for the particular unit being overhauled. Flows are determined in step (2) below.

(2) Centrifugal pump with a capacity of 2 to 4 gpm times the number of cooling plates in the unit to be cleaned. The pump must be capable of maintaining 75 psi pressure.

NOTE: Units with 2 or more oil passes will use a flow proportioned to the number of plates in 1 pass.

(3) Hydraulic pressure gauge, 0 to 200 psi (2 required).

(4) Full flow filter.

(5) 100-Mesh screen (2 required).

(6) Pressure relief valve, 75 psi.

(7) Hose (assorted lengths).

(8) Steam cleaning apparatus.

(9) Compressed air supply, 125 psi minimum.

(10) Cleaning solutions (see paragraph 4B).

(11) Corrosion-preventive compound (see paragraph 4B).

B. Test equipment required to perform cooler tests in paragraph 8 is listed below:

(1) Hydrostatic test equipment consisting of: Water reservoir, hydraulic pump, relief valve, control valve, 0 to 500 psig pressure gauge, and hose. The equipment must be capable of supplying 400 psi hydrostatic pressure.

(2) Compressed air source, 200 psi minimum.

(3) Water tank (large enough to submerge core).

C. Repair equipment necessary to perform the repair procedures in paragraph 9 is listed below:

(1) Inert gas shielded tungsten arc welding unit (Heliarc or equivalent) having an output of 3 to 300 amps, at 40 volts.

(2) Two (2) gas torches, each equipped with a Selas PRS-3 tip for use with manufactured gas. For natural gas, use a PR-6 tip.

(3) Acetylene torch with No. 3, 4, 5, and 8 tips, and a preheat adapter.

(4) Temperature stable furnace capable of 950° F. and large enough to accommodate the unit being overhauled.

(5) Alcoa #33 torch brazing flux or equivalent.

(6) Welding rod, 1/8-inch diameter, U.S. Federal Spec. QQ-R-566, Class FS-RA1-43 (Alcoa #43S or equivalent).

(7) Brazing wire, 3/32-inch diameter, U.S. Federal Spec. QQ-R-566, Class FS-RA1-718 (Alcoa #718 or equivalent).

(8) Brazing wire, 1/16-inch diameter, U.S. Federal Spec. QQ-R-566, Class FS-RA1-716 (Alcoa #716 or equivalent).

4. CLEANING

A. Equipment Setup

(1) To clean the interior of an oil cooler assembly core, the pump equipment as specified in paragraph 3A is required. Four solutions are used for the cleaning procedure. There are several possible arrangements of the equipment depending upon equipment availability and versatility. If provision can be made for flushing pump lines, one set of pump equipment can be used with four storage tanks to provide the required four solutions for rinsing, cleaning, and flushing. If such provisions cannot be made conveniently, four sets of pump equipment are required.

(2) Connect the pump equipment as shown in figure 2.

(3) On units incorporating by-pass features, block the by-pass passage prior to cleaning as follows: Remove the thermostatic valve from the valve housing. Press a rubber plug into the by-pass opening in the valve housing. Reinstall valve into the valve housing so that the valve bears up against the rubber plug.

B. Cleaning Operations

CAUTION: USE ONLY CLEANING SOLUTIONS RECOMMENDED IN THESE INSTRUCTIONS OR ONES SATISFACTORY FOR ALUMINUM. MANY SOLUTIONS SATISFACTORY FOR CLEANING COPPER OR COPPER NICKEL COOLERS ARE HIGHLY CORROSIVE TO ALUMINUM AND IF USED WILL RESULT IN THE DESTRUCTION OF THE COOLER. IF EQUIPMENT HAS BEEN PREVIOUSLY USED WITH ANY OTHER CLEANING SOLUTIONS, IT SHOULD BE THOROUGHLY WASHED OUT AND FLUSHED WITH THE RECOMMENDED SOLUTION.

WARNING: CLEANING SOLVENTS AND SOLVENT CLEANING COMPOUNDS ARE TOXIC AND FLAMMABLE, AND MUST BE USED ONLY IN A WELL-VENTILATED ROOM. TAKE ADEQUATE SAFEGUARDS FOR FIRE PREVENTION IN WORK AREA. USE PROTECTIVE CLOTHING AND AVOID CONTACT OF THESE SOLUTIONS WITH THE SKIN.

(1) Steam clean the exterior surfaces and corrugated air fins of each core.

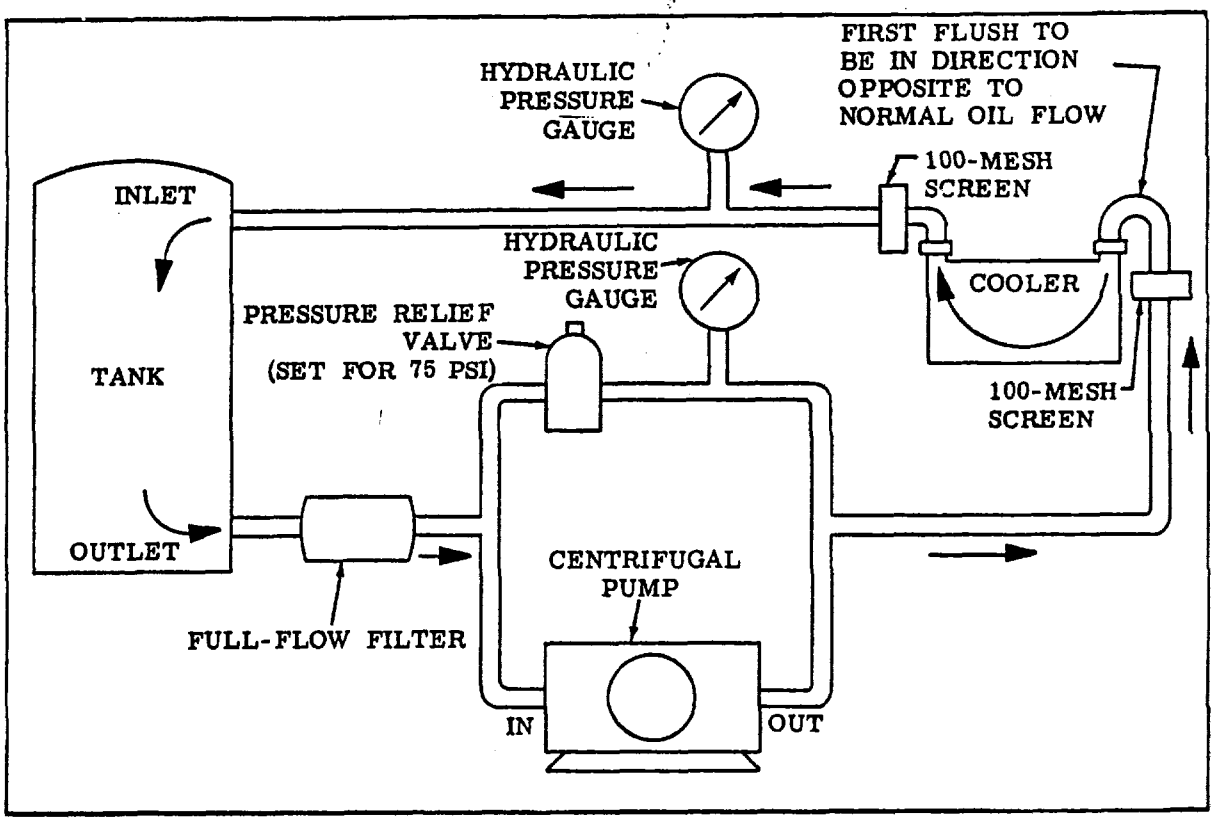

Figure 2. Cleaning Setup

(2) Preclean core interior to remove oil and loose sludge from the core to reduce contamination of cleaning solution in subsequent operations. Connect pump equipment so that fluid flow will be in the reverse direction of normal flow. Use mineral spirits, Federal Spec. TT-T-291, or kerosene, Federal Spec. VV-K-211, or dry cleaning solvent, Federal Spec. P-S-661. Flush core in reverse direction for 30 minutes or until solution appears clean. Reverse lines and flush approximately 15 minutes in the opposite direction. Drain cooler.

(3) Remove carbon deposits, engine oil, gums, lead deposits and foreign contamination by flushing cooler in opposite direction to normal oil flow for 30-60 minutes. Use solvent cleaning compound such as Turco "Surjax" (Turco Products, Los Angeles, California), Beck "OCC-3" (Beck Equipment Company, Cleveland, Ohio), or equivalent compounds conforming to Spec. MIL-C-6864. Reverse lines and flush in opposite direction for 15 minutes.

(4) Remove plug installed in by-pass opening (step 4A (3)) and block cooling section opening. Flush for 15 minutes to clean by-pass passage. Remove plug from cooling section opening and replace in by-pass opening.

(5) Rinse cooler for 10 minutes by circulating clear petroleum solvent such as dry cleaning solvent (Federal Spec. P-S-661), or kerosene (Federal Spec. VV-K-211). System shall be suitably filtered to prevent circulation of foreign matter.

(6) Flush core interior to detect presence of metal particles in the core, and to remove combustible liquids from the core in preparation of repair instructions. Use water at 100^{0} to 160^{0} F. If repairs are not anticipated, cleaning solvent P-S-661 can be used, but if during testing it is found that repairs are required, an additional water flush must be made. Flush ten minutes in each direction with a 100-mesh screen installed at the cooler inlet and outlet. Reflush cooler for 5 minutes in each direction and recheck screens. Remove rubber plug from by-pass opening and replace valve.

CAUTION: IF METAL PARTICLES ARE FOUND AT THE SCREEN DURING THE ABOVE FLUSHING OPERATIONS, IT IS AN INDICATION THAT THE OIL COOLER WAS INSTALLED ON EQUIPMENT THAT FAILED MECHANICALLY. SUCH A COOLER SHOULD BE SCRAPPED UNLESS AN APPROVED METHOD IS KNOWN FOR SALVAGING.

(7) Flush cooler with a preservative oil consisting of three parts MIL-L-6082, Grade 1065, and one part MIL-C-6529, or, for systems employing MIL-L-7808 oil, preservative oil MIL-C-8188B, or equivalent, in preparation for shipment or storage. Connect cooler to pump equipment and flush in each direction for 10 minutes, checking the mesh screen after each flush to ensure that no metal particles have appeared. After flushing operations, install plugs in inlet and outlet ports.

5. DISASSEMBLY

A. Disassemble oil coolers by removing lockwires, bolts, and oil fittings on units having removable fittings.

B. Remove by-pass thermostatic control valves. Do not disassemble valves. If assembly malfunctions or does not pass test, replace valve.

C. Discard any gaskets and "O" rings.

D. Further disassembly of cores is not practical because each core is a brazed and welded unit.

6. INSPECTION

A. Examine the air fins and air passages for distortion or foreign particles that may obstruct the air flow.

B. Inspect the cooler for damaged and bulged plates, cracked castings and flanges, broken welds, and stripped threads. Inspect hardware items for stripped threads, ineffective lock units, and damaged bolt heads.

C. Inspect all openings in core and valve housing assemblies for evidence of foreign matter inside the cooler.

D. Inspect gasket surfaces for scores that may prevent the gaskets from sealing.

E. On units having a thermostatic valve, inspect the valve seat and the control valve housing seat for scoring and wear that would allow excessive leakage when the valve is seated. Inspect the valve for stripped threads and broken spring.

F. Test cores for leaks and test thermostatic valves for proper functioning in accordance with paragraphs 8A and 8B.

7. REASSEMBLY

A. Reassembly of the unit is essentially the reverse of disassembly.

B. Use new gaskets and/or "O" rings.

C. Tighten all bolts and nuts.

D. Install lockwire after final testing.

8. TESTING

A. Cooler Tests

(1) Preliminary cooler test. Conduct an air leak test on the assembled unit as follows: Plug the cooler outlet and attach an air hose to the inlet. Attach the other end of the air hose to an adjustable pressure source. Adjust air pressure to 12 PSIG. Submerge cooler in water at 140^{o} F - 180^{o} F (Heat water to 185^{o} F to expand metal.)

WARNING: INCREASE AIR PRESSURE GRADUALLY TO AVOID BURNS FROM HOT WATER SPLASHING FROM LARGE LEAKS, IF PRESENT.

After five minutes of submersion increase air pressure to 100 PSIG to detect small leaks, if present. Inspect cooler for leaks as evidenced by presence of air bubbles. Mark leaks, remove from water, release air, and blow cooler dry. Repair in accordance with paragraph 9 and retest.

(2) Final cooler test. Conduct a hydrostatic test on the assembled cooler as follows (see figure 3). Plug outlet and apply room temperature water at test pressure to the other port. Lock fluid in cooler for 10 minutes. Examine cooler for blown or bulged plates. Release pressure, drain cooler, and dry with compressed air. Repair and retest.

CAUTION: TEST PRESSURE SHOULD BE IN ACCORDANCE WITH THE ENGINEERING DRAWING SPECIFICATION. IN THE ABSENCE OF THE ENGINEERING DRAWING, DO NOT EXCEED 150 PSIG.

(3) If the unit is found serviceable after completing preliminary to final tests, flush with suitable corrosion preventative compound such as specified in paragraph 4B (7).

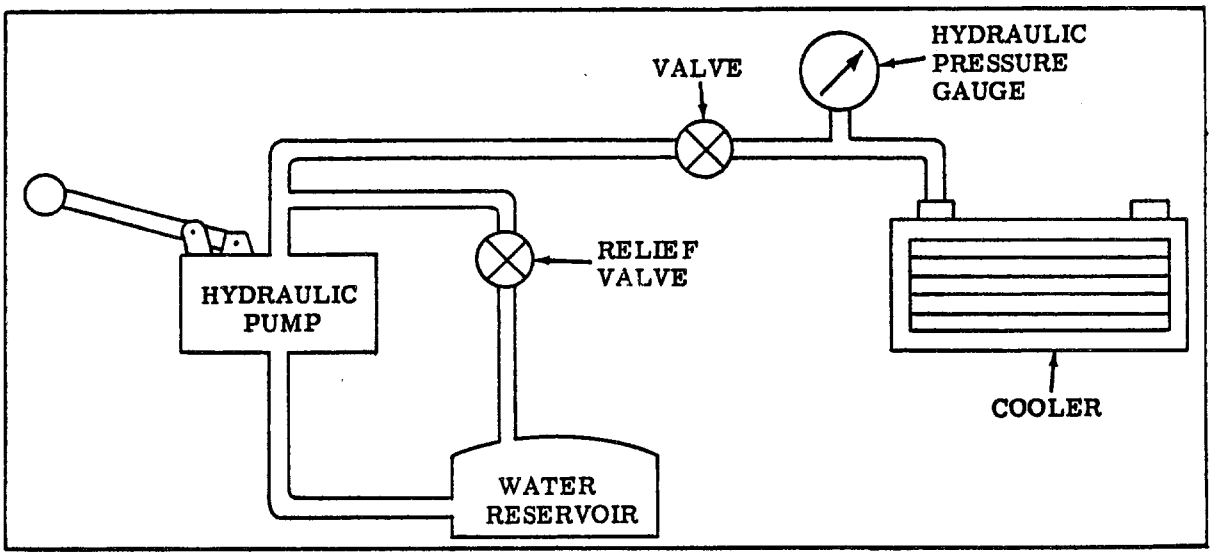

Figure 3. Hydrostatic Test Setup

B. Control Valve Function Test

(1) Check function of control valve by submerging valve in water at Start to Close temperature, indicated in the following table, for five minutes. Remove valve and measure length. Submerge valve in water at Fully Closed temperature, indicated in the table, for five minutes. Remove valve and measure length. Minimum increased length shall be equal to that shown in the table.

(2) Inches of travel should occur between the two temperatures shown.

(3) If valve under test does not function properly, replace with new valve.

NOTE: Start to Close temperatures are approximate.

9. REPAIR

A. Scope

(1) Repair of the cooler assembly is limited to the corrections of accessible leaks by welding and brazing, and should be performed following cleaning (paragraph 4) and testing procedures (paragraph 8).

CAUTION: THE MANUFACTURER DOES NOT RECOMMEND REPAIRING DAMAGED COOLERS. A DAMAGED COOLER SHOULD BE RETURNED TO THE MANUFACTURER FOR REPAIRS. HOWEVER, WHEN MINOR REPAIRS ARE NECESSARY THEY SHALL BE EXECUTED ONLY BY FACTORY TRAINED PERSONNEL. WHEN THE CONDITIONS NOTED IN STEP 9A(2) FOLLOWING ARE PRESENT, THE COOLER MUST BE RETURNED TO THE FACTORY.

(2) Return the cooler to the manufacturer for inspection and repair or replacement if repairs for the following damages are required:

(a) Blown, bulged, or badly dented plates.

Valve Part No.	Temp. Range + - 5° F.		Minimum travel - inches
	Start To Close	Fully Closed	
8509198	150	185	.235
8518329	130	160	.235
8518629	150	185	.160
8518815	50	80	.195
8520496	110	128	.235
8520589	120	150	.235
8520618	110	140	.160
8522532	80	160	.250
8522776	50	80	.195
8522852	80	160	.140
8523427	150	185	.160
8523464	110	128	.235
8524200	125	160	.160
8525961	80	160	.250
8526034	130	160	.235
8526113	120	148	.090
8526613	80	140	.235
8526799	160	183	.090
8527429	80	185	.195
8527855	160	178	.080

8528933	130	160	.080
8529080	120	150	.100
8530018	120	150	.125
8530249	150	173	.090
8530269	165	183	.250
8530815	140	160	.090
8532003	158	198	.090

TABLE OF OPERATING TEMPERATURES

(b) Leaks in areas where reinforcement plates, strips, or gussets are joined to the core and usually located on the outside plates.

(c) Non-repairable damage or distortion to the valve seat.

(d) Damaged threads in aluminum fittings, ports, drain bosses, or valve housing.

(e) Major dents and similar damage in tube edges, tanks, or valve bodies, which do not leak but could impair cooler performance and life.

(f) Leaks in difficult locations such as interior plate-to-header leaks, or leaks in the plate away from plate edge.

(3) Replace control valves which do not function properly when tested in accordance with paragraph 8B.

NOTE: Valves should not be replaced until all welding and brazing on the unit has been accomplished.

B. Repair of Leaks

WARNING: PURGE COOLER OF ANY COMBUSTIBLE FLUIDS OR VAPORS BEFORE ATTEMPTING REPAIRS. PURGE WITH WATER, DRAIN, AND DRY COOLER WITH COMPRESSED AIR.

NOTE: Before using any type of torch, apply a light coat of Alcoa #33 flux, or equivalent, which has been mixed with water in accordance with the manufacturer's instructions. Flux and metal changes indicate the reaching of brazing temperature of approximately 1080° F. The flux passes through a color change of green to white. It then melts to a watery appearance and becomes extremely active at brazing temperature. The aluminum will change from a greyish color to a shiny appearance.

(1) Repair accessible leaks or cracks in tanks, casting, Heliarc welds, by-pass tubes, control valve housing pads, inlet or outlet fitting pads, and mounting pads using an inert arc welding process (Heliarc or equivalent) and 1/8-inch diameter welding rod.

If this equipment is not available, or if cracks tend to "creep", or if casting impurities tend to "bubble" using Heliarc, then substitute acetylene torch for repairs. Preheat with a preheating adapter on the torch if the leaking area is adjacent to thin-walled cooler parts. When flux grows shiny, sweat-in 3/32-inch brazing wire, using a #8 tip. Switch to a #3 tip for final braze-in, using 3/32-inch or alternately 1/16-inch brazing wire and #33 flux.

CAUTION: ALL ALUMINUM FLUXES ARE HIGHLY CORROSIVE. USE BOILING WATER TO REMOVE ALL TRACES OF FLUX FROM INTERIOR AND EXTERIOR OF COOLER. KEEP UNITS DRY BETWEEN OPERATIONS INVOLVING FLUX, PARTICULARLY WHEN INTERVALS OF MORE THAN ONE HOUR ARE INVOLVED, AS MOISTURE ACCELERATES CORROSION.

(2) Repair plate seam leak (located at the edge of the plate) using a gas torch and 1/16-inch brazing wire. Use Selas PRS-3 tip (with manufactured gas) or Selas PRS-6 tip (with natural gas). Hold the torch flame about two inches away from the leaking area and rotate in a circular pattern. Air fins may be pushed back or lifted away from the leaking area to gain access. Reposition and tack air fins after the leak has been sealed. If seam leaks are within one inch of the tank header, it may be necessary to direct the flame of a second gas torch on the tank to hold the heat at the leak. If a gas torch is not available, repair with an acetylene torch. First preheat the cooler to 950° F. in an oven. Further preheat the area with a preheating adapter on the acetylene torch. At brazing temperature, use a #3 tip for final braze-in.

(3) Repair leaks or voids along the bottom of the by-pass tube by first heating the unit in a furnace at 900° F. until the unit is up to temperature. Remove to work bench. Apply #33 flux to leaking area and heat with a gas torch until flux grows shiny and 3/32-inch diameter brazing wire is sweated in. Put protective shield made from scrap metal on top of the shroud to prevent burning through.

(4) Repair plate-to-header leaks at outside accessible edges of the unit as in paragraph 9B (2).

C. Remove all traces of flux by scrubbing all accessible areas with a brush dipped in boiling water. Areas not so reached should be thoroughly flushed with boiling water. Complete removal of flux is extremely important to prevent subsequent corrosive destruction of the cooler. Dry with compressed air or in an oven at 250° F.

10. STORAGE

After the cooler has been completely overhauled and flushed with preservative oil, install plugs in the inlet and outlet ports. Package the cooler in a container that will provide suitable protection against damage and deterioration. The container should be so constructed as to permit periodical removal and inspection of the cooler without damage to the container or labels. Labels on the container should contain, in addition to complete identification data, the date of overhaul and an indication of repair performed, parts replaced, and general condition.

OVERHAUL INSTRUCTIONS
FOR
ALUMINUM PLATE TYPE
LIQUID-TO-AIR COOLERS

PART NOS. 8538777 &
8540012.

HARRISON
RADIATOR DIVISION
GENERAL MOTORS CORPORATION

SERVICE BULLETIN HES-62-77F
REVISED JULY 1969

REPLACEMENT PARTS

Replacement Parts List for Harrison Model AP09AN13-08,
Part No. 8540012, Oil Cooler Assembly:

NUMBER/ COOLER	PART NO.	NAME
1	8540011	Thermostatic Control Valve
-	8531588	Gasket, Thermo Valve
1	8534211	Seat, Valve
1	8534212	Spring, Seat Control
1	8534213	Plug, Valve Seat
1	8534163	Gasket "O" Ring
1	8529791	Plug, Drain
1	8534162	Gasket, "O" Ring

REPLACEMENT PARTS

NUMBER/ COOLER	PART NO	NAME
1	8537927	Thermostatic Control Valve
-	8531588	Gasket, Thermo Valve
1	8534211	Seat, Valve
1	8534212	Spring, Seat Control
1	8534213	Plug, Valve Seat
1	8534163	Gasket "O" Ring
1	8529791	Plug, Drain
1	8534162	Gasket, "O" Ring

OVERHAUL INSTRUCTIONS
ALUMINUM PLATE TYPE LIQUID-TO-AIR COOLERS

1. GENERAL INFORMATION

A. This service bulletin provides overhaul instructions for commercial aluminum plate-type liquid-to-air coolers. Instructions are included for lightweight and standard thickness plate material. Lightweight material is designated by the letter "N" in the model number; standard weight thickness by the letter "U". For example, AP16AN09-01 indicates lightweight tube material while AP12AU09-01 would indicate standard thickness.

B. All lightweight units prior to Serial Number KK-4334 (and date 1/9/58) and having the letter "N" in the model number have been heat treated. On these units, it is recommended that no repairs be attempted.

C. Records should be kept of the type and extent of repairs performed and the test data prior to re-installation. Over a period of time, this data will provide a standard for repairs and service.

2. BASIC CONSTRUCTION

A. Cooler assemblies fall into several basic classifications, determined by the physical configuration, and design of the units. Examples of characteristics which classify a unit are: Lightweight design; drawn cup design; round, square, crescent (saddle) profile; with or without by-pass tube (s); and with or without thermostatic and pressure relief valves.

B. The basic constructions used for the cooling plate are shown in figure 1 and explained below.

(1) Bar and plate construction consists of two (2) tube plates with bars at the edges.

(2) Drawn cup type construction consists of two equal size plates incorporating end tanks as part of the plate.

(3) Formed plate-fin type construction consists of a male and female stamping.

(4) Prime surface type construction consists of stacked stampings.

(5) All four designs incorporate turbulator features which break up the liquid stream, add to the structural strength, and improve heat transfer.

C. The entire core mass is brazed and welded together. Under no circumstances can it be disassembled.

D. Some units incorporate an oil by-pass passage. The flow through the by-pass is usually controlled by a combination thermostatic and pressure relief valve on the outlet side of the system. With cold oil (or with pressures exceeding the valve setting), the valve is open permitting the oil to flow through the by-pass and back to the system. When fully closed the thermostat plugs the by-pass passage and full cooling action is effected on the oil going through the cooling plates.

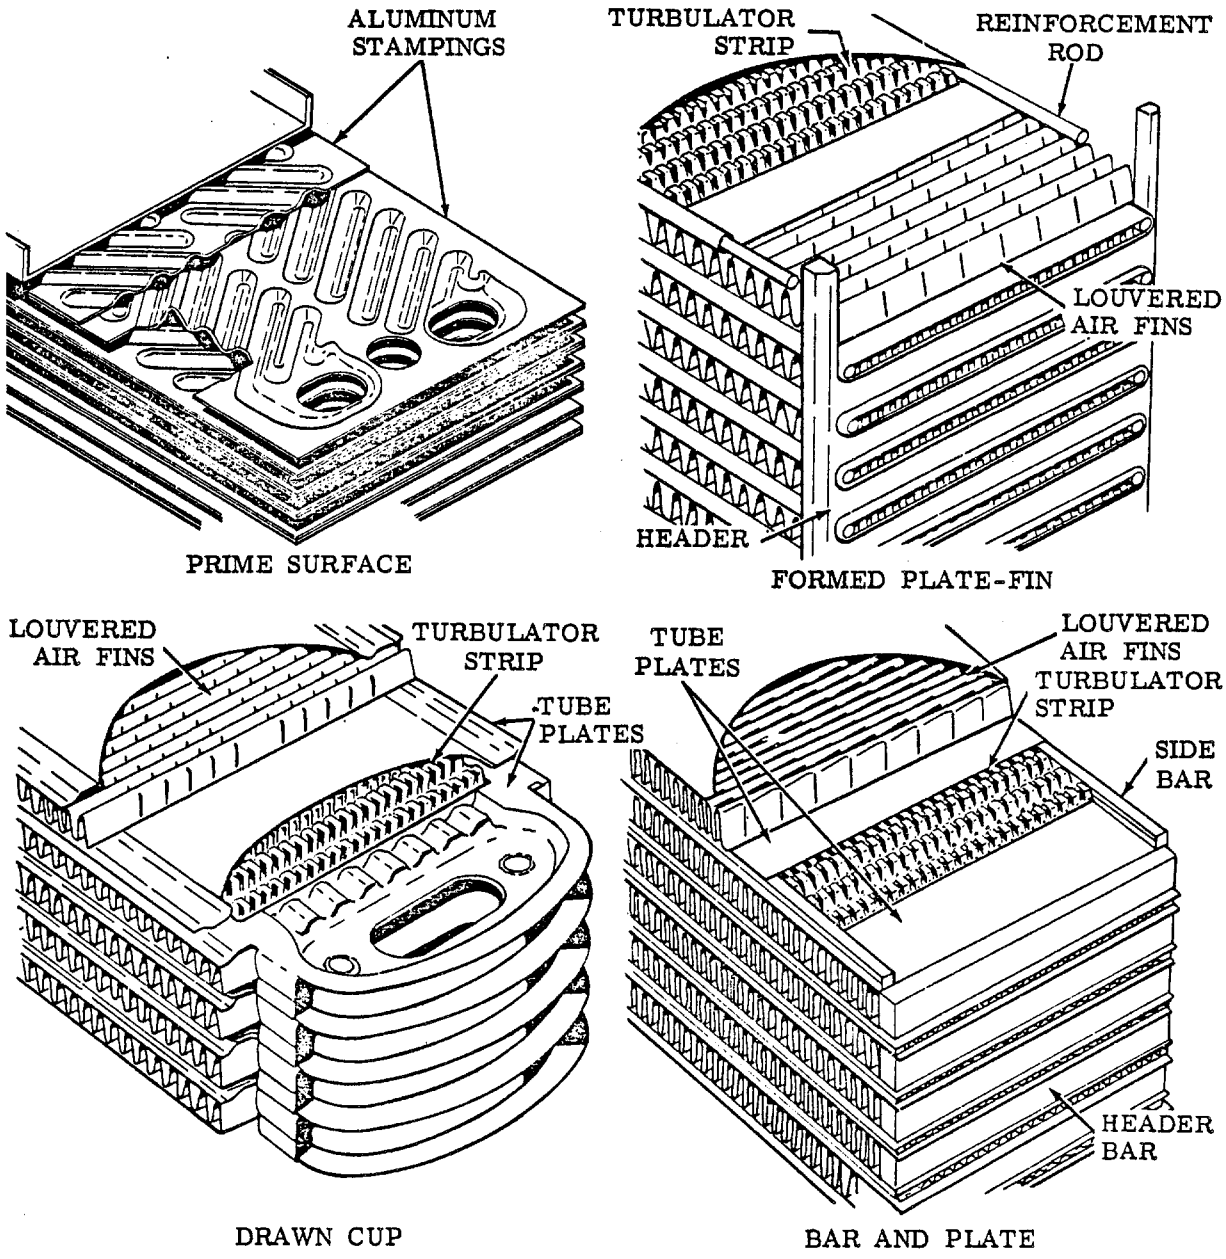

Figure 1. Basic Constrution, Cutaway

3. TOOLS, FIXTURES AND EQUIPMENT

A. Cleaning equipment and supplies required for cleaning operations performed in paragraph 4 follows:

(1) Four (4) storage tanks with inlet at top and outlet at the bottom. These tanks should be large enough to give flows required for the particular unit being overhauled. Flows are determined in step (2) below.

(2) Centrifugal pump with a capacity of 2 to 4 gpm times the number of cooling plates in the unit to be cleaned. The pump must be capable of maintaining 75 psi pressure.

NOTE: Units with 2 or more oil passes will use a flow proportioned to the number of plates in 1 pass.

(3) Hydraulic pressure gauge, 0 to 200 psi (2 required).

(4) Full flow filter.

(5) 100-Mesh screen (2 required).

(6) Pressure relief valve, 75 psi.

(7) Hose (assorted lengths).

(8) Steam cleaning apparatus.

(9) Compressed air supply, 125 psi minimum.

(10) Cleaning solutions (see paragraph 4B).

(11) Corrosion-preventive compound (see paragraph 4B).

B. Test equipment required to perform cooler tests in paragraph 8 is listed below:

(1) Hydrostatic test equipment consisting of: Water reservoir, hydraulic pump, relief valve, control valve, 0 to 500 psig pressure gauge, and hose. The equipment must be capable of supplying 400 psi hydrostatic pressure.

(2) Compressed air source, 200 psi minimum.

(3) Water tank (large enough to submerge core).

C. Repair equipment necessary to perform the repair procedures in paragraph 9 is listed below:

(1) Inert gas shielded tungsten arc welding unit (Heliarc or equivalent) having an output of 3 to 300 amps, at 40 volts.

(2) Two (2) gas torches, each equipped with a Selas PRS-3 tip for use with manufactured gas. For natural gas, use a PR-6 tip.

(3) Acetylene torch with No. 3, 4, 5, and 8 tips, and a preheat adapter.

(4) Temperature stable furnace capable of 950° F. and large enough to accommodate the unit being overhauled.

(5) Alcoa #33 torch brazing flux or equivalent.

(6) Welding rod, 1/8-inch diameter, U.S. Federal Spec. QQ-R-566, Class FS-RA1-43 (Alcoa #43S or equivalent).

(7) Brazing wire, 3/32-inch diameter, U.S. Federal Spec. QQ-R-566, Class FS-RA1-718 (Alcoa #718 or equivalent).

(8) Brazing wire, 1/16-inch diameter, U.S. Federal Spec. QQ-R-566, Class FS-RA1-716 (Alcoa #716 or equivalent).

4. CLEANING

A. Equipment Setup

(1) To clean the interior of an oil cooler assembly core, the pump equipment as specified in paragraph 3A is required. Four solutions are used for the cleaning procedure. There are several possible arrangements of the equipment depending upon equipment availability and versatility. If provision can be made for flushing pump lines, one set of pump equipment can be used with four storage tanks to provide the required four solutions for rinsing, cleaning, and flushing. If such provisions cannot be made conveniently, four sets of pump equipment are required.

(2) Connect the pump equipment as shown in figure 2.

(3) On units incorporating by-pass features, block the by-pass passage prior to cleaning as follows: Remove the thermostatic valve from the valve housing. Press a rubber plug into the by-pass opening in the valve housing. Reinstall valve into the valve housing so that the valve bears up against the rubber plug.

B. Cleaning Operations

CAUTION: USE ONLY CLEANING SOLUTIONS RECOMMENDED IN THESE INSTRUCTIONS OR ONES SATISFACTORY FOR ALUMINUM. MANY SOLUTIONS SATISFACTORY FOR CLEANING COPPER OR COPPER NICKEL COOLERS ARE HIGHLY CORROSIVE TO ALUMINUM AND IF USED WILL RESULT IN THE DESTRUCTION OF THE COOLER. IF EQUIPMENT HAS BEEN PREVIOUSLY USED WITH ANY OTHER CLEANING SOLUTIONS, IT SHOULD BE THOROUGHLY WASHED OUT AND FLUSHED WITH THE RECOMMENDED SOLUTION.

WARNING: CLEANING SOLVENTS AND SOLVENT CLEANING COMPOUNDS ARE TOXIC AND FLAMMABLE, AND MUST BE USED ONLY IN A WELL-VENTILATED ROOM. TAKE ADEQUATE SAFEGUARDS FOR FIRE PREVENTION IN WORK AREA. USE PROTECTIVE CLOTHING AND AVOID CONTACT OF THESE SOLUTIONS WITH THE SKIN.

(1) Steam clean the exterior surfaces and corrugated air fins of each core.

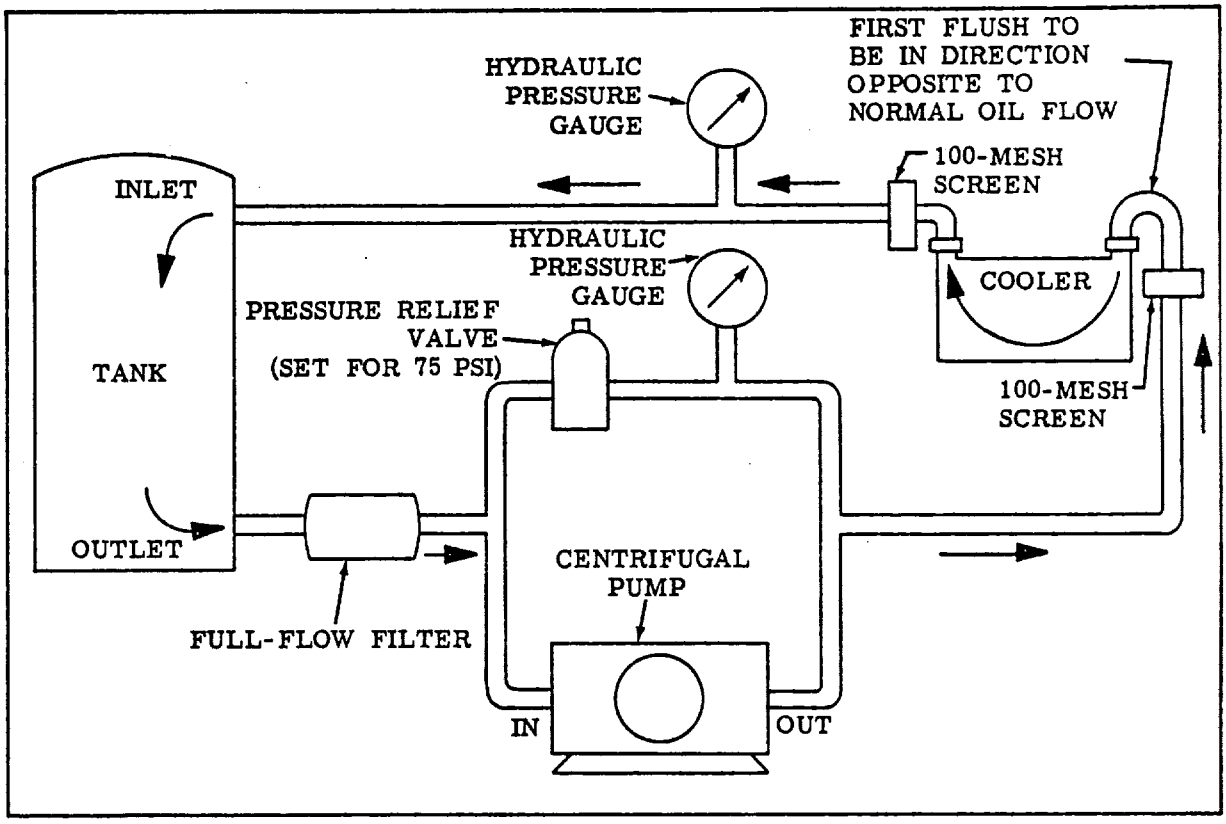

Figure 2. Cleaning Setup

(2) Preclean core interior to remove oil and loose sludge from the core to reduce contamination of cleaning solution in subsequent operations. Connect pump equipment so that fluid flow will be in the reverse direction of normal flow. Use mineral spirits, Federal Spec. TT-T-291, or kerosene, Federal Spec. VV-K-211, or dry cleaning solvent, Federal Spec. P-S-661. Flush core in reverse direction for 30 minutes or until solution appears clean. Reverse lines and flush approximately 15 minutes in the opposite direction. Drain cooler.

(3) Remove carbon deposits, engine oil, gums, lead deposits and foreign contamination by flushing cooler in opposite direction to normal oil flow for 30-60 minutes. Use solvent cleaning compound such as Turco "Surjax" (Turco Products, Los Angeles, California), Beck "OCC-3" (Beck Equipment Company, Cleveland, Ohio), or equivalent compounds conforming to Spec. MIL-C-6864. Reverse lines and flush in opposite direction for 15 minutes.

(4) Remove thermostatic valve and plug installed in by-pass opening (step 4A (3)). Replace valve with fitting which does not block by-pass. Flush for 15 minutes to clean by-pass passage. Remove fitting and reinstall by-pass plug and by-pass valve.

(5) Rinse cooler for 10 minutes by circulating clear petroleum solvent such as dry cleaning solvent (Federal Spec. P-S-661), or kerosene (Federal Spec. VV-K-211). System shall be suitably filtered to prevent circulation of foreign matter.

(6) Flush core interior to detect presence of metal particles in the core, and to remove combustible liquids from the core in preparation of repair instructions. Use water at 100° to 160° F. If repairs are not anticipated, cleaning solvent P-S-661 can be used, but if during testing it is found that repairs are required, an additional water flush must be made. Flush ten minutes in each direction with a 100-mesh screen installed at the cooler inlet and outlet. Reflush cooler for 5 minutes in each direction and recheck screens. Remove rubber plug from by-pass opening and replace valve.

CAUTION: IF METAL PARTICLES ARE FOUND AT THE SCREEN DURING THE ABOVE FLUSHING OPERATIONS, IT IS AN INDICATION THAT THE OIL COOLER WAS INSTALLED ON EQUIPMENT THAT FAILED MECHANICALLY. SUCH A COOLER SHOULD BE SCRAPPED UNLESS AN APPROVED METHOD IS KNOWN FOR SALVAGING.

(7) Flush cooler with a preservative oil consisting of three parts MIL-L-6082, Grade 1065, and one part MIL-C-6529, or, for systems employing MIL-L-7808 oil, preservative oil MIL-C-8188B, or equivalent, in preparation for shipment or storage. Connect cooler to pump equipment and flush in each direction for 10 minutes, checking the mesh screen after each flush to ensure that no metal particles have appeared. After flushing operations, install plugs in inlet and outlet ports.

5. DISASSEMBLY

A. Disassemble oil coolers by removing lockwires, bolts, and oil fittings on units having removable fittings.

B. Remove by-pass thermostatic control valves. Do not disassemble valves. If assembly malfunctions or does not pass test, replace valve.

C. Discard any gaskets and "O" rings.

D. Further disassembly of cores is not practical because each core is a brazed and welded unit.

6. INSPECTION

A. Examine the air fins and air passages for distortion or foreign particles that may obstruct the air flow.

B. Inspect the cooler for damaged and bulged plates, cracked castings and flanges, broken welds, and stripped threads. Inspect hardware items for stripped threads, ineffective lock units, and damaged bolt heads.

C. Inspect all openings in core and valve housing assemblies for evidence of foreign matter inside the cooler.

D. Inspect gasket surfaces for scores that may prevent the gaskets from sealing.

E. On units having a thermostatic valve, inspect the valve seat and the control valve housing seat for scoring and wear that would allow excessive leakage when the valve is seated. Inspect the valve for stripped threads and broken spring.

F. Test cores for leaks and test thermostatic valves for proper functioning in accordance with paragraphs 8A and 8B.

7. REASSEMBLY

A. Reassembly of the unit is essentially the reverse of disassembly.

B. Use new gaskets and/or "O" rings.

C. Tighten all bolts and nuts.

D. Install lockwire after final testing.

8. TESTING

A. Cooler Tests

(1) Preliminary cooler test. Conduct an air leak test on the assembled unit as follows: Plug the cooler outlet and attach an air hose to the inlet. Attach the other end of the air hose to an adjustable pressure source. Adjust air pressure to 12 PSIG. Submerge cooler in water at 140° F - 180° F (Heat water to 185° F to expand metal.)

WARNING: INCREASE AIR PRESSURE GRADUALLY TO AVOID BURNS FROM HOT WATER SPLASHING FROM LARGE LEAKS, IF PRESENT.

After five minutes of submersion increase air pressure to 100 PSIG to detect small leaks, if present. Inspect cooler for leaks as evidenced by presence of air bubbles. Mark leaks, remove from water, release air, and blow cooler dry. Repair in accordance with paragraph 9 and retest.

(2) Final cooler test. Conduct a hydrostatic test on the assembled cooler as follows (see figure 3). Plug outlet and apply room temperature water at test pressure to the other port. Lock fluid in cooler for 10 minutes. Examine cooler for blown or bulged plates. Release pressure, drain cooler, and dry with compressed air. Repair and retest.

CAUTION: TEST PRESSURE SHOULD BE IN ACCORDANCE WITH THE ENGINEERING DRAWING SPECIFICATION. IN THE ABSENCE OF THE ENGINEERING DRAWING, DO NOT EXCEED 150 PSIG.

(3) If the unit is found serviceable after completing preliminary to final tests, flush with suitable corrosion preventative compound such as specified in paragraph 4B (7).

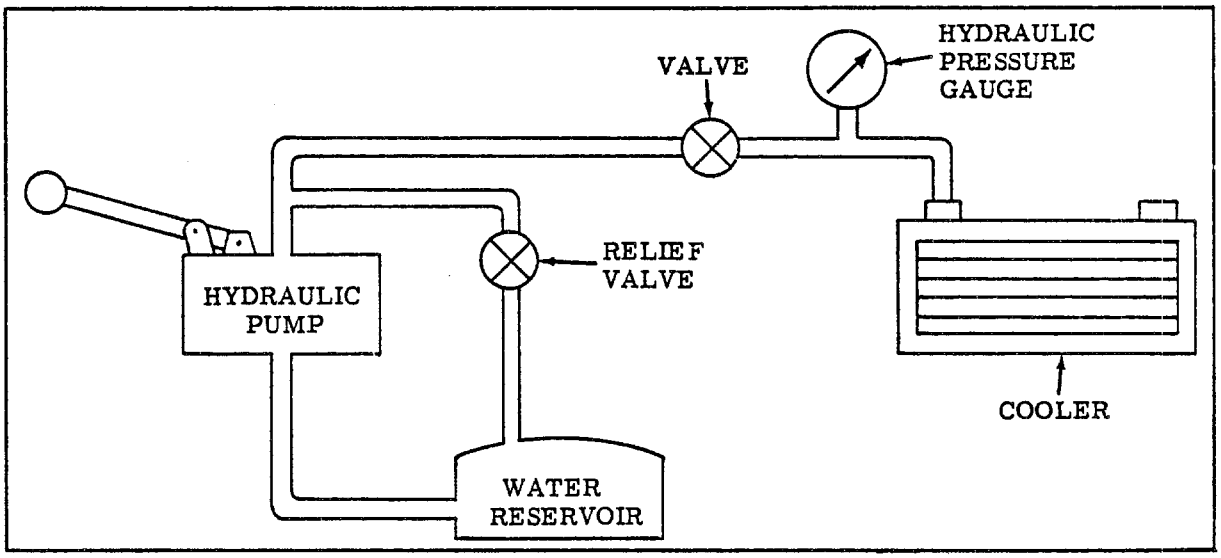

Figure 3. Hydrostatic Test Setup

B. Control Valve Function Test

(1) Check function of control valve by submerging valve in water at Start to Close temperature, indicated in the following table, for five minutes. Remove valve and measure length. Submerge valve in water at Fully Closed temperature, indicated in the table , for five minutes. Remove valve and measure length. Minimum increased length shall be equal to that shown in the table.

(2) Inches of travel should occur between the two temperatures shown.

(3) If valve under test does not function properly, replace with new valve.

NOTE: Start to Close temperatures are approximate.

9. REPAIR

A. Scope

(1) Repair of the cooler assembly is limited to the corrections of accessible leaks by welding and brazing, and should be performed following cleaning (paragraph 4) and testing procedures (paragraph 8).

CAUTION: THE MANUFACTURER DOES NOT RECOMMEND REPAIRING DAMAGED COOLERS. A DAMAGED COOLER SHOULD BE RETURNED TO THE MANUFACTURER FOR REPAIRS. HOWEVER, WHEN MINOR REPAIRS ARE NECESSARY THEY SHALL BE EXECUTED ONLY BY FACTORY TRAINED PERSONNEL. WHEN THE CONDITIONS NOTED IN STEP 9A(2) FOLLOWING ARE PRESENT, THE COOLER MUST BE RETURNED TO THE FACTORY.

(2) Return the cooler to the manufacturer for inspection and repair or replacement if repairs for the following damages are required:

(a) Blown, bulged, or badly dented plates.

TABLE OF OPERATING TEMPERATURES

Valve Part No.	Temp. Range + — 5° F.		Minimum travel — inches
	Start To Close	Fully Closed	
8509198	150	185	.235
8518329	130	160	.235
8518629	150	185	.160

(b) Leaks in areas where reinforcement plates, strips, or gussets are joined to the core and usually located on the outside plates.

(c) Non-repairable damage or distortion to the valve seat.

(d) Damaged threads in aluminum fittings, ports, drain bosses, or valve housing.

(e) Major dents and similar damage in tube edges, tanks, or valve bodies, which do not leak but could impair cooler performance and life.

(f) Leaks in difficult locations such as interior plate-to-header leaks, or leaks in the plate away from plate edge.

(3) Replace control valves which do not function properly when tested in accordance with paragraph 8B.

NOTE: Valves should not be replaced until all welding and brazing on the unit has been accomplished.

B. Repair of Leaks

WARNING: PURGE COOLER OF ANY COMBUSTIBLE FLUIDS OR VAPORS BEFORE ATTEMPTING REPAIRS. PURGE WITH WATER, DRAIN, AND DRY COOLER WITH COMPRESSED AIR.

NOTE: Before using any type of torch, apply a light coat of Alcoa #33 flux, or equivalent, which has been mixed with water in accordance with the manufacturer's instructions. Flux and metal changes indicate the reaching of brazing temperature of approximately 1080° F. The flux passes through a color change of green to white. It then melts to a watery appearance and becomes extremely active at brazing temperature. The aluminum will change from a greyish color to a shiny appearance.

(1) Repair accessible leaks or cracks in tanks, casting, Heliarc welds, by-pass tubes, control valve housing pads, inlet or outlet fitting pads, and mounting pads using an inert arc welding process (Heliarc or equivalent) and 1/8-inch diameter welding rod.

If this equipment is not available, or if cracks tend to "creep", or if casting impurities tend to "bubble" using Heliarc, then substitute acetylene torch for repairs. Preheat with a preheating adapter on the torch if the leaking area is adjacent to thin-walled cooler parts. When flux grows shiny, sweat-in 3/32-inch brazing wire, using a #8 tip. Switch to a #3 tip for final braze-in, using 3/32-inch or alternately 1/16-inch brazing wire and #33 flux.

CAUTION: ALL ALUMINUM FLUXES ARE HIGHLY CORROSIVE. USE BOILING WATER TO REMOVE ALL TRACES OF FLUX FROM INTERIOR AND EXTERIOR OF COOLER. KEEP UNITS DRY BETWEEN OPERATIONS INVOLVING FLUX, PARTICULARLY WHEN INTERVALS OF MORE THAN ONE HOUR ARE INVOLVED, AS MOISTURE ACCELERATES CORROSION.

(2) Repair plate seam leak (located at the edge of the plate) using a gas torch and 1/16-inch brazing wire. Use Selas PRS-3 tip (with manufactured gas) or Selas PRS-6 tip (with natural gas). Hold the torch flame about two inches away from the leaking area and rotate in a circular pattern. Air fins may be pushed back or lifted away from the leaking area to gain access. Reposition and tack air fins after the leak has been sealed. If seam leaks are within one inch of the tank header, it may be necessary to direct the flame of a second gas torch on the tank to hold the heat at the leak. If a gas torch is not available, repair with an acetylene torch. First preheat the cooler to 950° F. in an oven. Further preheat the area with a preheating adapter on the acetylene torch. At brazing temperature, use a #3 tip for final braze-in.

(3) Repair leaks or voids along the bottom of the by-pass tube by first heating the unit in a furnace at 900° F. until the unit is up to temperature. Remove to work bench. Apply #33 flux to leaking area and heat with a gas torch until flux grows shiny and 3/32-inch diameter brazing wire is sweated in. Put protective shield made from scrap metal on top of the shroud to prevent burning through.

(4) Repair plate-to-header leaks at outside accessible edges of the unit as in paragraph 9B (2).

C. Remove all traces of flux by scrubbing all accessible areas with a brush dipped in boiling water. Areas not so reached should be thoroughly flushed with boiling water. Complete removal of flux is extremely important to prevent subsequent corrosive destruction of the cooler. Dry with compressed air or in an oven at 250° F.

10. STORAGE

After the cooler has been completely overhauled and flushed with preservative oil, install plugs in the inlet and outlet ports. Package the cooler in a container that will provide suitable protection against damage and deterioration. The container should be so constructed as to permit periodical removal and inspection of the cooler without damage to the container or labels. Labels on the container should contain, in addition to complete identification data, the date of overhaul and an indication of repair performed, parts replaced, and general condition.

OVERHAUL WITH PARTS BREAKDOWN TEMPERATURE INDICATORS, LEWIS 163B103, 163B103A & 163B103B

DESCRIPTION AND OPERATION

1. Introduction

The types 163B103 and 163B103A are electrical resistance thermometers, both having a temperature range of -70°C to +150°C and using a Standard resistance bulb. The instruments differ slightly in dial configuration but are otherwise identical. The indicators are manufactured by the Lewis Engineering Company, Naugatuck, Connecticut, U.S.A.

2. Description

A. General. The indicator is housed in a 1-1/2" steel case, suitable for clamp mounting. Electrical connections are brought out to a four-pin male receptacle at the rear of the case. Refer to Figure 1 for details of dimensions and mounting.

B. Dial Configurations. The dial markings are generally dull white (FED STD 595, color 37875) for numerals, lettering and both major and minor graduations. The background is durable dull black (FED STD 595, color 37038). Other markings are as follows:

(1) Indicator Type 163B103. (Dial S 1287)

(a) Graduation at 100°C, dull white, color 37875.

(b) Arc from +10°C to +93°C, green, color 34108.

(c) Arc from -40°C to +10°C, yellow, color 33538.

(d) Red radial line at +93°C (6 o'clock position), color 31136.

(2) Indicator, Type 163B103A (Dial S 1287A)

(a) No graduation at 100°C.

(b) Arc from +10°C to +93°C, green, color 34108.

(c) Arc from -40°C to +10°C and arc from +93°C to +99°C, yellow, color 33538.

(d) Red radial line at +99°C. Color 31136.

DESCRIPTION AND OPERATION (CONT'D)

(3) Indicator, Type 163B103B. (Dial S 1287B).

(a) No graduation at 100°C.

(b) Arc from +10°C to +99°C, green, color 34108.

(c) No yellow arcs.

(d) Red radial line at +99°C (6 o'clock position), color 31136.

C. Resistance Bulb. Both instruments are calibrated for use with a resistance bulb, having a resistance of 90.38 ohms at zero °C (32°F).

D. Circuit Description. Refer to Figure 2, which is a schematic diagram, of either indicator. The basic circuit is a Wheatstone bridge arrangement, with the resistance bulb forming the variable arm of the bridge, while resistance spools 71A13-9 and 71A19-2 are the fixed arms. The bridge is energized from the aircraft's 28 vdc supply through resistance spool 71A13-8. The voltage dropped across the resistance spool is regulated by a zener diode in series with it to ground. This regulation of the bridge excitation compensates for any variation of supply voltage. The indicator proper consists of a milliammeter (M) in series with resistance spool 71A18-6 and this circuit is connected across the output of the bridge. Spool 71A19-2 has a slide wire series resistor, which permits adjustment of the milliammeter reading to the exact temperature value when calibrating. Temperature compensation is provided by a thermal resistor (T) connected in parallel with a tap on spool 71A18-6. This adjusts the resistance value of the spool to provide automatic compensation for changes in indicator reading due to changes in ambient temperature.

3. Operation

The electrical resistance thermometer operates using a resistance bulb calbrated to the AN 3-19 curve. The resistance of this bulb varies from 68.27 ohms at -70°C to 151.91 ohms at +150°C. The values of the resistance spools forming the fixed arms of the bridge are chosen so that the variation through 83.64 ohms of the temperature bulb gives full scale deflection of the milliammeter indicator. The slide wire resistor is used to set the dial reading at the calibration point (zero °C = 90.38 ohms). For the calibration adjustment to be fully effective, the resistance of the leads connecting the temperature bulb to the indicator must not exceed 2 ohms per lead and should be the same value for each lead.

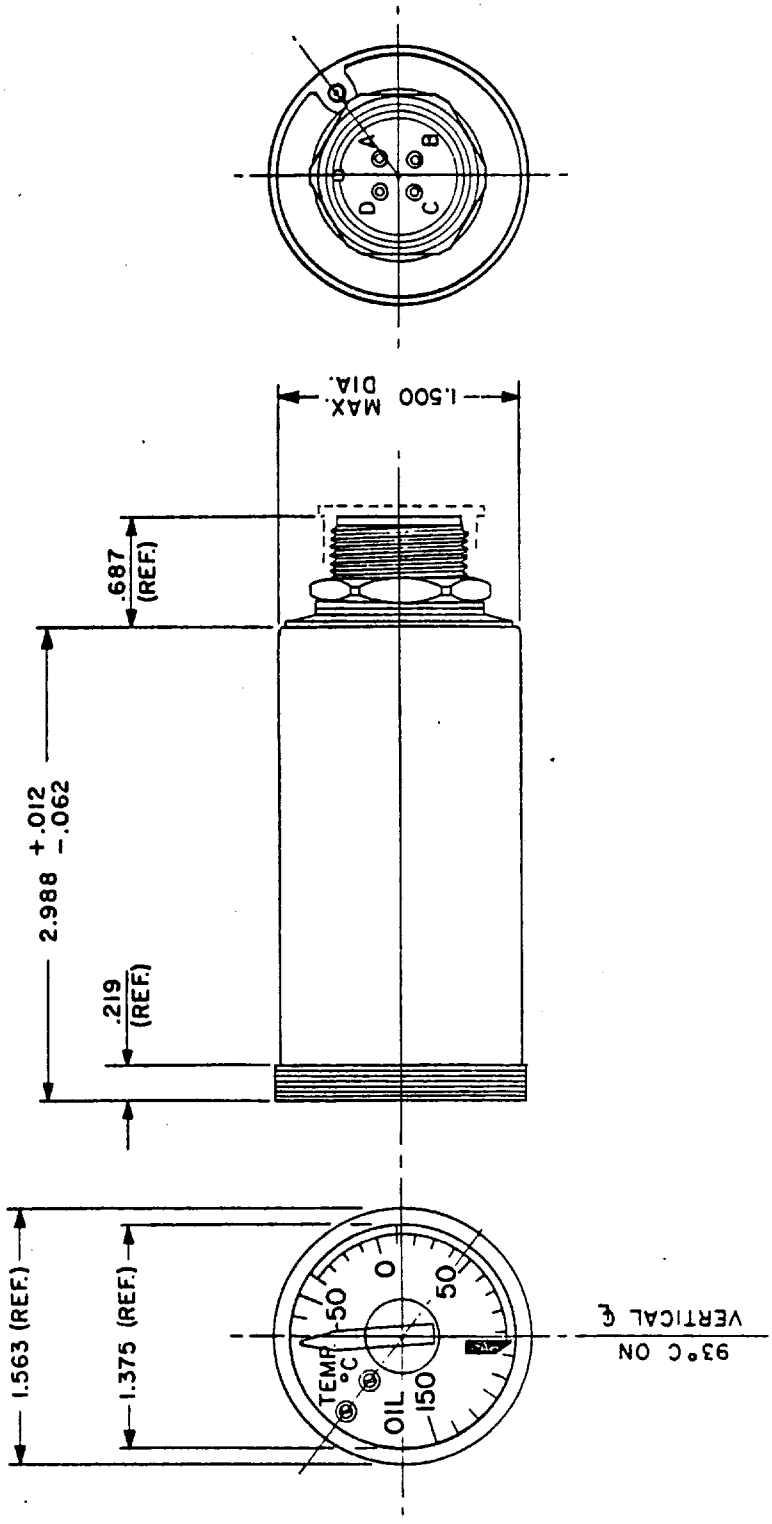

Figure 1 Details of Dimensions and Mounting

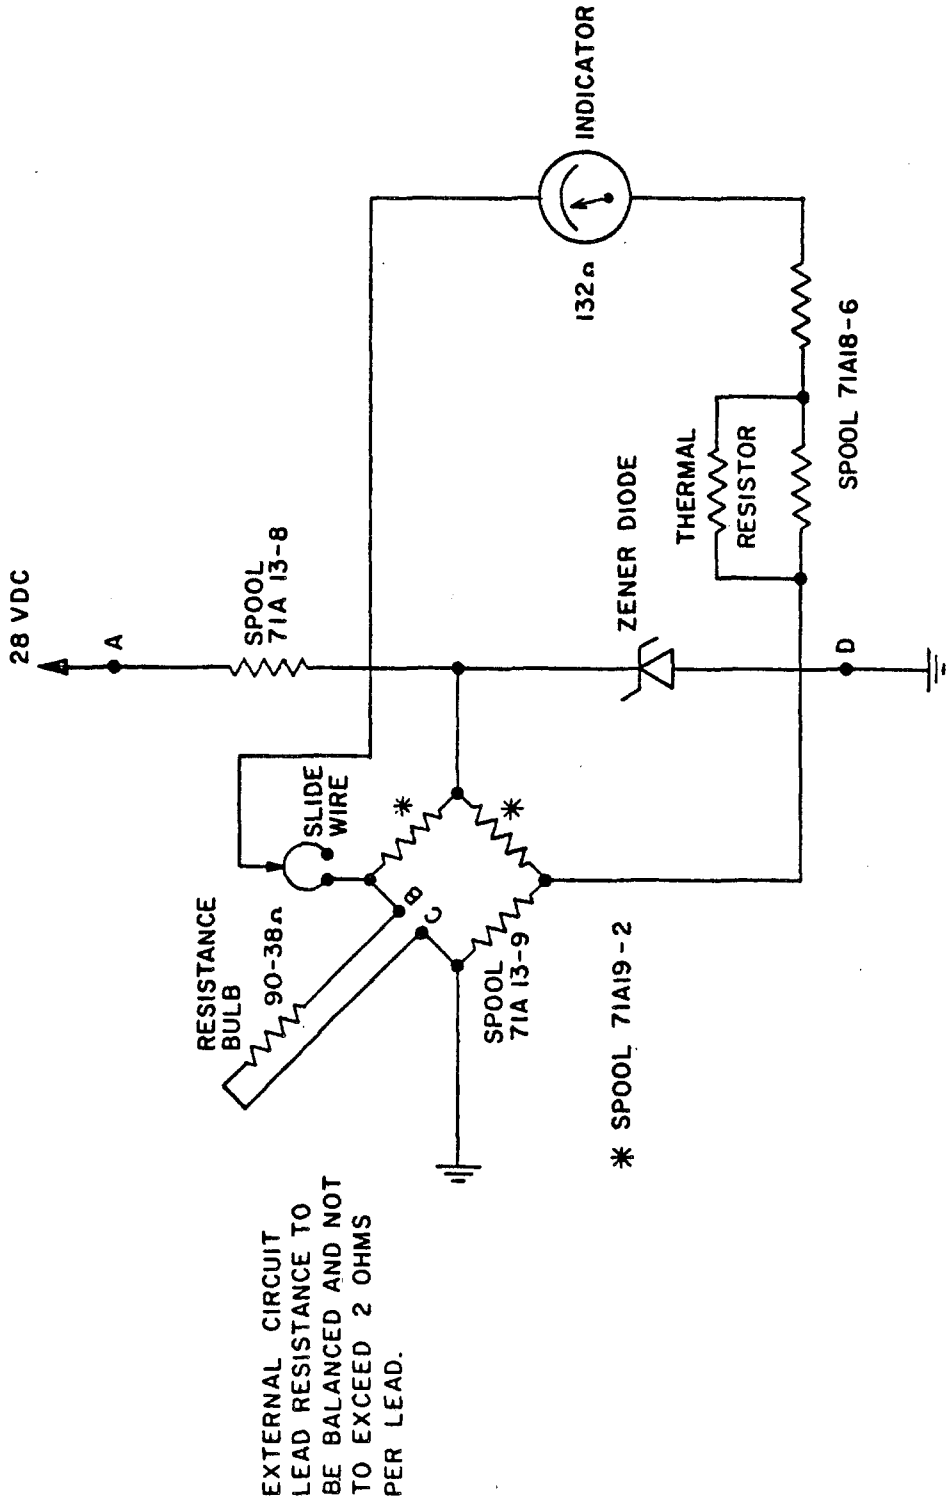

Figure 2 Schematic Diagram. Electrical Resistance Thermometers

OVERHAUL WITH PARTS BREAKDOWN TEMPERATURE INDICATORS, LEWIS 163B103, 163B103A & 163B103B

DISASSEMBLY

1. Refer to Figure 1101. Disassemble the indicator in approximately the same order as the index numbers assigned to this figure.

   NOTE: These instruments operate on jewelled bearings. Handle them as you would an expensive watch.

   Disassembly procedure is as follows:

   A. Using an induction heater or large soldering iron, apply it to sealing strap (1) to soften solder bond. Peel off strap and discard.

   B. Remove screws (8) and slide off housing assembly (2), and shield assembly (7).

   C. Remove nut, hex (11), lockwasher (12) and flat washer (13). This releases connector (9) and identification plate (10). Do not unsolder wires from connector unless defective.

   D. Carefully unsolder the wires from the terminals on the movement assembly (28). The black wire connects to the top bridge and the yellow wire to the bottom bridge.

   E. Remove the parts attaching base assembly (14), hex nut (29) and lockwasher (30). Base (15) and insulator (16) are now released from movement assembly (28). The base assembly (14) need only be disassembled if defective. Proceed as follows:

      (1) Refer to the wiring diagram, Figure 101 before unsoldering any wires from the resistor spools, note color coding and positions of wires.

      (2) Thermal resistor (17) can be replaced by unsoldering it from the terminal posts on base (15). Grip leads on zener diode (33) with pliers to provide heatsink, and unsolder leads from resistor spool No. 1 (18) and pin D on connector (9).

      (3) To remove resistor spools Nos. 1, 2, 3 (18, 19, 20), take out screws (24). To remove resistor spool No. 4, take out screw (25). All spools have a lockwasher (22) and flat washer (23) under the head of their screw. On resistor spool No. 2 (19), removal of screw (24) also releases shouldered washer (26) and slide wire clip (27).

OVERHAUL WITH PARTS BREAKDOWN TEMPERATURE INDICATORS, LEWIS 163B103, 163B103A & 163B103B

DISASSEMBLY (CONT'D)

F. Remove dial screws (58), lockwashers (59). Lift dial (57) carefully over pointer.

G. Remove screws (34) which release diode holder (32) and diode (33).

H. Remove screws (37), and take off dial mounting plate (35). Unsolder outer ends of control springs (42, 56). Unscrew dial mounting plate spacer (38) and remove bumper assembly (36). Remove top bridge assembly (39). Jewel screw (40) should be removed if it requires replacement.

I. Grasp armature assembly (41) with tweezers by the pointer and turn it carefully to remove it from pole piece assembly (31). Slide armature coil through slotted core.

J. Do not disassemble armature assembly (41) further unless control springs (42, 56) or balance weights (43, 44) require replacement. If any other part of the armature assembly is damaged, replace the entire assembly.

K. To remove bottom bridge assembly (45) and bridge insulating pad (46) remove screws (47). This releases lockwasher (49), insulator washer (50) and insulating bushing (51).

L. Bottom bridge assembly (45) can be further dismantled by removing sleeve nut (52) which releases spring washer (53), bottom spring terminal (54) and unlocks jewel screw (55).

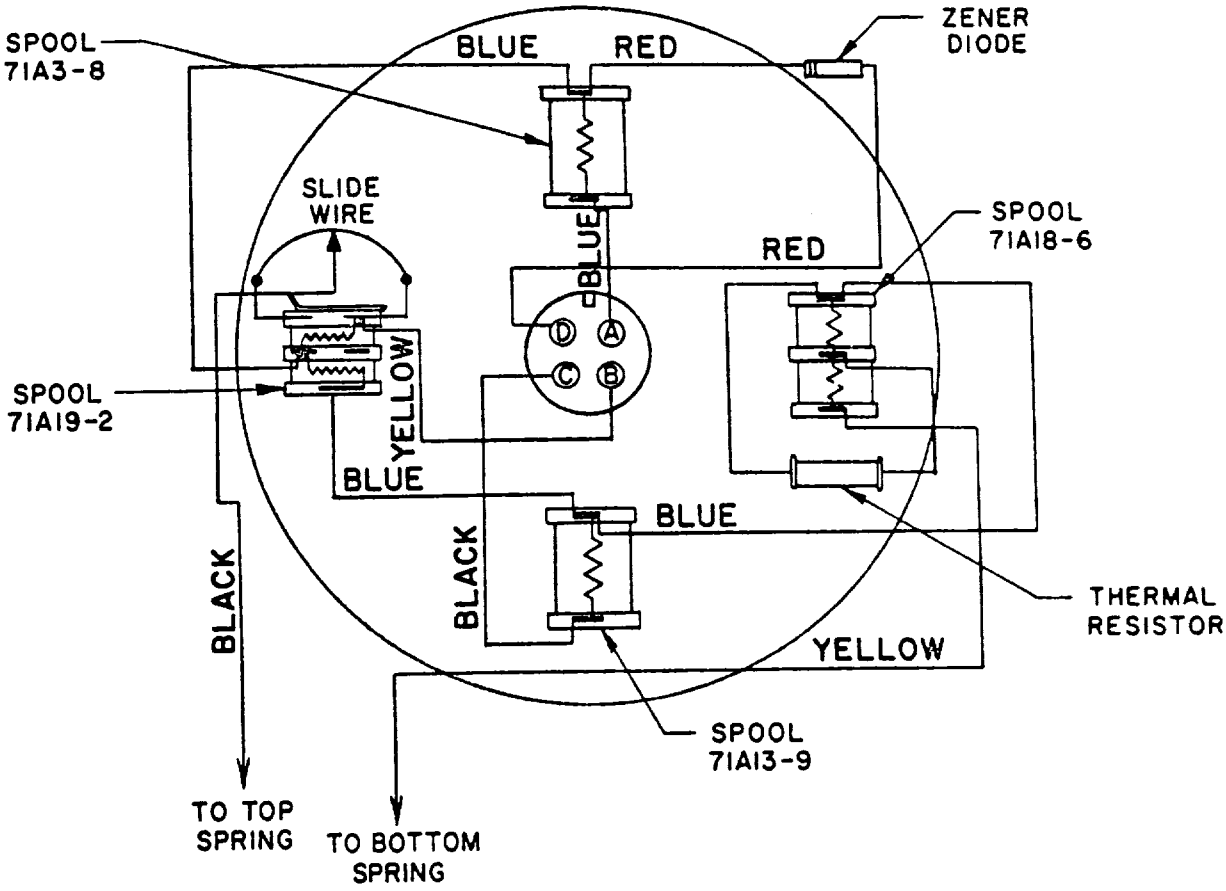

Figure 101 Internal Wiring Diagram

CLEANING, INSPECTION AND REPAIR

1. Cleaning and Inspection

Refer to Table 201. Carry out the inspection and cleaning procedures listed therein.

Part	How to Clean or Inspect
Jewels (40, 55)	Clean with orangewood stick. Insert fine pointed needle into and over jewel cup to detect fractures.
Pivots	Examine pivots on armature assembly (41) using seven power eye loupe. Clean by rotating pithwood on point.
Dial (57)	Check for clipped or discolored paint. Clean with soft camel hair brush.
Armature assy.	Check for discolored paint on pointer.
(41)	Check coil with ohmmeter. Resistance should be 132 ohms ± 10%.
Control Springs (42, 56)	If mis-shapen, reposition by means of fine tweezers. Clean with fine camelhair brush and trichloroethylene, Fed. Spec. O-T-634A.
Thermal resistor (17)	Test with ohmmeter when unsoldered.
Window (4)	Check for striae or chipped surface. Clean with moist chamois

Table 201 Cleaning and Inspection Procedures

2. Repair

When necessary, the following repairs may be made.

A. Replace fractured jewels (40, 55).

B. If pivots are chipped or flattened replace armature assembly (41).

2. Repair (Cont'd)

C. Replace dial (57) if bent. Refinish if paint chipped or discolored.

D. Straighten pointer if bent. Refinish paint on pointer if chipped or discolored. If coil defective, replace armature assembly (41).

E. If control springs (42, 46), cannot be repositioned or are badly damaged, replace springs.

F. Replace thermal resistor (17) if defective.

G. Replace terminal (54) if damaged.

H. To replace a defective window (4), place housing (3) on an electric hot plate, to soften bond to window, scrape excess solder from under housing. Place new window in housing. Cut a piece of 1/32 inch diameter solder to form a ring inside housing in such a position that when the solder melts it will flow evenly around edge of window. Add solder if required. Do not overheat. An induction heater may be substituted for the hotplate.

3. Lubrication

No lubrication is necessary.

ASSEMBLY

1. Preliminary

Assembly is performed in approximately the reverse order of index numbers on Figure 1101.

CAUTION: NEVER TIGHTEN JEWEL SCREWS SUFFICIENTLY TO CAUSE THEM TO BIND ON PIVOTS AS CRACKED JEWELS OR DAMAGED PIVOTS WILL RESULT.

Proceed as follows:

A. Attach bottom bridge assembly (45) to pole piece assembly (31). Ensure that bridge insulating pad (46), insulating bushing (51), insulator washer (50), flat washer (49) and lockwasher (48) are assembled in the proper sequence. Secure with screws (47).

B. Screw jewel (55) into bottom bridge assembly. Install terminal (54), spring washer (53) and sleeve nut (52). Do not tighten nut fully.

C. Insert armature assembly (41) into pole piece assembly (31) by carefully sliding it through the slotted cove until its bottom pivot rests in the cup of bottom jewel (55). Resolder control springs to their terminals.

D. Mount top bridge (39) on the ends of screws (47) which are protruding through pole piece assembly (41). Secure bridge to pole piece with spacers (38). Screw in top jewel until top pivot is within the cup of the top jewel. Do not tighten.

E. Grasp tail of pointer and gently rock armature assembly (41) from side to side to observe side play of pivot in jewel. Slowly tighten top jewel until side play is approximately 0.004 inch. Tighten sleeve nut (52), making sure that bottom pivot (55) does not turn.

F. Install bumper assembly (36) and dial mounting plate (35) on spacers (38), secure with screws (37).

G. Slide movement assembly (28) onto the posts of base assembly (14) and secure them together using lockwashers (30) and nuts (29).

H. Install diode holder (32) and diode (33) on movement assembly using screws (34). Resolder any wires previously removed as per internal wiring diagram Figure 101.

ASSEMBLY (CONT'D)

I. Pass dial (57) carefully over pointer and secure dial to dail mounting plate using screws (58) and lockwashers(59).

J. Balance armature with pointer in horizontal and vertical positions, moving top balance weight (43) and side balance weights (44) as required to obtain balance. Use wrench 16 or 16B, ref. Table 1001.

K. Carry out test procedures detailed in Section 701.

22. Sealing, Evacuation and Filling

After successful completion of the test procedures (Section 701), fill and and seal the indicator case with a dry gas mixture of 90% nitrogen and 10% helium. Filling and sealing procedure is as follows:

A. Support indicator in LF 30 sealing fixture and solder sealing strap (1) in place. Use a 150 watt soldering iron to flow solder from strap to housing. Remove excess solder with coarse file.

B. Test for leaks by immersing indicator in a water jar with filler tube connected to a DRY compressed air supply of 30 psi max. If no leaks are detected remove air hose, hold finger over filler tube and dry indicator by blowing off excess moisture.

C. Place indicator in an air oven heated to about 70°C (158°F) for 30 minutes.

D. Connect filler tube to gas supply and vacuum pump as shown in Figure 501. Evacuate to approximately two mm of mercury as indicated on the vacuum (absolute pressure) gauge. Close valve "B" and slowly open valve "A" to fill indicator with gas.

E. Close valve "A" and open "B" to again evacuate indicator. Close valve "B" and open "A" to again fill with gas.

F. Close valve "A", pinch tube closed with pliers, remove hose and cut off excess length of tube and solder cut end of tube closed.

G. Make final leak test by placing indicator in desiccator jar as shown in Figure 502. Close valve "B" and open "A". Dray a vacuum of about 25 mm of mercury then close valve "A" and slowly open "B" until vacuum falls to about 63 mm of mercury.

ASSEMBLY (CONT'D)

H. Check indicator carefully for leaks by watching for a continuous flow of bubbles. If no leak is observed, SLOWLY open valve "B" to equalize pressure within desiccator with atmosphere.

I. Thoroughly dry indicator and paint with dull black, instrument lacquer, Fed. Std. 595 Color 37038.

J. Repeat test procedure described in Section 701.

3. Packing for Transportation or Storage

A. Use specification PPB-B-636 Type I, Class II carton 7-1/2 x 7-1/2 x 7-1/2 inches. Insert a pad eight inches wide by five foot long by one-half inch thick, specification PPB-C-843A Type 2, crepe cellulose wadding on bottom of carton.

B. Wrap indicator in crepe cellulose wadding three inches wide by ten foot long by one-half inch thick and place in carton.

C. Place another pad of eight inch wide by five foot long by one-half inch thick crepe cellulose wadding on top of indicator.

D. Seal carton with specification UU-T-116 tape.

NOTE: To prevent damage to internal components, NEVER ship an indicator unless it has a minimum of three inches of cushioning material on all sides.

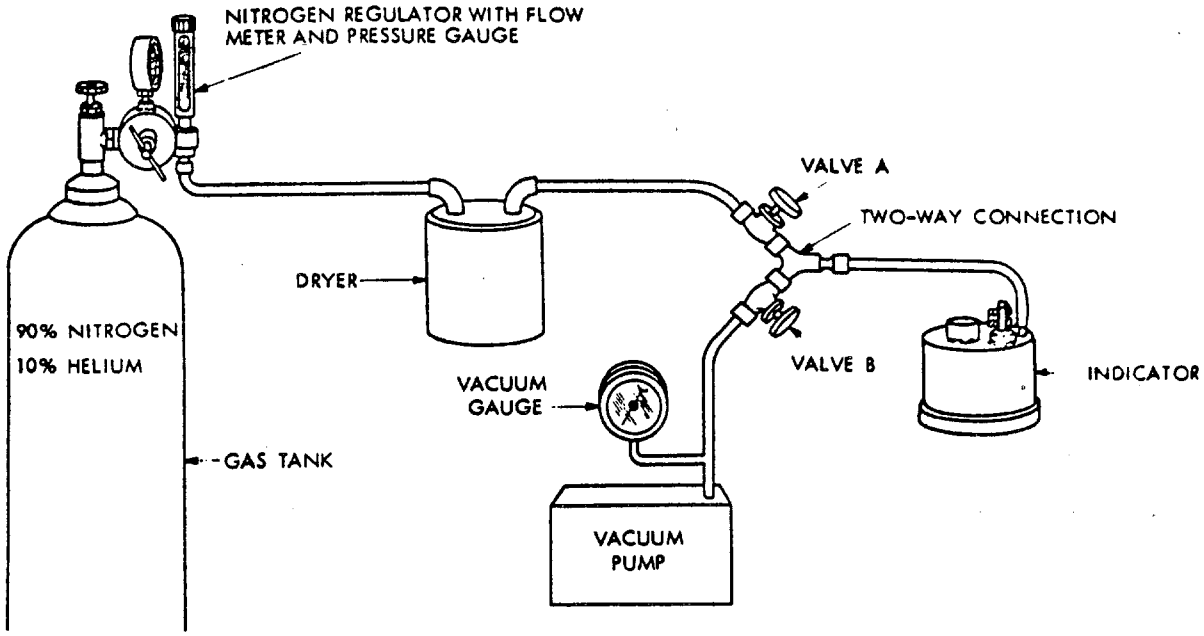

Figure 501 Evacuation and Gas Filling Equipment

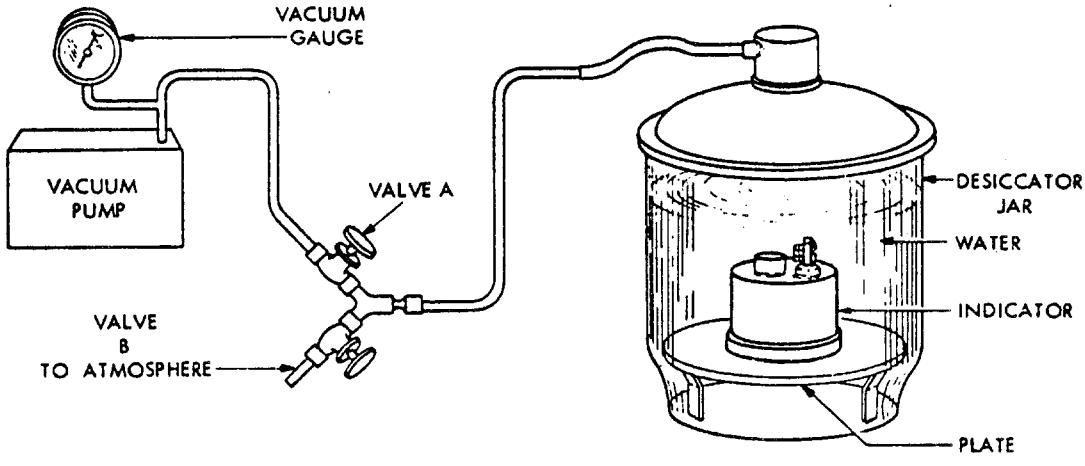

Figure 502 Final Leak Test Under Vacuum

OVERHAUL WITH PARTS BREAKDOWN TEMPERATURE INDICATORS, LEWIS 163B103, 163B103A & 163B103B

TESTING

1. Test Connections

Connect the indicator to a test circuit consisting of a decade box (Ref. Table 701), rheostat and a nominal 28 vdc supply. See Figure 701.

CAUTION: DO NOT APPLY POWER TO THE TEST CIRCUIT WITH THE DECADE BOX DISCONNECTED.

2. Test Procedure

A. Set decade box to the nearest value to 90.38 ohms, simulating 0°C.

Note: The lowest step on the decade box is 0.1 ohm, so adjust it to the nearest 0.1 ohm. For example, 90.38 would be set at 90.4 ohms.

B. Apply power to test circuit and adjust rheostat until voltage measured across pins A and D reads 28 volts ± 0.5 v.

C. Adjust the slide wire clip (27) until the indicator pointer is against the 0°C graduation.

D. Refer to Table 701 and set the decade box to the values listed therein for -70°C to +150°C. The dial indications shall be correct within ± 4.4°C at -70°C, -50°C, 0°C, +50°C +100°C and +150°C.

Note: Tap indicator lightly with fingertip when taking the above readings.

E. Friction Test. Hold indicator in operating position, then, without tapping set the decade box to the resistance values for -70°C, -50°C, 0°C, +50°C, +100°C and +150°C. Tap lightly at each setting and note any change in pointer position. Change is friction error which shall not exceed 4.4°C. Clean air gap with needle or replace pivots and jewels if error is greater than the specified value.

F. Balance Test. Set decade box to give 0°C reading. Hold indicator with pointer in vertical plane and repeat. Hold indicator in normal position and rotate 90° clockwise and counter-clockwise. The reading shall not change more than ± 4.4°C.

G. Reduced Voltage Test. Adjust the rheostat until the test voltage is reduced to 14 volts. Apply the test resistance for 0°C. The pointer reading shall not change more than ± 4.4°C.

TESTING (CONT'D)

3. Final Assembly and Test

A. Pass connector (9) through the rear of shield assembly (7) and install identification plate (10) on the outside. Place flat washer (13) and lockwasher (12) over the connector shell. Secure these parts together with nut (11).

B. Attach shield assembly (7) to base assembly (14) using four screws (8).

C. Install housing assembly (2) on the indicator and secure with four screws (8).

D. Repeat the test procedures given in the previous paragraph. If the tests are satisfactory, carry out the sealing, evacuation and filling procedures described in paragraph 2, Section 501.

STEWART-WARNER
10528A

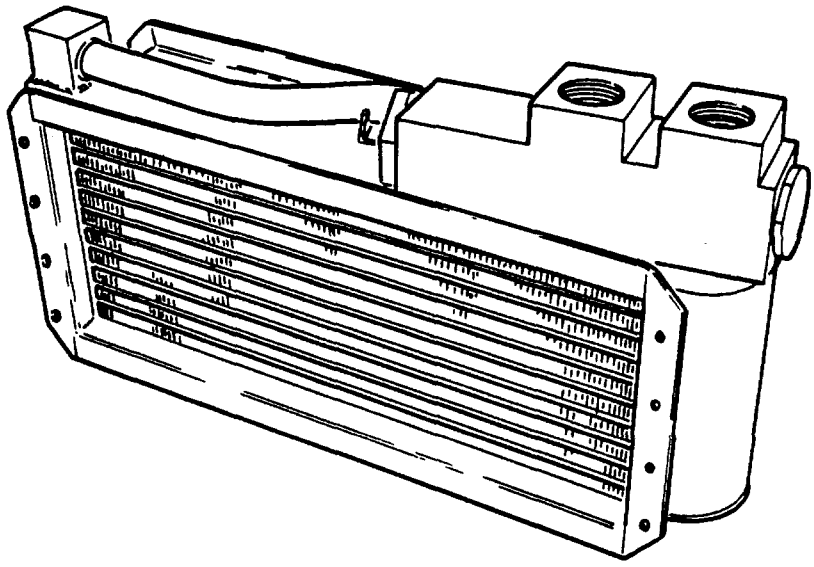
INTRODUCTION

This manual contains instructions for the overhaul of the Stewart-Warner Corporation (South Wind Division) Oil Cooler Assembly 10528A.

STEWART-WARNER
10528A

OIL COOLER



1. Description and Operation

A. Description (Figure 1)

The oil cooler consists of an aluminum body with a plate-fin core construction and a temperature control valve. The core collectors, mounting flanges and control valve body are a single all-brazed assembly.

B. Operation

The cooler is a heat exchanger which reduces the temperature of oil flowing through it by transferring heat to air passing through the cooler core. At an oil inlet temperature below 155° F, the temperature control valve allows all of the oil to by-pass the core and flow directly back to the system. Between an oil temperature of 155° F and 175° F, the thermostatic control of the temperature control valve directs the oil partly through the core and partly through the by-pass. When the oil temperature rises above 175° F, all of the oil will flow through the cooler core.

Oil Cooler Assembly
Figure 1

C. Data

(1) Specifications

Construction:	Plate and Fin with By-Pass Valve
Material:	Aluminum
Weight:	8.60 lb Dry

(2) Performance

	Cold Side	Hot Side
Fluid	Air	Oil
Flow Rate (lbs/min)	160	100
Inlet Temperature	100°F	225°F
Outlet Temperature	136.4°F	197.4°F
Allowable Pressure Differential	10.2 inches of water	18.5 psi
Heat Rejection Rate	1400 BTU/min	

2. Disassembly

A. Disassemble Oil Cooler (Figure 3)

(1) Cut lockwire and unscrew thermostat (1) from end of valve body. Remove gasket (2) from thermostat.

(2) Withdraw spring (3) and poppet valve (4) from inside valve body.

(3) Cut lockwire and unscrew plug (5) from end of valve body and withdraw spring (7) and pushrod (8). Remove O-ring (6) from plug.

(4) Cut lockwire and remove plug (9) from core (11). Remove O-ring (10) from plug.

3. Cleaning

A. Clean Cooler Core

CAUTION: USE ONLY CLEANING SOLUTIONS RECOMMENDED IN THESE INSTRUCTIONS OR ONES SATISFACTORY FOR ALUMINUM. MANY SOLUTIONS SATISFACTORY FOR CLEANING COPPER OR COPPER NICKEL COOLERS ARE HIGHLY

CORROSIVE TO ALUMINUM AND IF USED WILL RESULT IN THE DESTRUCTION OF THE COOLER. IF EQUIPMENT HAS BEEN PREVIOUSLY USED WITH ANY OTHER CLEANING SOLUTIONS, IT SHOULD BE THOROUGHLY WASHED OUT AND FLUSHED WITH THE RECOMMENDED SOLUTION.

WARNING: CLEANING SOLVENTS AND SOLVENT CLEANING COMPOUNDS ARE TOXIC AND FLAMMABLE, AND MUST BE USED ONLY IN A WELL-VENTILATED ROOM. TAKE ADEQUATE SAFEGUARDS FOR FIRE PREVENTION IN WORK AREA. USE PROTECTIVE CLOTHING AND AVOID CONTACT OF THESE SOLUTIONS WITH THE SKIN.

NOTE: Item numbers refer to Figure 3.

(1) Insert suitable plug into internal by-pass port; access is through hole at thermostat position. Insure that after installation of plug, sufficient clearance remains to install thermostat.

(2) Install plug (5) with O-ring (6). Install thermostat (1) with gasket (2). Install plug (9) and O-ring (10).

(3) Steam clean the exterior surfaces and air fins of each core.

(4) Using mineral spirits, kerosene or dry cleaning solvent, remove oil and loose sludge by flushing in reverse direction to normal flow for 30 minutes or until solution appears clean.

NOTE: Carefully examine flushing solution for metal particles.

CAUTION: IF METAL PARTICLES ARE FOUND DURING FLUSHING OPERATIONS, IT IS AN INDICATION THAT THE OIL COOLER WAS INSTALLED ON EQUIPMENT THAT FAILED MECHANICALLY, AND FURTHER INVESTIGATION IS NECESSARY.

(5) Reverse lines and flush approximately 15 minutes in the opposite direction. Drain cooler.

(6) Remove carbon deposits, engine oil, gums, lead deposits and foreign contamination by flushing cooler in opposite direction to normal oil flow for 30 to 60 minutes. Use

solvent cleaning compound such as Turco "Surjax", Beck "OCC-3", or equivalent compounds conforming to Spec MIL-C-6864. Reverse lines and flush in opposite direction for 15 minutes.

(7) Remove plug (5) and thermostat (1).

(8) Remove plug from by-pass port installed in step (1), and hand-flush by-pass port.

(9) Repeat steps (1) and (2).

(10) Rinse cooler for 10 minutes by circulating clear petroleum solvent such as dry cleaning solvent, or kerosene. Install suitable filters, one at cooler inlet and one at cooler outlet, to prevent circulation of foreign matter.

(11) Flush core to remove combustible liquids from the core in preparation for any repairs. Use water at 100° to 160°F. If repairs are not required, dry cleaning solvent can be used. Flush 10 minutes in each direction and check filters for metal particles. Reflush cooler for 5 minutes in each direction and recheck filters.

(12) Remove plug from by-pass port.

B. Clean Temperature Control Valve

(1) Remove deposits by soaking valve components in cleaning compound used in paragraph 3.A., step (6) for 30 minutes. Brush with stiff non-metallic brush.

(2) Rinse components in dry cleaning solvent or kerosene.

Table 1

Cleaning Materials and Compounds

MATERIAL	SPECIFICATION OR MANUFACTURER
Mineral Spirits	TT-T-291
Kerosene	VV-K-211
Dry Cleaning Solvent	P-D-680
Solvent Cleaning Compound	) Surjax (Turco Products, Los Angeles, California)) OCC-3 (Beck Equipment Co., Cleveland, Ohio)) MIL-C-6864

4. Inspection/Check

A. General

(1) Inspect components for defects under a strcng light, using magnification.

(2) Inspect for cracks using the fluorescent penetrant method, or an approved dye penetrant method.

(3) Inspect all parts visually for damage such as galls, scores, scratches, excessive wear and corrosion.

B. Inspect Cooler

(1) Examine the core structure and air passages for distortion or foreign particles that may obstruct the air flow.

(2) Inspect the cooler for damaged and bulged plates, cracked valve body, distorted flanges, broken welds, and stripped threads.

(3) Inspect all openings in core and valve housing assemblies for evidence of foreign matter inside the cooler.

(4) Inspect gasket seats on thermostat and valve body for scores that may prevent the gaskets from sealing.

(5) Inspect inlet pipe for dents, cracks and distortion.

(6) Pressure test and test for leaks as detailed in Testing.

C. Inspect Temperature Control Valve

(1) Check that springs conform to the values given in Table 3.

(2) Examine component parts of valve for wear, cracks and distortion. In particular, check seating surfaces of poppet valve and valve pushrod. See Table 4 for service limits.

5. Repair

A. General

(1) When anodized parts have had protective surface treatment

damaged or removed, apply a protective coating of Alodine solution No. 1200S to affected area or reanodize the part.

(2) Replace gasket (2), O-ring (6) and O-ring (10) at each overhaul. (Refer to Figure 3.)

(3) Replace defective temperature control components.

(4) Replace thermostats which do not meet test requirements. Refer to Testing.

NOTE: Accomplish any welding or brazing repairs before installing temperature control valve components.

(5) Repair of the cooler assembly is limited to the corrections of accessible leaks by welding and brazing, and should be performed following cleaning (paragraph 3) and testing procedures (paragraph 8).

CAUTION: THE MANUFACTURER DOES NOT RECOMMEND REPAIRING DAMAGED COOLERS. A DAMAGED COOLER SHOULD BE RETURNED TO THE MANUFACTURER FOR REPAIRS. HOWEVER, WHEN MINOR REPAIRS ARE NECESSARY THEY SHALL BE EXECUTED ONLY BY APPROVED PERSONNEL. WHEN THE CONDITIONS NOTED IN STEP (6) FOLLOWING ARE PRESENT, THE COOLER MUST BE RETURNED TO THE MANUFACTURER.

(6) Return the cooler to the manufacturer for inspection and repair or replacement if repairs for the following damages are required:

(a) Blown, bulged, or badly dented plates.

(b) Non-repairable damage or distortion to the valve seat.

(c) Damaged threads in aluminum fittings, ports, drain boss, or valve housing.

(d) Major dents and similar damage to core structure, inlet pipe or valve body, which do not leak but could impair cooler performance and life.

(e) Leaks in inaccessible locations such as in the plate away from plate edge.

B. Repair of Leaks

WARNING: PURGE COOLER OF ANY COMBUSTIBLE FLUIDS OR VAPORS BEFORE ATTEMPTING REPAIRS. PURGE WITH WATER, DRAIN, AND DRY COOLER WITH COMPRESSED AIR.

NOTE: Before using any type of torch, apply a light coat of Alcoa No. 33 flux, or equivalent, which has been mixed with water in accordance with the manufacturer's instructions. Flux and metal changes indicate the reaching of brazing temperature of approximately 1080°F. The flux passes through a color change of green to white. It then melts to a watery appearance and becomes extremely active at brazing temperature. The aluminum will change from a greyish color to a shiny appearance.

CAUTION: ALL ALUMINUM FLUXES ARE HIGHLY CORROSIVE. USE BOILING WATER TO REMOVE ALL TRACES OF FLUX FROM INTERIOR AND EXTERIOR OF COOLER. KEEP UNITS DRY BETWEEN OPERATIONS INVOLVING FLUX. PARTICULARLY WHEN INTERVALS OF MORE THAN ONE HOUR ARE INVOLVED, AS MOISTURE ACCELERATES CORROSION.

(1) Repair accessible leaks or cracks in end casing welds, inlet pipe, control valve housing, inlet or outlet fittings, and drain boss using an inert arc welding process (Heliarc or equivalent) and 1/8-inch diameter welding rod.

(2) If inert arc welding equipment is not available, or if cracks tend to "creep", or if casting impurities tend to "bubble" using Heliarc, then substitute acetylene torch for repairs as follows:

(a) Preheat with a preheating adapter on the torch if the leaking area is adjacent to thin-walled cooler parts.

(b) When flux grows shiny, sweat-in 3/32-inch brazing wire, using a No. 8 tip.

(c) Change to a No. 3 tip for final braze-in, using 3/32-inch or alternately 1/16-inch brazing wire and No. 33 flux.

(3) Remove all traces of flux by scrubbing all accessible areas with a brush dipped in boiling water. Areas not so reached should be thoroughly flushed with boiling water. Complete removal of flux is extremely important to prevent subsequent corrosive destruction of the cooler. Dry with compressed air or in an oven at 250°F.

Table 2

Repair Materials and Compounds

MATERIAL	SPECIFICATION OR MANUFACTURER
Alodine Solution 1200S	MIL-C-5541 (Amchem Products)

6. Assembly

A. Assemble Oil Cooler Assembly (Figure 3)

(1) Install O-ring (10) on plug (9) and screw plug into core (11). Lockwire plug with MS20995NC20.

(2) Install O-ring (6) and spring (7) on plug (5). Insert short end of pushrod (8) into plug (5) and screw plug with pushrod and spring into valve body. Lockwire plug with MS20995NC20.

(3) Support cooler with valve body vertical and open end uppermost.

(4) Insert poppet valve (4) into valve body and slide it onto exposed end of pushrod (8).

(5) Install spring (3) on poppet valve (4).

(6) Install gasket (2) on thermostat (1).

NOTE: Insure that thermostat has been tested. Refer to Testing.

(7) Screw thermostat (1) into valve body. Lockwire thermostat with MS20995NC20.

7. Fits and Clearances

(1) Check strength of springs. Refer to Table 3. Reject any spring not within service limits.

Table 3

Spring Values

FIGURE 3 ITEM NO.	CONDITION	LENGTH (INCHES)	LOAD (POUNDS)	SERVICE LIMITS (POUNDS)
3	Free Length	2.93		
	Installed Length	2.015	13.4	12.0
7	Free Length	2.50		
	Installed Length	1.50	39 ± 3	36.0

(2) Refer to Table 4 for original tolerances and service limits. Replace parts worn in excess of service limits.

Table 4

Original Tolerances and Service Limits

FIGURE 3 ITEM NO.	NAME	DISCREPANCY LOCATION	ORIGINAL DIMENSION (INCHES)	SERVICE LIMIT (INCHES)	DISPOSITION
5	Plug	I.D.	$0.250^{+0.004}_{-0.000}$	0.255	Replace
8	Pushrod, Valve	O.D. at plug (5) location	0.247 ± 0.001	0.245	Replace
		O.D. at valve (4) Location	0.247 ± 0.001	0.245	Replace
4	Valve, Poppet	I.D.	$0.250^{+0.004}_{-0.000}$	0.255	Replace

8. Testing

A. Test Equipment

Refer to paragraph 11.

B. Proof Pressure and Leak Test

(1) Seal oil cooler outlet port. Connect pneumatic test rig to oil cooler inlet port.

CAUTION: EXERCISE CARE DURING TESTS TO PRECLUDE ENTRY OF BATH LIQUID INTO THE OIL PASSAGES OF THE OIL COOLER ASSEMBLY.

(2) Submerge oil cooler in liquid bath with the air sides open to atmosphere.

(3) Pressurize the oil circuit to 225 $\pm \frac{5}{0}$ psi air pressure and hold for one minute. There must be no evidence of leakage.

(4) Reduce air pressure to 150 $\pm \frac{5}{0}$ psi and make a close-up inspection for internal and external leakage. There must be no evidence of leakage. Reduce pressure and remove from bath.

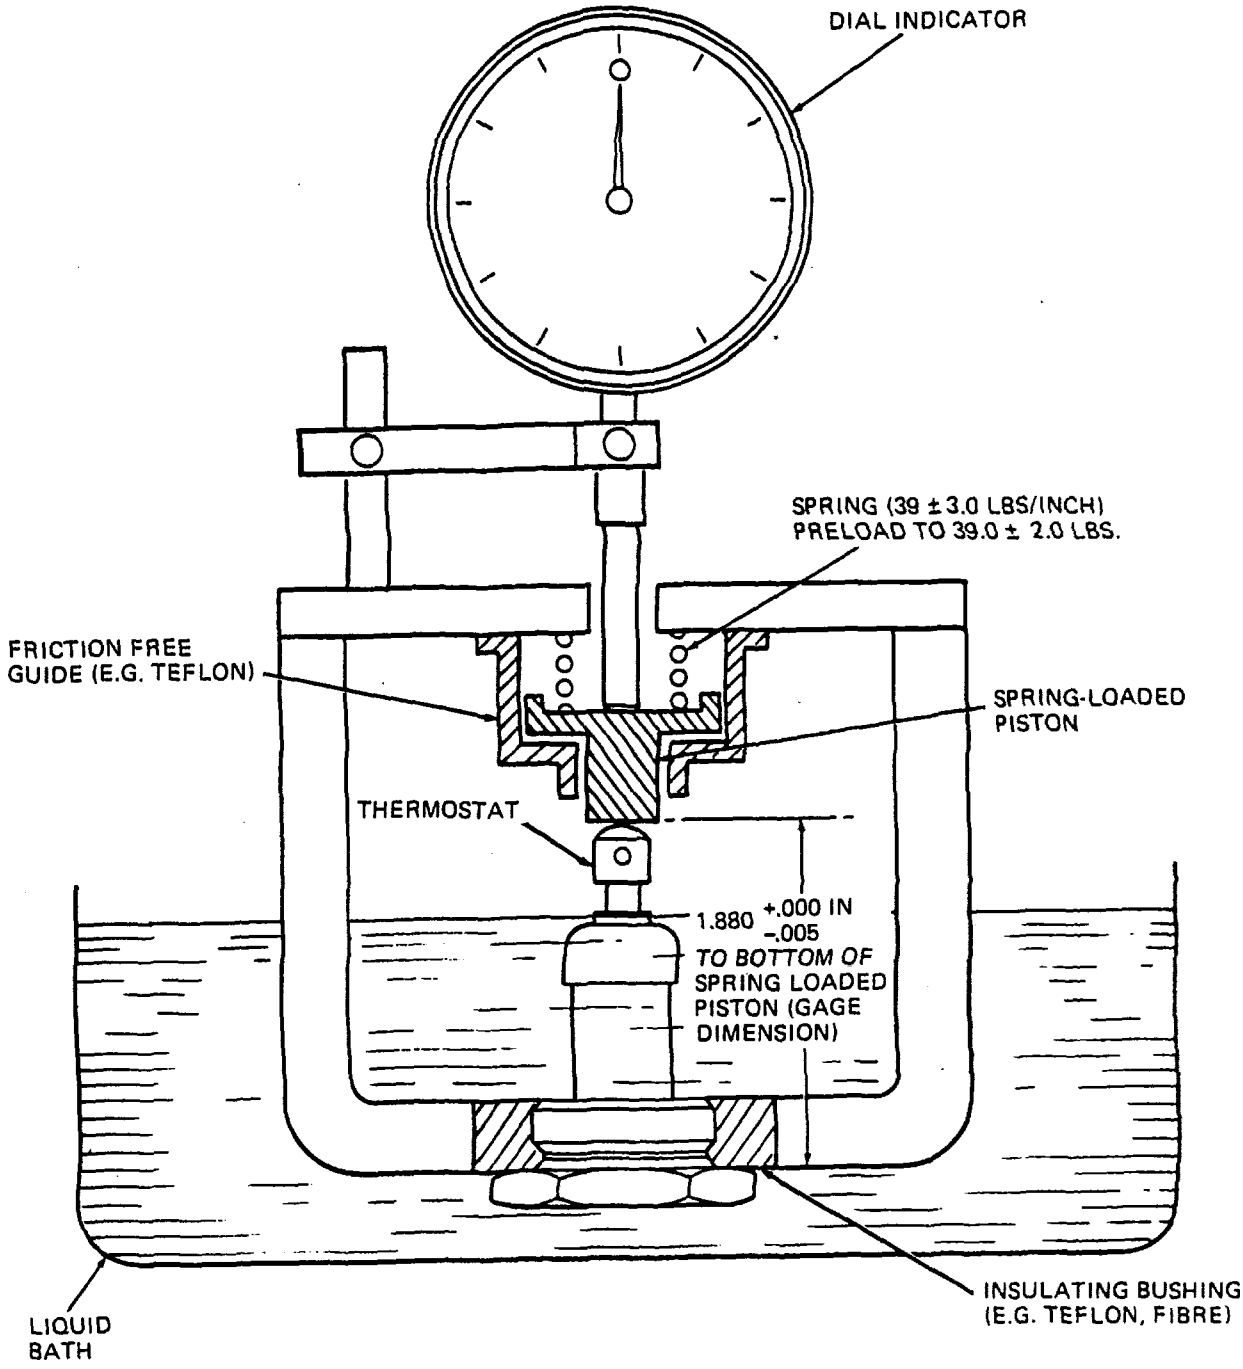
(5) Clean and dry oil cooler.

C. Pressure Drop Test

(1) Connect oil ports to recirculating oil supply source.

(2) Adjust and maintain the oil flow rate to 90 $\pm$ 1 pounds/min, oil temperature to 225 $\pm \frac{0}{2}$°F and oil inlet pressure of 27 $\pm$ 5 psi. Check that oil circuit pressure differential is 15 psi maximum.

(3) Remove oil cooler and cap connections.



D. Thermostat Test (Figure 2)

(1) Prepare test fixture by setting dial indicator to zero with gage dimension maintained by a suitable gage block installed below spring-loaded piston.

NOTE: Gage dimension of 1.880 $\pm \frac{.000}{.005}$ inch is distance between underside of spring-loaded piston and lower face of test fixture.

(2) Remove gage block and install thermostat (without washer) in test fixture.

(3) Immerse test fixture in controlled temperature bath to a depth that insures complete immersion of the thermostat.

Thermostat Test Fixture

Figure 2

(4) Raise bath temperature slowly to 155 $^{+1}_{-0}$ F. The indicator must now read between -0.024 inch and +0.035 inch.

(5) Raise bath temperature slowly to 175 $^{+1}_{-0}$ F, taking care not to exceed this temperature. Allow thermostat movement to stabilize and check that indicator now reads 0.205 inch to 0.220 inch. Note indicator reading.

(6) Decrease bath temperature slowly to 155 $^{+0}_{-1}$ F, taking care to prevent temperature from falling below this figure. Allow thermostat movement to stabilize and note indicator reading. Compare with reading taken in step (5) and check that thermostat has moved more than 0.100 inch.

(7) Remove test fixture from heated bath and immediately immerse in bath containing fluid at room temperature. Check that thermostat reduces in length and stops at an indicator reading of 0.000 to -0.040 inch.

9. Trouble Shooting

Not applicable.

10. Storage Instructions

A. Preparation

(1) Flush cooler in each direction with preservative oil consisting of three parts MIL-L-6082, Grade 1065 and one part MIL-C-6529 or, for an oil system using oil MIL-L-7808, corrosion-preventive oil MIL-C-8188B, or equivalent. Heat flushing oil to above 175°F to insure full circulation through cooler core.

(2) Install plugs in inlet and outlet ports.

(3) Wrap oil cooler in water vapor resistant barrier material.

(4) Package cooler in a container that will provide suitable protection against damage.

(5) Affix label giving following information:

(a) Identification

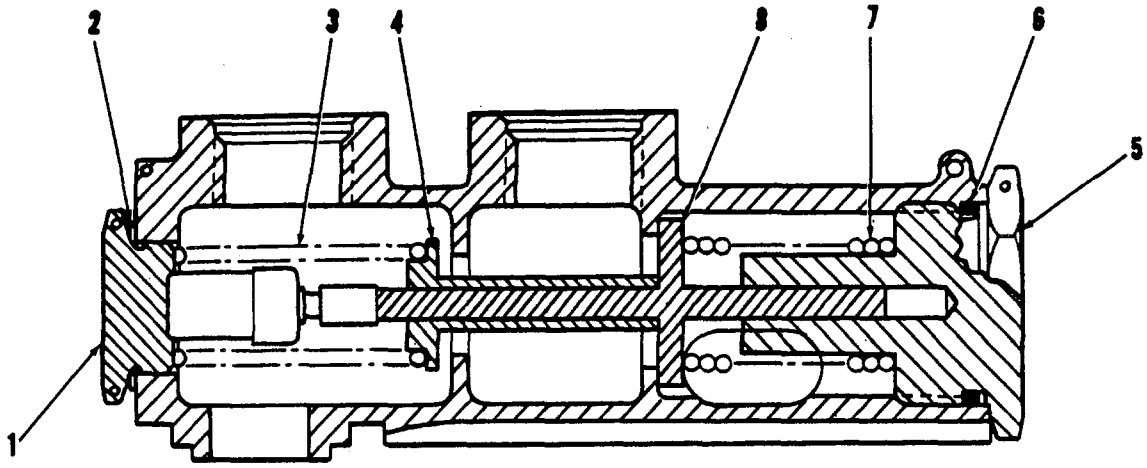
(b) Date of overhaul

(c) Inspection

Table 5

Storage Materials and Compounds

MATERIAL	SPECIFICATION OR MANUFACTURER
Barrier Material	MIL-B-121
Lubricating Oil, Grade 1065	MIL-L-6082
Corrosion Preventive	MIL-C-6529
Corrosion - Preventive Oil	MIL-C-8188B



11. Special Tools and Equipment

The tools and equipment required for overhaul are listed in Table 6.

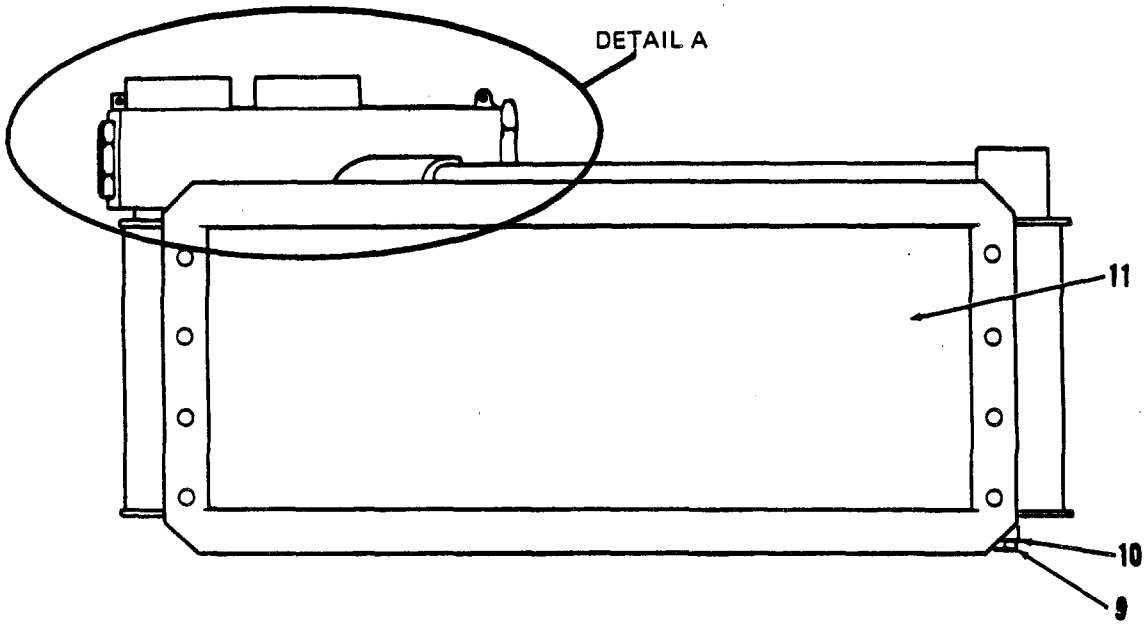


Table 6

Tools and Equipment

EQUIPMENT	MANUFACTURER
Liquid bath (leak test)	Local
Pneumatic test rig capable of supplying and maintaining 225 $\pm \frac{5}{0}$ psi.	-
Recirculating oil supply source capable of supplying 90 pound/min of non-aerated oil (MIL-L-7808) at 35 psi inlet pressure and a temperature of 225°F.	Local
Thermostat test fixture (refer to Figure 2).	Local
Gage block for use with thermostat test fixture.	Local
Liquid bath with agitater and a temperature control of 1°F/min change in the 155 to 175 to 155°F range.	Local
Calibrated thermometer in 1°F increments	-
Dial Indicator	-
Welding equipment (Heliarc or Oxy-Acetylene)	-
Steam cleaning equipment	-
Flushing equipment	-

FUEL SHUTOFF SOLENOID VALVE ASSEMBLY

PART NO. U-9500

Notice is hereby given that the item described in this publication is proprietary to United Aircraft Products, Inc. The customer to whom furnished, by accepting this publication assumes custody thereof and agrees (A) That all information set forth in this publication will be held confidential; and (B) that this publication will be used for maintenance purposes only and under no circumstances for the manufacture or reproduction of the articles or part disclosed thereby. Parts covered by this publication may be procured from United Aircraft Products, Inc., Dayton, Ohio

UNITED AIRCRAFT PRODUCTS, INC.
BOX 1035 • DAYTON, OHIO

TABLE OF LEADING PARTICULARS

Operating Voltage	18 to 30 volts
Max. Current	0.9 amp at 30 volts
Port Threads	7/16-20 internal thd for 1/4 in. tube
Spring Length (free)	1 inch
Spring Load	1-7/8 lb at 0.675 in. length
Connector	AN3102A-10SL-4P

1. SPECIAL TOOLS. None.

2. DISASSEMBLY. (See figure 1.)

a. Disassemble in order of index numbers shown on exploded view, noting the following special instructions:

b. It is not practical to drill out pin (1) because of the soft metal surrounding it and because of its small size. If necessary to remove pin, insert fine hack saw blade at opening between body (2) and coil and retainer assembly (6). Remove body and pick out pieces of pin.

c. Avoiding distorting strains, clamp coil and retainer assembly (6) to unscrew body (2) from it. Avoid loss of loose parts (3, 4, 5).

3. CLEANING.

a. Wash in dry cleaning solvent, Federal Specification No. P-S-661, but do not allow plunger assembly or coil and retainer assembly to soak in solvent. Dry thoroughly after cleaning.

4. INSPECTION.

a. Plunger and plunger bore in coil for damage causing sticking of plunger.

b. Valve seat in body and seal on plunger for damage interfering with sealing action.

c. Spring for free length and load at design length.

d. Corrosion at breaks in plated or anodized parts.

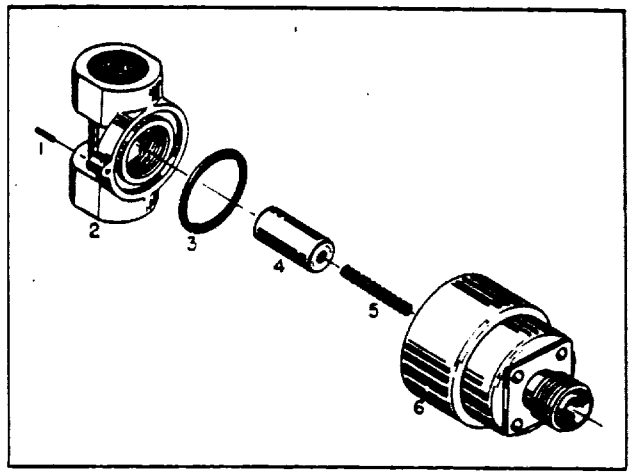

Figure 1. Fuel Shutoff Valve (Exploded)

FIG. & INDEX NO.	PART NO.	DESCRIPTION 1 2 3 4 5 6 7	UNITS PER ASSY
1-	U-9500	VALVE ASSY, Fuel shutoff	1
-1	U-3116	. PIN	1
-2	U-3101-3	. BODY	1
-3	MS29513-20	. PACKING	1
-4	U-3112	. PLUNGER ASSY	1
-5	U-3102	. SPRING	1
-6	U-9502	. COIL AND RETAINER ASSY	1

e. All threads for condition and cleanliness.

f. Check resistance using potentiometer. Readings should be between 35 and 42 ohms. Or, using a voltmeter and ammeter in circuits, initial amperage at 18 volts should be 0.43 to 0.52; at 24 volts, 0.57 to 0.69.

5. REPAIR AND REPLACEMENT.

a. Do not repair plated or anodized parts if repairs will break protective coating, as corrosion will occur in service.

b. Replace "O" ring packing. Replace plunger assembly if condition is at all doubtful.

6. LUBRICATION. None.

7. REASSEMBLY.

a. Reassembly is the reverse of disassembly. When body is tight on coil and retainer assembly, holes for pin (1) should be in line. If not (because of new body or coil assembly), use No. 56 (0.0465 inch) drill but do not make hole over 1/4 inch deep. Drive new pin home.

8. TEST PROCEDURE.

a. Connect to variable d-c source through switch and apply 50 psi fluid pressure to inlet port. Use standard hydrocarbon test fluid, Specification No. MIL-F-7024. Valve must operate satisfactorily at 18 volts with maximum current of 0.5 ampere. Reduce test pressure to zero.

b. Energize solenoid at 30 volts. Operation must be satisfactory with maximum current not over 0.9 ampere.

c. De-energize solenoid. Apply fluid pressure at inlet from 0 to 75 psi. Check for leakage for 3 minutes.

d. Connect fluid pressure source to outlet port and apply 15 psi against closed valve with inlet port open. Hold for 3 minutes and check for leakage.

e. Any external leakage or internal leakage through closed valve is cause for rejection. Repeated failure of valve to operate smoothly is cause for rejection. Rejected valves must be rebuilt or scrapped.

f. Before attaching tag noting test results, seal both ports against dirt and stamp curing date tag with date of oldest rubber compound used.
